IAS 2023, the 12th IAS Conference on HIV Science

ias2023.org

IAS 2023 Organizing Committee

Co-Chairs

Sharon Lewin, Australia
Charles Gilks, Australia

Members

Beatriz Grinsztejn, Brazil
Birgit Poniatowski, Switzerland
Kenneth Ngure, Kenya
Jessica Whitbread, Bulgaria
Glory Alexander, India
Erika Castellanos, Netherlands
Doan Thanh Tung, Vietnam
Marina Caskey, United States

James McMahon, Australia
Sinead Delany-Moretlwe, South Africa
Carlos F Cáceres, Peru
Sunil Solomon, United States
Tan Kay Jin Rayner, China
Meg Doherty, Switzerland
Sarah Read, United States

Track Committees

Track A – Basic Science

Lead

Marina Caskey, United States

Members

Afam Okoye, United States
Anthony Kelleher, Australia
Gabriela Turk, Argentina
Kiera Clayton, United States
Michaela Müller-Trutwin, France
Mirko Paiardini, United States

Track B – Clinical Science

Lead

James McMahon, Australia

Members

Anchalee Avihingsanon, Thailand
Gail Matthews, Australia
Laura Waters, United Kingdom
Rosie Mngqibisa, South Africa
Roy Gulick, United States
Wong Chen Seong, Singapore

Track C – Epidemiology and prevention science

Lead

Sinead Delany-Moretlwe, South Africa

Members

Harriet Nuwagaba-Biribonwoha, Eswatini
Ines Dourado, Brazil
Iskandar Azwa, Malaysia
Kenneth K Mugwanya, United States
M Kate Grabowski, United States
Rebecca Guy, Australia

Track D – Social and behavioural sciences

Lead

Carlos F Cáceres, Peru

Members

Brian J Hall, China
Deevia Bhana, South Africa
Hamid Vega, Mexico
Jennifer Power, Australia
Judith Auerbach, United States
Marie Préau, France

Track E – Implementation science, economics, systems and synergies

Lead

Sunil Solomon, United States

Members

Abhina Aher, India
Anna Grimsrud, South Africa
Jason Ong, Australia
Neil Martinson, South Africa
Ruanne Barnabas, United States
Viet Trinh, Vietnam

Over 3,800 abstracts were submitted to the 12th IAS Conference on HIV Science.

The Organizing Committee (OC) is very grateful for all the abstract submissions received. While the OC found many very high-quality abstracts among the submissions, due to limitations in the conference programme, more abstracts were rejected than accepted – with an overall acceptance rate of 38%.

All abstracts went through a blind peer-review process completed by over 700 abstract reviewers. These reviewers are international experts in the field of HIV, including members of the OC and track committees. Each abstract was reviewed by three to four reviewers. The abstracts were reviewed for the quality and originality of the work. Late-breaking abstract reviews included an additional assessment of the late-breaking nature of the research.

All reviewers were instructed to abstain from scoring any abstract on which they were an author or co-author, had a financial or personal conflict of interest, or did not have the appropriate expertise to evaluate. Each abstract was scored numerically against five pre-determined criteria, which were equally weighted to get a final score. The final score ranged from one (the lowest) to six (the highest). Any abstracts that received less than two reviews or where there was a scoring discrepancy between reviewers were additionally reviewed by the track committees.

Statistics for abstracts

3,857	Regular abstracts submitted
1,474	Regular abstracts accepted
92	Oral abstracts
225	Poster exhibition abstracts
1,100	E-poster abstracts
395	Late-breaking abstracts submitted
97	Late-breaking abstracts accepted
28	Late-breaking oral abstracts
15	Late-breaking poster exhibition abstracts
54	Late-breaking e-poster abstracts
4,252	Total abstracts submitted
1,571	Total abstracts accepted

The 12th IAS Conference on HIV Science received more than 3,800 abstract submissions, which went through a blind, peer-reviewed process carried out by an international panel of reviewers who play a critical role in designing a strong scientific programme.

More than 700 specialists from around the world volunteered their time and expertise to serve as peer reviewers, helping to ensure that the abstracts presented were selected on the basis of rigorous review and were of the highest scientific quality.

We extend our special thanks to the large pool of abstract reviewers for the time they dedicated to the success of the conference.

TABLE OF CONTENTS

Oral abstract sessions

OAA01	Viral replication and reservoirs beyond the periphery: A deeper look at tissues	11
OAA02	Immune-based interventions towards an HIV cure	13
OAA03	Novel insights into viral persistence	16
OAA04	Mechanisms of transmission and novelties in vaccine design	18
OAB01	Prioritizing the clinical HIV care of women and children in 2023	20
OAB02	What's up with ART? Latest studies in HIV treatment	23
OAB03	It's all about the bugs: Other conditions in people with HIV	25
OAB04	Beyond suppression: Improving the trajectory of co-morbidities in people with HIV	28
OAC01	Progress towards HIV elimination: Are we there yet?	31
OAC02	Colliding epidemics: Prevention of HIV and co-infections	33
OAC03	Achieving HIV prevention and treatment at scale	36
OAC04	Strengthening sexual and reproductive health for diverse populations	38
OAC05	Differentiated service delivery with focus on PrEP	41
OAD01	Situating gender-based violence in the HIV field: Evidence, advances and action	43
OAD02	Tackling stigma: Insights and interventions	46
OAD03	Younger and older: HIV across the life course	48
OAD04	More than just oral PrEP: Innovative approaches for HIV prevention services	50
OAD05	The HIV care continuum: Identifying barriers, devising solutions	52
OAE01	Designing services to optimize the delivery of PrEP for all who would benefit	55
OAE02	The Power of People: Community based models to improve HIV outcomes	58
OAE03	Show me the money: The cost of epidemic control	60
OAE04	From silos to solutions: Embracing integration for better health outcomes	63
OAE05	#SwitchUp4KeyPopulations: Worldwide advancements in meeting the growing needs of key populations	65

Poster exhibition abstracts

Track A:	Basic science	68
Track B:	Clinical science	82
Track C:	Epidemiology and prevention science	109
Track D:	Social and behavioural sciences	134
Track E:	Implementation science, economics, systems and synergies	164

E-poster abstracts

Track A

EPA0001-009	HIV virology	197
EPA0010-028	HIV pathogenesis	202
EPA0029-052	Host immune responses, vaccines and immunotherapies	213
EPA0053-082	Understanding and targeting persistent HIV reservoirs	226
EPA0083-086	Novel treatment and prevention strategies	243
EPA0087-093	HIV-associated viruses, co-infections and co-morbidities	246
EPA0094-107	SARS-CoV-2 virology, pathogenesis, and host immune responses, vaccines and immunotherapies	250

Track B

EPB0108-109	Course of HIV disease	259
EPB0110-126	Diagnostic and monitoring tools	260
EPB0127-158	Co-infections (including opportunistic infections)	270
EPB0159-186	Co-morbidities	290
EPB0187-199	Clinical complications of HIV and antiretroviral therapy	307
EPB0200-203	HIV and ageing	314
EPB0204-234	Antiretroviral therapies and clinical issues in adults	317
EPB0235-262	Antiretroviral therapies and clinical issues in infants, children and adolescents	335
EPB0263-269	Clinical issues specific to key populations	352
EPB0270	Other strategies and therapies	356
EPB0271-276	ART resistance	356
EPB0277-288	SARS-CoV-2, COVID-19 and HIV	361

Track C

EPC0289-320	Epidemiology of HIV	369
EPC0321-347	Surveillance: Measuring the HIV epidemic	387
EPC0348-355	Modelling the HIV epidemic	402

EPC0356-405	HIV prevention research	407
EPC0406-416	Sexual and reproductive health and HIV prevention	434
EPC0417-452	Population-specific interventions for HIV prevention	441
EPC0453-479	HIV testing	462
EPC0480-515	Cascades of HIV care and treatment	476
EPC0516-530	Epidemiology of COVID-19	496

Track D

EPD0531-540	Social science theories, concepts and methods	505
EPD0541-611	Social and behavioural aspects and approaches to HIV	510
EPD0612-639	Social, political, legal and behavioural determinants of health in different contexts	549
EPD0640-719	Key populations and other vulnerable populations: Behavioural, social and cultural issues and contexts	564
EPD0720-735	Sexuality, gender, relationships and sexual cultures	607
EPD0736-741	Sexualities and sexual cultures: Meanings, identities, norms and communities	616
EPD0742-760	Social and behavioural aspects and approaches to COVID-19	619

Track E

EPE0761-788	Implementation science and scale up of HIV testing	631
EPE0789-820	Implementation science and scale up of prevention	646
EPE0821-876	Implementation science and scale up of treatment	663
EPE0877-884	Global and national financing, economic evaluation and sustainability	694
EPE0885-896	Costing, cost effectiveness and affordability	698
EPE0897-935	Health systems, health systems strengthening and partnerships	705
EPE0936-938	HIV and development synergies	728
EPE0939-968	Integration of HIV services with other health and support services	729
EPE0969-1003	Innovations in data collection, monitoring and evaluation	747
EPE1004-1011	Impact of COVID-19 on HIV prevention, testing and treatment (including financing)	767

Late Breakers

Late-breaker oral abstracts

OALBA05	Track A late-breaker	773
OALBB05	Track B late-breaker	775

Resident microbiota enhance HIV acquisition, replication, and pathogenesis in vivo

A. Wahl¹, W. Yao¹, B. Liao¹, M. Chateau¹, C. Richardson¹, L. Ling¹, J. Tucker¹, I. McGowan², R.B. Sartor¹, J.V. Garcia¹
¹University of North Carolina at Chapel Hill, Chapel Hill, United States, ²University of Pittsburgh Medical School, Pittsburgh, United States

Background: Resident microbiota maintain intestinal homeostasis by regulating digestion, metabolism, immune development, and providing protection from infection. Pioneering work has also shown that resident microbiota enhance the transmission of a limited number of viruses that target the intestinal tract. The intestinal tract is a major site of HIV infection. However, the effect of resident microbiota on HIV acquisition, replication, and pathogenesis in the intestinal tract is unknown due to the strict species tropism of HIV.

Methods: Bone marrow/liver/thymus (BLT) humanized mice have been extensively utilized to study HIV acquisition, pathogenesis and prevention strategies *in vivo*. To examine the role of resident microbiota in HIV acquisition and infection, we constructed germ-free (GF) BLT mice and BLT mice colonized with resident intestinal microbiota. First, we rederived a GF strain of immune deficient mice by sterile embryo transfer. GF-BLT humanized mice were then surgically constructed in a sterile gnotobiotic surgical isolator. All GF mice were housed and experiments performed in sterile gnotobiotic isolators and the GF status of mice confirmed longitudinally. BLT mice colonized with resident microbiota were also constructed. We then evaluated HIV acquisition, replication, and pathogenesis in GF BLT mice and BLT mice colonized with resident microbiota following an oral or rectal HIV exposure. HIV-RNA levels were monitored longitudinally in the peripheral blood plasma of mice weekly by real-time PCR analysis. At necropsy, we measured the levels of HIV-DNA, HIV-RNA, and T cell activation blood and tissues.

Results: Our results show that HIV acquisition, replication and pathogenesis in the intestinal tract is greatly enhanced in the presence of resident microbiota. HIV acquisition was 300% higher following an oral HIV challenge ($P=0.013$) and 200% higher following a rectal HIV challenge ($P=0.0286$) in the presence of resident microbiota. Mean plasma viral loads were up to 34-fold higher and cell-associated HIV-RNA levels in tissue were also over a 1000-fold higher in the presence of resident microbes. Furthermore, HIV-associated CD8⁺ T cell activation was higher in the intestinal tract in the presence of resident microbiota.

Conclusions: These data directly demonstrate for the first time that resident microbiota are a major driver of HIV acquisition, replication, and pathogenesis.

OAA0103

Gut dysfunction as an independent driver of neuroinflammation in ART-suppressed SIV

S. Byrnes¹, K. Busman-Sahay², T. Angelovich¹, S. Younger², S. Taylor-Brill², M. Nekorchuk², S. Bondoc², R. Dannay², M. Terry², C. Cochrane¹, T. Jenkins¹, M. Roche³, C. Deleage⁴, S. Bosinger⁵, M. Paiardini⁵, B. Brew⁶, J. Estes², M. Churchill¹
¹RMIT, Melbourne, Australia, ²OHSU, Portland, United States, ³University of Melbourne, Melbourne, Australia, ⁴Frederick National Laboratory for Cancer Research, Frederick, United States, ⁵Emory, Atlanta, United States, ⁶UNSW, Sydney, Australia

Background: Currently ~30% of people with HIV (PWH) who are virally suppressed with antiretroviral therapy (ART) develop a form of HIV-associated neurocognitive disorder (HAND). The presence of a viral reservoir (and associated neuroinflammation) in the brain and ongoing systemic inflammation penetrating the central nervous system (CNS) are thought to play crucial roles. However, the precise effects of viral mediated and/or independent pathways on the brain remain ill-defined.

Methods: Here we characterized the CNS reservoir and immune environment of SIV-infected (SIV+) rhesus macaques (RMs) during acute ($n=4$), chronic ($n=12$) or ART-suppressed SIV infection ($n=11$) using spatial multiplex immunofluorescence analyses. Specifically, measures of SIV vRNA/DNA, blood-brain barrier integrity and ongoing immune activation/inflammation were quantified at a cellular level in the brain and matched gut tissue of SIV-infected animals.

Furthermore, immune activation/inflammation was also measured in a novel model of gut damage in SIV uninfected RMs ($n=4$) to understand whether gut damage alone can drive neuroinflammation independent of SIV.

Results: SIV DNA+ and RNA+ cells were detected in the brain and gut tissue of all SIV+ groups tested. Additionally, the frequency of vDNA+ cells were not reduced in the brain or gut in ART-treated animals ($P<0.05$), supporting the presence of a stable viral reservoir in the brain. SIV+ animals had enhanced inflammatory responses, expansion of activated astrocytes and myeloid cells as well as reduced BBB integrity compared to uninfected animals, which persisted despite ART ($P<0.05$ for all). Surprisingly, BBB breakdown and neuroinflammation correlated strongly with measures of gut inflammation, but not brain viremia. Similar immune activation profiles were present in the brains of the SIV uninfected gut damage model group, indicating that damage to the gut can contribute to immune activation in the brain independent of SIV-infection.

Late-breaker abstracts

Author Index

Conclusions: Here we show that ART-suppressed SIV+ RMs have BBB breakdown and heightened activation of astrocytes and myeloid cells which is associated in part with SIV vDNA and immune activation in the gut and not resolved by ART treatment. These findings provide the strongest evidence to date that the brain of SIV-infected animals remains in an activated state despite long-term ART treatment and that gut damage can induce neuro-immune activation.

OAA0104

Gut memory CD4+ T cells from people with HIV on suppressive ART express high levels of intracellular HIV sensors

A. George^{1,2}, J. Neidleman^{1,2}, X. Luo^{1,2}, J. Frouard^{1,2}, K. Yin^{1,2}, K. Young^{1,2}, T. Ma^{1,2}, A. Chaillon³, M. Porrachia³, B. Woodworth³, D. Smith³, S. Gianella³, N. Roan^{1,2}

¹Gladstone Institute of Virology, San Francisco, United States, ²University of California San Francisco, Department of Urology, San Francisco, United States, ³University of California San Diego, Division of Infectious Diseases and Global Public Health, La Jolla, United States

Background: Memory CD4+ T cells (CD4+ Tm) are major targets of HIV infection. Despite antiretroviral therapy (ART), HIV persists in tissues, with the gastrointestinal tract harboring a major proportion of the reservoir. Here, we test whether CD4+ Tm from different tissue sites differentially express viral sensors with potential roles in detecting, restricting, or responding to HIV infection.

Methods: We developed a CyTOF panel designed to quantify 19 intracellular viral sensors. To determine if sensor expression differs across tissues, we applied our CyTOF panel on freshly isolated CD4+ Tm from 8 tissue sites (gastrointestinal tract, lymph node, spleen, liver, kidney, bone marrow, heart, and lung) harvested by rapid research autopsy from five people with HIV (PWH) on suppressive ART enrolled in the Last Gift Cohort. Last Gift is an end-of-life cohort of PWH that were diagnosed with a terminal illness, and who donate their bodies for HIV cure research.

Results: The gastrointestinal tract uniquely harbored a sub-population of CD4+ Tm cells co-expressing high levels of multiple sensors targeting viral components from multiple stages of the HIV replication cycle. These sensors included PQBP1 and MX2 which sense incoming viral capsid protein, STING and IRF3 which indirectly sense HIV DNA, SLFN11 which senses HIV RNA and inhibits viral protein synthesis, and MX1 which responds to type I interferons induced as a result of viral sensing. This sub-population of CD4+ Tm was absent in the other tissues. As the gut is a main site of HIV persistence during ART suppression, elevated viral sensor expression at this site may reflect ongoing detection of viral components produced by the persistent HIV reservoir. Consistent with this observation, in vitro infection assays revealed that infection of CD4+ Tm upregulated expression of these same viral sensors.

Conclusions: CD4+ Tm express a diverse array of intracellular host factors capable of detecting and responding to the presence of HIV in a tissue-dependent manner, with particularly high levels in the gastrointestinal tract, a major site of HIV persistence. The constant sensing of HIV components in the gastrointestinal tract may contribute to ongoing low levels of chronic inflammation in PWH.

Are moto-neurons susceptible to SARS-CoV-2 infection?

G. Cappelletti¹, C. Colombrita², F. Limanaqi^{1,3}, S. Strizzi¹, C. Vanetti¹, M. Garziano^{1,3}, D. Trabattoni¹, S. Santangelo^{2,4}, V. Silani^{2,5}, A. Ratti^{2,4}, M. Biasin¹

¹University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy, ²IRCCS Istituto Auxologico Italiano, Department of Neurology and Laboratory of Neuroscience, Milan, Italy, ³University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy, ⁴University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy, ⁵University of Milan, Department of Pathophysiology and Transplantation, Dino Ferrari Center, Milan, Italy

Background: COVID-19 typically causes respiratory disorders, but surprisingly a high proportion of patients also reported CNS symptoms as well as myopathies during and after SARS-CoV-2 infection. Notwithstanding, the impact of SARS-CoV-2 exposure on motor neuronal cells has not been investigated so far. Thus, by using human iPSC-derived motor neurons (MNs) we assessed: their infectability by SARS-CoV-2; the expression of SARS-CoV-2 main receptors; and the effect of SARS-CoV-2 exposure on iPSC-MN transcriptome.

Methods: Human iPSC lines from healthy donors were obtained by reprogramming fibroblasts and MNs were obtained by iPSC differentiation. The expression of the main SARS-CoV-2 human-receptors was assessed in MNs by PCR and Immunofluorescence (IF). MNs were in vitro infected with SARS-CoV-2, and viral replication was assessed by qPCR on two viral targets (N1, N2) in cell culture supernatants at 24, 48 and 72 hours post infection (hpi). To confirm the results obtained these same supernatants were used to re-infect susceptible VeroE6 cells. Viral infection was monitored by IF and Qgene expression as well. In parallel, we profiled the gene expression of 46 different target involved in viral entry as well as antiviral and immune response in SARS-CoV-2 infected MNs.

Results: Gene expression profiling of the main receptors recognized by SARS-CoV-2 revealed that all of them are expressed with lower level of ACE2 compared to CD147 and NRP1. By analyzing N1 and N2 gene expression over time, we observed that human iPSC-MN were productively infected by SARS-CoV-2, although viral replication was not accompanied by cytopathic effect. Supernatant collected from SARS-CoV-2 infected MNs was able to re-infect Vero

E6 cells. Image analyses of SARS-CoV-2 Nucleocapsid proteins by IF confirmed the results obtained. Furthermore, SARS-CoV-2 infection was accompanied by the activation of the antiviral and inflammatory response (HLA-A, MX1, BCL2) in MNs.

Conclusions:

These results suggest for the very first time that SARS-CoV-2 can infect human MNs probably by binding CD147 and NRP1 receptors. New evidence, indicate that these proteins have higher and broader patterns of expression in the human brain than ACE2 or TMPRSS2.

Such information will be essential to unveil the neuromuscular disorders characterizing SARS-CoV-2 infection and the so called long-COVID symptoms.

and HIV-1 persistence. Depletion of pDCs or blocking of the IFN I receptor during ART-treated chronic HIV-1 infection in humanized mice reverses HIV-1 pathogenesis and rescues HIV-specific CD8⁺ T cells.

Methods: We performed pDC depletion in SIVmac251-infected rhesus macaques under long-term ART using 1D3, a novel anti-BDCA2/CD303 monoclonal antibody, and assessed the impact on CD8⁺ T cell exhaustion and SIV reservoirs. To study the SIV-specific CD8⁺ T cell response, we generated barcoded Gag-CM9 tetramers and performed CITE-Seq and TCR immune profiling.

Results: We achieved depletion of pDCs in the peripheral blood (PB), lymph nodes (LN) and bone marrow. In the LN, we observed a significant reduction in ISGs in CD4⁺ and CD8⁺ T cells at 16 days post-infusion and a reduced expression of PD-1 on central memory (CD95⁺ CCR7⁺) CD8⁺ T cells at 30 days post-infusion. Two out of six macaques that received 1D3 controlled viremia after ART interruption compared to 0/6 control animals. There was no change in SIV-DNA and SIV-RNA in PB and LN CD4⁺ T cells after pDC depletion. Gag-CM9 Tetramer⁺ CD8⁺ T cells of three Mamu-A*01⁺ control animals were tracked at 26 days before and at 5 weeks after treatment interruption. We identified two major populations of LN SIV-specific CD8⁺ T cells: exhausted (TOX⁺ PD-1⁺ TIGIT⁺) and stem-like cells (TCF1⁺ PD-1^{int}). By matching TCR clones at both time points, we demonstrate that the expansion of these populations to recrudescence SIV differs significantly.

Conclusions: Taken collectively, we report that in vivo pDC depletion was able to effectively suppress expression of ISGs and checkpoint blockade proteins in LN CD8⁺ T cells. Importantly, a subset of RMs in the depletion group maintained virological control off ART. These data suggest that therapeutics targeting the pDC/IFN axis are capable of functionally improving anti-SIV CD8⁺ T cell responses to control SIV infection. Ultimately, this is a promising strategy to reverse the effects of chronic inflammation in ART-suppressed PLWH that could be used to restore host immunity and contribute to an HIV cure.

OAA0203

In vivo genome engineering of human T cells results in ART-free control of HIV-1 in humanized mice

P. Kumar¹, J. Beloor¹, J. Rajashekhar¹, I. Ullah¹, P. Uchil², L. Zhu¹, Y. Sun¹, S. Zeller¹

¹Yale University School of Medicine, Internal Medicine/ Infectious Diseases, New Haven, United States,

²Yale University School of Medicine, Microbial Pathogenesis, New Haven, United States

Background: Autologous cell transplant approaches for HIV cure typically involve re-infusion of a person's own gene-modified hematopoietic stem and/or T cells. However, poor post-infusion engraftment of the gene-modified cells remains a major hurdle for achieving successful control of HIV-1 viral loads and ART-free remission. In vivo gene therapy, which does not involve ex-vivo cell manipulations, may address this issue. That said, effective transgene delivery to human hematopoietic cells in vivo is a formidable challenge in the gene therapy field.

Methods: We exploited the dominant surface expression of CD7 on human T cells and monocytes to allow targeted and effective transduction of these cell types with virus-like particles (VLPs) surface-decorated with a humanized antibody to human CD7. Importantly, as a key step toward clinical application, we adapted this platform for the delivery of genome-integrating ORFs encoding short-hairpin RNA (long-term expression) and/or 'scarless' delivery of packaged CRISPR ribonucleoprotein complexes (RNPs, transient expression). The platform was tested for abrogating expression of HIV-1 host dependency factors in human T cells in humanized mouse models of HIV-1 infection after systemic (intravenous) administration.

Results: Simple intravenous injection of CD7 antibody-guided VLPs into humanized mice resulted in selective transduction of primary human T cells (and monocytes) with negligible off-targeting and hepatotoxicity. We obtained impressive *in vivo* gene marking frequencies of > 50% of human T cells. Gene-marked CD4 T cells selectively expanded in HIV-1_{JRC5F}-infected humanized mice after withdrawal of antiretroviral therapy (ART) resulting in control of plasma viral loads and stabilization of CD4 T cell levels.

Importantly, treated mice were resistant to repeated challenge with HIV-1. ART-free control of viral loads was also achieved in humanized mice transplanted with CD4 T cells from people living with HIV (PLWH) demonstrating potential applicability as a cure strategy for HIV-1.

Conclusions: The approach we report here represents an important advance to the field of gene therapy-based cure for HIV in that it obviates the need for cell transplant protocols with ex-vivo transduced hematopoietic cells. We expect our work to be a significant advance towards achieving ART-free remission and of compelling interest to the fields of clinical gene-therapy for HIV-1 and other diseases.

OAA0204

The EZH2 inhibitor Tazemetostat increases MHC-I antigen presentation *in vitro* and *in vivo*, enhancing antiviral activities of HIV-specific CTLs

A. Gramatica¹, A. Danesh¹, F. Kahn¹, I. Miller¹, J. Weiler¹, D. Copertino¹, A. Ward¹, T. Mota¹, L. Leyre¹, U. Chukwukere¹, B. Jones^{1†}

¹Weill Cornell Medical College, New York, United States

Background: Infected cells vary in their intrinsic susceptibilities to cytotoxic T-lymphocytes (CTLs) mediated killing. We reported that overexpression of the survival factor BCL-2 in reservoir cells confers a degree of resistance to CTLs, and that inhibiting BCL-2 potentiated 'shock and kill' reservoir reduction *ex vivo*. Here, we evaluate Enhancer of Zeste Homolog 2 (EZH2) as additional mechanism of resistance, implicated by its transcriptional overexpression in HIV-infected CD4+ T-cells that survive CTL co-culture. EZH2 is a histone-methyltransferase that negatively regulates MHC-I expression and is inhibited by the FDA-approved drug Tazemetostat.

Methods: CD4+ T-cells isolated from HIV+ donors were superinfected with HIV-1_{JRCSP} treated with Tazemetostat and cocultured with HIV-specific CTLs (*in vitro*-killing assay), or co-cultured with autologous CD8+ T-cells in the presence of Tazemetostat (viral-inhibition assay). Enhancement in the individual's antiviral response, driven by Tazemetostat, was evaluated by comparing reduction in Gag(p24)+CD4- T-cells in treated versus untreated conditions. NodSCID-/-IL2rnull mice were engrafted with memory CD4+ T-cells from an HIV+ donor. Mice were then infected with HIV_{JRCSP} and either co-engrafted or not with autologous memory CD8+ T-cells. Tazemetostat or vehicle control were administered orally, up to 500mg/kg BID. Viral loads and phenotypical analysis of T-cells were conducted weekly.

Results: In both the *in vitro*-killing and viral-inhibition assays, co-cultures of infected cells with HIV-specific CTL clones, or bulk CD8+ T cells, resulted in elimination of 50-70% of infected cells. However, treatment with Tazemetostat induced higher MHC-I levels on infected cells and significantly greater killing (up to 80-90%). No such enhancement was observed with cells infected with a Nef-deficient virus, suggesting that Tazemetostat may act by offsetting Nef-mediated MHC-I downregulation. In mice, viral loads were significantly reduced in +CD8 versus no-CD8 mice. Tazemetostat drove a 2.1-fold increase in surface MHC-I on infected cells (n=8, p value = 0.0004), and a further decrease of 1-log (mean value) of viral load, relative to vehicle control +CD8 mice.

Conclusions: Tazemetostat increases MHC-I expression in infected cells, counterbalancing Nef-mediated immunoevasion. This resulted in enhanced infected-cell elimination *in vitro* and decreased viral loads *in vivo*. Our results provide impetus for pre-clinical studies assessing impact on reservoir formation and for consideration of future clinical studies.

OAA0205

Anti-PD-1 chimeric antigen receptor T cells efficiently target SIV-infected CD4+ T cells in germinal centers of rhesus macaques

K. Eichholz¹, Y. Fukazawa², C. Peterson¹, F. Haeseleer¹, M. Medina², S. Hoffmeister², D. Duell², B. Varco-Merth², S. Dross³, H. Park², C. Labriola², M. Axthelm², R. Murane⁴, J. Smedley², L. Jin¹, B. Rust¹, D. Fuller³, H.-P. Kiem¹, L. Picker², A. Okoye², L. Corey¹

¹Fred Hutchinson Cancer Center, Vaccine and Infectious Disease Division, Seattle, United States, ²OHSU, Vaccine and Gene Therapy Institute, Portland, United States, ³University of Washington, Department of Microbiology, Seattle, United States, ⁴University of Washington, Washington National Primate Research Center, Seattle, United States

Background: Programmed cell death protein 1 (PD-1) is an immune checkpoint marker commonly expressed on memory T cells and enriched in latently-infected CD4+ T cells containing replication-competent human immune deficiency virus 1 (HIV) provirus in people with HIV on anti-retroviral therapy (ART).

Methods: We engineered novel chimeric antigen receptor (CAR) T cells that can efficiently kill PD-1 expressing cells *in vitro* and *in vivo* to assess the impact of PD-1 depletion on viral reservoirs and rebound dynamics in simian immunodeficiency virus (SIV) mac239-infected rhesus macaques (RMs). Adoptive transfer experiments of anti-PD-1 CAR T cells were done in 2 SIV naïve and 4 SIV-infected RMs on ART.

Results: In 3 of 6 RMs, one SIV naïve and 2 SIV+ RMs, anti-PD-1 CAR T cells expanded efficiently and persisted for up to 100 days concomitant with the depletion of PD-1+ memory T cells in blood and tissues, including CD4+ follicular helper T cells (T_{FH}). This depletion of T_{FH} in lymph nodes was also associated with depletion of detectable SIV RNA from the germinal center (GC).

However, following ART interruption, there was a marked increase in SIV replication in extrafollicular portions of lymph nodes, a 2-log higher plasma viremia relative to controls and accelerated disease progression, associated with the acute depletion of CD8+ memory T cells after CAR T infusion in SIV+ RMs on ART.

Conclusions: These data indicate anti-PD-1 CAR T cells can target and deplete PD-1+ T cells *in vivo* including GC T_{FH} cells and eradicate SIV from this immunological sanctuary. Approaches to limit CAR T cell-mediated depletion to PD-1+ CD4+ T cell reservoirs and reduced off target CD8+ memory T cell depletion should be pursued.

Differential susceptibility of cells infected with defective and intact proviruses to HIV-selective cell killing by small molecule therapies

G.N. Kadiyala¹, S. Telwatte², A. Wedrychowski¹, J. Janssens¹, S.J. Kim¹, P. Kim³, S. Deeks⁴, J. Wong¹, S. Yuki¹

¹University of California, San Francisco (UCSF) and San Francisco VA Medical Center, Medicine, San Francisco, United States, ²The University of Melbourne, Infectious Diseases, Melbourne, Australia, ³San Francisco VA Medical Center, San Francisco, United States, ⁴University of California, San Francisco (UCSF), Medicine, San Francisco, United States

Background: Some drugs that augment cell-intrinsic defenses or modulate cell death/survival pathways have been reported to selectively kill HIV-infected cells and/or reduce HIV DNA. We hypothesized that these drugs may differ in their ability to kill cells infected with intact and defective proviruses.

Methods: We tested drugs currently in clinical use or human trials, including interferon alpha2A, interferon gamma, acitretin (RIG-I inducer), GS-9620/vesatolimod (TLR7 agonist), nivolumab (PD-1 blocker), auranofin (p53 modulator), obataclax (Bcl-2 inhibitor), FX-1 (Bcl-6 inhibitor), bortezomib (proteasome inhibitor), birinapant (IAP inhibitor), and INK128/sapanisertib (mTOR[c]1/2 inhibitor). Drug concentrations were chosen based on levels attainable in plasma (if known) or previously tested in vitro. PBMCs were isolated from eight ART-suppressed PWH, aliquoted into single or duplicate wells (6x10⁶ cells/well), and cultured for six days with ARVs and either DMSO (negative control), anti-CD3/CD28+IL-2, or individual drugs. After six days, we measured cell counts/viabilities and extracted DNA/RNA. Total, intact, and defective HIV DNA were measured by IPDA (4-10 replicates), normalized to copies/million cells (using DNA mass and housekeeping genes), expressed as percent of the DMSO control, and compared to DMSO (Wilcoxon signed rank test).

Results: A trend toward lower cell viability was observed with auranofin (median=86.7% of DMSO; P=0.11), FX-1 (median=84.6%; P=0.063), and obataclax (median=93.9%; P=0.078), so the doses were subsequently reduced. Obataclax reduced intact HIV DNA (median=17.0% of DMSO [range 0-82.9%]; P=0.0078) but not defective or total HIV DNA. A trend towards lower intact HIV DNA was also observed with auranofin (median=53.9%[0-156.5%]; P=0.11), bortezomib (median=78.6%[0-121.5%]; P=0.11), and INK128 (median=33.2%[0-138.2%]; P=0.12). IFNalpha2A resulted in the lowest median intact HIV DNA (18.2%), but effects were not consistent (range:0-232%; P=NS). Vesatolimod reduced 3'-defective HIV DNA (median=63.7%[0-87.3%]; P=0.031) and tended to reduce 5'-defective DNA (medi-

an=75.0%[0.5-101.4%]; P=0.063) but not intact or total HIV DNA. Other drugs showed no statistically significant effects.

Conclusions: Several drugs induced selective ex vivo depletion of cells with intact proviruses (obataclax, possibly auranofin, INK128, and bortezomib) or defective proviruses (vesatolimod). Their distinct modes of action on cell death/survival and innate immune response provide a strong rationale to compare the effects of drug combinations ex vivo and in animal or human trials.

OAA0303

Follicular T helper cells (TFH) are a minor source of the active HIV reservoir in secondary lymphoid tissues of people with HIV (PWH) on prolonged suppressive antiretroviral therapy (ART)

J.M. Folkvord¹, M. Ollerton¹, B.I. Mitchell², F. Yost², C.M. Shikuma², L.C. Nahlovu³, A. Chaillon⁴, D. Smith⁴, M. Porrachia⁴, S. Gianella⁴, E. Connick¹

¹University of Arizona, Tucson, United States, ²University of Hawaii/Hawaii Center for HIV/AIDS, Honolulu, United States, ³Weill Cornell Medicine, New York, United States, ⁴University of California San Diego, San Diego, United States

Background: TFH are considered major HIV RNA expressing (vRNA+) cells in secondary lymphoid tissues during chronic, untreated HIV/SIV. TFH are variably defined based on location in germinal centers, and/or expression of the canonical transcription factor BCL6 and multiple cell surface markers including PD-1. The phenotype of vRNA+ cells within secondary lymphoid tissues of PWH on prolonged suppressive ART is unknown. We investigated the distribution and expression of BCL-6 and PD-1 by vRNA+ cells in lymph nodes (LN) and spleen of PWH receiving virally suppressive ART.

Methods: Formalin-fixed paraffin-embedded LN tissue from 6 males on suppressive ART a median of 20 years were sectioned, baked at 60°C, deparaffinized and subjected to antigen retrieval and protease treatment. In situ hybridization (ISH) for vRNA (ACDbio), and immunofluorescent antibody staining for CD20 was performed and vRNA+ cell frequencies determined. Spleen from 6 male PWH on suppressive ART a median of >5 years were embedded in OCT, sectioned and fixed in paraformaldehyde. ISH for vRNA and BCL6, and immunofluorescent antibody staining for PD1 and CD20 was performed in 3 LN and 6 spleens and vRNA+ cell phenotypes determined. CD20+/CD20- areas defined follicular/extrafollicular regions, respectively. Data are reported as medians.

Results: Most vRNA+ cells in LN (55%; range, 33-69%) and spleen (91%; range 82-100%) were located in extrafollicular regions. Frequencies of vRNA+ cells were higher in follicular vs extrafollicular regions in LN (0.28 vs 0.17 cells/mm²) and spleen (0.07 vs 0.05 cells/mm²), but only 31% and 5.4% of tissue consisted of follicle, respectively. Twenty-five

HIV RNA+ cells were evaluated in LN (9, range 7-9 cells; n=3) and 182 in spleen (32, range 6-52 cells; n=6). Germinal centers were not observed. BCL6 was observed in 71% and 27%, and PD1 in 14% and 12% of vRNA+ cells in LN and spleen, respectively. Of vRNA+ cells, 14% (range 0-33%) in LN and 4% (range, 0-17%) in spleen were TFH (BCL6+/PD1+).

Conclusions: TFH are a minor source of the active reservoir in secondary lymphoid tissues of PWH on prolonged suppressive ART. Strategies to eliminate the active reservoir must identify and target additional cell phenotypes.

OAA0304

Hypoxic adaptation uncovers a glycolytic dependence of HIV-1 latency reversal

Y.I. Kayode¹, D.C. Clemmer¹, A.A. Owolabi¹, L.M. Clark¹, H.E. Taylor¹

¹SUNY Upstate Medical University, Microbiology and Immunology, Syracuse, United States

Background: The main barrier to HIV-1 curative strategies is the persistence of latently infected CD4 T cells in lymphoid tissue compartments which readily fuel viral rebound following antiretroviral therapy (ART) interruption in people living with HIV (PLWH).

However, our incomplete understanding of the role of the unique metabolic microenvironment in these tissues in controlling latency reversal remains a limitation to advancements in the field of HIV curative research.

Based on prior associations of glycolytic metabolites with post-translational modifications that facilitate HIV-1 replication during primary infection, and with viral rebound following ART interruption, we directly tested the hypothesis that glycolysis facilitates epigenetic modifications that promote HIV-1 latency reversal.

Methods: We utilized orthogonal pharmacological, metabolomic, and genetic tools in functional cell-based assays using multiple CD4 T cell models of HIV-1 latency. We also utilized Epi-FLOW, a single-cell flow cytometry-based assay developed in our lab to assess global epigenetic marks in reactivating cells.

All experimentation was performed in our hypoxic workstation which is maintained at 1% oxygen (physiologic hypoxia) or in standard normoxic tissue culture conditions (21% O₂).

Results: We show that CD4 T cell adaption to physiological hypoxia present in lymphoid tissues drives glucose sensitivity and glycolytic-dependence of HIV-1 latency reversal. By modelling physiologic variations in oxygen and glucose availability as found in HIV-1-harboring tissues *in vivo*, we uncover a differential glycolytic dependence of compounds from two clinically relevant latency reversal agent (LRA) classes; the PKC agonists and histone deacetylase inhibitors (HDACis) during physiologic hypoxia. Our metabolomic profiling reveals that this differential dependence on glycolysis is attributable to differential capacities of LRAs to induce glucose uptake and glycolytic

flux. We further define a role for glycolysis in facilitating both histone acetylation and lactylation, post-translational modifications associated with latency reversal.

Conclusions: Taken together, our current findings uncover glucose and oxygen availability as critical metabolic determinants of HIV-1 latency reversal and underscore the importance of executing studies of latency reversal under physiological conditions to identify compounds that effectively target the latent reservoir *in vivo*.

Analysis of HIV transcribing cells from viremic and virally-suppressed individuals living with HIV using novel single-cell RNAseq method

S. Telwatte^{1,2,3}, J. Frouard⁴, X. Luo⁴, D. Arneson⁵, GN. Kadiyala³, A. Wedrychowski³, R. Hoh⁶, A. Butte⁵, S. Deeks⁶, S. Lee⁶, N. Roan⁴, S. Yuk^{1,2,3}

¹The Peter Doherty Institute for Infection and Immunity, Infectious Diseases, Melbourne, Australia, ²University of California, San Francisco, Infectious Diseases, San Francisco, United States, ³San Francisco Veteran Affairs Medical Center, Infectious Diseases, San Francisco, United States, ⁴Gladstone Institute of Virology and Immunology, San Francisco, United States, ⁵University of California, San Francisco, Bakar Computational Health Sciences Institute, San Francisco, United States, ⁶San Francisco General Hospital, San Francisco, United States

Background: Latently-infected CD4+ T cells are considered the main barrier to a cure for HIV-1. During viral suppression under antiretroviral therapy (ART), a proportion of infected cells transcribe HIV and these are predictive of time to viral rebound after ART cessation. Characterization of this HIV-transcribing "reservoir" has been limited by technical challenges, including the very low frequency of HIV-1-transcribing cells, the low levels per cell of HIV RNA (most of which is not polyadenylated) in ART-treated individuals, the lack of cellular biomarkers to identify HIV-infected cells, and the fact that most HIV-infected cells reside in lymphoid tissues.

Methods: To address these limitations, we developed "HIV-Seq", a new single-cell (sc)RNAseq approach that incorporates custom-designed HIV-specific capture sequences and DNA-barcoded antibodies to key cell surface proteins (CITE-seq) into a single cell RNAseq (scRNAseq) workflow (10X Genomics).

Using this approach, we characterized the transcriptome and surface proteome of unstimulated HIV-infected cells from blood and gut tissue from people living with HIV (PWH).

HIV-Seq was applied to longitudinal samples obtained from 4 PWH before ART (Week 0) and after ART suppression (Week 24 or 45). CD4+ T cells were enriched using magnetic beads and stained with DNA-tagged antibodies. HIV capture sequences were incorporated during library preparation.

We also characterised leukocytes (CD45+) and T cells (CD3+) from the blood and gut of one ART-suppressed individual. scRNAseq and CITE-seq analyses were performed and sequences were aligned to a constructed subtype B consensus reference sequence.

Results: In the viremic samples, HIV-seq enabled identification of 32-72% more HIV RNA+ cells than scRNAseq without HIV-specific primers. HIV transcripts aligned to pol and gag regions at the highest frequency, irrespective of capture, however HIV-seq typically yielded more HIV transcripts/infected cell.

In total, we identified 1345 HIV RNA+ cells from viremic timepoints and 26 HIV RNA+ cells from the ART-suppressed timepoints representing the transcriptionally-active reservoir.

Conclusions: Our HIV-Seq method enables efficient identification and characterization of HIV-infected cells including in the context of ART suppression, allowing for in-depth transcriptomic and surface phenotypic analysis of HIV-transcribing reservoir cells.

Novel V1 deleted-envelope vaccine based on VLP protects against SHIV infection

I. Silva de Castro¹, A.M. Rahman¹, M. Bissa¹, J.D Stamos¹, S. Sarkis¹, M. Doster¹, A. Gutowska¹, K. N'guessan², D. Paquin-Proulx², T. Cardozo³, G. Franchini¹

¹NIH, CCR, Bethesda, United States, ²MHRP, Walter reed Army Institute of Research, Silver Spring, United States, ³New York University School of Medicine, New York, United States

Background: Our group have demonstrated that vaccination based in Viral Like Particles (VLP) using DNA/ALVAC/gp120+Alum platforms delivering SIV envelope immunogens engineered by V1 deletion to favor α -helix conformation of V2, was superior to wild type (WT) envelope immunogens in decreasing the risk of SIVmac₂₅₁ acquisition in macaques. In the current study we investigate whether a similarly engineered vaccine based on HIV also differed from WT-based envelope immunogens in immunogenicity and efficacy.

Methods: We created a DV1 gp160 DNA vaccine by deleting V1 (DV1 gp160) in the envelope of HIV clade A/E (HIV A244) and expressed also the corresponding DV1 A244 gp120 protein in CHO cells. DV1 or WT gp160 combined with p55Gag DNA vaccine were given at week 0, 4, followed by two immunizations with ALVAC-HIV at week 8 and 12; one WT or DV1 HIV A244 gp120 protein boost in alum was given at week 12. Two months following the last immunization animals were exposed to 11 weekly low doses of SHIV 1157(QNE) Y173H intrarectally.

Results: The DV1 immunogens decreased the risk of SHIV 1157 (QNE) acquisition by 81% compared to controls, whereas the WT immunogens did not, recapitulating the results obtained with SIV-based vaccines.

Analyses of immune response elicited by the HIV A244WT and A244DV1 immunogens revealed several differences. Immunization with DV1, elicited higher V2-specific ADCC, and more efficient efferocytosis, responses correlating with the decreased risk of virus acquisition also in the SIV.

Similarly, the frequency of mucosal CD14 + cells, IgG envelope specific B-cells (that correlated directly with V2-specific ADCC), CCR2+ and of CD73+ rectal macrophages and in non-classical blood monocytes was higher in DV1 than WT immunized animals. The two immunization regimens differed also in the level of trogocytosis, that was higher in WT immunized animals and correlated negatively with V2-specific ADCC.

Conclusions: Thus, for reasons that are unclear at present, we conclude that V1 affects protective responses against HIV and further studies will be needed to address the mechanism(s).

OAA0403

Perturbation of mucosal granulocytic effector cells in lentivirus infections

C. Manickam¹, A. Afifi², R. Jones², S. Sugawara², R.K. Reeves²

¹Duke University, Surgery, Durham, United States,

²Duke University, Durham, United States

Background: Granulocytes including eosinophils and neutrophils, are critical innate effector cells bearing high Fc receptor expression and armed with a preformed pool of inflammatory and cytotoxic mediators and are also highly enriched in the GI mucosae. However, their roles in lentiviral-mediated intestinal pathology and immunoprotection have been largely overlooked.

To address this deficit, we studied granulocyte phenotypes, distribution, function and signaling using nonhuman primate models of HIV infection and as well as human blood samples.

Methods: Mononuclear cells and tissue samples from jejunum, colon, cervix, vagina, lymph nodes, spleen, liver, and whole blood of naïve, acute SIVmac251-, and chronic SHIVsf162p3-infected rhesus macaques (RM) were analyzed by imaging cytometry and advanced polychromatic flow cytometry.

Peripheral granulocytes of naïve RM and humans were used for controls and for functional assays, including respiratory burst assay by flow cytometry, 'net'osis assay by confocal microscopy and multiplex signaling analyses.

A neutrophil antibody-mediated cell phagocytosis (ADNP) assay used HIV-gag opsonized fluorescent microbeads and HIV-specific antibodies.

Results: Flow cytometric and imaging data confirmed granulocyte phenotypes as CD45⁺CD66abce⁺CD14⁺CD49d⁺ neutrophils and CD45⁺CD66abce⁺CD14⁺CD49d⁺ eosinophils

based on their surface marker expression, nuclear morphology, and cytoplasmic granularity in whole blood and tissues.

Significant modulation of granulocytic subsets was observed in mucosal sites of SIV/SHIV replication as evidenced by depletion of jejunal eosinophils and vaginal neutrophils and eosinophils. Interestingly, neutrophils in circulation and colorectal biopsies were elevated indicating tissue-specific modulation of granulocytes in chronic SHIV infection.

Further, the efficacy of RM and human granulocytes as Fc effector cells was substantiated in vitro by their ability to generate reactive oxygen species, phosphorylation of important signaling adaptors including Syk, ZAP70, Lck and LAT upon CD32 and CD16 crosslinking and extracellular trap generation. In addition to FcγR-mediated responses, we observed elevated phagocytosis when neutrophils were cultured in the presence of VRC01-IgA compared to the VRC01-IgG subtype, indicating HIV-specific mucosal activity.

Conclusions: Granulocytes are depleted in SIV/SHIV infection, notably in the gastrointestinal and reproductive mucosae where significant inflammation and disruption occurs in lentivirus-induced disease. Mucosal depletion of granulocytes could potentially lead to pathogenic co-morbidities and also adversely affect the outcome of antibody-based therapies and HIV cure, thus warranting further studies.

OAA0404

Diverse envelope trimers with altered glycan coverage around the CD4-binding site elicit neutralizing antibodies of >50% breadth in NHPs

X. Chen¹, T. Zhou¹, C. Cheng¹, Z. Sheng², E.-S. Stancovski¹, A.R. Corrigan¹, E. Sarfo¹, S. Charaf¹, K. McKee¹, M. Louder¹, N.A. Doria-Rose¹, B. Zhang¹, J.R. Mascola¹, R. Koup¹, L. Shapiro², P. Kwong¹

¹VRC/NIAID/NIH, Bethesda, United States,

²Columbia University, New York, United States

Background: Vaccine elicitation of broadly neutralizing antibodies (bnAbs) remains a challenge to the development of an effective HIV-1 vaccine. BnAbs targeting the conserved CD4-binding site (CD4BS) have been identified in many HIV patients and are often broad and potent. Immunization with stabilized HIV-1 envelope trimers (Env) generally only elicits autologous or narrow-breadth neutralization.

We previously reported that Env trimers with four glycans removed around the CD4BS elicited strong neutralizing response to the glycan-removed CD4BS but not to wild-type glycan-covered envelopes in NHPs.

Methods: We further boosted the above NHPs with diverse Env trimers, first with removed glycans partially restored (2-3x each) and then with natively glycosylated HIV-1 Envs (6x). Sera and PBMCs were collected two weeks

after each immunization and analyzed for neutralization and B cell recognition. B cell sorting and RT-PCR for antibody identification were performed at terminal time point. Binding, neutralization, and cryo-EM analyses were performed on identified IgGs. Longitudinal NGS was performed for two NHPs with bnAb lineages.

Results: Boosting with partially glycan-restored and natively glycosylated HIV-1 Envs resulted in broadly serum neutralizing responses in a subgroup of nonhuman primates, four of which neutralized more than 10 out of 17 tested tier II isolates.

From B cell sorting with BG505.SOSIP and its CD4BS-knock-out mutant as probes, we isolated multiple neutralizing antibodies from these four NHPs. The top two antibodies, A11V093-10 and A13V144-91, from two different NHPs, neutralized 56% and 54% of viruses in a 208-isolate panel, respectively.

Cryo-EM structures showed that they both targeted the CD4BS with heavy-light chain orientation flipped relative to that of VRC01. Both mimicked key CD4 and VRC01 interactions to HIV-1 gp120, but A13V144-91 used a flexible and shortened CDR-H1 to accommodate glycan 276 while A11V093-10 bound to gp120 with an epitope that shifted away from glycan 276 to reduce interaction to this glycan and achieve broad neutralization. Longitudinal NGS analyses of the two bnAb lineages indicate that the initial expansion of the lineages coincided with immunization by the first glycan-restored trimer containing a restored glycan at N197.

Conclusions: Env trimer immunization with glycans modulated around the CD4BS can elicit broadly neutralizing CD4BS antibodies in NHP.

Protective efficacy of intranasal vaccination with a Sendai virus vector expressing a spike antigen against SARS-CoV-2 infection in mice

H. Ishii¹, K. Miyauchi¹, S. Harada¹, M. Nakamura-Hoshi¹, S. Seki¹, D. Kaneda^{1,2}, M. Okazaki¹, T. Matano^{1,2,3}

¹AIDS Research Center, National Institute of Infectious Diseases, Tokyo, Japan, ²Institute of Medical Science, University of Tokyo, Tokyo, Japan, ³Joint Research Center for Human Retrovirus, Kumamoto University, Kumamoto, Japan

Background: Currently approved COVID-19 vaccines have shown strong protective efficacy against disease onset and progression after SARS-CoV-2 infection. However, systemic immune responses induced by intramuscular vaccination have limited impact on protection of viral transmission. Intranasal vaccination is an important strategy for induction of mucosal immune responses for protection of viral transmission.

We have previously reported protective efficacy of intranasal vaccination with a Sendai virus (SeV) inducing CD8⁺ T cell responses against SARS-CoV-2 infection (Cell Rep

Med 3:100520, 2022). In the present study, we investigated the potential of intranasal SeV vaccination inducing mucosal neutralizing antibody responses to prevent SARS-CoV-2 infection in a mice model.

Methods: BALB/c mice received two times of intranasal vaccination with a SeV vector expressing SARS-CoV-2 S1 domain fused with foldon, the trimerization domain of T4 fibrin (SeV-S1-fol), produced by ID Pharma, Co., Ltd. SeV-S1-fol-vaccinated and unvaccinated mice were intranasally challenged with a mouse-adapted SARS-CoV-2 strain QHmusX provided by Noriyo Nagata (Sci Adv 8:eabh3827, 2022). Viral sgRNA levels and infectious viral titers were examined in bronchoalveolar lavage fluid (BALF) obtained on day 3 post-challenge.

Results: Intranasal SeV-S1-fol vaccination induced not only anti-S IgG in plasma but also anti-S IgA in BALF and nasal wash. Anti-SARS-CoV-2 neutralizing activity was detected not only in plasma but also in BALF in the vaccinated mice. After SARS-CoV-2 challenge, all the nine unvaccinated mice showed significant body weight loss and high viral loads, sgRNA levels and infectious viral titers, in BALF. In contrast, all the wight vaccinated mice with no body weight loss had no detectable viral sgRNA nor infectious viruses in BALF except for one mouse with marginal sgRNA.

Conclusions: The present study indicates the potential of intranasal SeV-S1-fol vaccination to efficiently induce mucosal anti-SARS-CoV-2 neutralizing antibody responses and confer sterile protection from SARS-CoV-2 infection.

changes in PHIV+ and healthy controls enrolled in the Cape Town Adolescent Antiretroviral Cohort Study (CTAAC).

Methods: The Illumina EPIC array was used to generate blood DNA methylation data from 60 PHIV+ adolescents and 36 age-matched controls aged 9–12 years old at baseline, and again at a 36-month follow-up. Epigenetic clock software estimated two measures of epigenetic age acceleration: extrinsic epigenetic accelerated aging (EEAA) and age acceleration difference (AAD) at both timepoints.

At follow-up, each participant completed neuropsychological testing, structural magnetic resonance imaging, and diffusion tensor imaging.

Results: At follow-up, PHIV status remained associated with increased EEAA and AAD. Accelerated epigenetic aging remained positively associated with viral load and negatively associated with CD4 ratio. EEAA was positively associated with whole brain grey matter volume and alterations in whole brain white matter integrity. These results did not differ between genders. AAD and EEAA were not associated with cognitive function within the PHIV+ group.

Conclusions: Measures of epigenetic aging, as detected in DNA methylation patterns, remain increased in PHIV+ adolescents across a 36-month period. Associations between epigenetic aging measures, viral biomarkers, and alterations in brain micro and macrostructure also persist at 36-month follow-up. Increased variance in DNAmAg-ing might indicate varying degrees of immune health response to treatment and development trajectories.

Accelerated epigenetic aging is also associated with virologic and treatment related variables such as CD4 ratio and VL, indicating the importance of disease management during the adolescent stage.

Neuroimaging results showed that epigenetic aging is associated with reduced white matter fractional anisotropy and increased mean diffusion, indicating white matter microstructural damage. PHIV+ additionally have larger grey matter volumes, possibly due to ineffective pruning during the adolescent period.

Background: Cytomegalovirus (CMV) is a cause of severe pneumonia in children with advanced HIV. Valganciclovir, the oral prodrug of ganciclovir, is used to treat CMV in immunocompromised hosts. No pharmacokinetic data is available to support valganciclovir dosing in infants living with HIV.

This study aimed to determine adequacy of dosing and sources of pharmacokinetic variability of ganciclovir in infants living with HIV with severe pneumonia.

Methods: The study was conducted within EMPIRICAL trial (#NCT03915366) for the treatment of severe pneumonia in infants living with HIV. Participants randomized to receive valganciclovir for empirical CMV treatment were recruited from hospitals in Zimbabwe, Zambia, Mozambique and Uganda between August 2020-August 2022. Valgan-

ciclovir reconstituted syrup was given at 16mg/kg/dose every 12 hours and pharmacokinetic sampling was done 2 and 5 hours post-administration on day 3 of enrolment after at least 3 doses. Ganciclovir area-under-curve for a 12-hour dosing interval (AUC_{0-12h}) was estimated using a limited sampling equation ($AUC_{0-12h} = 2.7 \cdot AUC_{2-5h} + 6$) [Villevue 2013]. The geometric mean AUC_{0-12h} and number of subjects within the pharmacokinetic target for CMV treatment ($AUC_{0-12h} = 80-120 \text{ h} \cdot \text{mg/L}$) were determined. Spearman's rank test was applied to test the extent to which baseline parameters (age, weight, weight-for-age, eGFR and BSA) correlated with ganciclovir AUC_{0-12h} .

Results: Geometric mean AUC_{0-12h} (%CV) was 77.7 (54.4) $\text{h} \cdot \text{mg/L}$. Of the 85 recruited participants, only 30 (35%) had AUC_{0-12h} within the pre-defined efficacy target for CMV treatment. The remaining subjects were either below (40 (47%)) or above (15 (18%)) the target. There was a positive correlation between AUC_{0-12h} and weight-for-height z-score ($r(83) = .22$, $p = .042$). A negative correlation was observed between AUC and age ($r(83) = -.41$, $p < .001$), eGFR ($r(83) = -.36$, $p = .001$) and BSA ($r(83) = -.25$, $p = .021$).

Conclusions: A significant number of participants did not achieve the PK target for CMV treatment when receiving valganciclovir at 16mg/kg/dose twice daily. This could result in decreased treatment response or failure. Exposure to valganciclovir decreased with increasing age, BSA, eGFR, and poorer nutritional status. Future studies should investigate the clinical significance of these findings and if higher dosing or an alternative dosing strategy is required. This project is part of the EDCTP2 programme supported by the European Union (grant number RIA RI-A2017MC-2013).

Virological Studies (IDEV), Santiago, Dominican Republic

Background: Safe, effective, and convenient treatment options are needed for pregnant women with HIV. Bictegravir (BIC) is highly protein bound and metabolized by uridine diphosphate glucuronosyltransferase 1A1 (UGT1A1) and cytochrome P450-3A4 (CYP3A4). Physiological changes during pregnancy, including increased CYP3A4 and UGT1A1 activities, have been reported; however, limited data exist on B/F/TAF pharmacokinetics, safety, and efficacy during pregnancy.

Methods: A dedicated open-label study (NCT03960645) was conducted in 33 virologically suppressed pregnant women with HIV-1. Steady-state plasma samples were collected over 24 hours following oral administration of B/F/TAF during second and/or third trimesters of pregnancy, and 6 and 12 weeks postpartum. For BIC and TAF, protein binding was measured and serial sparse samples collected in neonates. Geometric least-squares mean (%GLSM) ratios were calculated for pharmacokinetic comparisons between pregnancy and postpartum samples. Plasma HIV-1 RNA and trough peripheral blood mononuclear cell (PBMC) tenofovir diphosphate (TFV-DP) levels were measured. The proportion of participants with HIV-1 RNA <50 copies/mL (missing=excluded) at delivery was calculated.

Results: GLSM values for plasma B/F/TAF were lower during pregnancy versus postpartum (%GLSM ratios <100). For BIC and TAF, %GLSM ratios were higher when adjusted for protein binding, although they remained lower during pregnancy (Table).

	BIC		FTC		TAF	
	AUC ₀₋₂₄	Unbound AUC ₀₋₂₄ *	AUC ₀₋₂₄	AUC ₀₋₂₄	Unbound AUC ₀₋₂₄ *	
Second trimester vs. 6 weeks postpartum	n=20/31		n=21/31		n=15/27	
	44.65 (40.04, 49.79)	61.78 (55.34, 68.97)	64.26 (60.95, 67.75)	62.50 (50.76, 76.96)	83.61 (72.86, 95.94)	
Second trimester vs. 12 weeks postpartum	n=20/32		n=21/32		n=15/30	
	41.24 (36.71, 46.32)	59.73 (52.48, 68.09)	67.38 (63.45, 71.56)	77.62 (65.40, 92.14)	89.27 (79.02, 100.84)	
Third trimester vs. 6 weeks postpartum	n=30/31		n=30/31		n=17/27	
	44.40 (39.95, 49.34)	62.40 (55.68, 68.93)	65.09 (61.79, 68.57)	56.52 (46.32, 68.96)	86.16 (71.91, 103.23)	
Third trimester vs. 12 weeks postpartum	n=30/32		n=30/32		n=17/30	
	40.57 (36.77, 44.76)	58.84 (52.74, 65.66)	89.19 (85.88, 92.56)	69.67 (56.57, 82.88)	89.15 (78.23, 101.58)	

Table. %GLSM ratios (90% CI) of AUC₀₋₂₄ for B/F/TAF between second or third trimester in pregnancy (test) versus 6 weeks or 12 weeks postpartum (reference).

Trough PBMC TFV-DP levels were generally similar during pregnancy and postpartum. All pregnant women maintained virologic suppression, with HIV-1 RNA <50 copies/mL at delivery (n=32 [100%]). In neonates, median (IQR) BIC half-life was 43 (38, 58) hours, and TAF was below the quantitation limit in all neonates.

There were no adverse events (AEs) leading to premature discontinuation and no drug-related AEs in pregnant women or neonates.

Conclusions: Despite the comparatively lower exposure to BIC, emtricitabine, and TAF during pregnancy versus postpartum, all adult participants maintained virologic suppression, and B/F/TAF was generally well tolerated, suggesting appropriateness for use of B/F/TAF during pregnancy and indicating that no dose change is needed.

OAB0105

Virological dynamics among children living with HIV transitioned to a dolutegravir-based regimen in Nigeria

I. Ani¹, M. Unimuke², F. Agu³, E. Umana³, A. Achanya³, E. Udofia², C. Ezissi¹, A. Idemudia⁴, E. Nwanja¹, U. Akpan¹, K. Agu³, O. Toyo¹, A. Adeoye¹, O. Onyedinachi¹, D. Ogundehin⁵, E. James⁵, A. Eyo¹, O. Omeh³, D. Oqua³
¹Excellence Community Education Welfare Scheme, Uyo, Nigeria, ²Achieving Health Nigeria Initiative, Uyo, Nigeria, ³Howard University, Abuja, Nigeria, ⁴FHI 360, Abuja, Nigeria, ⁵USAID, Abuja, Nigeria

Background: Nigeria adopted the use of dolutegravir (DTG)-based regimen as the preferred first line ART regimen for children living with HIV (CLHIV) in July 2021 and immediately commenced transitioning those on protease inhibitor (PI)-based regimen to DTG. This paper aims to assess virological dynamic upon transitioning from PI- to DTG-based regimen amongst CLHIV in Nigeria.

Methods: We conducted an institutional-based retrospective cohort study using data from the electronic medical records from 155 health facilities in Akwa Ibom and Cross River States support by PEPFAR through United State Agency for International Development (USAID). The cohort included CLHIV (<=9 years) who were transitioned from PI-based to DTG-based regimen between July 2021 and December 2021.

The baseline viral load at transitioning and 12 months after transition was abstracted, and categorized as undetectable viral load (<=40 copies/ml), low-level viremia (41-999copies/ml), or unsuppressed) viral load (>=1000 copies/ml). Chi-square statistics was used to compare proportional difference in viral load change using STATA version 14 with statistical significance set at p<0.05.

Results: A total of 2,358 CLHIV were transitioned to DTG-based regimen as of December 2021. Median age was 6years [IQR: 4-7years], and 51.0% (n=1,203) were females. At baseline 81.6% (n=1,924) were undetectable, 14.6% (n=345) had low-level viremia while 3.8% (n=89) were unsuppressed (>=1000 copies/ml). Of the 2,148 (91.1%) CLHIV who remained on ART 12 months after transitioning, 90.6% (n=1,947) were undetectable, 7.0% (n=150) had low-level viremia while 2.4% (n=51) were unsuppressed (>=1000 copies/ml). There was no sex difference in virological dynamics [Male = 91.7% versus Female = 92.5%; p = 0.374].

Conclusions: Children living with HIV achieved favourable virological changes when transitioned to DTG-based regimen. Programs should prioritize DTG-based regimen in children in order to improve their treatment outcomes.

OAB0202

Prior M184V/I and multiple prior virological failures have no impact on the efficacy of switching HIV+ adults to DTG/3TC through 96Wks in SOLAR-3D

G. Blick¹, E. Cerreta¹, G. Mancini¹, A. Cosenza¹, L. Fang²

¹Health Care Advocates International, Stratford, United States, ²Pharstat Inc., Raleigh, United States

Background: DTG/3TC is approved for virologically suppressed HIV+ adults switching from stable ART with no prior DTG or 3TC resistance or prior virologic/treatment failure. SOLAR-3D prospectively evaluated the ability of DTG/3TC to maintain virologic suppression in adults switched in the setting of prior and current M184V/I and multiple virologic failures.

Methods: SOLAR-3D is a prospective, open-label, comparative 96-week study of HIV-1+ adults virologically suppressed for ≥6mos, with ≥3 prior ART and prior virologic failures, enrolled from May 2019-April 2020 and stratified by history of prior M184V/I. There were no exclusions for prior INSTI use, any CD4, prior M184V/I, or 3TC-associated mutations detected at BL by proviral DNA NGS.

Primary and Secondary Efficacy Endpoints: participants with PCR≥50 at Wk48 and 96, resp. by FDA snapshot (ITT-E and PP). **Additional Secondary Endpoints:** PCR<50 at Wk48 and 96 (ITT-E, PP), incidence of AEs and discontinuation due to CVF (PCR≥50 followed by PCR >200).

Results: 100 adults switched to DTG/3TC, n=50 with historical/prior M184V/I (n=15 with current M184V/I by proviral DNA NGS) and n=50 without prior M184V/I. Those with prior M184V/I had more prior virologic failures (n[IQR]: 9[7-13]v4[3-5], p<0.001) and longer median duration HIV (28.4v15.5yrs, p<0.001), were older, and had lower nadir CD4, longer ART duration, and longer duration PCR<50c/mL. Median time on DTG/3TC was 137wks for both groups. At Wks 48 and 96, no difference in efficacy was observed in those with prior M184V/I compared to those without prior M184V/I:

- Primary Endpoint: PCR≥50c/mL, n[%]: Wk48: 1[2]v3[6], ITT-E (2.1v6.4, PP); Wk96: 2[4]v1[2], ITT-E (4.6v2.2, PP);
- Secondary Endpoint: PCR<50, n[%]: Wk48: 46[92]v44[88], ITT-E (97.9v93.6, PP); W96: 42[84.0]v44[88.0], ITT-E (95.5v97.8, PP);
- Viral blips ≥50 at Wk96 (2v1) re-suppressed at follow-up. No CVF were observed in either group;
- At Wk96, no differences regarding PCR TND (<20), viral blips, AEs, or discontinuations were observed;
- Baseline Proviral DNA NGS demonstrated M184V/I was no longer present in 64.4% of those with prior M184V/I.

Conclusions: Through 96wks, SOLAR-3D, the largest prospective trial evaluating DTG/3TC switch in individuals with prior 3TC-associated mutations, confirms prior his-

tory/current presence of M184V/I doesn't impact the efficacy of switching virologically suppressed HIV+ adults with multiple prior virologic failures.

Background: Some components of approved antiretroviral therapies (ART) are associated with weight gain and/or lipodystrophy (peripheral lipodystrophy and/or central fat hypertrophy). We evaluated changes in weight and body composition 48 weeks after switch to once-daily DOR/ISL (100/0.75mg) in two phase 3 studies.

Methods: P017 (NCT04223778) was an open-label study in adults receiving any oral 2- or 3-drug ART regimen. P018 (NCT04223791) was a double-blind study in adults receiving bicitgravir/emtricitabine/ tenofovir alafenamide (B/F/TAF).

Participants with HIV-1 RNA <50 copies/mL were randomized (1:1) to switch to once-daily DOR/ISL (100/0.75mg) or to continue baseline ART (bART) (P017) or B/F/TAF (P018); P017 randomization was stratified by bART, which was PI-based in 14% of participants, INSTI-based in 52%, and Other (mainly NNRTI-based) in 34%. Peripheral fat and trunk fat were measured by DEXA scan and were evaluated by a central imaging reader.

Results: 658 participants switched to DOR/ISL (100/0.75mg), 336 remained on bART, and 319 remained on B/F/TAF. Baseline weight differed by prior regimen in P017 (Table). Mean weight gain was similar for DOR/ISL vs continued B/F/TAF or other INSTI-based regimens but was higher for DOR/ISL vs continued PI-based or NNRTI-based regimens (Table).

Mean changes from baseline in peripheral and trunk fat were similar for DOR/ISL vs continued B/F/TAF in P018 but were higher for DOR/ISL vs continued bART in P017 (Table). In a post hoc analysis of P017, mean increases in weight, peripheral fat, and trunk fat were higher for DOR/ISL vs

continued bART containing efavirenz (EFV) and/or TDF but were similar for DOR/ISL vs continued non-EFV/non-TDF regimens (Table).

	Switch to DOR/ISL (100/75mg)			Continue bART (P017) or B/F/TAF (P018)			Difference (95% CI)*
	N	Baseline Mean	Mean Change	N	Baseline Mean	Mean Change

w/ EFV or TDF	92	12052.9	785.5	90	13215.8	-152.9	918.2 (396, 1441)
No EFV or TDF	190	11985.1	139.1	179	11480.3	-34.5	157.8 (-169, 485)
P018	230	11345.2	19.0	232	11265.3	26.6	-6.6 (-259, 247)
Trunk fat (g)							
P017 Overall	282	13861.9	406.7	278	13589.0	-19.3	444.9 (94, 794)
w/ EFV or TDF	92	13119.8	1298.3	90	13589.8	-18.8	1281.5 (659, 1908)
No EFV or TDF	190	14221.2	4.0	179	13525.0	-6.8	52.7 (-384, 490)
P018	230	14343.7	-13.9	232	14360.1	85.0	-95.4 (-459, 261)

* Treatment difference is DOR/ISL versus comparator. For the P017 analysis overall and by presence of TDF or EFV in baseline regimen, the 95% CI for treatment difference were calculated from ANCOVA models with terms for baseline weight, sex at birth, race, the controlled weight factor, and treatment groups. For the P017 analysis by baseline ART status and for P018, the 95% CI for treatment difference are calculated from ANCOVA models with terms for baseline weight, sex at birth, race, and treatment groups.

* Treatment difference is DOR/ISL minus comparator. For the P017 analysis overall and by presence of TDF or EFV in baseline regimen, the 95% CIs for treatment difference were calculated from ANCOVA models with terms for baseline weight, sex at birth, race, the corrected stratification factor, and treatment group. For the P017 analysis by baseline ART strata and for P018, the 95% CIs for treatment difference are calculated from ANCOVA models with terms for baseline weight, sex at birth, race, and treatment group.

Table. Change from baseline in weight and body fat at week 48 by treatment group in P017 and P018.

Conclusions: Changes in weight and body fat after switch to DOR/ISL were similar to continuing bART, except among participants who switched from EFV and/or TDF, which are known to suppress weight gain. Switching from InSTI-based regimens to DOR/ISL did not reduce weight over 48 weeks.

OAB0204

High rates of long-term HIV RNA re-suppression after virological failure on dolutegravir in the ADVANCE trial

B. Bosch¹, S. Sokhela¹, G. Akpomiemie¹, N. Chandiwana¹, W.D.F. Venter¹, B. Simmons², K. McCann³, M. Mirchandani³, A. Hill⁴

¹Ezintsha, University of the Witwatersrand, Faculty of Health Sciences, Johannesburg, South Africa,

²London School of Economics and Political Science, LSE Health, London, United Kingdom, ³Imperial College London, Faculty of Medicine, London, United Kingdom,

⁴University of Liverpool, Department of Pharmacology and Therapeutics, Liverpool, United Kingdom

Background: WHO Guidelines currently recommend switching to next-line antiretroviral treatment (ART) for individuals with sustained HIV RNA viral load (VL) ≥ 1000 copies/mL despite adherence counselling. However, individuals can re-suppress after adherence counselling, with no change in treatment.

We compared rates of virological failure and re-suppression in the ADVANCE trial of first-line treatment in South Africa.

Methods: In ADVANCE, 1053 treatment-naïve individuals were randomised to TAF/FTC/DTG, TDF/FTC/DTG or TDF/FTC/EFV for 192-weeks. All individuals with VL > 1000 copies/mL received enhanced adherence counselling within

4 weeks. Time to first VL ≤ 50 copies/mL was compared between treatment arms using Kaplan-Meier methods. Rates of virologic failure (any VL ≥ 1000 copies/mL after Week-24) were then compared. For individuals with virological rebound, rates of VL re-suppression < 50 copies/mL were compared with follow up to Week 192.

Results: Time to suppression ≤ 50 copies/mL was significantly shorter in the combined DTG arms (4 weeks) compared to the EFV arm (12 weeks); (log-rank $p < 0.001$). The proportion with virologic failure was similar across arms (combined DTG 87/702 [12%] vs EFV 33/351 [9%]; log-rank $p = 0.343$). However, more individuals on EFV remained viraemic prior to failure (12/33 [36%] compared with DTG 10/87 [11%]; $p = 0.002$). For individuals with rebound ≥ 1000 copies/mL after Week 24, time to re-suppression was significantly shorter for DTG (12 weeks) than EFV (26 weeks); log-rank $p < 0.001$. There were no cases of treatment-emergent DTG resistance in the individuals with virological failure ≥ 1000 copies/mL.

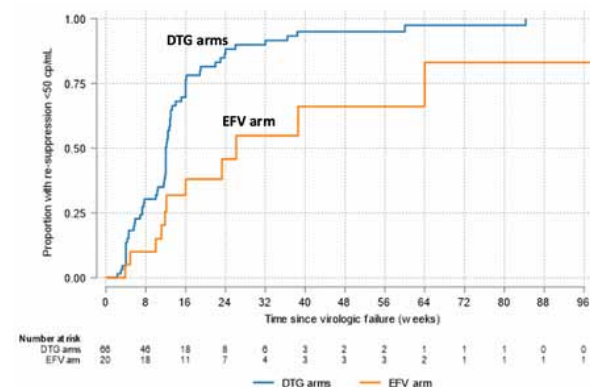

Figure. HIV RNA re-suppression rates in ADVANCE trial. Time from HIV RNA > 1000 to resuppression < 50 copies/mL

Conclusions: In ADVANCE, episodes of viraemia ≥ 1000 copies/mL were seen at similar rates across treatment arms. However, HIV RNA re-suppression after viraemia ≥ 1000 copies/mL was significantly more likely for individuals taking either TDF/FTC/DTG or TAF/FTC/DTG, compared with TDF/FTC/EFV. Long-term follow-up suggests most individuals on continued DTG after viraemia elevation can re-suppress with enhanced adherence counselling. These results question the need for switch to 2nd line PIs after VF on DTG.

OAB0205

Lenacapavir oral bridging maintains efficacy with a similar safety profile when SC LEN cannot be administered

O. Ogbuagu¹, A. Avihingsanon², S. Segal-Maurer³, H. Wang⁴, M. Rhee⁴, H. Dvory-Sobol⁴, P. Sklar⁴, J.-M. Molina⁵
¹Yale University School of Medicine, New Haven, United States, ²Thai Red Cross AIDS Research Centre, HIV-NAT, Bangkok, Thailand, ³New York Presbyterian Queens, New York, United States, ⁴Gilead Sciences, Inc., Foster City, United States, ⁵University of Paris Cité, Paris, France

Background: Lenacapavir (LEN) is a first-in-class, long-acting, HIV-1 capsid inhibitor, recently approved, in combination with other antiretrovirals, for treatment of multidrug-resistant (MDR) HIV-1. Subcutaneous (SC) LEN provides a Q6M treatment option for HIV-1; however, potential SC treatment interruptions may lead to management challenges due to SC treatment gaps. This subanalysis investigated the efficacy and safety of an oral bridging (OB) regimen (LEN 300 mg PO QW) in participants with MDR HIV-1 as well as treatment-naïve people with HIV-1 (PWH) enrolled in the CAPELLA and CALIBRATE studies, respectively, when SC LEN dosing was interrupted due to its clinical hold.

Methods: Virologic suppression, CD4+ cell counts, and safety outcomes were assessed from available data at baseline (time of initiation of OB) and until SC resumption or early discontinuation from OB due to FDA clinical hold (12/2021–05/2022).

Results: Of 72 participants who received SC LEN in CAPELLA, 57 received OB (79%) and were included in this analysis. Of 105 participants who received SC LEN in CALIBRATE, 82 received OB (78%). In both studies, demographic and baseline characteristics were similar between OB and overall analysis sets. Median OB exposure was 19 weeks, and OB adherence (by pill count) was ≥95% in most participants. Results were consistent across both subanalyses. High virologic suppression rates were maintained among those already suppressed (HIV-1 RNA <50 copies/mL) at OB baseline in CAPELLA and in all participants in CALIBRATE (Table).

n/N (%)	CAPELLA ^{a,b}	CALIBRATE ^b
OB Baseline	46/46 (100)	82/82 (100)
OB Week 10	44/45 (98)	77/77 (100)
OB Week 20	30/31 (97)	58/58 (100)
OB Week 30	10/10 (100)	5/5 (100)

^aParticipants had virologic suppression at OB Baseline ^bDenominators reflect participants who reached the specified duration of OB.

Table: Number and Proportion of Participants With HIV-1 RNA < 50 copies/mL by Visit, Missing = Excluded

CD4 (abs/%) remained stable or increased from OB baseline. One participant (CAPELLA) who missed 2 non-consecutive oral LEN doses did not maintain virologic suppression during OB. Treatment-emergent AEs were similar to

SC LEN. Two participants in CAPELLA (3.5%) and 1 participant in CALIBRATE (1.2%) experienced treatment-related diarrhea.

Conclusions: High rates of virologic suppression, and stable or increased CD4, support efficacy of OB in PWH, including those with MDR HIV-1 whose SC LEN treatment was interrupted. During OB, LEN was generally safe and well tolerated.

OAB03 It's all about the bugs: Other conditions in people with HIV

HIV among mpox cases: clinical characteristics and outcomes in the WHO global surveillance 2022

A. Hoxha¹, S. Kerr², H. Laurenson-Schafer¹, N. Sklenovská¹, P. Ndumbi Ngamala¹, B.B. Mirembe¹, J. Fitzer¹, V. Ndarukwa¹, I. Hammermeister Nezu¹, K. Kaasik-Aaslav¹, B.J. Greene-Cramer¹, L. Alexandrova Ezerska¹, T.P. Metcalf¹, E. Hamblion¹, M. Doherty¹, M. Prochazka¹, A.N. Seale¹, R. Lewis¹, O. Le Polain de Waroux¹, B.I. Pavlin¹, WHO Global Monkeypox Epidemiology Team
¹World Health Organization, Geneva, Switzerland, ²CPC Analytics, Berlin, Germany

Background: Since May 2022, the ongoing multi-country mpox outbreak has primarily affected gay, bisexual and other men who have sex with men (GBMSM). In some countries up to 50% of cases have been reported among people living with HIV (PLHIV), and although HIV is not a risk factor for mpox, it might lead to increased risk for complications and severe disease.

Methods: We analysed data from January to December 2022 from the mpox global case-based surveillance system, established by WHO in collaboration with regional and national partners. We included all cases with available information on HIV status, and described epidemiological, clinical characteristics and outcomes in PLHIV. We used binomial logistic regression to explore whether living with HIV and immunosuppression (reported as Yes/No) were risk factors for hospitalization, ICU admission or death.

Results: Information on HIV status was available for 44% (34,973/80,843) of reported cases. Of these, 48% (16,788/34,973) were PLHIV, most of whom were male (99%; 16,497/16,550). Among PLHIV with information, 92% reported being GBMSM (12,071/13,166), 85% aged 18–44 years old (14,197/16,782), and sexual contact was reported as the main route of acquisition in 63% of cases (5,360/8,529).

Clinical symptoms among PLHIV with information included any rash (79%; 10,248/12,997), fever (64%), genital rash (53%), lymphadenopathy (35%) and headache (35%). Among PLHIV, immunosuppression was reported in 5,023 cases, 735 were hospitalized, 20 admitted to intensive

Author Index

care, and 23 died. When compared to cases who were HIV-negative and not immunosuppressed, immunosuppressed PLHIV were found to be at higher risk for hospitalization (OR=2.00, CI=1.64-2.43, $p<0.001$) as were those who were immunosuppressed and HIV-negative (OR=3.56, CI=1.80-7.01, $p<0.001$). Living with HIV alone was not a risk factor. Due to the small sample size, no risk factors for ICU admission and death were found.

Conclusions: Among cases with mpox, PLHIV were not at increased risk for hospitalization unless immunosuppressed. Given that uncontrolled HIV might have led to disproportionate mpox morbidity, health systems need to ensure PLHIV are aware of their diagnosis, linked to care, on effective antiretroviral treatment and achieve viral suppression. For individuals with unknown HIV status, mpox testing can be an opportunity for HIV testing, prevention and care.

¹SEARCH Research Foundation, Bangkok, Thailand, ²Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, ³U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, ⁴Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, MD, United States, ⁵Dreamlopmnts Foundation, Bangkok, Thailand, ⁶Institute of HIV Research and Innovation, Bangkok, Thailand

Background: Hepatitis C virus(HCV) infection has been increasing among men-who-have-sex-with-men(MSM) living with HIV. Direct-acting antivirals(DAAs) are associated with high HCV cure rates, but re-infection can occur if exposed to HCV again. This analysis describes HCV incidence, treatment outcomes, and reinfection rates in an early-treated acute HIV infection (AHI) cohort in Thailand. **Methods:** SEARCH010/RV254 enrolls participants with AHI. HCV antibody was measured at enrolment and annually. Participants with HCV viremia initiated DAAs. Sustained virological response(SVR) was assessed ≥ 12 weeks after treatment completion. HCV RNA was monitored annually in participants with HCV clearance (spontaneous or SVR). HCV incidence rates and reinfection rates with 95% confidence intervals(CI) per 100 person-years of follow-up (PYFU) were calculated using the exact method.

Results: Between 2009-2022, 694 HCV seronegative participants were enrolled. Most (92.5%) were MSM with median age 26.0 years (IQR 23.0-32.0). During total 3,678 PYFU, 98 (14.1%) acquired HCV infection; incidence rate was

2.7/100 PYFU (95% CI 2.2-3.3). Median time to HCV diagnosis after AHI was 3.0 years (IQR 0.5-5.5). Differences in baseline demographic characteristics between participants who developed HCV and who remained HCV negative were not statistically significant (Table 1). Among 98 incident cases, the most common HCV genotype was 1/1a(N=70, 93.3%). Sofosbuvir/ledipasvir (56.8%) and sofosbuvir/velpatasvir (33.8%) were the most frequently initiated DAAs. Of 72 participants who completed treatment, 68 (94.4%) achieved SVR. Additionally, 10 participants spontaneously cleared HCV RNA. HCV reinfection occurred in 9/78(11.5%) during 106.6 total PYFU after clearance; at a rate of 8.5/100 PYFU(95% CI 3.9-16.0). The median time to reinfection was 1.0 years(IQR 0.9-2.5). 3/10(30.0%) reinfections occurred after spontaneous clearance and 6/68(8.8%) after SVR.

Abbreviation: HCV, hepatitis C virus; HIV, human immunodeficiency virus; IQR, interquartile range; IVDU, intravenous drug use; MSM, men who have sex with men; VL, viral load

Differences in HCV negative and HCV positive participants were evaluated with Wilcoxon rank sum tests for continuous variables and Fisher exact tests for categorical variables.

Table 1. Demographic characteristics of people living with HIV with and without incident HCV infection in acute HIV infection cohort in Thailand.

Conclusions: In this early-treated AHI cohort of Thai MSM, there is high incidence of HCV infection. Treatment with DAAs resulted in high SVR rates, but HCV reinfection was common. Post-clearance follow-up with harm reduction measures is essential to identify and minimize HCV reinfection.

Background: Rifapentine-based regimens have been shown to have a high completion rate for latent tuberculosis infection (LTBI) treatment; however, rifapentine reduces plasma concentrations of co-administered ART among PLWH. This study aimed to retrospectively evaluate the outcomes of short-course rifapentine-based regimens among PLWH who received integrase strand-transfer inhibitor (INSTI)-based ART.

Methods: During August 2019 to October 2022, PLWH testing positive or indeterminate for interferon-gamma release assay (IGRA) were advised to receive directly-observed therapy for LTBI after excluding active tuberculosis. Those receiving 3-month once-weekly rifapentine plus isoniazid (3HP) or 1-month daily rifapentine plus isoniazid (1HP) combined with INSTI-based ART were included. The primary outcome was maintenance of virologic response (PVL<200 copies/mL) at months 3-6 after completion of LTBI treatment.

Results: During the study period, 456 PLWH were included; they were mostly male (94.3%) with a median age of 43 years, and 91.9% received INSTI-based ART with a median CD4 count of 651 cells/mm³ and 97.6% having achieved PVL<200 copies/mL. Among those receiving INSTI-based ART, 142 PLWH received 1HP and bictegravir (BIC)-containing regimens (1HP/BIC group), 46 received 1HP and dolutegravir (DTG)-containing regimens (1HP/DTG group), 28 received 3HP and BIC-containing regimens and (3HP/BIC group), and 203 received 3HP and DTG-containing regimens (3HP/DTG group). In the per-protocol analysis, the proportions of PLWH who maintained PVL <200 copies/ml at months 3-6 after the completion of LTBI treatment in the 4 study groups were 100% (125/125), 100% (44/44), 100% (17/17), and 96.7% (178/184), respectively. The completion rates were similar in the 1HP and 3HP groups (92.7% vs 90.0%). None of the PLWH discontinued INSTI-based ART that had been taking before combinations with rifapen-

tine-based LTBI treatment. The rates of PLWH experiencing any adverse event (AE) were also similar in the 1HP and 3HP groups (60.9% vs 57.4%), and the AEs were mainly of grade 1 (40.1%) or 2 (13.4%) in severity. While the most commonly reported AEs were flu-like symptoms (40.1%), more dermatologic AEs were observed in the 1HP group compared with the 3HP group (17.8% vs 9.6%).

Conclusions: Combinations of INSTI-containing regimens and short-course rifapentine-based regimens had a good safety profile and maintained higher rates of viral suppression.

Research, Nairobi, Kenya, ¹¹Kenya Medical Research Institute, Center for Virus Research, Nairobi, Kenya

Background: Virus-associated cancers have emerged in recent years and account for 15% of cancers reported globally. Cancer-causing viruses include high-risk Human Papillomavirus (HR-HPV), the causative agent of cervical cancer, and Human T-cell Lymphotropic Virus type-1 (HTLV-1), the causative agent of adult T-cell leukemia (ATL). In Kenya, there is a paucity of data on the burden of HR-HPV/ HTLV-1 co-infection among women living with HIV (WLHIV). We determined the co-infection of HR-HPV and HTLV-1 among WLHIV on antiretroviral therapy (ART) at the Kenyatta National Hospital (KNH).

Methods: We conducted a cross-sectional study among WLHIV attending KNH (Kenya's national referral hospital) ART clinics. Cervical cytology was performed by KNH medical providers per standard of care. Study nurses collected a cervical sample with a cytobrush for HPV genotyping using Gene Xpert® assays and HPV Genotypes 14 Real-

TM Quant" V67-100 FRT kits. Peripheral blood mononuclear cells (PBMCs) were used for HTLV-1 DNA detection (Bioline Ltd., London, UK). The association of HR-HPV and HTLV-1 co-infections was done using the Chi-square function for trends.

Results: A total of 647 WLHIV enrolled in this study and had a mean age of 42.8 years (SD 8.7). All of the study participants were on ART; 7% were initiated on ART in ≤ 12 months and about 8.8% were not virally suppressed (>1000 copies/mL). The HTLV-1 positivity rate among WLHIV was 3.1% and 7.6% among those with HR-HPV. Participants with HR-HPV/ HTLV-1 co-infections were significantly older (50+ years, 35.3%) than those having HPV mono-infection or did not have any infection ($p = <0.001$). A significantly higher proportion of women with HR-HPV/ HTLV-1 co-infections had their sex debut before the age of 18 years ($p = 0.015$). A higher proportion of participants (52.2%) with HPV mono-infection had previously been treated for STDs as compared to WLHIV without either HR-HPV or HTLV-1 infections ($p = 0.006$).

Conclusions: The study showed increasing trends of HR-HPV/ HTLV-1 co-infections among WLHIV on ART despite their CD4 cell count or HIV 1 RNA viral suppression at Kenya's national referral hospital.

OAB04 Beyond suppression: Improving the trajectory of co-morbidities in people with HIV

Background: Integrase strand inhibitor (INSTI) use in people living with HIV (PLWH) has been associated with increased body mass index (BMI). BMI increases have also been associated with a higher risk of diabetes (DM). This study explored the relationship between INSTI and non-INSTI regimens use, BMI changes, and the risk of DM.

Methods: RESPOND participants were included if they had CD4, HIV RNA, and multiple BMI measurements. Those with prior DM, and pregnant women, were excluded. DM was defined as a random blood glucose >11.1 mmol/L,

HbA1c >6.5%/48 mmol/mol, use of antidiabetic medication or clinical diagnosis. Poisson regression assessed the association between time updated log BMI, current INSTI/non-INSTI and TDF/TAF use, and their interactions, on DM risk.

Results: 20,865 PLHIV were included, most were male (74%) and white ethnicity (73%). The median age was 45 years (IQR 37–52) with a median BMI of 24 kg/m² (IQR 22–26). Over 107,641 PYFU, there were 785 DM diagnoses, a crude rate of 0.73 (CI 0.68 – 0.78) /100 person years. Log BMI was strongly associated with DM (aIRR 18.2 per log increase, 95% CI 11.7, 28.3; p<0.001). In univariate analyses, current INSTI use was associated with increased risk of diabetes (IRR 1.58, 95% CI 1.37, 1.82; p<0.001). This was partially attenuated when adjusted for time updated log BMI and other variables (aIRR 1.48, 95% CI 1.28, 1.72; p<0.001) (Figure 1).

In adjusted analyses current TAF use had similar DM risk to current TDF (aIRR=0.98, 95%CI 0.79–1.20, p=0.818). There was little evidence of an interaction between log BMI, INSTI and non-INSTI use, and DM (p=0.130).

Note: Figure 1 shows the predicted risk per 1000 person years of DM for BMI (antilog of logBMI) among INSTI and non-INSTI users when adjusted for sex, natural log of Age, HIV risk group, ethnicity, CD4, current TDF/TAF use. Among INSTI users, raltegravir (RAL) 12%, dolutegravir (DTG) 68%, other INSTIs (shikogravir (EVQ), bictegravir (BIC), cabotegravir (CBQ)) 20%.

Figure 1. Predicted risk of DM by current INSTI use and BMI.

Conclusions: In RESPOND, current use of INSTIs vs. non-INSTI was associated with an increased risk of diabetes which partially attenuated when adjusted for BMI changes and other variables. There was no difference in DM risk between current TAF and TDF users.

¹The Health Research Unit Zimbabwe (THRU ZIM), Harare, Zimbabwe, ²London School of Hygiene & Tropical Medicine, MRC International Statistics and Epidemiology Group, London, United Kingdom, ³University Teaching Hospital, Lusaka, Zambia, ⁴London School of Hygiene & Tropical Medicine, Clinical Research Department, London, United Kingdom, ⁵London School of Hygiene & Tropical Medicine, Department of Population Health, London, United Kingdom, ⁶University of Zimbabwe, Faculty of Medicine and Health Sciences, Harare, Zimbabwe, ⁷University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, ⁸Research Center Borstel-Leibniz Lung Center, Department of Cellular Microbiology, Borstel, Germany, ⁹University of Bristol, Bristol Medical School, Bristol, United Kingdom

Background: Adolescents living with HIV (ALWH) have lower bone density despite antiretroviral therapy (ART), and the aetiology may be multifactorial. We investigated whether dietary vitamin D and calcium intake were associated with bone density at baseline in peripubertal ALWH in Zambia and Zimbabwe, enrolled in a trial of Vitamin D and calcium supplementation.

Methods: ALWH aged 11–19 years, established on ART for ≥6 months were enrolled from five HIV clinics in Lusaka and Harare. A clinical history and examination was undertaken and HIV viral load was measured. Dual-energy X-ray absorptiometry was used to measure total body-less head bone mineral density (TBLH-BMD) Z-score.

The association between vitamin D/calcium daily dietary intake (calculated from a validated diet questionnaire) and TBLH-BMD Z-score was investigated using multi-variable linear regression. A vitamin D dietary intake of <4mcg/day was defined as low. Height- and weight- for-age z-scores of <-2 using UK reference standards were defined as stunting and wasting respectively.

Results: 842 ALWH (420 from Zambia and 422 from Zimbabwe, 448 (53.2%) female, mean age 15.0 years) were enrolled between February and November 2021. Unsuppressed HIV viral load (>1000 copies/ml) was observed in 11.7%; 29.9% were stunted and 30.3% were wasted. A low vitamin D intake was reported by 31.2%.

Among 818 participants who had a DXA scan, lower dietary vitamin D was associated with lower TBLH-BMD Z-score; 0.07 (95%CI 0.01–0.13, p=0.025) lower for each 1mcg vitamin D, after adjusting for sex, Tanner stage, socioeconomic status and country.

Similarly, lower dietary calcium intake was associated with lower TBLH-BMD Z-score; 0.10 (95%CI 0.02–0.17, p=0.015) for

each 100mg calcium, adjusting for the same covariates. Mean TBLH-BMD Z-score was 0.26 lower in participants with unsuppressed HIV viral load.

Conclusions: ALWH in Zimbabwe and Zambia have low vitamin D and calcium dietary intake, and may benefit from supplementation to improve bone health.

OAB0404

Effects of lifestyle modification and annual screening in the prevention of cardiovascular risk factors in South African women with HIV

S. Hanley¹, D. Moodley², M. Naidoo¹, S.S. Brummel³

¹University of KwaZulu-Natal, Family Medicine, Durban, South Africa, ²University of KwaZulu-Natal, Obstetrics and Gynaecology, Durban, South Africa, ³Harvard T.H. Chan School of Public Health, Boston, United States

Background: Women with HIV (WHIV) are faced with an added burden of obesity and hypertension, particularly in under-resourced settings. We sought to assess the effectiveness of regular screening and lifestyle modification interventions in modifying CVD risk factors in South-African WHIV.

Description: Women with HIV aged 18-<50 years were enrolled in a quasi-experimental study (intervention [I-arm] and control arm [C-arm]) from two clinics in Umlazi, South Africa between November 2018 and May 2019. Women in the I-arm received lifestyle modification advice and annual screening for CVD risk. The CVD risk factors were assessed through standardised questionnaires, clinical and laboratory procedures at baseline and at end of three years of follow-up.

Prevalence of metabolic syndrome (MetS) and other CVD indices were compared between arms at end-of-study (EOS) and incidence of CVD risk factors were measured within the intervention arm from baseline to EOS.

Lessons learned: A total of 372 WHIV (186 in each arm) were enrolled, and 269 WHIV (149 I-arm and 120 C-arm) with mean(SD) age of 36(1) years were included in the EOS analyses after 32 (2) months of follow-up. The MetS prevalence at EOS was 17% (25/149) in the I-arm, and 20% (24/120) in the C-arm (aRR 0.9; 95%CI 0.5-1.1). Proportion of women with low-density lipoprotein (LDL) > 3mmol/L in I-arm and C-arm were 19% (28/149) and 30% (36/120) respectively (aRR 0.6;95%CI 0.4-0.9;p<0.05). Fasting blood glucose>5.6mmol/L was reported in 3% (4/149) of women in I-arm and 13% (16/20) in the C-arm (aRR 0.2;95%CI 0.07-0.6;p<0.01). High-density lipoprotein (HDL) improved within the I-arm with mean difference of -0.09 (95%CI: -0.16, -0.03); p<0.01) from baseline to EOS. Mean body mass index increased in both arms: I-arm from 29.6(7) kg/m² to 31.5(7); C-arm from 27.8(7) to 29.9(7) kg/m².

Conclusions/Next steps: Regular screening and lifestyle modification advice play an important role in preventing CVD risk factors such as LDL, HDL and glucose levels, and should be well integrated into HIV programmes.

Further exploration is needed to understand the social determinants and perceptions of obesity in WHIV from under-sourced settings, to inform future targeted interventions comprised of a culturally acceptable, multidisciplinary approach in the alleviation of obesity and CVD risk.

OAB0405

Re-evaluating risk: evaluating opioid-related harm associated with stimulant use in people with chronic pain living with and without HIV

A. Appa¹, V. McMahan², K. Long², S. Shade¹, P. Coffin²

¹University of California San Francisco, San Francisco, United States, ²San Francisco Department of Public Health, San Francisco, United States

Background: Chronic pain, opioid therapy, and substance use (particularly cocaine and methamphetamine) are all prevalent among people living with HIV (PLWH). However, there is lack of clarity regarding the impact of and optimal clinical response to stimulant use among people prescribed long-term opioid therapy (LTOT) for chronic, non-cancer pain.

We sought to determine if a urine drug test (UDT) positive for stimulants was associated with opioid-related harm or subsequent discontinuation of LTOT in a publicly insured population with a high proportion of PLWH.

Methods: 300 PLWH on LTOT were matched to 300 clients without HIV on LTOT (based on age, race/ethnicity, and sex) and followed from January through June 2019. Using logistic generalized estimating equations, we assessed whether stimulant positive UDT results were associated with increased:

1. Opioid-related emergency department (ED) visits (over-sedation, constipation, infections associated with injecting opioids, and opioid seeking), and;
2. LTOT discontinuation 90 days following a stimulant-positive UDT.

Results: Overall, 1562 (24%) of 6,471 UDTs were positive for stimulants; however, 30 clients had 39% of stimulant-positive UDTs. There was no statistically significant association found between stimulant-positive UDTs and opioid-related ED visits or death within 90 days when accounting for repeated ED visits within individuals (adjusted hazard odds ratio [OR]=1.24; 95% CI 0.73-2.11). This relationship did not differ by HIV status. Stimulant-positive UDTs were associated with subsequent discontinuation of LTOT within 90 days (OR=1.95; 95% CI=1.68-2.27). This relationship was more likely among Latinx individuals (positive interaction; OR=1.97; 95% CI=1.08-3.60), and less likely among PLWH (negative interaction; OR=0.59; 95% CI=0.44-0.79).

Conclusions: The association between stimulant-positive UDT and opioid-related harm was concentrated in a minority of clients on LTOT with stimulant-positive UDT. Despite this, stimulant-positive UDT often led to LTOT discontinuation, though with heterogeneity across de-

mographic and clinical groups. It is unknown whether less LTOT discontinuation among PLWH using stimulants reflects a more holistic approach to patient care among HIV providers, difficulty with opioid stewardship, or both. Overall, these results suggest that detection of stimulant use should result in a discussion of substance use and risk, rather than reflex to discontinue LTOT.

OAC01 Progress towards HIV elimination: Are we there yet?

OAC0102

Australia's progress towards ending HIV as a public health threat: trends in epidemiological metrics over 2004-2021

R. Gray¹, H. McManus¹, J. King¹, K. Petoumenos¹, A. Grulich¹, R. Guy¹, S. McGregor¹

¹Kirby Institute, UNSW Sydney, Sydney, Australia

Background: We describe Australia's overall progress towards achieving the UNAIDS 95-95-95 targets by analysing the trends in epidemiological metrics over 2004-2021.

Methods: We used mathematical modelling and national HIV notification, cohort, and administration data to calculate annual estimates for the HIV cascade, the number of annual new HIV infections, and other HIV epidemic metrics during 2004-2021.

We used piecewise negative binomial regression to determine changes in trends and annual rate ratios (ARRs) for each cascade step and metric.

Results: We estimate there were 29,460 (range: 25,230-34,070) people living with HIV in Australia at the end of 2021. All 90-90-90 targets were achieved in 2020, with 91.1% of people living with HIV diagnosed, 91.6% of those diagnosed on Treatment and 97.8% of those on treatment being virally suppressed (achieving the final 95 target) at the end of 2021. There were reductions in each gap of the cascade and the number of people living and diagnosed with HIV is stabilising.

However, the percentage diagnosed and receiving treatment has plateaued under 92% since 2015 after a large fall in the number untreated over 2011-2014. Changes in the cascade gaps coincided with a slow increase in HIV notifications from 2004 to 2014, followed by a slow decline to 2019, and then a rapid fall.

Similar trends were found for the estimates of new HIV infections. Most metrics showed substantial improvement since 2004, particularly after the emergence of COVID-19 in 2020, with the incidence prevalence ratio falling below the UNAIDS global target of 0.03 in 2019.

Conclusions: While Australia saw substantial progress in the HIV cascade and achieved the 90-90-90 targets in 2020, reaching all 95-95-95 targets by 2025 is not guaranteed. Despite large falls in new infections, particularly

since the start of the COVID-19 pandemic, gaps in the cascade related to diagnosis and treatment remain. Further efforts are needed to achieve the UNAIDS targets and end HIV as a public health threat in Australia.

OAC0103

Characterising HIV incidence among people who inject drugs engaged with harm-reduction programs in four provinces in South Africa

R. Perry¹, A. Artenie¹, A.L. McNaughton¹, T. Jankie², M. Mahaso², P. Vickerman¹, A. Scheibe^{3,4}

¹University of Bristol, Bristol, United Kingdom,

²NACOSA, Cape Town, South Africa, ³Durban

University of Technology, Durban, South Africa,

⁴TB HIV Care, Cape Town, South Africa

Background: HIV incidence among people who inject drugs (PWID) in South Africa has never been estimated, yet it is essential for informing prevention efforts and tracking progress towards ending HIV/AIDS by 2030. We estimated HIV incidence and associated risk factors among PWID engaged with harm-reduction services in four provinces in South Africa.

Methods: Programmatic data over April 2019–March 2022 were obtained from harm-reduction services funded by the Networking HIV and AIDS Community of South Africa (NACOSA), which serve PWID in four provinces (Gauteng, KwaZulu-Natal, Western Cape and Eastern Cape). At each visit, clients who were not known to be HIV-positive were offered HIV testing. They also self-reported socio-demographic characteristics, drug use patterns and uptake of harm-reduction services. HIV incidence was estimated using the person-time method among PWID at-risk of infection tested at least twice.

Characteristic	Strata	HIV incidence (95%CI)	Incidence rate ratio (95% CI)	Characteristic	Strata	HIV incidence (95% CI)	Incidence rate ratio (95% CI)
Province	Gauteng	18.9 (16.5 - 21.6)	Ref.	Gender	Male	14.2 (12.6 - 15.9)	Ref.
	KwaZulu-Natal	17.1 (13.3 - 21.7)	0.9 (0.7 - 1.2)		Female	10.1 (6.7 - 14.8)	0.7 (0.5 - 1.1)
	Western Cape	3.4 (2.1 - 5.2)	0.2 (0.1 - 0.3)	Use of opioid substitution therapy	No, never	14.7 (13.2 - 16.6)	Ref.
	Eastern Cape	6.3 (3.2 - 11.2)	0.3 (0.2 - 0.6)		Yes, prior to the first HIV test	8.4 (2.1 - 22.9)	0.6 (0.1 - 1.7)
Age (years)	17-27	18.5 (15.2 - 22.2)	Ref.	Number of harm-reduction packs received	Yes, following the first HIV test	3.8 (1.7 - 7.6)	0.3 (0.1 - 0.5)
	28-30	15.7 (12.3 - 19.8)	0.9 (0.6 - 1.2)		0-2	17.5 (15.1-20.1)	Ref.
	31-35	13.7 (10.9 - 16.9)	0.7 (0.6 - 1.0)		3-5	10.3 (8.3-12.6)	0.6 (0.5 - 0.8)
	36-75	7.4 (5.4 - 9.9)	0.4 (0.3 - 0.6)		≥6	8.7 (5.4 - 13.3)	0.5 (0.3 - 0.8)

Table.

Results: Data were available for 31,873 PWID, of whom 2,457 (7.7%) were initially HIV-negative and had ≥ 2 HIV tests, forming the sample for this study. At baseline, most were male (90.2%), black (72.2%), homeless or unstably housed (62.6%) and used heroin (97.3%).

Median age was 30 yrs and few (7.9%) ever received opioid agonist treatment (OAT). 300 (12.2%) PWID acquired HIV over 2190.2 person-years, resulting in an HIV incidence of 13.7/100 person years (95%CI: 12.2-15.3). The risk of HIV acquisition varied by province, being higher in Gauteng and KwaZulu-Natal compared to Western and Eastern Capes, and by age, being higher in younger relative to older PWID (Table).

PWID who have received OAT and a greater number of harm-reduction packs had lower risks of HIV acquisition (Table).

Conclusions: Our results indicate that HIV incidence among PWID engaged with harm-reduction services in South Africa is very high and illustrate the value of using programmatic data to monitor the HIV epidemic in this vulnerable population. An urgent expansion of prevention services is needed.

OAC0104

The effect of unplanned care interruptions on the mortality of adults resuming antiretroviral therapy in South Africa: a survival analysis

H. Moolla¹, M.-A. Davies¹, C. Davies², J. Euvsard¹,
H.W. Prozesky³, M.P. Fox⁴, C. Orrell⁵, P. von Groote⁶,
L.F. Johnson¹

¹Centre for Infectious Disease Epidemiology and Research, University of Cape Town, Cape Town, South Africa,

²Division of Epidemiology and Biostatistics, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa, ³Stellenbosch University, Department of Medicine, Cape Town, South Africa, ⁴Health Economics & Epidemiology Research Office, Department of Internal Medicine, University of the Witwatersrand, Johannesburg, South Africa, ⁵Desmond Tutu HIV Centre, Institute of Infectious Diseases and Molecular Medicine & Department of Medicine, University of Cape Town, Cape Town, South Africa, ⁶Institute of Social and Preventive Medicine (ISPM), University of Bern, Bern, Switzerland

Background: Interrupting antiretroviral therapy (ART) is associated with adverse outcomes such as viral resistance, AIDS-defining illnesses, and mortality. However, little is known about the mortality of those resuming ART after unplanned interruptions.

The objective of this study is to estimate the relative rate of mortality among adults resuming ART after unplanned interruptions compared to those who do not interrupt care.

Methods: We included data from 44386 adults with HIV initiating ART between 2014 and 2019 at four South African cohorts of the International epidemiology Databases to

Evaluate AIDS. We defined care interruption as a gap in contact longer than 180 days. Observation time prior to interruption was allocated to the "no interruption" group. Observation time after the first interruption was allocated to one of two groups based on whether the first interruption occurred before or after 6 months of ART. We determined vital status from clinic records and linkage to the National Population Register. Cox regression was used to estimate hazard ratios, which were adjusted for the effects of sex, baseline age, baseline CD4 count, year of ART initiation, and cohort.

Results: There were 79762 person-years of observation and 797 deaths. 12601 people interrupted care, of whom 7038 interrupted within the first 6 months of ART. Those resuming ART experienced increased mortality compared to those without an interruption: those whose first interruption occurred within 6 months of starting ART had a 208% (95% CI: 158%-268%) increase in mortality, and those whose first interruption occurred after 6 months had a 147% (95% CI: 96%-211%) increase in mortality. Table 1 shows adjusted hazard ratios for selected variables.

Variable		Person-years of observation	Deaths	Crude mortality rate per 1000 person-years (95% CI)	Adjusted hazard ratio (95% CI)
Interruption status	No ART interruption	62 228	484	7.78 (7.11 - 8.50)	1.00
	Interruption within the first 6 months	10 835	206	19.01 (16.59 - 21.79)	3.08 (2.58 - 3.68)
	Interruption after the first 6 months	6 699	107	15.97 (13.21 - 19.30)	2.47 (1.96 - 3.11)
Sex	Female	54 724	410	7.49 (6.80 - 8.25)	1.00
	Male	25 038	387	15.46 (13.99 - 17.08)	1.47 (1.27 - 1.70)
CD4 count at ART initiation (cells/mm ³)	500+	11 851	55	4.64 (3.56 - 6.04)	1.00
	350-499	18 656	110	5.90 (4.89 - 7.11)	1.31 (0.94 - 1.81)
	200-349	24 547	192	7.82 (6.79 - 9.01)	1.60 (1.18 - 2.17)
	<200	24 708	440	17.81 (16.22 - 19.55)	3.00 (2.25 - 4.00)

Table 1: Adjusted hazard ratios for predictors of mortality

Conclusions: The substantially increased mortality of those resuming ART after an interruption highlights the need to prioritise and support retention in care, particularly during the first 6 months of ART.

OAC0105

The impact of same-day and rapid ART initiation under the Universal Health Coverage program on HIV outcomes in Thailand

S. Teeraananchai^{1,2}, D.C. Boettiger³, C. Lertpiriyasuwat⁴, R. Triamwichanon⁵, P. Wareechai⁵, P. Benjarattanaporn⁶, N. Phanuphak⁷

¹Department of Statistics, Faculty of Science, Kasetsart University, Bangkok, Thailand, ²Biomedical Data Science Program, Faculty of Science, Kasetsart University, Bangkok, Thailand, ³Kirby Institute, University of New South Wales, Sydney, Australia, ⁴Bureau of AIDS and STIs, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, ⁵National Health Security Office, Bangkok, Thailand, ⁶Joint United Nations Programme on HIV/AIDS, Bangkok, Thailand, ⁷Institute of HIV Research and Innovation, Bangkok, Thailand

Background: Antiretroviral therapy (ART) initiation regardless of CD4 count has been recommended since 2014 in Thailand, with same-day ART initiation recommended in 2021. We assessed HIV outcomes among Thai people living with HIV (PLHIV) by time from HIV diagnosis to starting ART under the Universal Health Coverage (UHC) program and determined factors associated with virological failure (VF).

Methods: PLHIV aged ≥15 years initiating ART between 2014 to August 2022 were included and categorized into 4 groups based on duration from HIV diagnosis (or registration) to ART initiation:

1. Same-day or 2-7 days,
2. <1 month,
3. 1-3 months, and;
4. >3 months.

VF was defined as viral load (VL) ≥1000 copies/mL after at least 6 months of ART. Factors associated with VF were analysed using a competing risk model considering death and loss to follow-up (LTFU) as competing events. Vital status was confirmed with Death Registry.

Results: Of 229,171 PLHIV who started ART, 65% had date of HIV diagnosis recorded. Median (IQR) age was 34 (26-43) years and pre-ART CD4 count was 232 (77-419) cells/mm³. ART initiation happened same-day in 17%, 2-7 days in 6%, <1 month in 23%, 1-3 months in 25% and >3 months in 30%. ART initiation within 7 days significantly increased from 19% during 2014-2016 to 30% during 2020-2022. ART initiation within 7 days resulted in the lowest mortality [10%: 1.31 (95%CI 1.27-1.36) per 100 person-years (PY)], but the highest rate of LTFU [8%: 2.29 (95%CI 2.22-2.36) per 100 PY] when compared with others initiating ART groups. VF occurred with a rate of 3.44 (95%CI 3.40-3.489) per 100 PY. PLHIV initiating ART within 1 month were at lower risk of VF (aSHR 0.79, 95%CI 0.75-0.81) when compared to ART initiation >3 month after diagnosis/registration.

Conclusions: ART initiation within 7 days became more common in Thailand over time although this occurred in less than one-third of PLHIV in the last 3 years of the

UHC program. ART initiation within 7 days significantly reduced mortality. ART initiation within 1 month significantly lowered risk of VF. To further optimize health outcomes, innovative strategies are urgently needed to implement earlier ART initiation in Thailand.

Background: Some evidence suggests that people living with HIV (PLWH) and people who inject drugs (PWID) may experience lower COVID-19 vaccine effectiveness (VE).

This lower VE may be due to a direct impact of HIV acquisition / substance use on immune function, and/or an indirect effect via other comorbidities that are common in these populations. Our objective was to assess COVID-19 VE by HIV status and injection drug use (IDU) history.

Methods: We applied validated algorithms to administrative datasets in the British Columbia COVID-19 Cohort (BCC19C) to create a population-based cohort of PLWH and a matched HIV-negative cohort, and to ascertain history of IDU. We included individuals who received RT-PCR testing for SARS-CoV-2 between Dec 15th, 2020, and Nov 21, 2021. A test-negative study design was used to estimate VE. Analyses were performed using logistic regression with crossed terms for vaccination status, PLWH status and IDU history, adjusting for sociodemographics, calendar time and co-morbidities.

IAS 2023

Oral abstracts

Poster exhibition

Late-breaker abstracts

Author Index

Results: The analysis included 2,700 PLWH and 375,043 matched HIV-negative individuals – of whom 40.7% and 4.3% had a history of IDU, respectively. VE with 2 doses was lower among PLWH with IDU history (65.8%, 95% CI= 43.5%-79.3%) than PLWH without (80.3%, 95% CI= 62.7-89.6), and VE increased slower and decreased more quickly in the former, although confidence intervals were wide. The finding of lower VE among people with IDU history was also present in the HIV-negative cohort but was more pronounced among PLWH.

	PLWH		HIV-negative individuals	
	History of IDU	No history of IDU	History of IDU	No history of IDU
1 st dose	44.1 (-25.8-75.2)	-	36.5 (22.1-48.2)	56.3 (52.7-59.6)
2 nd dose (days)				
≥ 7*	65.8 (43.5-79.3)	80.3 (62.7-89.6)	82.1 (79.9-84.1)	88.6 (88.2- 89.0)
7-59	65.7 (17.9-85.7)	80.3 (50.9-92.1)	87.7 (85.1-89.9)	91.5 (91.1-92.0)
60-89	91.3 (62.3-98.0)	85.9 (56.8-95.4)	83.9 (80.3-86.9)	89.9 (89.4-90.3)
90-119	65.9 (21.6-85.2)	88.1 (63.6-96.1)	79.7 (75.2-83.4)	87.8 (87.2-88.4)
120-179	42.4 (-17.8-71.8)	64.0 (15.7-84.7)	71.8 (65.2-77.1)	84.6 (83.8-85.4)

Conclusions: PWID may experience lower VE against COVID-19 acquisition, particularly for people who are also living with HIV. These findings highlight the convergence of the dual public health crises and the importance of prioritizing PLWH and PWID for booster doses. The higher prevalence of IDU among PLWH may partly explain our previously published finding of slower buildup / quicker waning among PLWH overall compared to HIV-negative individuals.

Mpox vaccination among gay, bisexual, and other men who have sex with men in the United States, september-december 2022

T. Carpino¹, K. Atkins¹, K. Delaney², W. Abara³, M. Hannah⁴, E. Eschliman⁵, O.W. Edwards⁴, Y. Ogale⁶, S. Vos⁷, A. Rao¹, S. Murray⁸, S. Baral¹, T. Sanchez⁴

¹Johns Hopkins University, Epidemiology, Baltimore, United States, ²Centers for Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States, ³Centers for Disease Control and Prevention, Division of Sexually Transmitted Disease Prevention, Atlanta, United States, ⁴Emory University, Atlanta, United States, ⁵Johns Hopkins University, Health, Behavior, and Society, Baltimore, United States, ⁶Centers for Disease Control and Prevention, Division of Sexually Transmitted Disease Prevention & Epidemic Intelligence Service, Atlanta, United States, ⁷Centers for Disease Control and Prevention, Division of Violence Prevention & Epidemic Intelligence Service, Atlanta, United States, ⁸Johns Hopkins University, Mental Health, Baltimore, United States

Background: During the 2022 mpox outbreak, there was disproportionate mpox risk among gay, bisexual, and other men who have sex with men (MSM), especially Hispanic men, non-Hispanic Black men, and people living with HIV(PLWH). These communities reported varying degrees of vaccine access, uptake, and 2-dose completion. Studying individual and structural determinants of vaccination can inform vaccination program implementation for both new and ongoing vaccination efforts.

Methods: A convenience sample of 3041 cisgender MSM aged 15+ years participated in a cross-sectional survey including sociodemographic and behavioral factors related to mpox vaccination uptake and 2-dose completion from 09/2022-12/2022 as part of the American Men's Internet Survey. Mpox-related stigma was measured using a 9 item scale pooled as a binary "any" vs. no reported mpox stigma variable. We conducted bivariate analyses to explore associations with

1. Receiving any dose. and;
2. Completion of 2-dose mpox vaccination.

We further conducted unadjusted and adjusted logistic regression with age group and race/ethnicity. Associations between self-reported mpox vaccination and HIV PrEP use were explored among the subset of MSM at risk for HIV acquisition.

Results: 33.3% (n=1006) of participants received at least one dose of mpox vaccination; 16.6% (167/1006) received only one dose, 83.1% (n=836) received two doses, and 0.3% (n=3) reported >two doses. HIV status was significantly associated ($p<0.01$) with any mpox vaccination, but not mpox vaccine completion ($p>0.05$).

Factors associated with both mpox vaccination and completion included STI screening, mpox-related stigma, awareness, concern, and HIV PrEP visits for individuals at risk for HIV acquisition.

HIV PrEP use (within year)**	-	-	-	-

* Adjusted models included age group (15-20, 21-24, 25-34, 35-44, 45-59, 60+), and race/ethnicity (Hispanic, Non-Hispanic white, Non-Hispanic Black, Other).

** PrEP models considered for people at risk for HIV acquisition (HIV-negative).

Note: Blank cells indicate sample size not powered to determine an association.

Table 1. Determinants of mpox vaccination and mpox vaccination completion.

Conclusions: The associations between mpox vaccination and STI testing and PrEP, but low overall uptake, suggest opportunities for further integration of mpox vaccination with sexual health services. However, broader uptake will also require complementary vaccine delivery strategies to reach MSM less connected to sexual health delivery systems.

Risk of hepatitis C infection following bacterial sexually transmissible infections among gay and bisexual men in Australia 2016-2020

B. Harney^{1,2,3}, R. Sacks-Davis^{1,2}, P. Agius¹, D. van Santen^{1,2,4}, M. Traeger^{1,2}, A. Wilkinson^{1,2}, J. Asselin¹, C. El-Hayek^{1,2}, C. Fairley^{5,6}, N. Roth⁷, M. Bloch⁸, G. Matthews^{9,10}, B. Donovan⁹, R. Guy⁹, M. Stooze^{1,2}, M. Hellard^{1,2,3}, J. Doyle^{1,2,3}

¹Burnet Institute, Melbourne, Australia, ²Monash University, Melbourne, Australia, ³Alfred Health and Monash University, Department of Infectious Diseases, Melbourne, Australia, ⁴Public Health Service of Amsterdam, Amsterdam, Netherlands, ⁵Melbourne Sexual Health Centre, Melbourne, Australia, ⁶Monash University, Central Clinical School, Melbourne, Australia, ⁷Prahan Market Clinic, Melbourne, Australia, ⁸Holdsworth House Medical Practice, Sydney, Australia, ⁹University of New South Wales, Kirby Institute, Sydney, Australia, ¹⁰St Vincent's Hospital, Sydney, Australia

Background: In Australia, the incidence of hepatitis C virus (HCV) infection has declined among gay and bisexual men (GBM) with HIV since 2015 and is low among GBM using HIV pre-exposure prophylaxis (PrEP).

However, ongoing HCV testing, and treatment, is required to sustain HCV elimination. Annual HCV testing is recommended in Australia for all GBM with HIV and GBM using PrEP regardless of sexual or substance use behaviours.

Bacterial sexually transmissible infections (STIs) are associated with similar behaviours as HCV among GBM, and therefore may be useful to guide more person-centered and tailored HCV testing. To examine this, we measured the association between STIs and HCV from 2016 to 2020.

Methods: Data were from a national network of primary care and sexual health clinics participating in the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance (ACCESS). GBM included had at least one HCV antibody negative test during the observation period and ≥ 1 subsequent HCV test. Discrete time modelling estimated the association between a positive syphilis, rectal chlamydia, and rectal gonorrhoea diagnosis in the preceding two years on incident HCV infection, reported as an adjusted hazard ratio (aHR). Analyses were stratified by GBM with HIV and GBM prescribed PrEP and adjusted for age and the number of each STI test undertaken.

Results: Among 6,529 GBM with HIV, 92 had an incident HCV infection which was associated with a syphilis infection (aHR 1.99, 95%CI:1.11-3.56). Of 13,061 GBM prescribed PrEP, 48 had an incident HCV infection, which was associated with rectal chlamydia (aHR 2.73, 95%CI:1.40-5.30) and rectal gonorrhoea (aHR 2.58, 95%CI:1.30-5.13).

Conclusions: HCV was associated with bacterial STIs among GBM with HIV and GBM using PrEP. These findings suggest that an STI diagnosis should prompt a conversation about HCV testing, and that more frequent HCV testing may be justified among GBM with STIs.

OAC0205

Integration of PrEP services and assisted partner notification into an STI Clinic in Lilongwe, Malawi

C. Pedersen^{1,2}, J. Chen¹, M. Matoga², B. Ndalama², E. Mathiya², T. Munthali², N. Nyirenda², N. Bonongwe², E. Jere², D. Yatina², H. Nkhata², M. Kacheyo², Z. Mpande³, M. Hosseini^{1,2}, I. Hoffman^{1,2}, S. Rutstein¹

¹UNC Chapel Hill, Institute for Global Health and Infectious Disease, Chapel Hill, United States, ²UNC Project Malawi, Lilongwe, Malawi, ³Lighthouse Trust, Lilongwe, Malawi

Background: HIV pre-exposure prophylaxis (PrEP) has been integrated into sexually transmitted infection (STI) care in Malawi/sub-Saharan Africa (SSA); however, the success and prevention impact of integration has not been evaluated. Expanding prevention services to sexual partners of persons with STIs is another opportunity to increase PrEP reach. We evaluated an integrated PrEP and assisted partner notification (aPN) program in an STI clinic in Lilongwe, Malawi.

Methods: We enrolled "index" participants who were initiating oral PrEP at the Bwaila District Hospital STI Clinic (≥ 15 years, STI symptoms or exposure, HIV-seronegative). Participants completed surveys and provided contact information for sexual partners. Clinic staff contacted named partners who did not report to clinic within 14 days for STI treatment and HIV testing. Returning partners were screened for PrEP eligibility and, if interested and eligible, initiated PrEP and enrolled in the study.

Results: 175 index participants enrolled between March-December, 2022. The median age was 27 (interquartile range [IQR]: 23-32) and most were male (110/175; 63%).

Twenty-one percent (36/175) were adolescent girls and young women. In the preceding month, 40% (70/175) reported exchanging sex for goods/money/favors and 13% (23/175) had ≥ 1 known HIV-positive partner.

Before enrollment, 34% (60/175) had heard of PrEP. Forty-nine percent (86/175) of participants provided contact information for 100 sexual partners. Fifty-eight partners returned to clinic: 34% (20/58) were HIV-seropositive and ineligible (4 newly diagnosed; 16 previously diagnosed).

Of eligible partners, 71% (27/38) initiated PrEP and enrolled, and 29% (11/38) declined PrEP and/or study procedures. Median age of enrolled partners was 26 (IQR: 22-31) and most were female (20/27; 74%).

Conclusions: Ours is the first to demonstrate successful integration of PrEP within an STI clinic in SSA and highlights the benefits of aPN for promoting partner engagement in HIV prevention services. Although STI clinic-based PrEP does not explicitly target key populations, more than half of indexes fell into at least one priority category (exchanged sex for goods/money/favors or young women), and many were in serodiscordant relationships. Engaging young heterosexual men in PrEP care has been a historically under-examined opportunity to interrupt transmission and may be particularly powerful when coupled with PrEP referral for female partners.

OAC0302

Enhanced linkage to care following home-based HIV testing improves linkage, ART initiation and retention, and 12-month viral suppression—the Ekkubo study: a cluster randomized trial in Uganda

S.M. Kiene^{1,2}, R. Naigino^{1,2}, K. Schmarje Crockett¹, M. Ediau^{1,2}, A. Anecho², C.-D. Lin³, N.A. Menzies⁴, M. Bateganya⁵, S. Sekamatte⁶, S.C. Kalichman⁷, R.K. Wanyenze²

¹San Diego State University, School of Public Health, San Diego, United States, ²Makerere University School of Public Health, Kampala, Uganda, ³San Diego State University, Department of Mathematics and Statistics, San Diego, United States, ⁴Harvard T.H. Chan School of Public Health, Department of Global Health and Population, Boston, United States, ⁵USAID, Msasani, Tanzania, United Republic of, ⁶Gombe Hospital, Gombe, Uganda, ⁷University of Connecticut, Institute for Collaboration on Health, Intervention, and Policy, Storrs, United States

Background: HIV testing in the universal test and treat (UTT) era in settings where immediate ART initiation is not feasible may require support for care engagement to achieve viral suppression. The Ekkubo study, a cluster ran-

domized trial in rural Uganda, tested an enhanced linkage to care intervention vs standard-of-care+referrals to care in the context of home-based HIV testing.

Methods: Between November 2015 and March 2020, home-based HIV testing was conducted in pair-matched villages randomized to intervention or comparator arms across 4 districts in central Uganda. Individuals aged 15-59 newly diagnosed HIV positive or previously diagnosed but never linked to care in intervention villages received 3 brief sessions at-home and 1 phone follow-up focused on overcoming barriers to care, eliciting a plan to engage in care, and social support resources to address stigma and other needs. Those in standard-of-care+ villages received 2 brief sessions at-home referring them to care and reinforcing the referral.

The primary outcome was viral suppression (<20 copies/mL) at 12 months. Secondary outcomes included linkage, ART initiation, time to ART initiation, and ART retention. Intention-to-treat analyses accounted for the cluster design.

Trial registration: NCT02545673

Results: In the 56 clusters/villages (28 per arm), 284 (62.3% female) and 283 (62.9% female) individuals were enrolled in intervention and comparator arms, respectively. Average cluster size was 10.31 (SD 13.97, range 1-57). Average age was 30.77 (SD 9.45), 543 (95.8%) were newly diagnosed. At 12 months, 134/284 (47.2%) and 114/283 (40.3%) of participants in intervention and comparator clusters respectively achieved VL <20 (adjOR, 1.60, 95%CI 1.13-2.26, $p=0.008$). Intervention participants also did better for linkage to care (assessed as a 2nd visit; adjOR, 1.65, 95%CI 1.09-2.49, $p=0.017$) and ART initiation (adjOR, 1.97, 95%CI 1.33-2.90, $p<0.001$) and retention (adjOR 4.16, 95%CI 1.14-13.87, $p=0.015$) than standard-of-care+ participants, but there was no difference for time to ART initiation among those who initiated (adjHR 1.06, 95%CI 0.78-1.46, $p=0.69$). 12-month study retention was $>84\%$ in both arms, including deaths.

Conclusions: Focused linkage support at diagnosis and shortly thereafter increased linkage, ART initiation, retention, and viral suppression. This intervention may have utility with populations experiencing linkage and viral suppression challenges.

Background: Although Primary Health Care (PHC) is part of the AIDS care and prevention services, the effect of PHC on AIDS outcomes is poorly understood in low- and middle-income countries (LMICs). We evaluated the impact of one of the largest PHC programs in the world, the Brazilian Family Health Strategy (FHS), on AIDS incidence and mortality using a cohort of 3.4 million individuals over a 9-year study period in Brazil.

Methods: We analyzed AIDS data from individuals aged 13 years or older who were members of a nationwide cohort of the poorest Brazilian people (The 100 Million Brazilians Cohort) from January 1, 2007 to December 31, 2015 and compared residents in municipalities with no FHS coverage with residents in municipalities with full FHS coverage. We used multivariable Poisson regressions, adjusted for all relevant demographic, socioeconomic, and municipal variables, and weighted with inverse probability of treatment weighting (IPTW), to estimate the effect of FHS on AIDS incidence and mortality rates.

We also estimated effects by sex, age, race/ethnicity, and by AIDS municipal incidence. We conducted sensitivity and triangulation analyses.

Results: FHS coverage was associated with lower AIDS incidence (rate ratio [RR] 0.76, 95%CI 0.68–0.84) and mortality (0.68, 0.56–0.82). The effect of FHS on incidence was greater among females (0.70, 0.61–0.82) and Black population (0.64, 0.45–0.92). The effect of FHS on mortality was greater among males (0.64, 0.49–0.83).

For both outcomes, the effect of FHS coverage was stronger among people aged 35 years or older (0.62, 0.53–0.72 – incidence and 0.56, 0.43–0.72 – mortality), although a lower incidence was also observed among people aged 13–34 years (0.83, 0.72–0.96).

Conclusions: FHS coverage impacts AIDS morbidity and mortality among the most vulnerable populations in Brazil. Our results show the importance of expanding and strengthening PHC in LMICs to contribute to the goal of ending AIDS by 2030, including the improvement of infrastructure and human resources for the decentralization of care, treatment, and monitoring of people with HIV/AIDS.

Background: Pre-exposure prophylaxis (PrEP) is a highly effective intervention that can prevent HIV acquisition. Through the U.S. President's Emergency Plan for AIDS Relief (PEPFAR), the US Centers for Disease Control and Prevention (CDC) supports PrEP programs for key populations (KP) (i.e., Female Sex workers (FSW), men who have sex with men (MSM), transgender people (TG), people who inject drugs (PWID) and people in prisons and other enclosed settings). UNAIDS' current goal is to reach 10 million people with PrEP by 2025. We examined CDC's scale-up of PrEP during Covid-19 among KP beneficiaries to evaluate progress towards the UNAIDS goal.

Methods: Using programmatic data from PEPFAR's Monitoring, Evaluation and Reporting system, we assessed the number and percentage of KP beneficiaries who initiated PrEP, by KP group and by year, from 2019 to 2022 in 30 countries. We assessed trends by year among 27 countries with complete testing and PrEP initiation data. We also consulted narrative reports of program services to understand changes made to PrEP delivery.

Results: CDC supported 1,371,984 PrEP initiations during 2019–2022, of whom 520,981 identified as KP. The percentage of HIV-negative KP accepting PrEP increased by 532%, from 3.1% in 2019 to 19.6% in 2022. The largest relative increases in uptake were among PWID and prisoners, although the absolute percentages were <10%. Although FSW and MSM showed highest uptake in 2022, over 70% of these KP did not initiate PrEP.

Key Population groups	PrEP Initiation among Key Population beneficiaries supported by CDC in 27 PEPFAR-funded countries, 2019–2022. Numbers of KP enrolled in PrEP/ number of HIV-negative KP (%)				% Increase in proportion of HIV-negative KP accepting PrEP from 2019 to 2022
	2019	2020	2021	2022	
Female sex workers (FSW)	13,180/ 245,659 (5.4%)	34,978/ 508,598 (6.9%)	91,521/ 700,578 (13.1%)	163,638/ 695,078 (23.5%)	335%

Conclusions: Despite Covid-19 disruptions in service delivery, we observed substantial PrEP scale-up in CDC programs. Program modifications such as HIV self-testing, telemedicine, and community-based deliveries may have facilitated PrEP expansion during this time.

To reach UNAIDS' global goal, additional innovations, such as long-acting injectable PrEP, event-driven PrEP, and programs to increase PrEP awareness/literacy among beneficiaries and providers may increase uptake by KP. Continuous monitoring and evaluation of KP PrEP programs is critical to meet ambitious UNAIDS global targets.

Increased HIV prevention coverage among Australian gay and bisexual men with regular partners: results of national behavioural surveillance, 2018-22

T. Broady¹, C. Chan², J. MacGibbon¹, L. Mao¹, J. Rule³, H. Paynter⁴, B. Bavinton², M. Holt¹

¹Centre for Social Research in Health, UNSW, Sydney, Australia, ²Kirby Institute, UNSW, Sydney, Australia, ³National Association of People With HIV Australia, Sydney, Australia, ⁴Australian Federation of AIDS Organisations, Sydney, Australia

Background: Increasing use of biomedical HIV prevention methods has been reported among gay and bisexual men (GBM) in Australia with casual partners. Less attention has been paid to HIV prevention strategies among GBM with regular partners. We analysed trends in behavioural surveillance data to identify changes in HIV prevention methods by GBM with regular partners, and levels of prevention coverage (and risk).

Methods: Behavioural surveillance data from the Gay Community Periodic Survey (collected between 2018-22) were analysed. Trends in condom use, condomless sex with regular partners (i.e., use of any effective strategy, e.g., condoms, PrEP, undetectable viral load [UVL]) were assessed using logistic regression. Trends were stratified according to reported sexual activity with casual partners.

Results: 24,316 survey responses from participants with regular male partners were included for analysis. The mean age of the sample was 38.2 years, 68.6% were Australian-born, 90.0% gay-identified, and 8.6% living with HIV.

The proportion who reported consistent condom use declined from 12.3% in 2018 to 9.3% in 2022 while any CAIR increased from 67.2% to 74.8% (both $p < .001$). HIV prevention coverage with regular partners increased from 94.3% in 2018 to 98.4% in 2022 ($p < .001$).

The proportion of GBM with regular partners who were HIV-positive and reported UVL remained stable (6.2% to 5.5%, $p = .253$), as did the proportion of non-HIV-positive GBM whose regular partners were HIV-positive with UVL (1.2% to 1.0%, $p = .103$).

The proportion of participants with regular partners who were HIV-negative and on PrEP increased from 16.6% to 34.8% ($p < .001$), however, this increase in PrEP use was concentrated among participants with regular partners who also reported condomless sex with casual partners (from 38.0% to 68.4%, $p < .001$).

Conclusions: Risk of HIV transmission between regular partners was low and continually decreased between 2018 and 2022. GBM with regular partners increasingly use biomedical methods to prevent HIV transmission, and PrEP use was concentrated among those who also engaged in condomless sex with casual partners.

OAC04 Strengthening sexual and reproductive health for diverse populations

OAC0402

No association between in-utero PrEP exposure and bone mineral density at 36 months of age among mother-infant pairs in Kenya

L. Wu^{1,2}, J. Kinuthia³, F. Abuna³, J. Dettinger², L. Gomez², E. Mukenyi³, G. John-Stewart^{1,2,4,5}, M. Marwa³, N. Ngumbau³, B. Ochieng³, J. Pintye^{2,6}

Background: Previous studies found that tenofovir-based ART use during pregnancy among women living with HIV is associated with lower bone mineral density (BMD) in neonates. It is unknown whether these differences persist beyond the neonatal period or exist among neonates born to women without HIV who used tenofovir-based PrEP during pregnancy.

Methods: We utilized data from an ongoing evaluation of perinatal PrEP use in Kenya. In the parent study (NCT03070600), HIV-negative women were enrolled and offered tenofovir-based PrEP during pregnancy at 20 public clinics and followed through 9 months postpartum regardless of PrEP status. An extension cohort to evaluate safety outcomes enrolled mother-child pairs at 4 sites to be followed until the child's 5th birthday.

A subset of singleton children aged 36 months with in-utero PrEP exposure was randomly selected and matched to children without in-utero PrEP exposure on maternal age, education level, and child sex and age. Whole-body BMD was measured by dual-energy x-ray absorptiometry

(DEXA) at Aga Khan University Hospital in Nairobi, Kenya. Linear regression adjusting for matching characteristics was performed to evaluate the relationship between BMD and PrEP exposure.

Results: From December 2021 to December 2022, 40 children with in-utero PrEP exposure and 71 without PrEP exposure had whole-body BMD measurements. The median age at DEXA scanning was 36.7 months (IQR: 36.2-38.0), 40% of children were female, and the median maternal age at delivery was 27.6 years (IQR: 22.1-32.6).

The median height for children at DEXA scanning was similar between those with and without PrEP exposure (94.3 cm vs. 94.0 cm, $p=0.455$). The median whole-body BMD for children with and without in-utero PrEP exposure was 418.5 mg/cm² (IQR 399.2-440.0) and 423.0 mg/cm² (IQR 395.5-457.5.0), respectively. There was no difference between mean whole-body BMD among children with and without in-utero PrEP exposure (adjusted mean difference -21.6 mg/cm², 95% CI -60.1-17.0, $p=0.270$).

Conclusions: PrEP exposure was not associated with BMD or height at 36 months among children with mothers who used PrEP during pregnancy. Our findings suggest that in-utero PrEP exposure may not impact BMD into early childhood.

OAC0403

Cofactors of HIV self-testing and PrEP acceptance among pregnant women at high risk of HIV in Kenya

N.M. Ngumbau¹, J. Neary², A. Wagner³, F. Abuna¹, B. Ochieng¹, J. Dettinger³, L. Gómez², M. Marwa¹, S. Watoyi¹, E. Nzove¹, J. Pintye⁴, J. Baeten⁵, J. Kinuthia¹, G. John-Stewart^{2,3,6,5}

¹Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, ²University of Washington, Department of Epidemiology, Seattle, United States, ³University of Washington, Department of Global Health, Seattle, United States, ⁴University of Washington, Biobehavioral Nursing & Health Informatics, Seattle, United States, ⁵University of Washington, Medicine, Seattle, United States, ⁶University of Washington, Pediatrics, Seattle, United States

Background: PrEP and HIV self-testing (HIVST) for male partners are being scaled up within antenatal clinics (ANC). Few data are available on how co-distribution influences acceptance of both interventions and the cofactors for PrEP, HIVST or combined PrEP/HIVST use among pregnant women at high risk for HIV.

Methods: We utilized data from the PrIMA (NCT03070600) trial in Kenya. Women included in this analysis were determined to be at high HIV risk and offered PrEP and partner HIVST. Characteristics were compared between women who chose:

1. PrEP and HIVST,
2. HIVST-alone,

3. PrEP-alone, or;

4. Declined both (reference), excluding women with partners known to be living with HIV.

Results: Among 911 women, the median age was 24 years, 87.3% were married, and 13.0% had history of intimate partner violence (IPV); 68.8% accepted HIVST and 18.4% accepted PrEP. Of women accepting HIVST, 84% offered them to partners; 94% of partners used HIVST; 1.2% had a reactive HIVST.

Partner HIV testing increased from 20% to 82% and women's knowledge of partner HIV status increased from 4.7% to 82.0% between pregnancy and 9-months postpartum ($p<0.001$). Overall, 54.7% accepted HIVST-alone, 4.1% PrEP-alone and 14.3% both HIVST and PrEP. Compared to women who accepted neither, choosing:

1. HIVST-alone was associated with being married, participant and partner higher level of education, and residing with partner;
2. PrEP-alone with lower social support, IPV, not residing with partner, longer time with partner, and suspicion of other sexual partners, and;
3. PrEP and HIVST was associated with being married, IPV, and suspicion that partner had other partners.

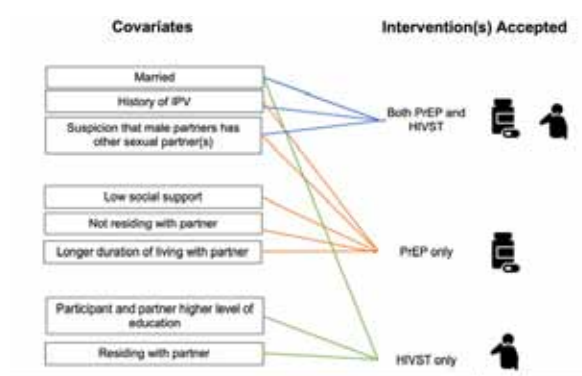

Figure 1. Cofactors for PrEP, HIVST, or combined PrEP/HIVST acceptance among pregnant women attending ANC.

Conclusions: Understanding factors associated with accepting HIVST, PrEP or both can inform HIV prevention programs for pregnant women. Strategies to improve women's self-efficacy to take up HIV prevention interventions are important to reduce incident infections during pregnancy and postpartum.

OAC0404

Drug-drug interaction between emtricitabine/tenofovir alafenamide (FTC/TAF)-based PrEP and feminizing hormones in transgender women: peripheral blood mononuclear cells and urine analysis from the iFACT3 study

A. Hiransuthikul^{1,2}, N. Thammajaruk¹, S. Kerr^{3,4}, R. Janamnuysook^{1,5}, S. Nonenoy¹, P. Hongchookiat¹, R. Trichavaroj¹, Y. Tawon⁶, J. Boonruang¹, N. Teeratakulpisarn¹, T.R. Cressey⁶, N. Phanuphak^{1,5}, the iFACT3 study team

¹Institute of HIV Research and Innovation (IHRI), Bangkok, Thailand, ²Chulalongkorn University, Department of Preventive and Social Medicine, Faculty of Medicine, Bangkok, Thailand, ³Chulalongkorn University, Biostatistics Excellence Centre, Faculty of Medicine, Bangkok, Thailand, ⁴HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, ⁵Chulalongkorn University, Center of Excellence in Transgender Health (CETH), Faculty of Medicine, Bangkok, Thailand, ⁶Chiang Mai University, AMS-PHPT Research Collaboration, Faculty of Associated Medical Sciences, Chiang Mai, Thailand

Background: We previously observed that plasma tenofovir (TFV) and emtricitabine (FTC) exposures were not significantly different among transgender women when FTC/TAF-based PrEP was administered with and without feminizing hormone therapy (FHT).

Herein, we report the impact on the intracellular TFV-diphosphate (TFV-DP) and FTC triphosphate (FTC-TP) concentrations, the therapeutically active forms, in peripheral blood mononuclear cells (PBMCs), and on TFV/FTC urine concentrations.

Methods: Twenty transgender women who had not undergone orchiectomy were enrolled between January and February 2022. FHT (estradiol valerate 2 mg and cyproterone acetate 25 mg) was initiated at baseline and prescribed until week 9, while PrEP (FTC 200 mg/TAF 25 mg) was initiated at week 3 and prescribed until the end of study at week 12. PK sampling for drug level measurement was performed at weeks 9 (with FHT) and 12 (without FHT). PBMC samples were collected at 2 and 24 hours after FTC/TAF administration to assess FHT effect on TFV-DP and FTC-TP levels; and a 24-hour urine collection was used to assess FHT effect on TFV/FTC.

Results: Eighteen participants completed the PK visits and were included in this analysis. Median (IQR) age and body mass index were 28 (23-32) years and 20.8 (19.9-21.9) kg/m², respectively. The PBMC 2 hour (C₂) and 24 hour (C₂₄) geometric mean ratios (GMRs) (95%CI) at week 9 and week 12 (reference) were as follows: TFV-DP, 1.04 (0.91-1.19, $p=0.59$) and 0.96 (0.82-1.13, $p=0.65$); and FTC-TP, 0.97 (0.85-1.10, $p=0.61$) and 0.91 (0.75-1.10, $p=0.33$) (figure). Urine GMRs for TFV and FTC were 1.05 (0.84-1.32, $p=0.67$) and 0.92 (0.75-1.13, $p=0.42$).

Figure. Geometric mean antiretroviral drug concentrations at week 9 (with FHT) and week 12 (without FHT)

Conclusions: Intracellular TFV-DP and FTC-TP levels in PBMCs and urine TFV and FTC concentrations were comparable when F/TAF-based PrEP was administered with and without FHT, suggesting no clinically significant drug-drug interaction from FHT towards FTC/TAF-based PrEP. Tissues rectal measurements of TFV-DP and FTC-TP levels are ongoing.

OAC0405

Experiences of reproductive coercion among women living with HIV in sub-Saharan Africa, eastern Europe and Central Asia

Background: Evidence suggests that women living with HIV (WLHIV) experience coercion by healthcare providers related to sterilization, contraception/family planning, pregnancy and feeding practices. However, there has been limited quantification of the prevalence and determinants of reproductive coercion among WLHIV.

Methods: The People Living with HIV (PLHIV) Stigma Index 2.0 study was implemented in 16 countries in Eastern Europe and Central Asia (EECA) and Sub-Saharan Africa (SSA). Study implementation was led by networks of PLHIV(2020-2022).

Interviewer-administered questionnaires were used to collect self-reported socio-behavioral measures among 10,555 cisgender 18+ year old WLHIV. Reproductive coercion in these analyses was categorized based on coercive experiences relating to recent (within last 12 months) sterilization; contraception/family planning; and pregnancy and feeding practices. Multilevel logistic regression models were used to assess hierarchical determinants of reproductive coercion.

Results: Among participants in SSA, 0.5% reported sterilization, 1.6% reported coercion of contraception and family planning; and 4.8% reported coercion of pregnancy and feeding practices. Among participants in EECA, 3.2% reported sterilization, 3.9% reported coercion of contraception and family planning; 8.5% reported coercion of pregnancy and feeding practices.

Women in EECA had an increased odds of sterilization, coercion related to contraception/family planning, and coercion related to pregnancy and feeding practices compared to women in SSA (Table 1).

Across regions, sex workers, migrants, and women who inject drugs, and women with disabilities had greater odds of reproductive coercion compared to other WLHIV.

Conclusions: In 2022, recent reproductive coercion is common among WLHIV globally. Programs with trainings on accurate, evidence-based, and person-centered care for PLHIV, and non-stigmatizing care practices may improve healthcare provision of reproductive and sexual health-care among WLHIV. Non-discrimination protections for WLHIV may support prevention of reproductive coercion and allow accountability when it occurs. Lastly, initiatives to support WLHIV in knowing their rights and how to seek justice may improve the health and wellbeing of WLHIV.

Characteristics	Reproductive coercion within the 12 last months			
	Sterilization - recent		Contraception and family planning - recent

* Multi-level logistic regression model with random intercepts adjusted for age, education, relationship, time from HIV diagnosis. Separate models are run for each exposure and each respective reproductive coercion outcomes.
Analysis 1: exposure is region and outcomes are reproductive coercion, comparing all women living with HIV in central Asia and eastern Europe to all women in sub-Saharan Africa.
Analysis 2: exposure is sex work and outcomes are reproductive coercion, comparing women who report engagement in sex work to women who do not report engagement in sex work. This analysis includes women in both regions.
Analysis 3: exposure is migrant, and outcomes are reproductive coercion, comparing women who report being a migrant to women who do not being a migrant. This analysis includes women in both regions.
Analysis 4: exposure is disability and outcomes are reproductive coercion, comparing women who report having a disability to women who do not report having a disability. This analysis includes women in both regions.
Analysis 5: exposure is injection drug use and outcomes are reproductive coercion, comparing women who report history of injection drug use to women who do not report injection drug use. This analysis includes women in both regions.

Table 1. Reproductive coercion among women living with HIV in Sub-Saharan Africa (Angola, Benin, Burkina Faso, Cote D'Ivoire, Ghana, Kenya, Mauritania, Nigeria, Lesotho, Togo, Zimbabwe) and Eastern Central Europe and Central Asia (Kazakhstan, Kyrgyzstan, Belarus, Russia, Ukraine).

OAC05 Differentiated service delivery with focus on PrEP

OAC0502

A pharmacist-led oral PrEP refill visit with client HIV self-testing significantly improved continuation in Kenya

K. Zewdie¹, K. Ngure², N. Mugo^{3,4}, J. Baeten³, D. Mwangi⁴, M. Mwangi⁴, S. Maina⁴, L. Etyang⁴, G. Maina⁴, V. Ogello⁴, E. Owidi⁴, K. Mugwanya¹

¹University of Washington, Epidemiology, Seattle,

United States, ²Jomo Kenyatta University of

Agriculture and Technology, Nairobi, Kenya,

³University of Washington, Seattle, United States,

⁴Kenya Medical Research Institute, Nairobi, Kenya

Background: Delivery of oral pre-exposure prophylaxis (PrEP) is being scaled up in Africa. However, health system barriers including lengthy visits endanger client continuation. We evaluated the efficiency and impact of direct-to-pharmacy PrEP refill visits with HIV self-testing (HIVST).

Methods: Between September 2020 and January 2022, we conducted a quasi-experimental study of differentiated direct-to-pharmacy PrEP refill visits among adult men and women receiving PrEP at four public health HIV clinics in Central Kenya. Two clinics implemented the intervention which included direct-to-pharmacy for PrEP refill, HIVST while waiting and 3-monthly refill visits with pharmacist-led rapid risk assessment. Two clinics comparable in size and client volume served as controls with the usual standard of care (SOC), which typically includes monthly refills with multiple client room stops.

We conducted 80 time and motion studies to determine client time in the clinics. PrEP continuation was evaluated by visit attendance and pharmacy refill records. We used logistic regression to assess the intervention effect on PrEP continuation and the Wilcoxon rank sum test to assess the impact on clinic time.

Results: Overall, 746 clients were enrolled: 338 in SOC and 380 in intervention clinics; 57% were female, the median age was 33, and 58% were in serodifferent partnerships. Prior to implementation, intervention, and controls clinics were comparable on client characteristics (female: 51% vs 47%; median age: 33 vs 33 yrs) and PrEP continuation (35% vs 37% at 1 month, and 37% vs 39% at 3 months; P>0.05 for all).

The intervention reduced total time spent at the clinic by 35%, the median time spent in SOC was 51 minutes while in intervention clinics was 33 minutes; p<0.001.

However, time spent on HIV testing (20min vs 20 min; p=0.50) and pharmacy (8min vs 8 min; p=0.8) was unchanged. Similarly, PrEP continuation was significantly higher in the intervention clinics compared to control clinics: 45% vs 33% at 1 month and 34% vs 25% at 3 months; P<0.05 for all.

Conclusions: A client-centered PrEP delivery approach with direct-to-pharmacy PrEP refill visits plus client HIV self-testing reduced clinic visit time and significantly improved PrEP continuation in public health HIV clinics in Kenya.

OAC0503

Same-day initiation of oral pre-exposure prophylaxis is high among adolescent men who have sex with men and transgender women in Brazil

F. Soares¹, L. Magno², J. Arrais Pinto Jr.³, A. Grangeiro⁴, K. Bruxvoort⁵, D. Greco⁶, I. Dourado¹

¹Federal University of Bahia, Collective Health Institute, Salvador, Brazil, ²Bahia State University, Department of Life Sciences, Salvador, Brazil, ³Fluminense Federal University, Institute of Mathematics and Statistics, Niterói, Brazil, ⁴University of São Paulo, Faculty of Medicine, São Paulo, Brazil, ⁵University of Alabama at Birmingham, School of Public Health, Birmingham, United States, ⁶Federal University of Minas Gerais, Faculty of Medicine, Belo Horizonte, Brazil

Background: In recent years, human immunodeficiency virus (HIV) incidence has increased among adolescent men who have sex with men (aMSM) and transgender women (aTGW). Expanding prevention strategies, including daily oral HIV Pre-Exposure Prophylaxis (PrEP), is crucial for controlling the epidemic. Recently, PrEP offer in the Unified Health System was expanded to individuals aged between 15 and 17 years, sexually active and vulnerable to HIV. This study aimed to analyze the sociodemographic and behavioral characteristics of adolescent men who have sex with men (aMSM) and transgender women (aTGW) initiating oral PrEP in HIV prevention clinics.

Methods: PrEP1519 is a prospective, multicenter, open-label PrEP demonstration cohort study of aMSM and aTGW aged 15–19 living in three large Brazilian capital cities. For this analysis, we included adolescents who enrolled in PrEP1519 from February 2019–August 2021 and were followed until February 2022 to assess PrEP initiation. Adolescents who visited the PrEP clinics were classified into four groups based on PrEP eligibility and on their decision to use PrEP:

- i. Ineligible for PrEP;
- ii. Eligible, initiated PrEP at first visit;
- iii. Eligible, initiated PrEP after first visit; and
- iv. Eligible, did not initiate.

The groups were described and compared using the χ^2 and Fisher's Exact tests.

Results: Of the 1,254 adolescents who visited the PrEP clinics, 61 (4.9%) were clinically ineligible for PrEP initiation (37.7%) or had a low HIV risk (62.3%). Of the 1,193 eligible for PrEP initiation, 1,113 (93.3%) initiated PrEP, and 80 (6.7%) did not. Of the 1,113 adolescents who initiated PrEP, 87.3% did so on the same day and 12.7% later.

Half of those who initiated PrEP in subsequent visits did so within 42 days from the first visit. Despite 90% of the PrEP decliners declaring a low risk of HIV infection, most reported condomless anal sex in the past six months (70%).

Conclusions: Same-day PrEP initiation among aMSM and aTGW was high, highlighting the importance and need for promoting effective PrEP offer and access among adolescents with increased vulnerability to HIV.

OAC0504

PrEP and service utilization among sexual and gender minority youth (SGMY) were significantly improved with an intervention that includes multiple intervention strategies: automated text messages, peer support and coaching

M. Rotheram¹, D. Swendeman², S. Cornulada¹, A.T.N. CARES Team, Comprehensive Adolescent Recruitment and Engagement Strategies³

¹University of CA, Los Angeles, Psychiatry, Los Angeles, United States, ²University of CA, Los Angeles, Psychiatry, Los Angeles, United States, ³University of CA, Los Angeles, Adolescent Medicine, Los Angeles, United States

Background: Uptake of both health care interventions, especially pre-exposure prophylaxis (PrEP) or Post-exposure prophylaxis (PEP) with antiretroviral drugs (ARV), and sustained engagement with social services to cope with comorbid conditions of homelessness, substance abuse, mental health disorders, or a lack of food, clothing, transportation and toiletries are need by young people at risk for HIV. This study evaluates the level of intervention needed to improve uptake of these services.

Methods: Gay, bisexual, transgender and gender diverse youth aged 12–24 years old (N=895), who were predominantly Black and Latino, were recruited from 2017–2019 from 13 community agencies in Los Angeles and New Orleans and assessed at 4-month intervals over 24-months with 90%–70% follow-up. Youth were randomized to interventions designed to support uptake of the HIV Prevention Continuum (linkage to healthcare, uptake and adherence to PrEP, PEP and/or 100% condom use) and hierarchies of needs (housing, income, social relationships, mental health, risks) in a four-arm factorial design: 1) automated messaging and monitoring (AMMI) via text-messages (n = 313); 2) AMMI plus peer support via private social media (AMMI-PS; n = 205); 3) AMMI plus strengths-based telehealth Coaching (AMMI-C; n=196); or 4) AMMI plus peer support and coaching (AMMI-PS-C; n = 181). Intent-to-treat analyses used Bayesian generalized linear modelling of intervention impact over 24-months.

Results: Significant benefits were found on two outcomes. PrEP uptake matched youth national rates initially (11.3% current, 18.8% lifetime) and increased at 4-months to 15% across intervention arms but continued to increase in the AMMI-PS-C arm over time compared to other groups (OR 2.35; 95% CI:1.27–4.39 vs. AMMI control). By 12 months,

over 23% of AMMI-PS-C participants reported PrEP use, with some fall-off at 20-24 months, concurrent with the COVID-19 epidemic. About half of the youth receive no ancillary services during each assessment period. Youth receiving the AMMI condition had significantly greater use of services when recruited; however, over time the rate of service use remained most consistent in the AAMI-PS-C condition.

Conclusions: The most intensive intervention group receiving AMMI, peer support, and coaching improved and sustained PrEP use and services utilization over time compared to other groups.

OAC0505

Increased use of event-driven PrEP during COVID-19 in Australia: results from behavioural surveillance 2019-2021

C. Chan¹, M. Holt², T.R. Broady², J. MacGibbon², L. Mao², G. Prestage¹, B. Wilcock³, B. Clifton⁴, B.R. Bavinton¹

¹Kirby Institute, UNSW Sydney, Sydney, Australia,

²Centre for Social Research in Health, UNSW, Sydney, Australia, ³Australian Federation of AIDS

Organisations, Sydney, Australia, ⁴National Association of People with HIV Australia, Sydney, Australia

Background: COVID-19 has impacted sexual behaviour and engagement with sexual health services including HIV/STI testing and PrEP. Event-driven PrEP (ED-PrEP) has been included in Australian PrEP guidelines since 2019 and may be an attractive option for gay and bisexual men (GBM) who reduced their sexual activity due to COVID-19.

Methods: ED-PrEP use trends between 2019 and 2021 were assessed using national data from the Gay Community Periodic Surveys. Additional analyses using data from the last available COVID-19-affected rounds (2020-21) were included to compare characteristics between daily PrEP users and ED-PrEP users.

Results: Between 2019-2021, 24,815 survey responses were included. Of these, 6,754 (27.0%) reported PrEP use in the last 6 months (25.6% in 2019 to 26.9% in 2021). Among PrEP users, ED-PrEP use increased from 7.8% in 2019 to 20.0% in 2021. There were 2,077 PrEP users in the last available round in 2020-2021; 79.5% were daily PrEP users and 20.5% ED-PrEP users. Compared to daily PrEP users, ED-PrEP users were less likely to identify as gay (84.2 vs 88.7%, aOR=0.70, 95%CI=0.50-0.97), have received an STI diagnosis in the last 12 months (29.4% vs 38.5%, aOR=0.74, 95%CI=0.58-0.96), or have engaged in condomless anal sex with casual partners in the last 6 months (64.0% vs 72.4%, aOR=0.72, 95%CI=0.56-0.94). ED-PrEP users were more likely to have reduced their PrEP use due to COVID-19 (60.8% vs 46.5%, aOR=1.75, 95%CI=1.38-2.21).

Conclusions: ED-PrEP use more than doubled between 2019 and 2021. ED-PrEP users had a lower risk profile as they are less likely to engage in condomless sex or receive an STI diagnosis. ED-PrEP users were more likely to report

PrEP disruptions due to COVID-19 and may have switched from daily to ED-PrEP. Continued monitoring of ED-PrEP use is recommended for tracking the impact of COVID-19 on PrEP use and uptake of this regimen generally.

OAD01 Situating gender-based violence in the HIV field: Evidence, advances and action

OAD0102

Reporting, prevention and response of gender based violence against men who have sex with men in Taraba State, Nigeria

C. Nwagbo¹, E. Anene²

¹University of Port Harcourt/International Centre for Total Health and Right Advocacy Empowerment(ICTHARAE), Programmes, Jalingo, Nigeria, ²International Centre for Total Health and Rights Advocacy Empowerment (ICTHARAE), Programmes, Jalingo, Nigeria

Background: Men who have sex with men (MSM) in Taraba state have HIV prevalence that is 10 to 15 times higher than the general population. They are also frequently affected by Gender-Based Violence (GBV). The experience of GBV has been associated with higher vulnerability to HIV among MSM. To prevent GBV and mitigate its effects on HIV outcomes and to promote well-being of its MSM participants, ICTHARAE has implemented GBV activities for HIV prevention, treatment and care program in Taraba between 2019 to 2022.

Description: ICTHARAE's GBV reporting, prevention, and care program component promotes a dynamic of empowerment of MSM. First, we used psychosocial education and funder-support capacity building to strengthen MSM's knowledge of their human and legal rights with an enlightenment on the constitutional and legal environment in the fight against GBV as well as de-normalize the violence that they experience frequently. MSM who have been victims of GBV received legal and psychosocial services and are assisted to report and prosecute if they wish. ICTHARAE leaders and MSM community members(MSM-CM) hold advocacy sessions with authorities Taraba.

Lessons learned: From 2019-2022, 189 cases of physical, sexual, social, and emotional GBV were reported by Key Population leaders (41 cases), ICTHARAE staff (50 cases) and MSM-CM (98 cases). Cases that have elements of physical GBV were 57, sexual GBV were 85, that of social GBV were 59 and emotional GBV were 157. Between 2019 to 2022, 69 authorities participated in advocacy sessions and 130 MSM participated in capacity building and psycho-education/sensitization on GBV. Also, with funder support, a new strategy that empowers ICTHARAE to support organizations with \$1000 to tackle GBV issues was also implemented and 5 organizations participated.

Conclusions/Next steps: Unfortunately GBV continues to be a barrier to HIV prevention and treatment for MSM in Taraba. In 2023, ICTHARAE plans to strengthen GBV reporting network to include beneficiary of the \$1000 support fund while planning to reach MSM community members in other states of Nigeria.

ICTHARAE is also exploring other means to strengthen referral of GBV survivors to medical, legal, social support services and to promote the systematic documentation of violence to support national advocacy.

OAD0103

Different forms of violence among displaced and conflict-affected women living with HIV (WLHIV) in Ukraine

A. Wolfe¹, M.A. Roach², G. Turpin¹, O. Syarif³, P. Looze³, K. Lalak³, J. Anoubissi³, S. Brion⁴, K. Dunaway⁴, D. Matyushina⁵, L. Sprague⁵, C. Garcia de Leon Moreno⁵, S. Baral¹, C. Lyons¹, K. Rucinski²

¹Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, ²Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, ³Global Network of People living with HIV (GNP+), Amsterdam, Netherlands, ⁴The International Community of Women living with HIV (ICW), London, United Kingdom, ⁵UNAIDS, Geneva, Switzerland

Background: Women living with HIV (WLHIV) in conflict zones are at high risk of sexual and physical violence due to instability, stigma, and proximity to military personnel. Given sustained ongoing conflict in parts of Ukraine, this study evaluated the relationship between displacement and sexual violence, health care-related stigma, and reproductive coercion among WLHIV in Ukraine.

Methods: Led by the All-Ukrainian Network of PLHIV (100% Life), WLHIV aged 18+ were recruited from 17 regions of Ukraine and completed a socio-behavioral questionnaire (July-August 2020). Displacement was defined as ever being a refugee, migrant worker, or internally-displaced person.

Outcomes included sexual violence, abuse perpetrated by healthcare workers, and reproductive coercion related to pregnancy, sterilization, and contraception.

Log binomial regression models estimated prevalence ratios (PR) and 95% confidence intervals (CI) for associations between displacement and each outcome. Models were adjusted for age, education, years knowing positive HIV status, and ever being on antiretrovirals.

Results: A total of 820 WLHIV completed the questionnaire. Displaced WLHIV were significantly more likely to have experienced sexual violence (PR: 2.72; 95%CI 1.69-4.36) and verbal or physical abuse in healthcare settings due to their HIV status (PR: 2.40, 95%CI 1.38-4.19) compared to non-displaced WLHIV. Displacement was also associated with contraceptive coercion (PR: 3.31, 95%CI 1.20-9.24).

Outcome ^a	PR	95% CI	aPR	95% CI
Sexual Violence	2.72	1.69-4.36	2.64	1.62-4.29
Abuse in Healthcare	2.40	1.38-4.19	2.36	1.30-4.31
Pregnancy Coercion	1.66	0.56-3.85	1.26	0.48-3.31
Sterilization Coercion	2.78	0.85-9.10	2.24	0.62-8.11
Contraception Coercion	3.34	1.21-9.07	3.31	1.20-9.14

^a Displacement was defined as ever being a refugee, migrant worker, or internally-displaced person.
^b Outcomes were modeled separately and compared for WLHIV who were and were not displaced; models were adjusted for age, education, years knowing positive HIV status, and ever being on antiretrovirals.

Table. Prevalence ratios (PR) and 95% confidence intervals (CI) for the association of displacement with outcomes related to sexual violence, health care-related stigma, and reproductive coercion among 820 women living with HIV (WLHIV) in Ukraine^a

Conclusions: Given the growing conflict in Ukraine, these data suggest that sexual violence and stigma are fundamental barriers to health and well-being among WLHIV in Ukraine. Training uniformed officers and clinicians at all levels to ensure understanding and accountability is likely central to mitigating these rights violations in the future, and scale-up of trauma-informed care for displaced WLHIV may serve to mitigate violations to date.

As short-term humanitarian health needs lessen and long-term reproductive health needs are re-prioritized for displaced populations living with HIV, a national focus on autonomy and client communication can also serve to mitigate rights violations.

OAD0104

Violence among adult Venezuelan migrants: results from a multi-site survey in Colombia

J. Guillen¹, A. Wirtz², M. Stevenson², M. Barriga³, D. Martinez³

¹Corporacion Red Somos, Colombia, ²John Hopkins University, Maryland, Baltimore, United States,

³Corporacion Red Somos, Bogota, Colombia

Background: While globally prevalent, violence victimization of migrant populations is a concern due to contexts of migration and associated social and structural vulnerabilities. We estimated the prevalence and correlates of violence victimization among Venezuelan migrants in Colombia.

Methods: Venezuelan adults who migrated since 2015 and resided in four cities from Colombia were sampled using RDS. Socio-behavioral surveys included measures of psychological, physical, sexual violence, and sexual exploitation during their time in Colombia and within the past 12 months. Referrals were provided to participants who reported victimization.

Descriptive statistics and RDS-weighted estimation were used to calculate sample characteristics and prevalence estimates, respectively. We calculate adjusted odds ratios (aOR) of correlates of victimization using logistic regression models, stratified by gender.

Results: Participants (N=6,087) were median age of 32 years; 65% women, 34% men, and 1% transgender/non-binary-identified. Twelve percent of participants reported any victimization while in Colombia (RDS-weighted population prevalence: 11.7; 95%CI:11.0-12.6), which was lower in

Oral

Late-breaker
abstractsAuthor
Index

Barranquilla/Soledad vs. Bogotá/Soacha (8.3% vs 14.9%, $p<0.001$) and higher among men (15%) than transgender/non-binary participants (13%) and women (10%, $p<0.001$). Five percent (RDS-weighted population prevalence: 6.0; 95%CI:5.4-6.7) reported any violence in the past 12 months. Victimization in Colombia included psychological (7%), physical (7%), forced sex (1%), and sexual exploitation (2%). Men more commonly reported psychologic and physical violence while women and transgender/non-binary participants more commonly reported forced sex and sexual exploitation. Strangers were the most common perpetrator across forms of violence, followed by intimate-partners, family members, other trusted individuals, and police.

Among women, violence was associated with unsafe housing: having 1-10 unsafe nights (aOR: 1.9, 95%CI:1.4-2.7), ≥ 11 unsafe nights (aOR: 2.6, 95%CI:1.7-4.0); food-insecurity (aOR: 2.4; 95%CI:0.9-6.7); exchange-sex (aOR: 12.8; 95%CI:7.5-21.8); and pregnancy while in Colombia (aOR: 1.4; 95%CI:1.2-1.8) after controlling for site and year of migration.

Among men, violence was associated with unstable housing: 1-10 nights unsafe nights (aOR: 1.7, 95%CI:1.2-2.5), ≥ 11 unsafe nights (aOR: 2.3, 95%CI:1.4-3.7); food insecurity (aOR: 2.0; 95%CI:0.8-5.2), exchange sex (aOR: 3.5; 95%CI:1.7-7.3), and same-sex partnerships (aOR: 1.5; 95%CI:1.0-2.2).

Conclusions: Reported violence victimization while in Colombia are slightly lower than anticipated and likely attributed to under-reported intimate partner violence due to perceived low severity of violence.

Findings highlight the experiences of violence among migrants that relate to structural vulnerabilities associated with housing instability, food-insecurity, transactional sex, and stigmatization of sexual orientation or transgender identity.

OAD0105

Prevalence of intimate partner violence among adolescent girls and young women enrolled in the determined, resilient, empowered, AIDS-free, mentored and safe program in Zimbabwe; evidence from sentinel survey, 2022

F.H. Mudzengerere¹, E. Tachiwenyika¹, D. Dhakwa¹, K. Yogo¹, F. Mudokwani¹, B. Nyamwanza², R. Yekeye², K. Muzondo¹, B. Madzima², C. Rugube³, T.A. Tafuma¹, H.W. Mafaune¹

¹Zimbabwe Health Interventions, Harare, Zimbabwe,

²National AIDS Council, Harare, Zimbabwe, ³Family Health International, Harare, Zimbabwe

Background: Intimate partner violence (IPV) is pervasive globally, with 27% of women aged 15-49 years having experienced IPV in 2021, whilst it was 36% in sub-Saharan Africa. IPV against women is a human rights concern with negative outcomes including physical and mental health problems, as well as associated with acquiring HIV.

IPV among adolescent girls and young women (AGYW) enrolled in the Determined, Resilient, Empowered, AIDS-free, Mentored and Safe (DREAMS) program has not been explored. We assessed the prevalence of IPV among the AGYW aged 9-19 years enrolled in the DREAMS program in Zimbabwe.

Methods: We conducted an analytical study among AGYW aged 9-19 years enrolled in the DREAMS program from the 1st of October 2021 to the 30th of September 2022. AGYW were randomly selected from the DREAMS program DHIS 2 database, and data were collected across all 9 Zimbabwe Health Interventions (ZHI) DREAMS districts. Data were collected using structured questionnaires with Kobo Toolbox and were analyzed using STATA generating descriptive statistics and measures of association. Study received ethics approval from Medical Research Council of Zimbabwe (MRCZ/A/2933).

Results: Of the 1,616 AGYW interviewed, 32.1% were aged 15-19 years, 3.8% were married, and 13.4% were sexually active. Nearly 7% (121/1,616) AGYW experienced different forms of IPV, and of these, 25% were slapped, 16% were hit by fist or threatened, 15% were pushed or shoved, and 14% were forced to have sex.

AGYW who were married were more likely to experience IPV than those single and widowed [COR =3.90 (95% CI =1.68: 9.05)]. AGYW who attained lower levels of education were more likely to experience IPV than those with higher levels of education [COR=4.71; 95% CI (4.11;5.40)].

Over 62% of AGYW reported that community leaders acted against perpetrators of IPV, and this was spearheaded through community norms change intervention under the DREAMS program.

Conclusions: A significant proportion of AGYW experienced IPV including slapping and forced sex. We recommend strengthening IPV reporting and service delivery through the DREAMS GBV platforms and to cascade community norms change intervention to all DREAMS districts to prevent IPV.

OAD02 Tackling stigma: Insights and interventions

OAD0202

An incognito patient approach to measure enacted HIV and gay stigma in healthcare settings

Y. Zhang¹, S. Sylvia², S. Meng³, H. Xie⁴, R. Zhao⁵, A. Kwan⁶, D. Luo³, K. Zhang³, I. Fei⁵, K. Smith⁵, spr

¹Kirby institute, UNSW Sydney, Sydney, Australia, ²UNC's Gillings School of Global Public Health, Charlotte, North Carolina, United States, ³UNC-Project China, Guangzhou, China, ⁴University of Wisconsin-Milwaukee, Milwaukee, United States, ⁵University of Minnesota Twin Cities, Twin Cities, United States, ⁶University of California, San Francisco, United States

Background: Enacted healthcare stigma has a complex and severe impact on physical and mental health of men who have sex with men (MSM). However, most studies measured enacted healthcare stigma using self-reported measures that may have been limited by social desirability bias.

This study applies standard patient (SP) approach to covertly observe provider behaviors to assess the impact of stigma against MSM in terms of HIV, sexual or its intersection on the quality of syphilis care in healthcare settings in China.

Methods: Trained SPs conducted unannounced visits with consenting providers. We randomly varied the HIV status and sexual orientation of each presented case to quantify stigma as differences in care across case scenarios. Care quality was assessed in 4 domains including adherence to clinical guidelines, diagnostic testing, patient-centred care, and visit duration. Item response theory models were used to calculate weighted indices for continuous care scores. Fixed effect linear and logistic regressions were used to assess differences in care quality across scenarios.

Results: SPs conducted 123 clinic visits with 41 providers across 17 clinics. Scores for clinical guideline adherence were lower in all stigmatized scenarios as compared to the referent condition of an HIV negative straight man, though only the estimate for HIV- MSM was statistically significant (β , - 0.61, 95% CI, -1.18, -0.04).

Appropriate diagnostic testing was less likely when SPs presented as HIV positive irrespective of sexual orientation (HIV+ straight: OR, 0.35, 95% CI 0.00-3.35; HIV+ MSM: OR 0.08, 95%CI 0.01- 0.77).

We did not observe differences in patient-centred care scores. No adverse events or overtly hostile provider behaviours were reported.

Conclusions: Our novel incognito patient approach documented notable declines in healthcare quality among cases presenting as HIV positive, MSM, or both. SPs presenting with stigmatized identities experienced less thor-

ough clinical assessments or diagnostic testing, suggesting that stigma most often manifests in the form of less attentive or even neglectful care. Our findings provide key insights to understand how stigma in marginalized populations can impair health even in the absence of grossly negligent. Results also informed the design of a pilot stigma reduction for providers, results of which are forthcoming.

OAD0203

Effects of a novel group-based cognitive behavioral therapy (CBT) intervention on stigma, psychosocial wellbeing and HIV service use among sexual and gender minorities in Nigeria

J. Pulerwitz¹, A. Gottert¹, W. Tun¹, A. Fernandez², P.L. Oladimeji³, S. Sangowawa³, A. Adedimeji²

¹Population Council, Washington DC, United States, ²Population Council, Abuja, Nigeria, ³Consultant, Abuja, Nigeria

Background: High levels of stigma due to identifying as a sexual or gender minority (SGM) as well as living with HIV (i.e., intersectional stigma) are increasingly documented in the African setting, and often manifest as self-stigma (also called internalized stigma). Such stigmas impede psychosocial wellbeing as well as HIV prevention/care, and there are few (if any) evidence-based internalized stigma reduction interventions in this context.

We developed and evaluated a novel, group-based CBT stigma intervention for men who have sex with men (MSM) and transgender women (TGW) at risk for/living with HIV in Lagos, Nigeria.

Methods: The intervention, adapted from a Canadian curriculum, comprised four weekly in-person sessions facilitated by community health workers. We conducted a delayed intervention group randomized controlled trial, with pre-post surveys plus 3-month follow-up, as well as qualitative interviews with participants / program staff. Outcomes included internalized stigma related to SGM and HIV status, depression, resiliency, and PrEP / HIV treatment use.

Results: Mean age of the 240 participants was 26 years (range 18-42). Seventy-seven percent were MSM and 23% TGW; 27% were living with HIV. Most (88%) participants attended all 4 sessions, and 98% expressed high intervention satisfaction.

There was significant improvement in each psychosocial outcome between baseline and second surveys, in both the immediate (post intervention) and delayed (pre-intervention) arms.

Qualitative data obtained from participants post intervention described enhanced self-confidence, resilience when facing stigma, and coping skills, and indicated that positive changes found in the delayed group (pre-intervention) were mainly due to perceived support from the interviewers / survey experience.

There were further positive changes from baseline to three-month follow-up in e.g., intersectional internalized stigma and depression, for the immediate intervention group. Controlling for baseline levels of ever PrEP use, 75% of immediate-group participants reported currently using PrEP at three months post-intervention vs. 53% of delayed-group participants right after the intervention ($p < 0.01$).

Conclusions: This study demonstrated feasibility and acceptability of a group-based CBT model in Nigeria. There were also indications of preliminary efficacy related to mental health outcomes and PrEP, despite the randomized design not holding up (where study participation/contact became an intervention in itself).

OAD0204

Political conservatism and social distancing from people living with HIV among medical students: mediating roles of negative stereotypes and negative intergroup emotions

S.A. Nemli¹, Y. Bayramoglu², B. Turan³

¹Izmir Katip Celebi University, Infectious Diseases and Clinical Microbiology, Izmir, Turkey, ²The University of Alabama at Birmingham, Psychology, Birmingham, United States, ³Koc University, Psychology, Istanbul, Turkey

Background: HIV-related stigma within the health care system is a major barrier preventing people living with HIV (PLWH) from accessing and continuing treatment. Psychosocial factors such as political orientation, personality characteristics, and personal moral values of health care providers have not been adequately investigated. Furthermore, a deeper understanding of the mechanisms in the effects of these drivers on social distancing from PLWH is needed, especially among medical students (future healthcare providers).

The present study aims to fill these gaps by studying stigmatizing attitudes of medical students from the perspective of the inevitability of prejudice due to negative intergroup emotions.

Methods: Participants were 609 medical students (326 women, 53.5%) attending a medical school in Izmir, Turkey. Demographic features, political orientation, endorsing stereotypes about PLWH, stigmatizing attitudes, emotional reactions toward PLWH, social distance from PLWH, and HIV knowledge were assessed via self-reported questionnaires between March 2021 and June 2021. Multiple regression analyses and a serial mediation analysis calculating indirect effects using bootstrapping were used by adjusting for demographic factors and HIV knowledge.

Results: Political conservatism, endorsing negative stereotypes about PLWH, and negative intergroup emotions toward PLWH were all significantly associated with attitudes toward social distancing from PLWH.

A serial mediation first by endorsing negative stereotypes about PLWH and then by negative intergroup emotions

toward PLWH in the association between higher political conservatism and higher social distancing from PLWH was found, supporting our hypothesis.

Conclusions: Findings suggest that interventions may target stereotyping and negative intergroup emotions to reduce discriminatory behaviors of medical students. Furthermore, to reduce HIV-related stigma and discrimination and to improve healthcare delivery to PLWH, more research is needed on the roles of stigma within the healthcare system specifically, and on governmental policies and societal factors that contribute to structural stigma in general.

OAD0205

Gender identity stigma and discrimination and condomless anal sex among transgender women of TransCITAR study from Buenos Aires, Argentina: mediating role of depressive symptoms

R. Caballero^{1,2}, E. Frontini³, V. Zalazar³, N. Cardozo^{3,4,5}, M. Duarte^{3,5}, S. Fabian^{3,6}, F. Vissicchio³, S. Cahn³, P. Radusky^{3,2}, C. Frola^{1,7}, M.I. Figueroa³, I. Aristegui³

¹Fundación Huésped, Research Department, Buenos Aires, Argentina, ²Universidad de Buenos Aires, Faculty of Psychology, Buenos Aires, Argentina, ³Fundación Huésped, Research Institute, Buenos Aires, Argentina, ⁴REDLACTANS, Buenos Aires, Argentina, ⁵Asociación de Travestis, Transexuales y Transgéneros de Argentina (A.T.T.A.), Buenos Aires, Argentina, ⁶Asociación Civil Gondolín, Buenos Aires, Argentina, ⁷Hospital Juan A. Fernández, Infectious Diseases Unit, Buenos Aires, Argentina

Background: Co-occurrence of stigma, depression and condomless anal sex (CAS) among transgender women (TGW) is widely reported. However, interactions between these factors remain unclear. TransCITAR is a prospective cohort study of 500 trans and non-binary individuals from Buenos Aires, Argentina; initiated in September, 2019.

This sub-analysis explored the mediating role of depressive symptoms in the relation between gender identity stigma, gender identity discrimination, and CAS in TGW participating in TransCITAR.

Methods: Until December/2022, 421 TGW, recruited by peer navigators, completed baseline psychosocial interviews that included questionnaires designed ad hoc to collect information on socio-demographic variables, gender identity discrimination (in healthcare, police, etc.) in lifetime, and CAS (receptive and insertive) in the last month, a gender identity stigma (GIS) scale and the CES-D (depressive symptoms). Path analysis was performed to examine the relationships between these variables. Parameters were estimated using maximum likelihood (ML) estimator.

Model fit was assessed through several goodness of fit indices including Comparative Fit Index (CFI), Tucker-Lewis index (TLI), and Root Mean Square Error of Approximation (RMSEA).

Results: Median age was 30 years (IQR 25–37), 50% reported incomplete high school or lower, 41% unstable housing, 45% receiving financial aid, 31% being migrant and 53% current engagement in sex work.

The prevalence of CAS was 26% (n = 109) and HIV laboratory-confirmed basal prevalence was 42%. The mediation model showed an excellent goodness of fit (CFI = 1.000; TLI=1.000; RMSEA = 0.000).

The indirect effect of GIS to CAI through depressive symptoms was significant (estimate = .057, p = .000), while the indirect effect of GIS experience of discrimination to CAS was not mediated by depressive symptoms (Estimate = .138, p = .38).

GIS was positively associated with depressive symptoms (Std. estimate = .356; p<0.001), which were positively associated with CAS (Std. estimate = .161, p = .000).

Conclusions: Depressive symptoms played a mediating role in the association between gender identity stigma and CAS. HIV and STIs preventive interventions for TGW should incorporate elements of trauma-informed and skills-building care.

Moreover, it is crucial for reducing CAS to advocate for social inclusion programs, trans-inclusive environments and anti-discriminatory policies that reduce stigma and its health-related effects.

OAD03 Younger and older: HIV across the life course

OAD0302

"We want them to know that we exist": how can we better meet the needs of sexuality and gender diverse young people living with HIV? Qualitative research from Zimbabwe

J. Lariat¹, W. Mavhu^{2,3}, T. Mudhuma⁴, P. Shaba², S. Sibanda², R. Mbundure², C. Wogrin⁴, A. Mutsinze⁴, N. Willis⁴, S. Bernays^{1,5}

¹University of Sydney, School of Public Health, Sydney, Australia, ²CeSHHAR, Harare, Zimbabwe, ³Liverpool School of Tropical Medicine, Liverpool, United Kingdom, ⁴Zvandiri, Harare, Zimbabwe, ⁵London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom

Background: There is a scarcity of research about the experiences, challenges, and needs of sexuality and gender diverse (SGD) young people living with HIV. Failing to recognise, understand and respond to this group's needs perpetuates long-standing inequities in the HIV response and restrains progress towards key targets. We present qualitative findings on experiences and challenges of SGD young people living with HIV in Zimbabwe.

Methods: We conducted two focus group discussions in 2022 with 14 self-identified SGD young people (18–24-years) all of whom were accessing a recently formed SGD HIV

support group at Zvandiri ('As I Am'), a community-based HIV program. We conducted interpretive thematic analysis to generate themes across the data.

Results: All the young people refuted the imposition of static binary categories of sexuality and gender. They understood their identities as fluid and still in the process of becoming. All participants described that being an SGD young person living with HIV had led to *"double stigma and double trouble"*. This manifested in physical and verbal harassment, social exclusion, and family rejection. In most situations, they had to keep both their sexuality and/or gender identity and HIV status hidden, but many also felt compelled to conceal their HIV status in SGD social spaces. This negatively impacted their psychosocial wellbeing and social connectedness.

Participants shared positive experiences of Zvandiri, describing the service as *"speaking to me"*. The mutual witnessing of others' experiences of living with HIV, in a safe and destigmatising environment, enhanced self-acceptance and improved motivation to maintain engagement in treatment.

However, reflecting their prevailing experiences, participants were cautious about being open about their gender and sexuality outside of their SGD group even within Zvandiri.

Conclusions: Understanding how intersectional stigma impacts SGD young peoples' social and relational lives, and their access to healthcare services, is a critical step toward appropriately responding to their needs. Community-based HIV support services who emphasise and promote principles of inclusivity are well-positioned to support and advance SGD young peoples' health rights.

Efforts to strengthen understanding and responsiveness to this group's needs should be prioritised as a mechanism to improve their wellbeing and HIV outcomes.

OAD0303

"It felt like a weight was being taken off my shoulders": the impact of lending a hand intervention in supporting migrant adolescents and young people, in KwaZulu-Natal, South Africa

N. Dlamini¹, J. Seeley², M. Shahmanesh³, N. Ngwenya¹, S. Hlongwane¹, C. Herbst¹

¹Africa Health Research Institute, Social Science Core, Mtubatuba, South Africa, ²London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom, ³University College London, London, United Kingdom

Background: In South Africa, many young people move away from their homes to semi-urban areas for education. They attend day schools while staying in rented accommodation. They may experience alcohol and drug abuse, sexual exploitation, and violence all of which put them at risk of contracting HIV.

Our aim was to develop and test the feasibility and acceptability of a support structure for migrant adolescents and young people (MAYP), aged 14-24, and to understand their experiences of the intervention, in KwaZulu-Natal, South Africa.

Methods: Five peer navigators (PNs) were trained on needs assessment (clinical, social, educational, and psychosocial) of MAYP. The PNs enrolled 283 MAYP, aged 14-24, between June 2021 and October 2022.

The intervention included:

1. Using a mobile phone to provide support identified during the needs assessment,
2. Facilitating the referral process at a call centre to the study social worker for psychosocial and emotional services, local health facilities for healthcare services and peer support on general issues.

We conducted repeat in-depth interviews (IDIs), n=20; and 5 key informant IDIs with PNs, n=5, both face-to-face and telephonically.

Results: The majority of MAYP were in grades 11 and 12 at day schools. They rented rooms in an unsafe environment on their own to be closer to their schools. Transitioning from living with their parents or guardians to living on their own in an unfamiliar environment caused physical (e.g. violence), psychological, and mental challenges. In describing the intervention most of them 'felt like a weight was being taken off of their shoulders'. They also felt that it was beneficial for them as they were linked to treatment for sexually transmitted infections, received psychosocial support from the intervention social worker, and were also supported by PNs in facing general challenges. This helped them develop adaptive coping strategies and avoid risky behaviours.

Conclusions: Interventions targeted for young people are much more effective when they are led by peers who understand young people's experiences. The intervention was designed for and centred around the needs of MAYP and the short turnaround time during the referral process made it acceptable and they felt respected.

OAD0304

"If I don't take care of me, then I can't be there for others:" a qualitative study of caregiving relationships among older women living with HIV

T. Vu¹, M. Quinn¹, J. Monin¹

¹Yale University School of Public Health, Social and Behavioral Sciences, New Haven, United States

Background: There are over 100,000 women ages 50+ diagnosed with HIV in the United States (U.S). Yet, the experiences of older women living with HIV (WLWH) remain understudied. Little is known about the social support networks that older WLWH use to manage their health. This study examines the social support, or care networks, of older WLWH, with an emphasis on their care giving and care receiving relationships.

Methods: We recruited women ages 50+ who are living with HIV from community-based organizations and clinics in the U.S. We conducted one-on-one, semi-structured phone interviews between May 2022 – August 2022. Interviews were recorded and transcribed verbatim. Following a Grounded Theory approach, two coders performed open coding and then thematic coding to generate themes.

Results: Participants (N = 23) came from 11 U.S states, were on average 60.3 years old (min 51, max 68), and had been living with HIV for an average of 23.7 years. 78.3% of participants were Black. 78.3% identified as heterosexual.

We identified five main themes regarding care networks and perceptions of caregiving in older adulthood:

1. Participants received the most care (i.e., instrumental/emotional support to help manage HIV) from their adult children and HIV support group peers. Participants provided the most care to their grandchildren and own parents.
2. Despite occasional periods of stress balancing caregiving responsibilities while managing HIV, participants have pride and joy in being caregivers to loved ones.
3. Caregiving and receiving networks not only help disease management, but also promote self-love and acceptance.
4. Despite receiving care, participants are highly proactive in their own HIV management.
5. Many had concerns about being able to keep up with their HIV care needs due to uncertainty about who will be in their care networks in the future and comorbidity.

Conclusions: Findings highlight that both being a care recipient and a caregiver can be sources of meaning for older WLWH to help in their HIV management. To address the concerns brought forth by our participants about aging with HIV, public health programs and policies for older WLWH may benefit from engaging their care networks in healthcare discussions and educational efforts.

OAD0305

Assessing the health-related quality of life and risk of poverty of older people living with HIV in Spain: a cross-sectional study applying a gender perspective

N. Nuño¹, A. Martínez¹, S. Martínez¹, M. Cobos¹, J.S. Hernández², R. Polo¹

¹Spanish Ministry of Health, Madrid, Spain, ²Working Group on HIV Treatments (gTt-HIV), Barcelona, Spain

Background: Modern antiretroviral therapies have increased the life expectancy of people living with HIV. However, the health-related quality of life and living conditions of older people living with HIV in Spain have yet to be studied.

Methods: We implemented a self-administered online questionnaire in 2022 to assess the health-related quality of life and risk of poverty of Spanish older people living with HIV (≥50 years) and identify gender differences. We

applied the standardised WHOQoL-HIV BREF questionnaire to estimate health-related quality of life and the Europe 2020 guidelines to calculate the risk of poverty. The statistical analysis included multivariate generalised linear models with potential confounding variables and robust estimates.

Results: A total of 242 older people living with HIV (187 men and 55 women) participated in the study. The average age of men and women was 57.1 (standard deviation (SD)=5.1) and 56.3 (SD=4.0) years respectively.

Women scored lower (compared to men) in 84% of the WHOQoL-HIV BREF questionnaire items. In consequence, women had significantly lower health-related quality of life in five (out of six) of the questionnaire domains: physical health (β : -1.5; 95% confidence interval (CI): -2.5 -0.5; p : 0.003), psychological health (β : -1.0; 95% CI: -2.0, -0.1; p : 0.029), level of independence (β : -1.1; 95% CI: -2.0, -0.2; p : 0.016), environmental health (β : -1.0; 95% CI: -1.8, -0.3; p : 0.007), and spirituality/personal beliefs (β : -1.4; 95% CI: -2.5, -0.3; p : 0.013).

The risk of poverty was substantial for both men (30%) and women (55%), but women were significantly more likely to be at risk of poverty (odd ratio: 3.3; 95% CI: 1.5, 7.7; p : 0.004).

Conclusions: Our study supports the need for policies focused on improving the structural and living conditions and comprehensive care of older people living with HIV and reducing gender inequalities in health-related quality of life.

Future policies and interventions for older people living with HIV in Spain should prioritise the improvement of the structural and living conditions in which they subsist.

Multilevel barriers to methadone for HIV prevention among people who inject drugs in Kazakhstan: opportunities for change

A.R. Liberman¹, E. Rozental², D.J. Bromberg³, R. Ivasyi¹, A.Z. Kussainova⁴, S. Primbetova², L.M. Madden^{1,5}, A. Terlikbayeva², F.L. Altice^{5,1,3,6}

¹Yale School of Medicine, Section of Infectious Diseases, New Haven, United States, ²Global Health Research Center of Central Asia, Almaty, Kazakhstan, ³Yale School of Public Health, Department of Social and Behavioral Sciences, New Haven, United States, ⁴Kazakhstan National Medical University, Almaty, Kazakhstan, ⁵APT Foundation, New Haven, United States, ⁶Yale University, Center for Interdisciplinary Research on AIDS, New Haven, United States

Background: Central Asia (EECA) remains one of few regions where HIV incidence and mortality continue to increase, and this epidemic is concentrated among people who inject drugs (PWID). In Kazakhstan, the prevalence of HIV among PWID (9.2%) is higher than for any other key population. Opioid agonist therapies (OAT) like methadone or buprenorphine are evidence-based treatment for opioid use disorder (OUD) and crucial primary and secondary HIV prevention. Though methadone has been provided for free in Kazakhstan since 2008 through support from international donors, there are currently only approximately 340 (<1%) people on OAT among the estimated 90,000 PWID.

Methods: To assess barriers and facilitators to methadone uptake for HIV prevention, we conducted nominal group technique (NGT) focus groups (FGs) with people with OUD in four cities in Kazakhstan.

Among the 8 FGs, 4 included people currently on methadone, while the other 4 included people who had never received methadone. Additionally, we conducted 2 focus groups with local doctors and in-depth interviews with the directors at the four OAT sites and with several political figures who shape methadone policy in Kazakhstan.

Results: Multi-level barriers included: Policy (e.g., required national registration as a "drug user" to access addiction treatment services); Structural (e.g., inaccessible locations of clinics, rigid enrollment requirements); Clinician (e.g., viewing potential methadone program participants as undisciplined, and therefore not ready for treatment); and Patient (e.g., too many logistical requirements). A detailed rank-ordered list of barriers and facilitators will be expanded below.

Conclusions: Findings from this study identify many opportunities for potential methadone scale-up, which is required to control the HIV epidemic in Kazakhstan and throughout Central Asia.

OAD0403

Dapivirine vaginal ring (DPV-R): An acceptable and feasible HIV prevention option. Evidence from Zimbabwe

M. Munjoma¹, J. Mavudze¹, T. Moga¹, I. Moyo¹, N. Shoko¹, N. Nhando¹, T. Sola², J. Majongosi¹, M. Mutseta², G. Ncube², B. Mutede¹, N. Tarubekera¹, S. Leuschner³

¹Population Solutions for Health, Harare, Zimbabwe,

²Ministry of Health and Child Care, Harare, Zimbabwe,

³Population Services International, Harare, Zimbabwe

Background: HIV burden remains high in Zimbabwe. Adolescent girls and young women (AGYW) are disproportionately affected with an HIV incidence of 0.54% compared to 0.13% among their male counterparts (ZIMPHIA, 2020). Whilst oral PrEP remains a key HIV prevention modality, pill burden, and privacy are key barriers to oral PrEP uptake and continuation. Population Solutions for Health, PSI, and the Ministry of Health and Child Care are implementing a demonstration project to determine the acceptability and feasibility of using monthly DPV-R as an alternative to oral daily PrEP for HIV prevention.

Methods: A two-arm prospective cohort design is being implemented across 8 districts in Zimbabwe. AGYW aged 18-25, screened as high-risk and eligible for PrEP chose between oral PrEP and DPV-R. Clients from both arms were followed up monthly between June and November 2022. Uptake and continuation rates were compared between the two arms for significant differences. Key informant interviews were conducted with clinicians involved in PrEP service provision.

Results: A total of 1,535 AGYW were screened for PrEP, 1,466 were eligible and of these 1,128 (76.9%) (95% CIs: 74.7-79.7) chose DPV-R. Uptake was similar by age but differed significantly by residence, with higher uptake observed in rural (97.5% - 95%CI: 96.0-98.6) relative to urban (61.0% - 95%CI: 57.6.0-64.3) districts. Continuation rates were consistently higher among clients on DPV-R compared to oral PrEP as shown below. Five of 1,128 high-risk AGYW (0.4%) tested HIV positive since commencement on DPV-R compared to 1/338 (0.3%) receiving oral PrEP over the same period. Service providers reported high motivation for DPV-R among AGYW for its convenience and discretion.

Figure. DPV Ring showing higher continuation rates than Oral PrEP

Conclusions: DPV-R is a feasible and preferable PrEP option for AGYW in Zimbabwe and should be scaled up. More demand-generation activities are required in urban settings for improved uptake.

"PrEP4U:" how edutainment, student outreach, and multisector engagement are helping youth in Vietnam access HIV prevention and sexual health care

T.T. Tran¹, T.M. Le², T.L.V. Tran², T.K. Cao³, M.C.H. Vu⁴, K.E. Green¹, D. Nguyen⁵, H.T. Nguyen¹, P.H. Vu¹, T.M. Phan¹, T. Ngo⁵, Z. Humeau¹

¹PATH, Hanoi, Vietnam, ²Glink Social Enterprise, Ho Chi Minh City, Vietnam, ³Vietnam Administration for HIV/AIDS Control, Vietnam Ministry of Health, Hanoi, Vietnam, ⁴Vietnam Network of Transgender People, Hanoi, Vietnam, ⁵USAID/Vietnam, Hanoi, Vietnam

Background: In Vietnam, students and youth have several risk factors for HIV acquisition and transmission including poor HIV risk perception and awareness and limited knowledge on sexual and reproductive health (SRH) services such as HIV testing and pre-exposure prophylaxis (PrEP). "PrEP4U" is a behavior change campaign co-created by the USAID/PATH STEPS Project (STEPS) and partners to promote HIV and sexual health care engagement and practices among students in Vietnam.

Description: To enhance student/youth knowledge about SRH and safe sex and encourage their use of PrEP and other health services, STEPS, the Vietnam Ministry of Health, and youth leaders generated student insights in designing the online-to-offline PrEP4U campaign.

PrEP4U targets educational settings in three urban provinces (Hanoi, Ho Chi Minh City, Dong Nai) through talk shows with clinical experts, interactive edutainment games focused on safe sex and sexual health, integration with sex-ed programs at schools, booth exhibitions, and other activities where students can interact with community influencers and staff from community-based clinics and receive HIV testing, PrEP counseling, and referral for other services directly on-site.

The campaign also runs across online platforms and leverages a network of PrEP4U Ambassadors and a PrEP4U Facebook page blending informative and humorous content derived by youth to motivate viewers to seek PrEP/SRH information and services.

Lessons learned: From March–September 2022, 32 in-person PrEP4U events reached more than 8,500 students, distributed 1,096 HIV self-test kits and enrolled 317 individuals on PrEP.

The PrEP4U Facebook page has become a hub of trustworthy SRH and PrEP information for students, supporting the campaign to garner over 1.1 million views cross-platform. Targeted edutainment activities centered around principles of choice, equity, and people-centeredness to

IAS 2023

ensure that PrEP4U messaging and imaging resonated with different youth segments, including gay, transgender, and gender nonbinary individuals.

Conclusions/Next steps: PrEP4U addressed a major gap in youth access to HIV and SRH services by offering these services directly within schools and engaging campaign ambassadors and influencers, and as a result increased health care access and convenience.

Drawing from lessons learned, youth-focused PrEP/SRH campaigns will be further scaled and adapted for other settings to bring PrEP and sex-ed closer to populations in need.

OAD0405

Racial inequalities in HIV testing among adolescent men who have sex with men and transgender women in three Brazilian capitals

M. França¹, I. Dourado², A. Grangeiro³, L. Magno^{1,2}

¹Bahia State University, Health Science, Salvador, Brazil, ²Institute of Collective Health, Bahia Federal University, Salvador, Brazil, ³São Paulo University, Medicine School, São Paulo, Brazil

Background: Black people have a higher prevalence of HIV infection in several countries worldwide, including Brazil. Studies have also highlighted barriers to HIV testing in these populations because of structural racism.

We aimed to investigate the association between HIV testing in a lifetime and race among adolescent men who have sex with men (aMSM) and transgender women (aTGW) in three Brazilian state capitals.

Methods: PrEP1519 is a prospective, multicenter, open-label PrEP demonstration cohort study of aYMSM and aYTGW aged 15-19 in three Brazilian capitals: Salvador, São Paulo, and Belo Horizonte. The outcome variable was having been tested for HIV in a lifetime (no, yes).

Race was self-reported in three categories: white, black, and mixed race (or brown; in Portuguese: "*pardo*"). In Brazil, the last one is historically combined with black in the analyses.

We compared black and mixed race combined vs. white. We conducted descriptive, bivariate, and multivariate analyses to estimate the adjusted odds ratio (aOR) and 95% confidence interval (95%CI).

Results: White adolescents underwent more HIV tests in their lifetime than black and mixed race combined (74.0% vs. 54.0%, respectively). The testing rates decreased as the skin tone darkened: 56.9% among exclusive blacks, 58.1% among exclusive mixed-race (or brown), and 63.9% among whites ($p=0.003$).

In the multivariate analysis, black and mixed-race combined people were 33% less likely to have been tested for HIV in a lifetime than whites (aOR=0.67, 95%CI: 0.51-0.90), adjusting for age, education, employment, living with family, mother's lack of knowledge about their sexual orientation, sex work, and unprotected anal sex.

Conclusions: The lower rate of HIV testing among black and mixed-race combined among aMSM and aTGW people indicates inequalities in health and structural barriers to accessing HIV testing and prevention services. Further, it evidences the structural racism in society and health institutions in Brazil.

OAD0502

Pill count effectiveness in detecting nonadherence in a mature HIV program with overall high viral suppression rates in Eswatini

L. Mamba¹, V. Williams¹, A. Mafukidze¹, P. Bongomin¹, P. Dlamini¹, G. Mchunu¹, S. Mhlamba¹, H. Byarugaba¹, J. Opoku², S. Kibwana³, S. Ojoo², D. Bazira², S. Haumba¹

¹Center for Global Health Practice and Impact, Georgetown University, Mbabane, Eswatini, ²Center for Global Health Practice and Impact, Georgetown University Medical Center, Washington DC, United States, ³Center for Global Health Practice and Impact, Georgetown University Medical Center, Washington, United States

Background: Pill count is widely used as an adherence measure among clients taking antiretroviral therapy (ART). Conducted before each refill, it is a self-reported process where the actual number of pills remaining is compared against the expected. Pill count is a standard of practice to identify non-adherence for early intervention, yet its effectiveness is unknown in Eswatini. This study examines the ability of pill count to detect non-adherence among ART clients in the Lubombo and Manzini regions in Eswatini.

Methods: We used a case-control study design with chart abstraction at 11 purposively selected health facilities in Lubombo and Manzini, based on the number of clients with a high viral load between October 2021 and September 2022. Controls were matched to cases at a ratio of 2:1 giving a total of 615 study participants (205 cases and 410 controls).

Cases were adult first-line ART clients with unsuppressed viral load (VL > 1000 copies/mL) while controls were clients with a suppressed viral load (\leq 1000 copies/mL) randomly selected from the government client management information system. Adherence of 95-105% was defined as good, and social determinants and mental health evaluated to assess adherence.

Results: All cases and controls had a pillcount done. Overall, 60% of all participants with a suppressed viral load had a good pill count classification, while 98% of clients with a high viral load had a suboptimal pill count (<95% or >105%). Forty six percent and 99.5% of the cases and

Oral
abstracts

Author
Index

controls had a good pill count classification respectively. Eighty percent of the poor adherence was caused by social and cognitive problems. Clients with good pillcount classification had significantly reduced odds of a high viral load (OR 0.007; 95% CI: 0.003, 0.04; $p < 0.001$).

Pill count had a sensitivity of 98% (CI:92%-100%); a specificity of 59% (CI:53%-64%); a positive predictive value of 30% (CI: 24%-37%) and a negative predictive value of 99.5% (CI:97%-100%).

Conclusions: Pill count predicted nonadherence among cases, but its specificity should be improved by using a modified approach. This is vital considering the changing landscape in HIV care and increased access to more tolerable antiretroviral medication for prevention and treatment.

OAD0503

Identifying longitudinal patterns of HIV treatment (dis)engagement and re-engagement from oral histories of virologically unsuppressed adults in Uganda: a thematic trajectory analysis

J.G. Rosen¹, N. Nakyanjo², W. Ddaaki², T. Zhao¹, A.V. Vo¹, R. Nakubulwa², C. Ssekya², D. Isabirye², R.L. Katono², P. Nabakka², R.J. Ssemwanga², G. Kigozi², S. Odiya², G. Nakigozi², F. Nalugoda², G. Kigozi², J. Kagaayi², M.K. Grabowski^{2,3}, C.E. Kennedy^{1,2}

¹Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, ²Rakai Health Sciences Program, Entebbe, Uganda, ³Johns Hopkins School of Medicine, Division of Pathology and Transfusion Medicine, Baltimore, United States

Background: There is limited study of persons deemed "harder to reach" by HIV treatment services, including those discontinuing or never initiating antiretroviral therapy (ART). We conducted narrative research in Rakai, Uganda, with virologically unsuppressed adults identified through population-based sampling to discern longitudinal patterns in HIV service engagement and identify factors shaping treatment engagement throughout the life course.

Methods: In mid-2022, we sampled adult participants with high-level viremia ($\geq 1,000$ RNA copies/mL) from the Rakai Community Cohort Study, a population-based HIV surveillance cohort. Using life history calendars, we conducted initial and follow-up in-depth interviews to elicit oral histories of participants' journeys in HIV care, from diagnosis to the present. We then used thematic trajectory analysis to identify discrete archetypes of HIV treatment engagement by "re-storying" participant narratives and visualizing HIV treatment timelines derived from interviews and abstracted clinical records.

Results: Overall, 38 participants (median age: 34 years, 68% men) completed 75 interviews. We identified six HIV care engagement archetypes from narrative timelines (Figure):

1. Delayed ART initiation,
2. Early treatment discontinuation,
3. Treatment cycling,
4. Prolonged treatment interruption,
5. Transfer-related care disruption, and;
6. Episodic viremia.

Patterns of service (dis)engagement were highly gendered, occurred in the presence and absence of optimal ART adherence, and were shaped by various factors emerging at different time points, including: denial of HIV serostatus and disclosure concerns; worsening HIV-related symptoms; psychological distress and depression; social support; intimate partner violence; ART side effects; accessibility constraints during periods of mobility; incarceration; and inflexible ART dispensing regulations.

Figure.

Conclusions: Identified trajectories uncovered heterogeneities in both the timing and drivers of ART (re-)initiation and (dis)continuity, demonstrating the distinct characteristics and needs of people with distinct longitudinal patterns of HIV treatment engagement.

Enhanced mental health service provision, expanded eligibility for differentiated service delivery models, and streamlined facility switching processes may facilitate timely (re-)engagement in HIV services.

OAD0504

Characterizing TB diagnosis and the associations with economic stability and employment discrimination among women living with HIV across 11 countries in sub-Saharan Africa during the COVID-19 pandemic

C. Lyons¹, G. Turpin¹, K. Rusinski², O. Syarif³, P. Looze³, K. Lalak³, J.d.D. Anoubissi⁴, S. Brion⁵, K. Dunaway⁵, L. Sprague⁶, C.d.L. Moreno⁶, T. Mwarekwa⁷, K.A. Hlomewoo⁸, K.A. Dokla⁸, E. Ayeh⁹, N.A.J.C. Vako¹⁰, N. Otwoma¹¹, A. Ouedraogo¹², C. Beyrer¹³, B. Genberg¹, S. Baral¹

¹Johns Hopkins School of Public Health, Epidemiology, Baltimore, United States, ²Johns Hopkins School of Public Health, International Health, Baltimore, United States, ³Global Network of People Living with HIV (GNP+), Amsterdam, Netherlands, ⁴Global network of People living with HIV (GNP+), Amsterdam, Netherlands, ⁵The International Community of women living with HIV (ICW), London, United Kingdom, ⁶UNAIDS, Geneva, Switzerland, ⁷Zimbabwe National Network of People Living with HIV (ZNNP+), Harare, Zimbabwe, ⁸RAS+, Lome, Togo, ⁹Ghana Network of Persons Living with HIV, Accra, Ghana, ¹⁰Ivorian Network of People Living with HIV/AIDS (RIP+), Abidjan, Cote D'Ivoire, ¹¹NEPHA, Nairobi, Kenya, ¹²REGIPIV-BF, Ouagadougou, Burkina Faso, ¹³Duke Global Health Institute, Durham, United States

Background: Among people living with HIV, Tuberculosis (TB) is the leading cause of death and TB-related mortality increased during the COVID-19 pandemic. While poverty is an established determinant for TB progression, characterizing the role of employment discrimination and legal protections on HIV and TB outcomes can inform both programs and policy.

Methods: The People Living with Stigma Index 2.0 study was implemented in 11 countries across Sub-Saharan Africa including Angola, Benin, Burkina Faso, Cote D'Ivoire, Ghana, Kenya, Mauritania, Nigeria, Lesotho, Togo, and Zimbabwe. Study implementation was led by networks of people living with HIV in each country between 2020 and 2022. Interviewer-administered questionnaires were used to collect self-reported socio-behavioral measures. The analytic sample included 10,555 cisgender adult women living with HIV. Multilevel logistic regression was used to assess associations between exposures and recent TB diagnoses in the context of varying discrimination protections for PLHIV.

Results: Among participants, 7.8% reported TB diagnosis within the last 12 months. Among individuals in countries without non-discrimination protections, recent TB diagnosis was negatively associated with employment (AOR:0.62; 95%CI:0.51,0.76). Among individuals in countries without non-discrimination protections recent TB diagnosis was positively associated with being unable to meet basic needs often (AOR:1.77; 95%CI:1.31,2.41), being refused employment and income due to HIV status (AOR:1.95; 95%CI:1.39,2.72) and being refused a promotion due to

HIV status (AOR:2.12; 95%CI:1.45,3.10). Among individuals in countries with non-discrimination protections, recent TB diagnosis was not associated with employment; being unable to meet basic needs often; being refused employment, income, or a promotion due to HIV status.

	Total n/N	Recent TB diagnosis			
		Lack of Non-discrimination protections (N=7186)		Non-discrimination protections (N=3369)	
	n/N	N	AOR ^a 95% CI	N	AOR ^a 95% CI
Economic stability					
Employment	6202/10554	4112	0.62 0.51 0.76	2090	1.05 0.79 1.41
Unable to meet basic needs - sometimes	5762/10554	3689	1.27 0.95 1.69	1863	0.84 0.65 1.07
Unable to meet basic needs - often	2658/10554	1992	1.77 1.31 2.41	669	0.83 0.54 1.25
Employment discrimination					
Ever refused employment or income due to HIV status	5076/10554	426	1.95 1.39 2.72	171	1.32 0.88 2.18
Ever refused promotion due to HIV status	4218/10554	298	2.12 1.45 3.10	125	0.71 0.48 1.05

Table. Economic stability and employment discrimination and associations with recent TB diagnosis based on country level non-discrimination protections.

Conclusions: Employment discrimination may impede HIV and TB outcomes among women living with HIV, and may be a determinant of TB regardless of ART use. Establishment and enforcement of non-discrimination protections for women living with HIV may improve economic stability, support TB control, and reduce deaths among people living with HIV.

OAD0505

Improving mental well-being and economic empowerment of PLHIV through ODH-SEGT: An integrated and client-centered psycho-socioeconomic intervention for unemployed PLHIV experiencing homelessness in Caloocan City, Philippines

R.A. Olete^{1,2,3}, J. Cadelina^{1,4}, E. Arriola¹, C. Chu^{1,5}, J.M.P. Oyco³, A.L. Macalalag⁶, N.Y. Ko², C. Strong²

¹Gabay sa Pulang Laso Inc., Caloocan City, Philippines,

⁴De La Salle University, Department of Behavioral Science, Metro Manila, Philippines,

⁵Xavier University - Ateneo de Cagayan

University, Department of Psychology, Cagayan

de Oro City, Philippines, ⁶Iloilo Doctors' College, Research Department, Iloilo City, Philippines

Background: In the Philippines, a needs assessment showed significant associations between unemployment, homelessness, and mental distress among PLHIV. Gabay sa Pulang Laso Inc. (GPLI) integrated Supportive-Expressive Group Therapy (SEGT) into its Open Doors Home (ODH) initiative (a temporary shelter provision and socioeconomic support for unemployed PLHIV experiencing homelessness).

The core foundation of ODH-SEGT is reconnecting with oneself through a supportive and empowering environment where a PLHIV shares experiences with fellow PLHIV while addressing socioeconomic needs through employment and education opportunities.

Description: Through open social media invitations, 22 PLHIV voluntarily participated and completed the ODH-SEGT Programme between August 19 and October 30, 2022. The intervention was conducted in four phases:

1. Baseline screening for anxiety- and depression-related symptoms using a 7-item Generalized Anxiety Disorder and 9-item Patient Health Questionnaire (GAD-7 and PHQ-9),
2. Assessment of PLHIV perceived socioeconomic needs,
3. Conducting 12-week SEGT sessions with bi-monthly GAD-7 and PHQ-9 monitoring, and;
4. Linkage to employment or education.

Lessons learned: The participants' age ranged between 19 and 52 years old (mean=33.3 years old, SD=7.9). Among 22 participants, 18 were unemployed while four had stopped attending school.

At the end of the ODH-SEGT intervention, 16 were linked to employment while 5 were included in GPLI educational support and are currently attending the alternative learning system of the government.

While attending the SEGT, averages in PHQ-9 and GAD-7 at baseline were at moderate levels (12.2 and 12.4, respectively) and significantly decreased to be at low to no risk by Week 10 (4.8 and 4.8, respectively).

One participant reported to have stopped taking anti-retroviral medication for five years and was immediately linked back to HIV care.

Conclusions/Next steps: GPLI's ODH-SEGT has the potential to improve mental health of people living with HIV by addressing their non-biomedical needs and contributing to a higher quality of life. The next step for the project is the development of the Training of Trainers programme so that the SEGT framework can be replicated in other regions of the country. In addition, a multisectoral collaboration is currently being advocated with the local government unit, social welfare department, and academic institutions in the Philippines.

Anticipated preferences for long-acting HIV PrEP among current oral PrEP users at pharmacies: findings from a pilot study extension

S.D. Roche¹, V. Omollo², P. Mogere³, M. Asewe², S. Gakuo³, P. Banerjee¹, K. Harkey¹, J. Odoyo², P. Ongwen⁴, D. Were⁴, E. Bukusi^{2,5}, K.F. Ortblad¹, K. Ngunjiri^{3,6}

¹Fred Hutchinson Cancer Center, Public Health Sciences, Seattle, United States, ²Kenya Medical Research Institute, Kisumu, Kenya, ³Partners in Health Research and Development, Thika, Kenya, ⁴Jhpiego, Nairobi, Kenya, ⁵University of Washington, Seattle, United States, ⁶Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Background: As many sub-Saharan African countries prepare to implement two long-acting (LA) forms of HIV pre-exposure prophylaxis (PrEP)—injectable PrEP and the dapivirine vaginal ring (DVP-VR)—there is potential to expand delivery to new access points, such as private pharmacies.

A recent pilot study of private pharmacy-delivered oral PrEP in Kenya found that these venues may reach a different demographic than public clinics. During a six-month extension of this study, we assessed current oral PrEP users' anticipated preferences for LA PrEP.

Methods: At 12 pharmacies in Kisumu and Kiambu Counties, Kenya, trained pharmacy providers delivered oral PrEP to eligible clients ≥18 years. We surveyed PrEP clients one month following PrEP initiation, and asked whether, if given the option, they would choose to take oral PrEP every day or get a PrEP injection every two months. For those selecting "PrEP injection", we further explained that the injection would go into the muscles of the buttocks region and resolicited their preferences.

Lastly, we described the DVP-VR to female clients and asked them to rank oral PrEP, injectable PrEP, and DVP-VR in order of preference. We report our findings descriptively.

Results: From January-July 2022, we surveyed 491 pharmacy PrEP clients; 55% (270/491) were female, median age was 22 (IQR: 25-32), and 84% (412/491) had never taken oral PrEP prior to this study. About two-thirds (65%, 319/491) anticipated they would choose injectable over oral PrEP.

After being told details about the injection site, 58% (287/491) still reported a preference for injectable PrEP, with this preference notably higher among males (77%, 170/221) than females (43%, 117/270).

Among females, 57% (155/270) said their first choice would be injectable PrEP, followed by oral PrEP, then DVP-VR; an additional 30% (81/270) of females chose oral PrEP first, followed by injectable PrEP, then DVP-VR.

Conclusions: Over half of current oral PrEP users at private pharmacies anticipate that, if given the option, they would choose injectable over oral PrEP. Few female oral PrEP users in this setting thought they would choose the DVP-VR. More research is needed to test pharmacy delivery of LA PrEP and assess real-world uptake and product switching.

Drivers of pre-exposure prophylaxis choice for transgender women in 11 countries in Asia: a discrete choice experiment

W. Tieosapjaroen^{1,2}, B.R. Bavinton³, H.-M. Schmidt^{4,5}, K.E. Green⁶, N. Phanuphak⁷, M. Poonkasetwattana⁸, N.S. Suwandi⁹, D. Fraser³, C. Chan³, H. Boonyapisompan⁹, M. Cassell¹⁰, L. Zhang¹², W. Tang¹¹, J.J. Ong^{12,12}

¹Alfred Health, Melbourne Sexual Health Centre, Carlton, Australia, ²Monash University, Central Clinical School, Melbourne, Australia, ³University of New South Wales, Kirby Institute, Sydney, Australia, ⁴UNAIDS Regional Office for Asia and the Pacific, Bangkok, Thailand, ⁵Global HIV, Hepatitis and STIs Programme, World Health Organization, Geneva, Switzerland, ⁶The Program for Appropriate Technology in Health, Hanoi, Vietnam, ⁷Institute of HIV Research and Innovation, Bangkok, Thailand, ⁸APCOM Foundation, Bangkok, Thailand, ⁹Asian Pacific Transgender Network, Bangkok, Thailand, ¹⁰Family Health International 360, Hanoi, Vietnam, ¹¹The University of North Carolina at Chapel Hill Project-China, Guangzhou, China, ¹²London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom

Background: Transgender women (TGW) are approximately 66 times more at risk of HIV acquisition than the general population. Designing appealing pre-exposure prophylaxis (PrEP) programs for TGW is urgently needed. We evaluated the drivers of choice for PrEP among TGW living in 11 Asian countries and forecasted their PrEP uptake given different PrEP program configurations.

Methods: An online discrete choice experiment (DCE) survey was delivered through trans-networks in each country between May-November 2022. Participants who identified as TGW, age ≥ 18 years and had no prior HIV diagnosis were included. Final attributes included:

1. Type of PrEP;
2. Service location;
3. Cost;
4. Side effects;
5. Visit frequency; and
6. Extra services.

We calculated the relative importance of each attribute and PrEP uptake prediction using random parameters logit (RPL) models.

Results: Overall, 1,522 TGW were included, with a mean age of 28.1 (± 7.0), 63% (956/1,522) reported multiple partners, 38% (581/1,522) had condomless vaginal sex and 16%

(249/1,522) were diagnosed with an sexually transmitted infection (STI) in the last six months. The biggest drivers of PrEP uptake were cost (62% relative importance), type of PrEP (10%), location (8%), extra services (8%), visit frequency (7%) and side effects (5%). The most wanted PrEP service (with a predicted uptake of 87%) was: free injectable PrEP with no side effects, accessing PrEP from a peer-led community clinic that provided STI testing, and requiring 6-12 monthly visits.

The least preferred PrEP service (with a predicted uptake of 50%) was: PrEP implant with out-of-pocket fees and a rare chance of kidney problems, accessing PrEP from a hospital, no extra services, and requiring 2-monthly visits.

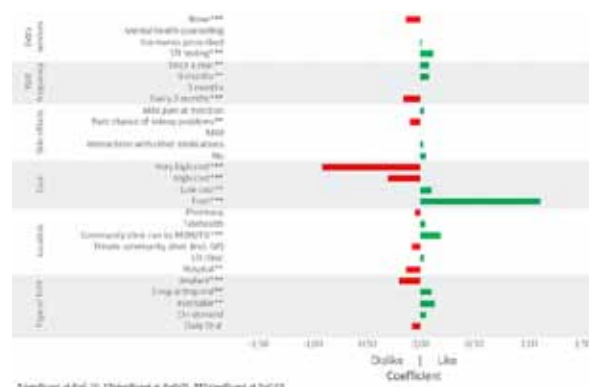

Figure. Preference for PrEP among trans women in the Asia-Pacific (N=1,522)

Conclusions: Our study, the largest DCE for TGW globally, emphasizes the importance of measuring and incorporating preferences for PrEP services to accelerate the scale-up of PrEP among TGW in Asia.

OAE0104

Snow balling peer to peer mModel - a silver bullet for improved PrEP uptake among FSWs in Zambia's border town of Chirundu

K. Mwanda¹, E. Berghammer², J. Masedza³, D. Mazunda³, M. Simata⁴

¹USAID CHEKUP II, Technical, Lusaka, Zambia,

²USAID, Social Protection, Lusaka, Zambia, ³USAID CHEKUP II, Clinical, Chirundu, Zambia, ⁴Ministry of Health, Clinical, Chirundu, Zambia

Background: With an annual HIV incidence rate of 47%, over 56% of the female sex workers in Zambia are living with HIV (UNAIDS, 2020). However, the uptake of pre-exposure prophylaxis among FSWs in the Zambia-Zimbabwe border town of Chirundu remains low at 22% of those that test negative.

Description: Between December 2022 and January, 2023, USAID CHEKUP implemented by John Snow Health Zambia, embarked on an initiative to orient and then engage FSWs already accessing PrEP to identify peers in their network, provide PrEP messaging and facilitate them to take up PrEP. In a snow ball approach, 5 trained health care

workers, trained a pool of 15 community health workers on how to provide orientation around PrEP messaging to 75 FSWs who were mostly (75%) aged 20-24 years. FSWs in turn delivered these PrEP promotion messages alongside sharing their lived experiences around the benefits of PrEP, addressed the misgivings, and facilitated linkage to PrEP.

Lessons learned: Over a three week period, the 75 FSWs reached out to 284 of their peers among which 43 (15.1%) were discovered to be positive and already on treatment, 61 (21.5%) were newly identified positives and were linked for antiretroviral therapy.

From the remaining 180 HIV negative FSWs, 164 (91.1%) were initiated on PrEP, while the rest (16) (8.9%) indicated that they needed to think about it, or the time was not appropriate and that they could commence at a later date.

The majority (52%) of the FSWs that took up PrEP were in the same age band (20-24 years old) as their PrEP promoting peers.

Being spoken to by someone who is in my situation and also taking the medicine (85%) and then making it convenient for me to access the medicine (71%) were the prominent reasons given by the new recipients for then to be initiated on PrEP.

Conclusions/Next steps: With the PrEP uptake under the peer to peer modality being significantly higher than the routine approach (91.1% vs. 22%), the peer to peer model has potential to increase both acceptability and uptake of PrEP among FSWs particularly for programs recording low PrEP usage among FSWs.

OAE0105

The acceptability of pharmacy-delivered PrEP and PEP in Kenya: provider perceptions

M. Asewe¹, B. Kwach¹, S. Zhang², K. Harkey³, G. Rota¹, P. Otieno¹, J. Odoyo¹, P. Ongwen⁴, D. Were⁴, S. Roche³, K. Ngure⁵, V. Omollo¹, E. Bukusi^{1,2}, K. Ortblad³

¹Kenya Medical Research Institute, Kisumu, Kenya,

²University of Washington, Seattle, United States, ³Fred

Hutchinson Cancer Center, Seattle, United States,

⁴Jhpiego, Nairobi, Kenya, ⁵Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Background: Pilot studies indicate that delivering oral HIV pre-and post-exposure prophylaxis (PrEP and PEP) at private pharmacies may help increase access to these highly effective HIV prevention products among individuals with HIV risk. In many high HIV prevalence settings, most of the core components of PrEP and PEP delivery (e.g., counseling, medical safety assessment, HIV testing, and drug dispensing) fall within pharmacy providers' scope of practice.

We assessed the anticipated acceptability of delivering PrEP and PEP at private pharmacies among pharmacy providers in Kenya.

Methods: Pharmacists and pharmaceutical technologists working at 20 private pharmacies in Kisumu County completed a cross-sectional questionnaire that assessed acceptability using questions informed by the Theoretical Framework of Acceptability (TFA). The TFA posits that acceptability is a multi-faceted construct, comprising seven component constructs (e.g., affective attitude towards the intervention, perceived effectiveness, burden, and opportunity cost).

We measured select acceptability component constructs using 5-point Likert items and analyzed these using descriptive statistics. Statements with which >80% of participants agreed or strongly agreed were classified as "acceptable".

Results: From May to June 2022, 40 pharmacy providers completed the questionnaire; 42% (n=17) were pharmacy owners, 60% (n=24) were male, and the median time in pharmacy practice was 6 years (IQR 4-10).

All or nearly all providers (97-100%) liked the idea of delivering PrEP and PEP (TFA construct: affective attitude) and thought that pharmacy-delivered PrEP and PEP services could reach people with HIV risk (TFA construct: perceived effectiveness).

Most pharmacy providers (96-99%) did not think it would be hard to deliver PrEP or PEP (TFA construct: burden) or that this would interfere with their other priorities (TFA construct: opportunity cost).

Conclusions: The Kenyan pharmacy providers in this study found the idea of pharmacy-delivered PrEP and PEP services to be highly acceptable. To inform whether and how pharmacy-delivered PrEP and PEP should be implemented and scaled up in Kenya and similar settings, additional research is needed to develop and test delivery models, assessing both effectiveness outcomes (e.g., uptake, continuation) and implementation outcomes (e.g., acceptability, feasibility, and cost).

OAE02 The Power of People: Community based models to improve HIV outcomes

OAE0202

Leveraging community and private-sector HIV self-testing (HIVST) distribution to improve access to HIV testing services (HTS) and treatment for adolescent girls and young women (AGYW) in Uganda

J. Tumusiime¹, G. Taasi², J. Musinguzi¹, P. Kikobye¹, A. Scott³, D. Canagasabey³, K. Granger³, I. Thior³, K.E. Green⁴

¹PATH, Kampala, Uganda, ²Ministry of Health, Kampala, Uganda, ³PATH, Washington DC, United States, ⁴PATH, Hanoi, Vietnam

Background: 29% of new HIV infections in Uganda occur among AGYW, and 32% of estimated adolescents living with HIV are not on treatment (Uganda AIDS Commission, 2021; Spectrum 2022). There is need for strategies that better engage AGYW in HIV case-finding and linkage to care given persisting gaps. Through the Unitaid/STAR-III project, PATH, with Ministry of Health, leveraged human-centered design to adapt HIVST services to improve reach and uptake of HIV services for AGYW.

Description: We introduced community and private-sector distribution models to expand outlets for AGYW to access HIVST beyond public-sector facilities, including targeted community outreach, hotspots, tertiary educational institutions, pharmacies, and nurse/midwife-led clinics. We trained AGYW peers to lead mobilization during community campaigns or at popular hangout areas; link interested clients to healthcare providers for assisted or unassisted HIVST; follow up by phone/WhatsApp to confirm results; and provide escorted referrals for those with reactive self-test results.

We developed easily downloadable HIVST training videos that peers could share through social media for AGYW who preferred anonymous access options.

We analyzed program data from three central Ugandan districts from November 2020 to November 2022 to understand impact of these adaptations on HIVST uptake and preferences among AGYW.

Lessons learned: AGYW (69% between 20-24 years) received HIVST kits, 60% through community distribution (primarily targeted community or hotspot modalities), 22% through public-sector (mainly outpatient services), and 18% through private sector (mainly nurse/midwife-led clinics). 224 (2.4%) had reactive results, among whom 184 (82%) were confirmed HIV positive (2.0% positivity), 182 (99%) were linked, and 144 (79%) initiated on treatment. AGYW demonstrated preference for directly assisted HIVST (51%), and half had not tested in the last 12 months. Using peers to lead engagement/escort referrals for follow-on care was key to high follow-up and linkage rates.

Conclusions/Next steps: Our results highlight the feasibility and acceptability of using community and private-sector outlets, shareable online content, and peer-led outreach and referral to effectively reach and link AGYW to treatment through HIVST. Diversifying HTS access points and reinforcing peer-driven models are core approaches that should be scaled up to address persisting access barriers among adolescents and enable Uganda to reach epidemic control.

OAE0203

Community Led Monitoring (CLM): A new CLM toolkit to generate evidence to support community-led HIV service improvements

M. Kusen¹, C. Byambaa², G. Nyampurev², J. Oorloff³, P. Vjayabandara⁴, T. Dendup⁵, J. Norbu⁵, B. Morris⁶, S. Anthony⁷, M. Merrigan¹

¹Australian Federation of AIDS Organisations, Bangkok, Thailand, ²Youth for Health Centre, Ulaanbaatar, Mongolia, ³Family Planning Association of Sri Lanka, Colombo, Sri Lanka, ⁴Positive Hopes Alliance, Colombo, Sri Lanka, ⁵Save the Children, Thimpu, Bhutan, ⁶The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland, ⁷APCOM, Bangkok, Thailand

Background: Community Led Monitoring (CLM) shifts the dynamic of monitoring from HIV service providers to monitoring led by the people using the services. In order to build an evidence-base for CLM, the Global Fund supported Sustainability of HIV Services for Key Populations in Asia (SKPA-2) program has developed the "Sustainable Community-led Monitoring of HIV Services Toolkit for Key Populations". This provides a framework, indicators, and guidance on how to ensure the CLM process is community-led and guided through measurable bottom-up approaches.

Description: Launched in 2022, the CLM toolkit has been piloted in Mongolia, Bhutan and Sri Lanka for key population groups including men who have sex with men, transwomen, sex workers, people living with HIV, and people who use drugs. The toolkit provides a framework of 8 core indicators to monitor Availability, Accessibility, Acceptability, and Quality (AAAQ) along with 5 indicators to measure and ensure there is follow-up for those experiencing stigma, discrimination, and/or violence. The selection of final indicators, pilot sites, data processes and follow-up should be decided by CLM technical working group made up of national stakeholders and includes key population representatives.

Lessons learned:

- Helped identify the type of facilities where stigma and discrimination (S&D) was more prevalent to support more targeted efforts to reduce S&D in healthcare settings.
- Supported the identification of the type of services with the least availability including CD4 count and viral load testing.

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

- CLM data should be designed to share data visually and in an easy to digest manner to community groups such as through electronic dashboards.
- Funding for CLM is not assured as health programs also have their own feedback systems, so community led models need to be cost-effective.
- Identified the need to include well managed referral mechanisms to accountability mechanisms to manage and deal with experiences of S&D when accessing HIV services.

Conclusions/Next steps: The CLM toolkit helps provide interesting findings for other countries when designing and rolling out CLM. Future research and programs may include an evaluation to assess the impact CLM has on supporting countries to improve service quality and achieve their 95-95-95 targets as well as the sustainability of CLM funding.

OAE0204

Uptake of integrated HIV and sexual and reproductive health services for youth at community centres in Zimbabwe

V. Simms^{1,2}, E. Dauya², C. Dziva Chikwari^{1,2}, T. Bandason², K. Kranzer^{3,2}, R.A. Ferrand^{3,2}, CHIEDZA Trial Team

¹London School of Hygiene & Tropical Medicine, MRC International Statistics and Epidemiology Group, London, United Kingdom, ²The Health Research Unit Zimbabwe (THRU ZIM), Harare, Zimbabwe, ³London School of Hygiene & Tropical Medicine, Clinical Research Department, London, United Kingdom

Background: Limited engagement with health services contributes to the poorer HIV outcomes observed in youth. We conducted a cluster-randomised trial of a community-based integrated HIV and sexual and reproductive health (SRH) service (CHIEDZA) for youth in 3 provinces in Zimbabwe.

Methods: Weekly integrated HIV and SRH services were delivered from community centres in 12/24 intervention clusters to cluster residents aged 16-24 years over 30 months. Fingerprint scanning was used to anonymously identify clients and track their attendances and service uptake over time.

Services included HIV testing, treatment and adherence support, management of sexually transmitted infections (STIs), menstrual health management, contraception, counselling, and registration for text messages on SRH topics. All services were optional.

Results: In total 36,991 clients attended, for a total of 78,810 visits; each centre had a median of 55 clients per day; 40.6% of clients returned for more than 1 visit. Overall, 75.0% of clients were female and 53.0% were aged <20 years. In total 84.1% of eligible clients had at least one HIV test and 17.4% had more than one. At their first visit 78.6% of eligible clients had an HIV test, and out of those who were not tested at the first visit, 28.3% later returned

and were tested. 377 clients tested HIV positive at CHIEDZA (prevalence 1.3%) and 75% linked to care, while 1162 clients were previously diagnosed young people living with HIV. HIV incidence among those with repeated visits was 0.72 per 100 person years (95%CI 0.53-0.98).

The most popular services for women were menstrual hygiene products (taken up by 96.5% of those eligible), HIV testing (83.7%) and period pain management (59.9%); for men the most popular were condoms (93.9%), HIV testing (85.6%) and text messages on SRH (67.1%). Among women aged ≥20 years, 43.7% took condoms and 60.3% took up other forms of contraception.

Conclusions: An integrated HIV and SRH programme had high attendance and uptake, with most clients taking multiple services per visit, including HIV testing. There is need for accessible, youth-friendly sources of SRH information, menstrual health management, contraception, and HIV testing in Zimbabwe.

OAE0205

Utilizing Community HIV/AIDS service agents to Find, Link, and retain in care pregnant, breastfeeding mothers and children aged 0-14 living with HIV

G. Kadziyanhike¹, G. Kadziyanike¹, C. Mademutsa¹, A. Nhapi¹, T. Mwareka¹

¹Zimbabwe National Network of People Living with HIV, Harare, Zimbabwe

Background: Despite efforts to end the AIDS epidemic by 2030, pregnant and breastfeeding mothers, children, and young adolescents continue to face barriers to accessing quality HIV and other health-related services. The Zimbabwe National Network of People Living with HIV (ZNNP+) has collaborated with communities in four (4) districts of Zimbabwe to improve service access for these groups by increasing awareness of available services and referring those who have interrupted treatment into care. Furthermore, community cadres met with community leaders to discuss barriers to service access identified during their work.

Description: As a community partner the Zimbabwe National Network of People Living with HIV compliment the Ministry of Health and Child Care in ensuring that pregnant and breastfeeding women and children aged 0-14 are linked and retained in care. The organisation trained and deployed 40 mentor mothers and 40 young Community HIV/AIDS Service Agents (yCHASAs) in the community who helped to track and trace those not in care. Each month the cadres submit data on their activities electronically to the central server where it is analysed, and insights generated to inform advocacy at the facility or community.

Lessons learned: Between Jul 2022-September 2022, the mentor mothers referred 1612 individuals for HIV services, 52 (3%) who had an unknown HIV status got tested and

had a positive result. The newly diagnosed were initiated on treatment and linked to support groups, while community cadres continued to provide adherence counselling. During the same time, 48 (3%) of those who had been interrupted in treatment (IIT) successfully returned to care. Ten survivors of gender-based violence (GBV) were linked to appropriate services. The cadres coordinated three community dialogues, which were attended by 90 community leaders, to discuss feedback from recipients of care to jointly find solutions to structural barriers that prevent people from accessing services.

Conclusions/Next steps: With proper training lay cadres can identify peers who are not on treatment or those interrupted in treatment and successfully navigate them back into care. If properly engaged community leaders are willing to offer cadres a platform for them to air concerns from their peers and help break down barriers to service access.

OAE03 Show me the money: The cost of epidemic control

OAE0302

Long-acting HIV pre-exposure prophylaxis (PrEP) among adolescent girls and young women (AGYW) in South Africa: cost-effective at what cost?

E.Y. Jin¹, A.R. Ahmed¹, L.-G. Bekker², A. Ciaranello^{1,3,4}, C.F. Flanagan¹, K.A. Freedberg^{1,3,4,5}, C. Orrell², K.P. Reddy^{1,4,6}, M. Wallace², A.M. Neilan^{1,3,4,7}

¹Medical Practice Evaluation Center, Boston, United States, ²Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, ³Massachusetts General Hospital, Division of Infectious Diseases, Department of Medicine, Boston, United States, ⁴Harvard Medical School, Boston, United States, ⁵Massachusetts General Hospital, Division of General Internal Medicine, Boston, United States, ⁶Massachusetts General Hospital, Division of Pulmonary and Critical Care Medicine, Boston, United States, ⁷Massachusetts General Hospital, Division of General Academic Pediatrics, Department of Pediatrics, Boston, United States

Background: HIV Prevention Trials Network (HPTN) 084 demonstrated superior efficacy of long-acting, injectable cabotegravir (CAB-LA) compared to daily oral tenofovir/emtricitabine (TDF-FTC) for HIV PrEP in cisgender women. We projected the drug cost at which CAB-LA would provide good value compared to TDF-FTC among adolescent girls and young women (AGYW) in South Africa.

Methods: Using microsimulation modeling, we examined two PrEP strategies over 10 years among AGYW (ages 15-30y; scaled to n=10,000): TDF-FTC and CAB-LA. Published data informed model inputs, including: HIV incidence (TDF-FTC: 1.85/100 person-years, CAB-LA: 0.2/100 person-

years; HIV transmissions off-PrEP from 10,000 AGYW to partners (16/year); and 2-year retention (TDF-FTC: 88%, CAB-LA: 85%).

We assumed constant incidence and transmission risk over time. Annual costs included: PrEP drug+program (TDF-FTC: \$77+\$74, CAB-LA: \$153+\$75), ART (\$58 to \$834), and HIV-related care (\$215 to \$1,621). Model-projected outcomes include incident infections among and transmissions from AGYW, life-years (LYs), costs, incremental cost-effectiveness ratios (ICER=\$/LY), and CAB-LA's maximum price premium (MPP: the highest drug price at which CAB-LA would have an ICER below a willingness-to-pay [WTP] of 50% South Africa's per-capita GDP [\$3,500/LY]).

Results: Per 10,000 AGYW in South Africa, projected infections and transmissions were higher and LYs lower in TDF-FTC (2,050 infections / 658 transmissions / 85,889 LYs), compared to CAB-LA (1,151 / 342 / 86,057) (Table).

HIV infections avoided among male partners resulted in 143 LYs gained in CAB-LA over TDF-FTC. At \$153/year drug cost, CAB-LA would exceed the WTP threshold (ICER=\$6,600/LY). The projected MPP for CAB-LA to be cost-effective and cost-saving would be \$136/year and \$118/year, respectively. Accounting only for the benefits accruing to AGYW, the MPP to be cost-effective would be lower, \$122/year. Varying transmissions from 2/year to 40/year would yield an MPP of \$124-158/year to remain cost-effective.

Strategy	Incident infections in AGYW, n	Transmissions to male partners, n	Discounted LYs		Discounted costs, USD		ICER (\$/LY)*		CAB-LA maximum price premium, USD	
			AGYW	LYs gained from partners**	AGYW	Costs saved from partners**	AGYW	All	AGYW	All
TDF-FTC	2,050	658	85,889		12,579,969					
CAB-LA	1,151	342	86,057	143	14,979,829	340,232	14,300	6,600	122	136

Abbreviations: AGYW: adolescent girls and young women; CAB-LA: long-acting, injectable cabotegravir; ICER: incremental cost-effectiveness ratio; LY: life-year; PrEP: pre-exposure prophylaxis; TDF-FTC: tenofovir/emtricitabine; USD: United States Dollars.

*The ICER is the difference in cost divided by the difference in life expectancy for each strategy compared with the next less-costly strategy. Results are rounded to the nearest \$100.

**Life-years gained and costs saved are among male partners in CAB-LA compared to TDF-FTC who, in the absence of the PrEP strategy being provided to AGYW, would have acquired HIV. Life-years and costs are discounted at 3%/year and scaled to n=10,000 AGYW.

Table. 10-year model-projected outcomes of CAB-LA versus TDF-FTC for HIV PrEP among adolescent girls and young women in South Africa, (n=10,000)

Conclusions: Among AGYW in South Africa, CAB-LA could reduce transmissions and increase life-years compared to TDF-FTC. CAB-LA should be priced at less than twice the cost of TDF-FTC to be cost-effective in South Africa.

OAE0303

Predicted HIV acquisition rates for cabotegravir versus TDF/FTC as PrEP in Brazil: effects of compulsory licensing

A. Hill¹, S. Cross², T. Pepperrell³, K. Heath⁴, M. Mirchandani⁵¹University of Liverpool, Department of Pharmacology and Therapeutics, Liverpool, United Kingdom, ²Imperial College London, School of Medicine, London, United Kingdom, ³University of Edinburgh, School of Medicine and Veterinary Medicine, Edinburgh, United Kingdom, ⁴Burnet Institute, Melbourne, Australia, ⁵Imperial College London, Faculty of Medicine, London, United Kingdom

Background: Worldwide, 1.5 million people acquired HIV in 2021. Cabotegravir is the most effective drug to prevent HIV acquisition, with estimated efficacy of 90–95%, superior to oral tenofovir/emtricitabine (TDF/FTC). TDF/FTC is available as generic PrEP in most countries, costing \$48/year in LMICs. CAB-LA costs \$22,200/year in US, \$9000 in the UK. The ViiV-MPP licence permits generic companies to sell CAB-LA at low prices, estimated \$250/year.

However, the ViiV-MPP agreement excludes many middle-income countries, such as Brazil. CHAI estimated costs of production of \$34–\$63/year (median \$50).

Methods: We modelled the effects of 4 strategies for PrEP in Brazil: 1.No PrEP used 2.TDF/FTC generic used for PrEP, costing \$48/year. 3.CAB-LA used, with a high price, outside the ViiV-MPP license:\$3500/year, (68% below UK price), or \$250/year (target price). 4.CAB-LA used at CHAI target price \$50/year. TDF/FTC and CAB-LA were assumed to lower HIV acquisition risks by 70% and 94% respectively, versus no PrEP.

We assumed a target population of 125,000 people at high risk of HIV acquisition (incidence 6%), treated in Brazil with annual budget of \$6million.

Results: Using TDF/FTC costing \$48/year, the \$6 million Brazilian PrEP budget could treat all 125,000 people, lowering annual HIV acquisition from 8750 to 2525/year. By contrast, use of CAB-LA for \$3500/year covers 1714 people; the remaining 123,285 people receive no PrEP. Even at target prices of \$250/year, overall HIV acquisition rates are still higher. The CHAI cost price of \$50/year would provide for 120,000 people, lowering HIV acquisition to 854/year. CAB-LA needed to cost less than \$80/year to lead to fewer HIV acquisitions than TDF/FTC.

Budget	Cost of PrEP	Number given PrEP	HIV acquisitions
Current PrEP budget-\$6million			
No PrEP	\$0	0	8750
TDF/FTC	\$48	125,000	2250
CAB-LA base case	\$3500	1714	8637
CAB-LA target price	\$250	24,000	6632
CAB-LA cost price	\$50	120,000	732

Table.

Conclusions: When demand for PrEP is high and budgets limited, CAB-LA will only lower overall HIV acquisition rates if costing <\$80/year. If prices are higher, limited people can be given CAB-LA: then, mass use of TDF/FTC for \$48/year allows increased coverage, lowering overall HIV acquisition rates. Compulsory licensing may be required to lower CAB-LA prices in countries outside the ViiV-MPP voluntary license.

OAE0304

Cost-effectiveness and budget impact analysis of the implementation of differentiated service delivery models for HIV treatment in Mozambique – a modelling study

D. Moiana Uetela^{1,2}, M. Zimmermann³, O. Uetela², E. Samo Gudo¹, S. Chicumbe¹, A. Couto⁴, I. Gaspar⁴, K. Sherr^{2,5,6}¹Instituto Nacional de Saúde, Marracuene, Mozambique,²University of Washington, Department of Global Health, Seattle, United States, ³University of Washington, The Comparative Health Outcomes, Policy, and Economics (CHOICE) Institute, Seattle, United States,⁴Ministry of Health, National STI-HIV/AIDS Program, Maputo, Mozambique, ⁵University of Washington, Department of Epidemiology, Seattle, United States,⁶University of Washington, Department of Industrial & Systems Engineering, Seattle, United States

Background: In 2018 Mozambique's Ministry of Health launched a guideline to implement eight differentiated service delivery models (DSDMs) to optimize HIV service delivery, improve retention in care, and ultimately reduce HIV associated mortality.

The models were:

1. Fast-track (FT),
2. Three-month Antiretrovirals Dispensing (3M),
3. Community Antiretroviral Therapy (ART) Groups (CAGs),
4. Adherence Clubs (AC),
5. Family-approach (FA), and three one-stop shop models:
6. Adolescent-friendly health services (OSS-AFHS),
7. Maternal and child health (OSS-MCH), and
8. Tuberculosis (OSS-TB).

We conducted a cost-effectiveness analysis (CEA) and a budget impact analysis (BIA) comparing these DSDMs to conventional services.

Methods: We constructed a decision tree model based on the percentage of enrolment on each DSDM and the probability of the outcome (12-months retention on ART), with and without DSDMs implementation, for each year of the study period; three for CEA (2019 to 2021), and three for BIA (2022 to 2024). The economic and financial costs for CEA and BIA, respectively, were estimated per client-year from the health system perspective, and included start-up, ARV drugs, laboratory tests, and clinical and pharmacy visits. Effectiveness was estimated using the Mozambique ART database, employing an uncontrolled

interrupted time series analysis comparing the outcome before and during the implementation of DSDMs. A one-way sensitivity analysis was conducted to identify drivers of uncertainty.

Results: During the three years of DSDMs implementation, there was a mean increase of 14.9 percentage points (95% Confidence Interval (CI): 12.2, 17.8) in 12-months retention comparing DSDMs implementation (62.5% [95%CI: 60.9, 64.1]) to conventional care (47.6% [95%CI: 44.9, 50.2]), and the mean base-case economic cost per person-year was estimated to be \$253 and \$359 for DSDMs and conventional care, respectively; therefore, DSDMs dominated conventional care. The base-case 3-year financial costs associated with the DSDMs and the conventional care for a population of 1,535,575 were estimated to be \$1,653,814,275 and \$990,194,425, respectively. The results were most sensitive to clinical visits costs.

Conclusions: DSDMs were less expensive and more effective in retaining clients 12-months after ART initiation, and their implementation was estimated to save approximately \$670 million to the health system from 2022 to 2024.

OAE0305

Cost-effectiveness of the WHO-endorsed advanced HIV care package in Malawi

E. Hyle¹, T. Maphosa², A. Rangaraj³, M. Feser¹, K. Reddy¹, A. Shroufi⁴, P. Shrestha¹, R. Horsburgh⁵, N. Ford³, A. Tiam⁶, A. Phillips⁷, K. Freedberg¹

¹Massachusetts General Hospital, Boston, United States, ²Elizabeth Glaser Pediatric AIDS Foundation, Lilongwe, Malawi, ³World Health Organization, Geneva, Switzerland, ⁴The Global Fund, Geneva, Switzerland, ⁵Boston University School of Public Health, Boston, United States, ⁶Elizabeth Glaser Pediatric AIDS Foundation, Washington, D.C., United States, ⁷University College London, London, United Kingdom

Background: In sub-Saharan Africa, more than 20% of PLHIV present with advanced HIV disease (AHD). Our objective was to project the clinical outcomes, costs, and cost-effectiveness of the WHO-recommended AHD package of care in Malawi.

Methods: Using the validated CEPAC-I model, we simulated a cohort of PLHIV aged ≥18y initiating ART with measured CD4 count using published data and assessed 7 strategies applied to people identified with AHD (CD4<200/μL and/or WHO 3/4 disease):

1. No specific AHD care (sputum Xpert for people with TB symptoms), and then sequential addition of:
2. Urine LAM;
3. Co-trimoxazole (CTX);
4. Cryptococcal antigen (CrAg) and CTX;
5. LAM and CTX;
6. LAM, CTX, and CrAg;
7. LAM, CTX, CrAg, and isoniazid preventive therapy (IPT).

The cohort had mean age 37y, 51% were female, mean CD4 362/μL (15% with CD4 <200/μL and 4% with WHO3/4 disease and CD4 ≥200/μL). Among people with CD4 <200/μL, prevalence was: 18-37% TB disease; 20-39% latent TB; 5% asymptomatic cryptococcal disease; 87% of people with TB disease had symptoms.

Test costs were \$13 (Xpert), \$5 (LAM), and \$3 (serum CrAg); medication costs were \$0.83/month (CTX), \$4/month (Fluconazole), \$1/month (IPT). Model outcomes included life expectancy, costs, and incremental cost-effectiveness ratio (ICER, \$/year-of-life saved [YLS]); we considered ICERs <\$640/YLS (Malawi's annual *per capita* GDP) cost-effective.

Results: All AHD strategies would improve clinical outcomes and increase costs (Table). The full AHD package, LAM+CTX+CrAg+IPT, would result in the greatest life expectancy (21.61 life-years) and be cost-effective (ICER, \$250/YLS). All other strategies would be less efficient than the full AHD package at the cost-effectiveness threshold. Results are most sensitive to TB and cryptococemia prevalence.

Conclusions: Using published data, the full AHD package at ART initiation would be cost-effective in Malawi compared with only some elements of the package, when CD4 count is measured.

Strategy	1y survival (%)	Undiscounted life expectancy (y)	Discounted life expectancy (y)*	Lifetime costs (\$)*	ICER (\$/YLS)*
No AHD care (ART+Xpert)	93.89	20.89	13.62	1,354	--
+LAM	94.20	21.13	13.74	1,371	140
+CTX	94.31	21.21	13.81	1,412	dom
+CrAg+CTX	94.34	21.21	13.81	1,413	dom
+LAM+CTX	94.64	21.45	13.93	1,430	dom
+LAM+CTX+CrAg	94.66	21.46	13.94	1,431	dom
+LAM+CTX+CrAg+IPT	94.88	21.61	14.03	1,444	250

*Discounted at 3%/year. Dominated (dom): the ICER of this strategy compared to the next more costly strategy is higher and therefore not preferred.

Abbreviations: AHD, advanced HIV disease; PLHIV, people living with HIV; ICER, incremental cost-effectiveness ratio; YLS, years-of-life saved; LAM, liparabinomannan; CTX, co-trimoxazole; CrAg, cryptococcal antigen; IPT, isoniazid preventive therapy.

Table. Model-projected outcomes comparing the clinical outcomes, costs, and cost-effectiveness of different strategies for AHD care for PLHIV initiating ART in Malawi.

Blood pressure control among patients receiving Integrated care for HIV, diabetes and hypertension in primary health care facilities in Tanzania and Uganda

J.B. Birungi¹, I. Namakoola¹, J. Okebe², S. Kivuyo³, S. Jaffar⁴

¹MRC/UVRI & LSHTM, Entebbe, Uganda, ²Liverpool

School of Tropical Medicine, Liverpool, United Kingdom,

³National Institute for Medical Research, Dar es

Salaam, Tanzania, United Republic of, ⁴University

College of London, London, United Kingdom

Background: Non-communicable diseases (NCD) are a growing cause of morbidity and mortality among persons with or without HIV in sub-Saharan Africa. Diabetes and hypertension alone are estimated to cause about 2 million deaths annually. This dual burden requires that health care delivery systems are re-organized to address the needs of patients with chronic conditions for better outcomes. In partnership with public health services, we conducted a large cluster-randomised trial; INTE-Africa and compared blood pressure control among patients between the two arms; integrated management and standard care.

Methods: The study was part of a large cluster-randomised control trial. High volume primary care facilities were randomized. Study participants were selected systematically. In the integrated care clinic (intervention arm), participants with either HIV, diabetes or hypertension or combinations of these were managed in a single common clinic by the same clinical teams, had joint triage and waiting areas, and shared laboratory, counseling and pharmacy services. Standard care was organized in separate clinics. Participants were followed up for 12 months.

Results: A total 32 facilities were randomised. 16 to integrated care and 16 to standard care. We enrolled 7030 participants in the study, of whom 5150 (73.3%) were female. Of these 3081 (43.8%) had hypertension (either as a single or multiple condition) and had been in care for at least six months.

At the end of the study, 2440/3081 (79.2%) participants' blood pressure measurement was recorded, 1190 (48.8%) were in the integrated care arm and 1250 (51.2%) in the standard of care. In our study, 586/1190 (49.2%) participants in integrated care compared to 480/1259 (38.4%) participants in the standard of care arm had blood pressure controlled at the end of the study.

There was a difference in blood pressure control among patients with hypertension only, 379/692(54.8%) in the integrated care arm compared with 288/689(41.8%) in the standard of care arm of although not statistically significant

(p-value of 0.05). Among patients with diabetes and hypertension there was a statistically significant difference between the two arms (p=0.01).

Conclusions: There was some improvement in blood pressure control among patients in integrated care arm compared to those in the standard of care arm.

Scaling up cervical cancer prevention services among women living with HIV: lessons and experiences from FIKIA+ project in Mwanza, Tanzania

B. Msongole¹, A. Msalilwa¹, N. Shemndolwa¹, O. Joseph¹, M. Mahiti¹, M. Jalloh², M. Amuri², S. Mrema³, D. Magesa², O. Munishi¹, C. Wells⁴, N. Sugandhi⁴, J. Franks⁴, J. Kahemele¹, H. Maruyama¹

¹ICAP at Columbia University, Dar es Salaam, Tanzania,

United Republic of, ²U.S Center for Disease Control

and Prevention, Dar es Salaam, Tanzania, United

Republic of, ³Regional Administrative Secretary

Office, Mwanza, Tanzania, United Republic of, ⁴ICAP

at Columbia University, New York, United States

Background: Cervical Cancer Prevention (CECAP) is a priority intervention as part of comprehensive HIV care for women living with HIV (WLHIV). There was low uptake of CECAP services in Tanzania's Mwanza region in the first quarter of fiscal year 2022 (FY22), with 5% achievement of the annual programmatic target of screening 26,618 WLHIV (33% of women on ART) for precancerous cervical lesions. The initial poor performance was due to low service coverage, inadequate supplies, cryotherapy machine breakdown and scale up of 6 multi-months dispensing (6 MMD) of antiretroviral therapy (ART), which reduced WLHIV's clinic appointment frequency. We describe here progress in scaling up CECAP services in Mwanza.

Description: Between January and March 2022, facilities offering CECAP services were scaled up from 29 to 54. In addition, 97 facilities were added as outreach sites following onsite mentorship and provision of technical support by trained staff. Services were integrated with community ART refill through a mobile clinic to reach WLHIV who missed services, including those with 6 MMD of ART. Bio-medical engineers were engaged to conduct corrective and preventive maintenance of cryotherapy machines and monitoring and timely delivery of CECAP supplies was done. We analyzed routine program data to illustrate trends in cervical cancer screening and treatment and how they proportionally correspond to the pre-set targets.

Lessons learned: WLHIV screened for cervical cancer increased from 1,294 in the first quarter of FY22 to 10,188 in the second quarter. By end of FY22, 25,701 WLHIV were screened, corresponding to 97% of the annual target; 65% of WLHIV were screened at outreach sites. Among WLHIV screened, 753 (3%) were found to have precancerous cer-

vical lesions and 743 (99%) were linked to treatment with 92% completing treatment in the same visit. Out of 25,701 WLHIV screened, 103 (0.4%) were suspected to have cancer and were referred for further diagnosis.

Conclusions/Next steps: The target for cervical cancer screening was almost achieved (97%) with 99% linkage to treatment following a combination of enhanced service delivery.

The findings demonstrate that it is feasible to make substantial improvements in the uptake of CECAP services by implementing approaches to increase programmatic reach and quality.

Integrating hepatitis C services into ART clinics in low and middle income countries (LMICs) as an approach toward hepatitis C micro-elimination: pilot experience in Nigeria

C. Agwuocha¹, O. Adisa¹, O. Nwobi¹, M.-M. Akanmu¹, C.E. Boeke², I. Ikpeazu¹, A. Azania², I. Adamu³, A.Y. Ahmed³, R. Abade Bello³, J. Kama¹, O. Fernandes², F. Lufadeju¹, O. Wiwa¹

¹Clinton Health Access Initiative, Abuja, Nigeria,

²Clinton Health Access Initiative, Boston, United States,

³Nasarawa State Ministry of Health, Lafia, Nigeria

Background: Globally, an estimated one in ten people living with HIV (PLHIV) is co-infected with viral hepatitis B or C (HBV, HCV), which increases morbidity and mortality[1]. HCV can be cured with low-cost, well-tolerated direct acting antiviral treatment. Improving outcomes among PLHIV with HCV/HBV co-infection demands strategic service delivery approaches including integrating HCV/HBV services in antiretroviral therapy (ART) clinics. This abstract highlights HCV/HIV service integration outcomes achieved at 4 ART sites in Nasarawa State, Nigeria.

[1] <https://pubmed.ncbi.nlm.nih.gov/26922272/>

Methods: A baseline assessment was conducted at ART facilities and community ART engagements including home visits to identify critical points for service integration including HCV screening, viral load (VL) confirmatory testing, and treatment without disruption to existing services.

No routine HCV screening for PLHIV was previously available. Relevant healthcare workers were trained on HCV management and data reporting. From July 2020 – December 2022, PLHIV coming for ART visits received HCV screening during triaging and positive patients were linked to care.

Patient navigators and ART defaulter trackers identified unscreened PLHIV using facility HCV screening and enrolment data and prompted their return to the facility for HCV services through texts/calls or provided these services in community settings. Positive patients were linked to VL testing and treatment in either the facility or community.

Results: During this integration pilot, a total of 3831 PLHIV were screened of 4042 receiving ART across the sites (94.8%; Male (M)/Female (F) = 29%/71%). 426 (11.1%) were seropositive, 371 received a confirmatory HCV VL (87.1%), 218 were viremic (58.8%), and 175 initiated HCV treatment.

Figure. Hcv Care cascade for enrolled PLHIV in four ART facilities (July 2020 - December 2022).

Conclusions: Despite the effects of the COVID-19 pandemic, and financing barriers necessitating domestic resource mobilization, HIV/HCV service integration at ART clinics and community settings has been a successful strategy to dramatically expand HCV screening and treatment among HIV clients and a critical step to achieving HCV micro-elimination in PLHIVs in LMICs.

Willingness to access PrEP for adolescent girls and young women seeking emergency contraception at community pharmacies in Uganda

T.R. Muwonge¹, A. Nalumansi¹, K. Beima-Sofie², R. Nsubuga¹, E. Laker Agnes Odongpiny¹, M. Nakitende¹, A. Nakyanzi¹, A. Mujugira^{1,2}, R. Heffron³

¹Infectious Diseases Institute Makerere University, Kampala, Uganda, ²University of Washington, Seattle, United States, ³University of Alabama, Birmingham, United States

Background: Adolescent girls and young women (AGYW) account for 26% of new HIV diagnoses in Uganda, but only 4.6% of pre-exposure prophylaxis (PrEP) users. Differentiated delivery of PrEP services at private pharmacies, often frequented by this population, could increase prevention coverage.

Methods: We recruited AGYW, aged 18-24 years, seeking emergency contraception (EC) from 13 randomly selected community-pharmacies in central Uganda between May and December 2022. We hypothesized that AGYW seeking EC at community-pharmacies would be willing to access and use PrEP. Following brief training, pharmacy providers delivered study information to interested AGYW and referred them to the research clinic for data collection.

The primary outcome was willingness of AGYW to access PrEP, evaluated using an interviewer-administered cross-sectional survey. We used descriptive statistics and modified Poisson regression to analyze the data.

Results: We enrolled 130 AGYW, median age of 22 years (interquartile range [IQR] 20-24). Of these, 104 (80%) were living alone or had no partner, and 64 (49%) had no child. Eighty-four (65%) were employed and median monthly income was \$54.4[40.8-81.6]. AGYW accessed EC a median of 3 times (IQR 2-6) in the prior 3 months. Most (81%) chose

community-pharmacies as the most convenient place to receive PrEP services instead of public/private health facilities, or community outreach. Approximately half of AGYW (73; 56%) were willing to accept PrEP from community-pharmacies.

Willingness to access pharmacy-delivered PrEP was associated with PrEP awareness (adjusted prevalence ratio [APR] 1.90; 95% confidence interval [CI]:1.43-2.51; $P<0.001$), having a busy schedule (APR 1.60; 95%CI:1.20-2.13; $P=0.001$), experiencing symptoms of a sexually transmitted disease in the prior 3 months (APR 1.58; 95%CI:1.22-2.06; $P=0.001$), number of sexual partners in the previous 3 months (APR 1.15 per partner; 95%CI:1.02-1.31; $P=0.03$), and number of sex acts in the prior 3 months (APR 1.01 per act, 95%CI:1.00-1.02; $P=0.006$).

By contrast, dysuria and condom use were associated with decreased willingness to access PrEP (APR 0.38, 95%CI: 0.20-0.71; $P=0.003$) and (APR 0.78, 95%CI:0.67-0.92; $P=0.002$), respectively.

Conclusions: More than half of AGYW in our survey were willing to access PrEP from community-pharmacies. If scaled, pharmacy-based PrEP delivery models could significantly improve PrEP access for this population.

Tackling health facility intersectional stigma faced by men who have same-gender sex in Ghana: early results from a randomized control trial

L. Nyblade¹, E. Oga¹, S. Clay², M. Chonta², E. Mankattah³, R. Vormawor³, R.P. Amoh-Otu⁴, E. Gyamerah³, R. Akrong³, P. Appiah⁴, F. Boakye⁵, K. Saalim¹, M.A. Stockton⁶, G. Abu-Ba'are⁷, N. Smith Ordain¹, C. Logie⁸, K. Torpey⁹, L.E. Nelson¹⁰

¹RTI International, Washington, D.C., United States,

²3C Regional Consultants, Lusaka, Zambia, ³Educational Assessment & Research Center, Accra, Ghana, ⁴Youth Alliance for Health & Rights, Kumasi, Ghana, ⁵Priorities on Rights & Sexual Health, Accra, Ghana, ⁶Columbia University Irving Medical Center, Department of Psychiatry, New York, United States, ⁷University of Rochester, Rochester, United States, ⁸University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, ⁹University of Ghana, School of Public Health, Department of Population, Family & Reproductive Health, Accra, Ghana, ¹⁰Yale University, School of Nursing, New Haven, United States

Background: Intersectional stigma and discrimination (ISD) in the health system towards gay, bisexual, and other men who have sex with men (GBMSM) is a barrier to

HIV prevention and treatment for this underserved population, particularly in settings where same-gender sex is criminalized. Yet, few empirically tested health-facility (HF) ISD-reduction interventions exist. Therefore, we adapted an evidence-based HIV HF stigma-reduction intervention to address the intersection of HIV, same-gender sex and gender non-conforming stigma and discrimination in Ghana, where GBMSM are 11 times more likely to be living with HIV than the general population.

Methods: We assessed the effect of the facility-level stigma reduction intervention using baseline (n=200), 3-month (n=200) and 6-month (n=200) follow up survey data of staff in 8 HFs randomly assigned to intervention and wait-list control in Greater Accra and Ashanti regions, Ghana.

Differences-in-differences analysis was conducted to assess whole-facility intervention effects using the 18-item and 3 sub-scales validated HCF Intersectional Stigma Scale (HCF-ISS). The outcomes of interest were facility-level composite stigma scores for key stigma drivers.

Results: At 3-months post intervention, we observed a significant reduction in the whole-facility intersectional stigma score (and the gender-and-sexuality norms belief subscale) in the intervention HFs compared to wait-list facilities. This difference held at 6-months post intervention for the gender-and-sexuality norms belief subscale (Table).

Healthcare Facilities Staff Intersectional Stigma Scale (HCF-ISS)	Control			Intervention		
	Mean (SD)	Stigma Scores		Mean (SD)	Stigma Scores	
Scale is average score - range 1-5, with 5 highest corresponding to highest level of stigma (undesirable outcome)	Base-line	3-month	6-month	Base-line	3-month	6-month
Subscale 1: Intersectional Identities Discomfort (Cronbach's alpha = 0.71)	2.02 (0.69)	2.09 (0.74)	1.90 (0.57)	2.12 (0.74)	1.94 (0.67)	1.88 (0.73)
Subscale 2: Gender and Sexuality Norms Beliefs (Cronbach's alpha = 0.72)	3.67 (0.63)	3.55 (0.81)	3.52 (0.76)	3.88 (0.71)	3.43 (0.88)*	3.38 (0.87)*
Subscale 3: HIV stigma (Cronbach's alpha = 0.68)	2.23 (0.73)	2.22 (0.67)	2.23 (0.68)	2.27 (0.76)	2.24 (0.75)	2.22 (0.68)
Total Intersectional Stigma Score (Cronbach's alpha = 0.74)	2.72 (0.45)	2.7 (0.51)	2.61 (0.45)	2.85 (0.49)	2.58 (0.55)*	2.56 (0.58)

*Statistically significant change in average facility stigma score in intervention hospitals compared to control hospitals

Table.

Conclusions: Upholding human rights, delivering quality services for GBMSM and ending AIDS by 2030 is not achievable without reducing the ISD faced by populations that are disproportionately impacted by HIV and underserved by the health system. Reducing ISD in HFs is particularly critical, given their essential role in providing prevention and treatment services.

This study provides evidence that it is possible to reduce intersectional stigma towards GBMSM in health systems, even in the context of challenging political and social climates. It provides a replicable intervention approach as well as practical intervention tools.

OAE0503

Catalyzing access to HIV services and essential health care for key populations: effective innovations for African countries

F. Ilika¹, U. Ihekanandu¹

¹Palladium, Abuja, Nigeria

Background: About four-fifths of the 24 million people in Nigeria's Lagos State live below the poverty line and cannot afford to pay for essential healthcare without risking catastrophic financial consequences. A large number of key population groups—men who have sex with men, injection drug users, female sex workers, and transgender populations reside in Lagos state.

Nigeria, like many African counties, often criminalize and stigmatize these population groups with resultant lack of access to essential health care, risk of health catastrophe and poverty as traditional government programs do not fund their health care needs.

Description: The USAID Health Policy Plus Project HP+ supported Lagos State to expand its health insurance scheme and devised a special focus to target orphans, vulnerable children, people living with HIV, and key populations. HP+ collaborated with key actors including the Network of People living with HIV and State Health Insurance Agency and secured the release of the state's equity fund—an annual contribution by the government for provision of healthcare to poor and vulnerable communities—and for key populations to be prioritized as beneficiaries of this fund, for the first time.

The program also facilitated their enrolment into the social register which enables them to access government intervention funds for improving livelihoods.

Lessons learned: These efforts led to the release of NGN750-million in equity funds, for increased access to quality health care, and HIV services. 100,000 poor and vulnerable children and people living with HIV including 12,000 from key populations were enrolled.

This policy change allowed the targeted groups to be enrolled into health insurance and receive free health care at their preferred one stop shop facilities, increasing access to essential HIV and health care services, and financial protection.

Conclusions/Next steps: Catalyzing government funding for key populations is possible even in settings where they are criminalized through strategic, targeted, collaborative and integrated approaches. This can be adapted by other countries facing similar challenges in obtaining government funding for key populations. This integrated approach also provides health, economic and social ben-

efits which is essential for ensuring the complete well-being of key population groups— a critical factor for HIV epidemiological control

OAE0504

Increasing access to SelfCare: Employing an online-based demand generation strategy to increase uptake of peer-led unassisted HIV self-testing among key populations in the Philippines

R.M. Briñes¹, R. Domingo¹, J.D. Rosadiño¹, D. Cruz¹,

M. Brines¹, P. Junio¹, J.I. Dinglasan¹, R. Pagtakhan¹, J.P. Benito¹

¹LoveYourself Inc., Mandaluyong, Philippines

Background: Ease of access is one factor in getting tested for HIV. The imposed limited mobility due to COVID-19 limited this access even further. Since its introduction in 2020, unassisted HIV self-testing has been established as a choice for key populations to access HIV testing in the Philippines. Aiming to bring HIV testing awareness to key populations, a program designed to generate demand is introduced in SelfCare (LoveYourself's unassisted HIV self-testing program).

Description: Guided by the AIDA model (Figure 1), this program aimed to create awareness and demand generation by creating a massive number of leads of potential clients accessing SelfCare. A communications plan was designed by members of key populations to determine the campaign architecture, keeping in mind the target market: gay, bisexual, and other men who have sex with men (GBMSM) and transgender people. The key messages focused on testing information, access, and its impact on the lifestyle of clients.

The visual theme and the messages developed include a motivational tone of espousing self-empowerment. These campaigns are promoted on various social media platforms.

Figure 1.

Lessons learned: The communications plan was implemented starting in October 2020. The continuous posting of content has increased uptake by 1,012% compared to data from July-September 2020. During the campaign, a total of 513,024 clients were reached (as of Dec 2022).

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

These campaigns have generated 20,043 clients accessing SelfCare, with a reactivity rate of 6% among those who reported results. 39.13% of the clients tested for HIV for the first time. Among those reactive, 75.33% of clients have been enrolled in treatment.

Conclusions/Next steps: It was seen that demand generation campaigns powered by the community are effective in bringing awareness of HIV self-testing. Community consultations are essential in creating these programs for key communities. This momentum will be maintained with offline community engagement activities and campaigns promoted on other online platforms.

Differentiated online-to-offline (O2O) interventions for HIV services: impacts on HIV testing and case finding among key populations in Thailand, Nepal and the Philippines

P. Patpeerapong¹, T. Chaisalee², S. Janyam³, S. Sittikarn⁴, Y.R. Sapkota⁵, A. Sharma⁵, D. Ortiz⁶, G.-J. Alatiit⁷, S. Mills⁸, A. Arunmanakul⁸

¹Mplus Foundation, Chiang Mai, Thailand, ²Rainbow Sky Association of Thailand, Bangkok, Thailand, ³Service Workers in Group Foundation, Bangkok, Thailand, ⁴Caremat Foundation, Chiang Mai, Thailand, ⁵FHI 360, Kathmandu, Nepal, ⁶Laguna Medical Center, Laguna, Philippines, ⁷Hospital Ospital ng Biñan, Laguna, Philippines, ⁸FHI 360, Bangkok, Thailand

Background: The COVID-19 pandemic brought renewed emphasis on the strategic use of online to offline (O2O) interventions, since in-person outreach was reduced, and HIV service options were often limited. In Thailand, Nepal, and the Philippines, USAID EpiC Project-supported community-based organizations and hospitals adapted multiple O2O approaches to reach and test key populations, with a focus on reaching undiagnosed HIV-positive individuals. We identify and analyze here the impacts of these O2O approaches in the three countries from October 2021-September 2022.

Description: Social influencers, targeted ads, and online outreach engaged sexual, drug-use, and chemsex networks to promote HIV testing on social media and chat apps, e.g., Facebook, Twitter, LINE, TikTok, Grinder, Hornet, and Blued. A unique online reservation web application permitted in-depth analysis of client flow from the source of client online exposure to messaging through clinic attendance and service utilization, e.g., HIV testing.

Lessons learned: In Thailand, O2O interventions brought in 11% of all project-supported HIV testing clients (5% HIV case detection). A majority of online clients were reached by Facebook, but two apps – Blued and Twitter – had the highest case detection (10.4% and 7.8%, respectively). In Nepal, O2O interventions brought in 10.3% of all HIV testing clients, and Facebook was the most common site for recruiting clients (57% of all O2O activity). A total

of 8.4% of clients tested through O2O interventions were positive, though some platforms showed higher case detection, e.g. Whatsapp, 11.1%.

In the Philippines, O2O interventions specifically assisted project-supported government hospitals where they contributed more than one-third (37%) of the clients HIV tested and almost one-fifth (19%) of all identified HIV cases. At one government facility, the on-line reservation app contributed 56% of all HIV testing and 79% of all identified HIV cases.

Conclusions/Next steps: Differentiated O2O interventions focused on key populations clearly demonstrated their added value in HIV testing and case finding across three countries. Programs need to regularly analyze the effectiveness of specific platforms, use innovations such as online reservation apps that allow more in-depth analysis, and continually adapt O2O interventions so that they remain impactful and relevant to KP's dynamic use of social media.

Transcriptional activity of brain-derived HIV long terminal repeat sequences from ART-treated people with HIV

J. Jamal Eddine¹, C. Cochrane¹, T. Angelovich^{1,2,3}, M. Roche^{2,1}, M. Churchill^{1,2,4}

¹RMIT University, Bundoora, Australia, ²Doherty Institute, Melbourne, Australia, ³Burnet Institute, Melbourne, Australia, ⁴Monash University, Clayton, Australia

Background: Recently, we demonstrated that the brain of ART-treated people with HIV (PWH) harbours a pool of both intact and defective HIV proviruses. We and others have demonstrated that HIV long terminal repeats (LTRs) isolated from the brain of viremic PWH are functional and distinct from those isolated from matched peripheral tissues from the same individual. Despite the presence of intact potentially replication competent proviral genomes, whether the LTRs are functional and transcriptionally active is unclear.

Methods: Autopsy brain and matched peripheral tissue from ART-treated (n=9) or viremic PWH (n=2) were provided by the National NeuroAIDS Tissue Consortium. Droplet-digital PCR was utilised to quantify the presence of HIV *pol* DNA within brain tissue from these individuals. HIV LTRs from brain and matched peripheral tissue (where available) were isolated through single genome amplification. Phylogenetic sequence analysis was undertaken and transcription factor binding site analysis was performed through the transfection of LTRs into astrocyte and microglial cell lines under basal and tat-transactivated conditions.

Results: HIV *pol* DNA was detected in the brain of both ART-treated and viremic PWH (median (IQR) HIV *pol* DNA copies/10⁶ cells = 32.59 (13.9 – 310.1) vs 17015 (670.3 – 33359)). A total of 18 unique sequences were isolated from brain tissue (4 ART-treated and 2 viremic PWH) and 38 unique sequences were isolated from matched peripheral tissue (3 ART-treated and 2 viremic PWH). In contrast to our previous findings in viremic PWH, compartmentalisation was not observed between brain and peripheral sequences in ART-treated PWH. All sequences isolated from the brain of ART-treated PWH retained intact core promoter regions (TATA, SP1, NF- κ B), suggesting that they are capable of transcription. Interestingly, one sequence also contained additional SP1 sites. Isolated LTRs were transcriptionally active and capable of Tat-transactivation within brain cell lines (n=4 unique sequences from two ART-treated participants).

Conclusions: These findings support the presence of a potentially transcriptionally competent inducible pool of HIV in the brain of ART-treated PWH. Understanding the

function of HIV LTRs derived from intact proviral genomes in the brain may inform the role of the HIV reservoir in ongoing disease and as a barrier to HIV cure.

MOPEA02

Genetic variation of the HIV-1 subtype C transmitted/founder viruses long terminal repeat elements and the impact on transcription activation potential and clinical disease outcomes

P. Madlala^{1,2}, Z. Mkhize¹, S. Naicker¹, S. Khathi¹, S. Maikoo¹, K. Gopee¹, K. Dong^{3,4,5}, T. Ndung'u^{1,2,6,3,4}

¹HIV Pathogenesis Programme, The Doris Duke Medical Research Institute, Nelson R. Mandela School of Medicine, University of KwaZulu-Natal, Durban, South Africa, ²School of Laboratory Medicine and Medical Sciences, University of KwaZulu-Natal, Durban, South Africa, ³Ragon Institute of Massachusetts General Hospital, Massachusetts Institute of Technology, and Harvard University, Cambridge, United States, ⁴Division of Infection and Immunity, University College London, London, United Kingdom, ⁵Harvard Medical School, Boston, United States, ⁶Africa Health Research Institute (AHRI), Durban, South Africa

Background: A genetic bottleneck is a hallmark of HIV-1 transmission such that only very few viral strains, termed transmitted/founder (T/F) variants establish infection in a newly infected host. Phenotypic characteristics of these variants may determine the subsequent course of disease. The HIV-1 5' long terminal repeat (LTR) promoter drives viral gene transcription. HIV-1 5'LTR and 3'LTR have a same genetic sequence.

The major aim of this study was to investigate the genetic and functional of T/F LTR variants. We hypothesised that HIV-1 subtype C (HIV-1C) T/F virus LTR genetic variation is a determinant of transcriptional activation potential and clinical disease outcome.

Methods: The 3'LTR was amplified from plasma samples of 41 study participants acutely infected with HIV-1C (Fiebig stages I and V/VI) in Durban South Africa. Paired longitudinal samples were also available at one year post-infection for 31 of the 41 participants. 3'LTR (referred as LTR henceforth) amplicons were cloned into a pGL3-basic luciferase expression vector, and transfected alone or together with Transactivator of transcription (*tat*) into Jurkat cells in the absence or presence of cell activators (TNF- α , PMA, Prostratin and SAHA).

Results: Inter-patient T/F LTR sequence diversity was 5.7% with subsequent intrahost viral evolution observed in 48.4% of the participants analyzed at 12 months post-infection. T/F LTR variants exhibited differential basal transcriptional activity, with significantly higher Tat-mediated transcriptional activity compared to basal (p<0.001). Basal and Tat-mediated T/F LTR transcriptional activity showed a significant positive correlation with contemporaneous viral loads and negative correlation with CD4 counts (p<0.05) during acute infection respectively.

Furthermore, Tat-mediated T/F LTR transcriptional activity significantly correlated positively with viral load set point and viral load; and negatively with CD4 T cell counts at one year post infection (all $p < 0.05$). Lastly, PMA, Prostratin, TNF- α and SAHA cell stimulation resulted in enhanced yet heterologous transcriptional activation of different T/F LTR variants.

Conclusions: Our data suggest that T/F LTR variants may influence viral transcriptional activity, disease outcomes and sensitivity to cell activation. Future studies should investigate the impact of T/F LTR genetic variation on latency development and/or reactivation.

TGF- β drives HIV infected CD4⁺ T cells to adopt a tissue resident memory phenotype

S. Vimontpatranon^{1,2}, L.R. Goes^{2,3}, A. Chan², I. Licavoli², S.R. Wertz², D. Huang⁴, A. Jiang⁴, C. Huang⁴, C. Martens⁵, K. Virtaneva⁵, M.A. Soares^{3,6}, A.S. Fauci², J. Arthos², C. Cicala²

¹Armed Forces Research Institute of Medical Sciences, Retrovirology, Bangkok, Thailand, ²National Institute of Allergy and Infectious Diseases, Laboratory of Immunoregulation, Bethesda, United States, ³Instituto Nacional de Cancer, Oncovirology Program, Rio de Janeiro, Brazil, ⁴National Cancer Institute, Lymphoid Malignancies Branch, Bethesda, United States, ⁵National Institute of Allergy and Infectious Diseases, Rocky Mountain Laboratory, Hamilton, United States, ⁶Universidade Federal do Rio de Janeiro, Department of Genetics, Rio de Janeiro, Brazil

Background: Persistent reservoirs are established during the acute stage of HIV infection when high level replication occurs in gut associated lymphoid tissue (GALT). Long-lived gut CD4⁺ tissue resident memory cells (T_{RM}s) contribute to viral reservoirs. T_{RM} cell differentiation is not well understood. Identifying the cues that drive infected cells in the gut to become T_{RM}s may help identify strategies to prevent or disrupt the formation of these reservoirs.

Methods: In this study we carried out a combined gene expression and phenotypic analysis of MAdCAM costimulated cells by multicolor flow-cytometry. CD4⁺ T cells isolated from healthy donors were costimulated with MAdCAM, retinoic acid and TGF- β .

Results: 7 days after costimulation we noted upregulation of CD69 and CD103. Prolonged expression of CD69 is associated with tissue resident memory cells (T_{RM}). CD103 (integrin α_E) which combines with integrin β_7 to form $\alpha_E\beta_7$ heterodimers. Like CD69, $\alpha_E\beta_7$ is a marker of T_{RM} cells. We also observed upregulation of the gut-homing chemokine receptor CCR9. These three markers represent a signature of T_{RM} cells. Thus, MAdCAM costimulation established a differentiation program that resulted in the formation of CD4⁺ T cells with a T_{RM}-like phenotype. TGF- β is known inducer of CD103. Combining TGF- β with MAd-

CAM further differentiated CD4⁺ T cells toward a T_{RM}-like phenotype. The capacity of MAdCAM to upregulate CCR5⁺ rendered these cells susceptible to HIV infection, even in the presence of TGF- β .

Conclusions: A hallmark of acute HIV infection is infection in gut tissues. Our findings raise the possibility that during acute infection, interactions between CD4⁺ T cells and MAdCAM facilitate both the formation of T_{RM} cells, and their infection. Such an activity may contribute to the early establishment of persistent HIV reservoirs localized to the gut.

MOPEA04

Infection by high replication capacity HIV-1 viruses is associated with increased glucose metabolism by T cells

O.O. Baiyegunhi¹, K. Mthembu¹, A.-k. Reuschel², D. Ojwach³, O. Farinre³, M.J. Bunders⁴, M. Altfeld⁵, C. Jolly², J. Mann³, T. Ndung'u^{1,3,2,6}

¹Africa Health Research Institute, Durban, South Africa, ²University College London, Division of Infection and Immunity, London, United Kingdom, ³University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, ⁴University Medical Center Hamburg-Eppendorf, Department of Medicine, Hamburg, Germany, ⁵Heinrich Pette Institute, Research Department Virus Immunology, Hamburg, Germany, ⁶Ragon Institute of MGH, MIT, and Harvard University, Boston, United States

Background: HIV viruses with high replicative capacity (RC) are associated with elevated viral loads and faster disease progression in the absence of therapy. It has also been reported that in some circumstances, lower RC viruses may be selectively favored for transmission. Understanding the underlying mechanisms of the spread of viruses with variable RCs may inform novel anti-HIV interventions. Cellular metabolism plays an important role in regulating immune cell function and there is accumulating evidence that CD4⁺ T cells' metabolic reprogramming of glucose breakdown, glycolysis, and oxidative phosphorylation favor HIV infection.

We hypothesized that viruses differ according to their RC in the ability to modulate cellular metabolism and promote virus transmission and replication.

Methods: Chimeric viruses containing patient-derived gag-protease amplicons from HIV-1 subtypes B and C were constructed in the NL4-3 backbone (n=29). Viral RC was determined using a GFP-reporter cell line assay, and the ability for *in vitro* virus cell-to-cell spread in T cells was measured by gag p24 detection using flow cytometry. In addition, glucose and fatty acid metabolism in infected cultures were quantified using flow cytometry-based 2-NBDG and Bodipy uptake assays. Glutamine levels were also measured using a luminescence-based assay.

Results: Subtype B chimeric viruses had overall higher RCs than subtype C viruses ($p=0.0003$). Virus RC correlated with the amount of cellular glucose uptake ($p=0.02$, $r=0.5$),

but not fatty acid uptake in infected T cell cultures. Moreover, fatty acid uptake was higher in HIV-infected cells irrespective of virus RC compared to bystander cells within the same culture ($p=0.01$). Cell-to-cell spread, after 24 and 48 hours of co-culture, correlated with virus RC ($p=0.02$, $r=0.7$) and this was accompanied by increased glutamine consumption in infection cultures ($p<0.0001$).

Conclusions: These results suggest that virus characteristics such as RC, may influence the host cellular glucose metabolism and further enhance virus cell-to-cell spread. These data have implications for understanding the mechanisms underlying differential clinical outcomes by viruses with variable RCs.

MOPEA05

IL7RA single nucleotide polymorphisms and CMV co-infection associate with MAIT cell dysregulation in treated HIV-1 infection

F. Han^{1,2}, M.Y. Gulam³, Y. Zheng^{1,2}, N.S. Zulhaimi^{4,5}, W.R. Sia³, D. He^{1,2}, A. Ho^{1,2}, L. Hadadi³, Z. Liu¹, P. Qin^{1,2}, P.E. Lobie^{1,2}, A. Kamarulzaman^{4,5}, L.-F. Wang³, J.K. Sandberg⁶, S.R. Lewin⁷, R. Rajasuriar^{4,5}, E. Leeansyah^{1,2,3,6}

¹Tsinghua University, Institute of Biopharmaceutical and Health Engineering, Shenzhen International Graduate School, Shenzhen, China, ²Tsinghua University, Precision Medicine and Healthcare Research Centre, Tsinghua-Berkeley Shenzhen Institute, Shenzhen, China, ³Duke-NUS Medical School, Programme in Emerging Infectious Diseases, Singapore, Singapore, ⁴University of Malaya, Centre of Excellence for Research in AIDS (CERIA), Kuala Lumpur, Malaysia, ⁵University of Malaya, Department of Medicine, Kuala Lumpur, Malaysia, ⁶Karolinska Institutet, Center for Infectious Medicine, Department of Medicine Huddinge, Stockholm, Sweden, ⁷University of Melbourne, Peter Doherty Institute for Infection and Immunity, Melbourne, Australia

Background: Mucosa-associated invariant T (MAIT) cells are the most abundant antimicrobial T cells in humans and recognise riboflavin-related metabolites. MAIT cells are depleted and exhausted in HIV-1-infected individuals despite long-term combination antiretroviral therapy (cART).

IL-7 treatment supports MAIT cell reconstitution in HIV-1-infected individuals *in vivo* and rescues their functionality *in vitro*. Single-nucleotide polymorphisms (SNPs) of the *IL-7RA* gene modulate the levels of soluble (s)IL-7R α levels and influence bioavailability of circulating IL-7.

Here we evaluated the potential influence of *IL-7RA* polymorphisms on MAIT cell numbers and function in healthy control (HC) subjects and HIV-1-infected individuals on long-term cART.

Methods: The *IL-7RA* promoter haplotypes were identified by haplotype-tagging SNPs of *IL-7RA* from a cohort of 35 HC and 39 HIV-1-infected individuals. The number and phenotype of MAIT cells, levels of the MAIT cell-associated

transcription factors, and MAIT cell effector function and proliferation following cognate stimulations were measured by flow cytometry.

Results: The *IL-7RA* haplotype 2 (H2*T), defined as T-allele carriers at the tagging SNP rs6897932, affects the size of the peripheral blood MAIT cell pool and their production of cytokines and cytolytic effector proteins in response to bacterial stimulation in HC. H2*T carriers had lower sIL-7R α levels and higher MAIT cell frequency with enhanced functionality linked to higher expression of MAIT cell-associated transcription factors. Despite an average of 7 years on cART, MAIT cell levels and function in HIV-1-infected individuals were still significantly lower than those of HC. Notably, we observed a significant correlation between MAIT cell levels and cART duration only in H2*T HIV-1-infected individuals. Unexpectedly, the levels of anti-CMV IgG are correlated with sIL-7R α levels and inversely correlated with MAIT cell numbers.

Finally, treatment with sIL-7R α *in vitro* suppressed IL-7-dependent MAIT cell proliferation and function following cognate stimulations.

Conclusions: Collectively, these observations suggest that *IL-7RA* polymorphisms may play a significant role in MAIT cell biology and influence MAIT cell recovery in HIV-1 infection by modulating sIL-7R α levels and IL-7 bioavailability to MAIT cells.

Our findings also suggest that CMV co-infection may potentially contribute to MAIT cell dysregulation. The potential links between *IL7RA* polymorphisms, MAIT cell immunobiology, HIV-1 infection, and concomitant CMV infection warrant further studies.

MOPEA06

Long-term HIV control and breastfeeding: HIV DNA in breast milk cells from an exceptional elite controller and a woman on-ART. Are we ready to change the paradigm?

A.A. Osegueda Peña¹, L. Baquero¹, A. Czernikier¹, C. Mendez², Y. Ghiglione¹, G. Turk¹, N. Laufer¹

¹CONICET-Universidad de Buenos Aires. Instituto de Investigaciones Biomédicas en Retrovirus y Sida (INBIRS), Buenos Aires, Argentina, ²Subprograma de Maternidad e Infancia, Ministerio de Salud, Provincia de San Luis, San Luis, Argentina

Background: HIV has been found to be present in breast milk, even in the context of antiretroviral therapy (ART). Formula feeding is safe in high-income settings, therefore, women living with HIV (WLWH) are advised against breastfeeding and this recommendation has not changed over time.

However, WLWH with fully suppressed viral loads and exceptional elite controllers are challenging these guidelines and even choosing to breastfeed.

Here we aimed to study the HIV RNA and reservoir present in breast milk from an exceptional elite controller (EEC, the "Esperanza patient") and to compare it with another

Oral

Late-breaker
abstractsAuthor
Index

woman who has been under ART with dolutegravir, lamivudine and abacavir since march 2016 (WLWH-on-ART), maintaining undetectability for over 69 months.

Methods: 5.65 liters of breast milk from the first seven weeks of lactation were processed from the EEC, and 411 mL from WLWH-on-ART. Milk was centrifuged and the fluid portion (556 ml from EEC, 146 ml from WLWH-on-ART) was ultracentrifuged and used to determine HIV viral load (VL).

Also, 1,443 billion cells from EEC and 36.6 million cells from WLWH-on-ART were obtained. DNA was extracted and total HIV DNA qPCR and FLIP assays were performed.

Results: Breast milk VL was undetectable (<40 copies/mL) for both subjects throughout the first seven weeks of lactation. Seven copies of HIV DNA were found within 87 million cells analyzed from the EEC (0.08 copies/1M cells) and 2 copies were found within 2.7 million cells from WLWH-on-ART (0.74 copies/1M cells) by qPCR. For the EEC, 9.3 million cells were analyzed by FLIP-assay and no amplicons were obtained.

Conclusions: The Esperanza patient is an EEC, and her status correlates with lower levels of HIV reservoir in blood. Our studies in breast milk are still preliminary, however, they suggest that the characteristics of HIV reservoir in breast milk are also different from the peripheral blood and from non-controllers, showing lower levels of HIV DNA.

We intend to expand our study, including more lactating subjects on-ART with long-term undetectability. This would help to estimate more accurately the real risk of HIV transmission through breast milk in this population.

MOPEA07

Novel adjuvant ALFQ elicits a strong immune stimulatory signature that correlates with remarkable magnitude T cell and humoral immune responses following pox-protein vaccination

H. King^{1,2,3}, C. Subra^{1,2}, E. Tourtellott-Fogt^{1,2}, K. Om^{1,2}, M. Dong^{1,2}, M. Rao¹, D. Bolton^{1,2}

¹U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, ²Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, ³Vaccine Research Center, NIAID, NIH, Bethesda, United States

Background: Novel vaccine adjuvants may play an important role in eliciting immune responses capable of protecting against HIV-1 acquisition. One promising adjuvant under investigation is the monophosphoryl lipid A-containing Army Liposomal Formulation (ALF) with QS21 saponin (ALFQ). In a pox-protein vaccination study in nonhuman primates adjuvanted with ALFQ, the peak percentage of Env-specific CD4+ and CD8+ T cells were unprecedented, ranging between 0.9-5.9% and 0.4-3.4%, respectively.

We aimed to assess the contribution of ALFQ to this response by measuring innate immune activation following immunization.

Methods: Rhesus macaques were vaccinated with recombinant modified vaccinia virus Ankara encoding HIV-1 *gag/pol* and *env* in a prime-boost regimen with multimeric gp145 Env protein. gp145 was adjuvanted with either ALFQ or aluminum hydroxide followed by mixing with ALF (ALFA) (n=9/group). Soluble cytokines in the plasma were measured 0 and 24 h post-vaccination using a bead-based Luminex assay. Env-specific binding antibodies and T cell responses were measured in peripheral blood 2 weeks post-vaccination by ELISA and intracellular cytokine staining, respectively.

Results: Inflammatory cytokine levels transiently increased in plasma following vaccination. ALFQ adjuvanting induced a more robust inflammatory cytokine response than ALFA, with larger fold-change increases in IL-1RA, IL-6, IFN γ , IL-18, G-CSF, IL-15 and sCD40L one day post-vaccination ($P<0.05$).

Post-vaccination plasma cytokine levels positively correlated with the magnitude of Env-specific CD4+ T cell responses (IL-1RA, IL-18, MCP-1, IL-6, IL-15, IFN γ , IL-10, G-CSF, MIP-1 β , sCD40L) and Env-specific antibodies (IL-1RA, IL-18, IL-6, IFN γ , G-CSF, MIP-1 β , sCD40L).

In contrast, CD8+ T cell response associations with plasma cytokine levels were more limited: induction of high magnitude Env-specific CD8+ T cells correlated with levels of the pro-inflammatory cytokine, IL-6.

Conclusions: ALFQ adjuvanted pox-protein vaccination elicits vigorous innate immune activation one day post-vaccination, while the related liposomal adjuvant ALFA, lacking QS-21, was less pro-inflammatory. The cytokine milieu elicited by ALFQ may support development of exceptional T cell responses, such as via recruitment of immune cells (e.g. by MCP-1), direct action on T lymphocytes (e.g. IL-18), or antigen cross-presentation.

These results support further development of ALFQ adjuvant to augment adaptive immunity in HIV prophylactic and therapeutic immunization strategies.

MOPEA08

GITR is expressed on HIV-specific CD8⁺T-cells from people living with HIV (PLWH) and its *ex vivo* triggering enhances cell functionality: a possible target for immune reprogramming

A. Czernikier¹, L. Baquero¹, P. Benencio¹, A. Osegueda¹, J. Savarese¹, Y. Ghiglione¹, N. Laufer^{1,2}, M.F. Pascutti³, G. Turk¹

¹CONICET-Universidad de Buenos Aires. Instituto de Investigaciones Biomédicas en Retrovirus y Sida (INBIRS), Buenos Aires (CABA), Argentina, ²Hospital General de Agudos, Juan A. Fernández, Buenos Aires (CABA), Argentina, ³Leiden University Medical Center LUMC Building 1, Department of Immunology, Leiden, Netherlands

Background: A robust CD8⁺ T-cell (CD8TC) response is key for developing immunotherapies capable of achieving a sustained ART-free HIV remission. Glucocorticoid-induced TNF-related Protein (GITR) is a costimulatory receptor that, upon triggering, enhances the effector function of CD8TCs. However, little is known about the expression and function of this molecule in HIV infection. Here, we aimed to evaluate GITR expression and the effect of a novel GITR agonist on bulk and HIV-specific CD8TCs.

Methods: To characterize the immune-phenotype of GITR-expressing CD8TCs, peripheral blood mononuclear cells from 22 PLWH [on-ART (n=11), off-ART (n=11)] were stimulated with an HIV-peptide pool. Then, the surface expression of costimulatory molecules (GITR/41BB), exhaustion (PD-1) and memory markers (CD45RO/CCR7) were measured by flow cytometry. HIV-specific CD8TCs were defined by the expression of CD25/KI-67.

In addition, the data obtained were correlated with clinical parameters. To assess the GITR-mediated modulation of HIV-specific CD8TC function, cells from 6 on-ART PLWH were treated with a novel Fc-Flag-TNC-GITRL agonist, and IFN- γ production and degranulation (CD107a/b) were quantified by flow cytometry. When data distribution were not normal, non-parametric statistics were used.

Results: In both the on-ART and off-ART group, GITR expression was significantly higher on the HIV-specific CD8TCs compared to bulk CD8TCs ($p<0.001$).

In the off-ART group, a negative correlation was found between 41BB+/GITR+ HIV-specific CD8TCs and viral load (VL, $r=-0.523$, $p=0.024$). In both the on-ART and off-ART group, bulk PD1-expressing CD8+GITR+TCs positively correlated with an arrest in memory effector to terminal effector CD8TC differentiation ($r=0.550$ $p=0.018$ and $r=0.556$, $p=0.007$; respectively).

Finally, costimulation with GITR agonist at day four post-peptide stimulus led to a significant increase in the frequency of degranulating ($p=0.029$) and IFN- γ -producing ($p=0.031$) HIV-specific CD8TCs.

Conclusions: GITR was upregulated on HIV-specific CD8TCs and its expression pattern correlated with VL, suggesting a role of this molecule in the control of HIV infection. Moreover, GITR coexpression on exhausted CD8TCs and its association with CD8TC memory differen-

tiation arrest suggest that PD-1 and GITR could represent combined targets to revert this phenotype. Remarkably, findings indicate that costimulation through the GITR pathway enhances HIV-specific CD8TC functionality and, along with other immunomodulatory receptors, could act as a novel target for HIV immunotherapy.

MOPEA09

Patient-derived envelope sequences are differentially resistant to SERINC5-mediated restriction of HIV-1 infectivity

E. Nkuwi¹, G. P.Judicate^{1,2}, T. Seng Tan¹, G. Barabona¹, M. Toyoda¹, K. Matsumoto³, T. Kuwata³, S. Matsushita³, B. Sunguya^{4,5}, D. Kamori^{6,4}, T. Ueno^{1,4}

¹Kumamoto University, Division of Infection and Immunity, Joint Research Center for Human Retrovirus Infection, Kumamoto, Japan, ²National Institute for Medical Research, Muhimbili Medical Research Center, Dar es Salaam, Tanzania, United Republic of, ³Kumamoto University, Division of Clinical Retrovirology, Joint Research Center for Human Retrovirus Infection, Kumamoto, Japan, ⁴Kumamoto University, Collaboration Unit for Infection, Joint Research Center for Human Retrovirus Infection, Kumamoto, Japan, ⁵Muhimbili University of Health and Allied Sciences, Department of Community Health, Dar es Salaam, Tanzania, United Republic of, ⁶Muhimbili University of Health and Allied Sciences, Department of Microbiology and Immunology, Dar es Salaam, Tanzania, United Republic of

Background: The host protein SERINC5 restricts HIV-1 infectivity when incorporated into the nascent virions. Although Nef can abrogate this incorporation process, certain envelope sequence of laboratory strains can intrinsically resist SERINC5 restriction in the absence of Nef. However, it remains unclear what extent patient-derived envelope sequences resist it. We examined intrinsic properties of patient-derived envelope sequences that can modulate sensitivity to SERINC5.

Methods: We isolated a total of 75 envelope clones from 26 Japanese and 49 Tanzanians with HIV-1 infection, comprising of group M subtypes; A1, B, C, D and inter-subtypes recombinants. These clones were transfected to 293T cells with the nef-deficient HIV-1 proviral vector in the absence and the presence of SERINC5.

The resultant pseudoviruses were exposed to TZM-bl cells and the fold inhibition of virion infectivity by SERINC5 was determined.

Results: The pseudoviruses' infectivity was significantly reduced by the presence of SERINC5, with a median fold inhibition of 5.4 (IQR: 3.7-8.6), albeit lower compared to sensitive control, NL4-3 envelope (fold inhibition of 64.6). Subtype C envelopes exhibited least fold inhibition compared to other subtypes ($p=0.02$, Kruskal-Wallis test).

There was no correlation between the envelopes' sensitivity to SERINC5 and plasma viral load or recency of infection (all $p>0.1$, Spearman's correlation). Interestingly,

the five most SERINC5-sensitive (>20-fold inhibition) clones were also sensitive to antibodies targeting the MPER epitopes.

Moreover, domain swapping analysis of intra-host clones with diverse sensitivities revealed a context dependent modulation of SERINC5 sensitivity by the gp120 and gp41 subunits.

Conclusions: The HIV-1 envelope sequences of multiple subtypes derived from patients were relatively resistant to SERINC5-mediated restriction of infectivity, providing additional insights into viral evasion from host restriction factors.

MOPEA10

Structure and Immunogenicity of native-like HIV-1 Clade-C envelope trimers from a pediatric elite-neutralizer across diverse platforms

S. Singh¹, S. Kumar², A. Chatterjee³, S. Dutta³, K. Luthra¹, L. Malhotra⁴, E.A. Samath⁴

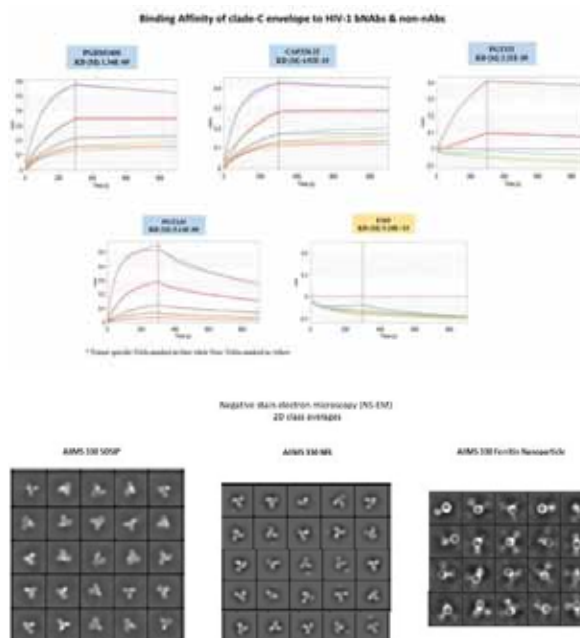

¹All India Institute of Medical Sciences, Biochemistry, New Delhi, India, ²International Center for Genetic Engineering and Biotechnology, New Delhi, India, ³ICGEB-Emory Vaccine Center, New Delhi, India, ⁴Indian Institute of Science, Bangalore, India, ⁵Molecular Biophysics Unit, Bangalore, India, ⁶All India Institute of Medical Sciences, Biophysics, New Delhi, India

Background: HIV-1-infected individuals that develop exceptionally strong broad neutralizing antibody (bNAbs) responses termed elite neutralizers (ENs), can inform HIV-1 vaccine design by providing blueprints for the induction of similar bNAb responses & can serve as templates for immunogen design. Clade-C accounts for the majority of HIV-1 infections worldwide, it is more challenging to produce well-ordered clade-C Env trimers due to their inherent instability.

Methods: Herein, we describe the design of native-like HIV-1 clade-C env trimers AIIMS 330 based on a chronically infected pediatric EN. The AIIMS 330 env was engineered and designed on SOSIP & NFL platforms along with the presentation of a repetitive array of env trimers on self-assembling ferritin nanoparticles (NPs) to attain multivalency.

Results: The cryo-EM structure demonstrated the formation of AIIMS 330 env in native-like prefusion closed conformations. It was correlated with a strong affinity to known HIV-1 bNAbs specifically to quaternary specific epitopes with little binding to non-nAbs rendering a superior antigenic profile of env. Biophysical characterization suggests high thermostability of env trimers.

Ferritin NPs and soluble SOSIP groups were able to elicit the potent neutralizing antibody response in rabbits over the NFL group with ID50 titers ranging from 300 to 1000 against autologous viruses along the tier-1 heterologous neutralizing responses. EM-PEM analysis of immune sera suggested the binding of multispecific nAbs both autologous and heterologous trimers.

Conclusions: Our study advances the understanding to shape conformationally stable clade-C env trimeric immunogens to induce a robust immune response and provide an arsenal of multivalent immunogens for HIV-1 vaccine development.

MOPEA11

Longitudinal profiling of immune responses to simian immunodeficiency virus throughout disease progression and antiretroviral treatment

S. Quinn^{1,2,3}, J. Ventura^{4,2}, S. Nguyen^{2,1,3}, D. Barouch^{4,2}, A. Shalek^{1,2,3,5}

¹Massachusetts Institute of Technology, Cambridge, United States, ²Ragon Institute of MGH, MIT, and Harvard, Cambridge, United States, ³Broad Institute of MIT and Harvard, Cambridge, United States, ⁴Beth Israel Deaconess Medical Center, Center for Virology and Vaccine Research, Boston, United States, ⁵Harvard Medical School, Immunology, Boston, United States

Background: Despite the fact that antiretroviral therapy (ART) has significantly reduced Human Immunodeficiency Virus (HIV)-associated deaths, its side effects and earlier onset of chronic illnesses continue to reduce quality of life for people living with HIV, suggesting the need for improved therapies.

However, this remains challenging due to the lack of a comprehensive understanding of the effects of viral progression and therapies on the immune system, particularly in the long term.

Methods: Using single-cell RNA-sequencing (scRNA-seq), we comprehensively characterized rhesus macaque (*Macaca mulatta*) immune responses during SIV (Simian Immunodeficiency Virus) disease and treatment, as well as viral transcripts. Peripheral Blood Mononuclear Cells (PBMCs) were analyzed from five rhesus macaques infected with SIVmac251 during acute and chronic phase of

infection (4 and 42 weeks post exposure) and short and long-term ART (12 and 72 weeks after ART initiation) using scRNA-seq to determine altered immune cell populations correlated to viral load and treatment longevity that may provide insights into improved therapeutic targets.

Results: Longitudinal comparisons of the transcriptomes of cells isolated from these samples showed an expansion of monocytes during acute infection that did not diminish to pre-infection levels at later time points, including after long term ART.

In addition, an enrichment of immune activation markers was observed during chronic infection, which may serve as targets for future studies interested in mediating immune response to high viraemia. Moreover, cells expressing viral RNA were also detected in both acute and chronic phase samples, predominantly in T cell populations.

Overall, our data highlight unreversed alterations to the immune system despite long-term ART and potential to simultaneously examine the host immune response and the phenotypes of infected cells.

Conclusions: The identification of expanding cell populations and upregulated immune activation markers further our understanding of the immune dysregulation that might underlie HIV infection and treatment, informing future therapeutic options aimed at improving quality of life for people living with HIV on long-term suppressive therapy.

The ability to identify virally infected cells while capturing host transcriptome additionally demonstrates a promising method for understanding dynamics specific to cells with viral transcripts.

TUPEA01

The impact of B cell activation on HIV-1 binding and *trans* infection of CD4⁺ T cells

A. Gerberick¹, N. Sluis-Cremer², G. Rappocciolo¹, C. Rinaldo²

¹University of Pittsburgh, Infectious Diseases and Microbiology, Pittsburgh, United States, ²University of Pittsburgh, Division of Infectious Diseases, Pittsburgh, United States

Background: Understanding the mechanisms by which the HIV-1 reservoir is established and maintained is critical in the search for a cure. We previously demonstrated that B cell-mediated HIV-1 *trans* infection of CD4⁺ T naïve cells has a more profound role than previously considered in establishing the viral reservoir (Gerberick et al., mBio 2021;12(2):e02998). In secondary lymphoid organs (SLO), B cells are activated in various ways, through both stromal cells and CD4⁺ T cell interactions, however the impact of these different stimulations on the efficiency of HIV-1 binding and *trans* infection remains unknown.

Methods: Human B cells and CD4⁺ T cells were isolated from buffy coats of HIVneg donors. B cells were stimulated alone or in combination with CD40L, BAFF, IL-4, and IFN-γ

for 48h. For *trans* infections, B cells were incubated with HIV-1_{BOL} (MOI 10⁻³), washed, and cultured with total CD4⁺ T cells. HIV-1 infection was determined by p24 ELISA. For HIV-1 uptake, B cells were incubated with HIV-1 Gag-iGFP-JRFL (MOI 10⁻¹), washed, and analyzed by FACS.

Results: B cells stimulated with CD40L/IL-4 were efficient mediators of HIV-1 *trans* infection of CD4⁺ T cells as compared to CD40L, CD40L/IFN-γ, BAFF, BAFF/IL-4, and BAFF/IFN-γ (one-way ANOVA, p<0.0001).

Using fluorescently labeled HIV-1, we show that CD40L/IL-4 stimulated B cells efficiently sequestered and bound virus compared to B cells treated with CD40L/IFN-γ, BAFF/IL-4, BAFF/IFN-γ or those that were unstimulated (one-way ANOVA, p=0.0116). Flow cytometry analysis highlights that the population of cells that take up virus are highly activated as evidenced by increased CD23 expression.

Ongoing studies include proteomic analyses of the stimulated cells to identify surface molecules associated with HIV-1 binding.

Conclusions: B cells are potentially important in the infection of CD4⁺ T cells *in vivo* via HIV-1 *trans* infection that occurs during the natural B:T cell interactions in SLO. Furthermore, certain immunologically relevant stimulations of B cells make these cells highly permissive to binding and transfer of HIV-1. Understanding the impact of B cell-mediated *trans* infection is fundamental for the design of effective treatments to significantly reduce or eliminate the viral reservoir.

The effects of HIV-1 antigen expanded specific T cell therapy (HXTc) and vorinostat on persistent HIV-1 in people living with HIV on antiretroviral therapy

C.L. Gay¹, P. Hanley², N. Archin¹, S.M. Pedersen¹, S.D. Falcinelli¹, S.L. Raines¹, R. Ke³, J.J. Eron¹, N. Goonetilleke⁴, C.M. Bollard², D.M. Margolis¹

¹UNC Chapel Hill, UNC HIV Cure Center, Department of Medicine, Chapel Hill, United States, ²Children's National Health System, Center for Cancer and Immunology Research, Washington, United States, ³Los Alamos National Laboratory, Theoretical Biology and Biophysics Group, MS-K710, Los Alamos, United States, ⁴UNC Chapel Hill, UNC HIV Cure Center, Department of Microbiology & Immunology, Chapel Hill, United States

Background: One approach to eradicate HIV is to interfere with mechanisms that maintain latency, and simultaneously enhance the clearance of infected cells without interrupting antiretroviral therapy (ART). The histone deacetylase (HDAC) inhibitor, vorinostat (VOR), can repeatedly induce the expression of latent HIV-1 *in vivo*, and allow clearance of infected cells *in vitro*.

However, when paired with HIV vaccines or antibodies, this approach has not yielded substantial depletion of the latent reservoir *in vivo*. Adoptive T cell therapy has had dramatic success in the treatment of virus-related malignancies.

nancies and infections following hematopoietic stem cell transplantation and has been adapted to produce ex-vivo expanded HIV-specific T cells (HXTCs), and other cell therapy products.

Methods: In this pilot study we administered VOR and HXTCs to antiretroviral (ART)-suppressed people with HIV (PWH). Six PWH received five infusions of 2×10^7 HXTCs/m² with VOR 400 mg every three days. Three PWH received five infusions of 10×10^7 HXTCs/m² with VOR. Leukapheresis was performed at baseline and after final HXTC infusion to measure the frequency of persistent HIV by Quantitative Viral Outgrowth Assay (QVOA) of resting CD4⁺ cells, cell-associated HIV RNA (rcaRNA), and intact HIV provirus assay (IPDA).

Results: Overall, PWH tolerated VOR and HXTCs, with only transient Grade 1 AEs related to study products. Biomarkers of serial VOR effect were detected in PBMCs, but evidence of enhanced antiviral activity in the total pool of circulating cells was not detected. One of 6 PWH exhibited a decrease in measures of persistent HIV after 2×10^7 HXTCs/m² infusions with VOR, and all three PWH exhibited such declines when 10×10^7 HXTCs/m² were given with VOR. However, most QVOA declines did not exceed 6-fold, a threshold required to definitively ($p > 0.05$) attribute QVOA decline to the study intervention, rather than assay variation.

Conclusions: These findings provide some support for the therapeutic strategy of HIV latency reversal and enhanced reservoir clearance, but the modest effects seen highlight the need for more effective latency reversal agents and clearance approaches that can be repeatedly employed to achieve the profound depletion of persistent HIV needed for clinical benefit.

Detection of intact HIV provirus in a microglia-enriched fraction of the CNS of a virally suppressed individual with HIV

M.M. Nühn¹, S.B. Gumbs¹, P.J. Schipper¹, L. Gharu¹, I. Drosou¹, N.V. Buchholtz¹, G.J. Snijders², F.A. Gigase², A.M. Wensing¹, J. Symons¹, L.D. de Witte², M. Nijhuis¹

¹University Medical Center Utrecht, Translational Virology, Department of Medical Microbiology, Utrecht, Netherlands, ²Icahn School of Medicine at Mount Sinai, Department of Psychiatry, New York, United States

Background: There is compelling evidence that the central nervous system (CNS) can function as a reservoir for HIV. HIV DNA has been detected in multiple CNS cells of virally suppressed individuals, of which the microglia are the major cellular reservoir. However, the question remains whether the detected HIV DNA is intact and capable of producing replication-competent virus.

Methods: Single-cell suspension was obtained post-mortem from three fresh human brain regions (frontal lobe, occipital lobe and the subventricular zone) of an individ-

ual on long-term suppressive antiretroviral therapy (ART). A microglia-enriched (CD11b⁺) and microglia-depleted (CD11b⁻) fraction was sorted from each region and examined for the presence of intact and defective provirus with the Intact Proviral DNA assay (IPDA). Full-length envelop reporter viruses were generated using HIV env sequences derived from the microglia-enriched and -depleted fractions. Co-receptor usage was predicted using the Geno2Pheno [coreceptor] algorithm.

Subsequently, these clones were phenotypically characterized in CD4⁺ T cells, primary microglia and monocyte-derived microglia (MDMs).

Results: Intact provirus represented 13% of the total provirus detected in the brain, and was more prevalent in the microglia-enriched (0.52%) than the microglia-depleted fraction (0.19%). In both microglia-enriched and microglia-depleted fractions, intact provirus was primarily found in the occipital lobe, whereas defective provirus was more prevalent in the frontal lobe.

Phenotypic characterization of the envelope reporter viruses revealed efficient viral entry and replication via the CCR5 HIV co-receptor in CD4⁺ T cells. False-positive rate (FPR) values ranged from 3.7 to 10.2 and supported CCR5 coreceptor tropism. Infection experiments in primary microglia and MDMs are ongoing.

Conclusions: This study provides evidence of intact provirus in microglia in different brain regions, but also within non-myeloid cells which may represent CNS resident CD4⁺ T cells or astrocytes. Moreover, we demonstrate that the viral envelope region of the viral sequences obtained from the microglia are replication competent in CD4⁺ T cells, and require CCR5 for viral entry.

Altogether, this points towards the presence of replication competent virus in the CNS which may fuel viral rebound upon ART interruption. This makes the CNS reservoir an essential component for the success of cure interventions.

HIV-1 infection: virus and host wrestle for control of the SUMOylation system

F. Imbert¹, C. Tice¹, Á. Garcia¹, N. Kalimuthusamy¹, D. Langford¹

¹Lewis Katz School of Medicine, Neural Sciences, Philadelphia, United States

Background: Microglia are the main HIV-1 target cells in the CNS and constitute an important reservoir for viral pathogenesis. In microglial cells, the co-repressor COUP-TF interacting protein 2 (CTIP2) recruits a multi-enzymatic chromatin-modifying complex at the HIV-1 promoter, leading to HIV-1 silencing.

Studies have shown that post-translational modifications (PTMs) like SUMOylation mediate CTIP2's interactions with other proteins and complexes. Whether HIV-1 manipulates the SUMO paralogs to control its replication and/or latency in glial cells like microglia is unclear.

We hypothesized that SUMOylation plays a role in productive HIV-1 infection, as well as, in the establishment and persistence of HIV-1 latency in microglia.

Methods: C20 cells were infected with vesicular stomatitis virus G (VSV-G) envelope pseudotyped HIV virus at a MOI of 0.25 and cultured for 72hrs. The latently infected cell line (HC69) was activated using tissue necrosis factor α (TNF- α), as previously described. Infection was confirmed by p24 ELISA and WB. Activation was confirmed using flow cytometry. Protein expression was assessed through immunofluorescence imaging and Western blot analysis.

Results: Here, we show that HIV-1 modulates the host cellular SUMOylation system. VSVG-pseudotyped HIV-1 infection in cultured C20 microglial cells impairs SUMO conjugation of both major SUMO paralogs, SUMO1 and SUMO2/3. Surprisingly, HIV-1 infection didn't appear to impair UBC9, the key SUMO E2 conjugating enzyme, which suggests HIV-1 likely targets other essential components of the host SUMOylation system, including the SUMO E1-activating enzyme, SUMO E3 ligases, and/or sentrin-specific proteases (SENPs).

Furthermore, the *host cellular SUMOylation system is impaired in latently infected HIV microglial cells*. Like productive HIV-1 infection both SUMO paralogs showed a modulation in SUMO conjugation following HIV-1 reactivation of the HC69 cell line. CTIP2 protein expression, which contributes to HIV-1 latency, was significantly higher in HIV-1 latency (HC69) compared to productive infection (C20).

Conclusions: Productive and latent HIV-1 infection in microglia was associated with impaired SUMOylation. Altering SUMO conjugation might be involved in abnormal anti-viral mechanisms in the CNS, leading to inflammation and neurocognitive impairment. The host SUMOylation machinery might represent potential targets of viral reservoirs in the CNS.

Emergence of genetically-distinct HIV-1 populations is associated with transient virological control during analytical interruption of antiretroviral therapy

K. Fisher^{1,2}, J.-S. Eden^{1,2}, E. Lee¹, G. Duetter¹, S.G. Deeks³, A.D. Kelleher⁴, S. Palmer^{1,2}

¹Westmead Institute for Medical Research, Centre for Virus Research, Westmead, Australia, ²University of Sydney, Sydney Medical School, Sydney, Australia, ³University of California San Francisco, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States, ⁴Kirby Institute, University of New South Wales, Sydney, Australia

Background: Understanding the mechanisms behind transient control of viral rebound (TCVR) following antiretroviral therapy (ART) interruption may reveal strategies to achieve an HIV-1 functional cure. Genetically-characterising rebound viruses during analytical treatment interruptions (ATI) could identify virus-related mechanisms behind this delayed viral rebound.

Methods: We obtained plasma samples from five participants (P1-P5) who initiated ART in acute/early infection, continued ART for 1 year, and underwent three successive ATIs over the course of the following year. Three participants were non-controllers with immediate rebound during the ATIs. Two participants exhibited TCVR during later phases of ART interruption. We used the plasma-derived HIV-1 RNA using long-range sequencing (PRLS) assay to genetically-characterise HIV-1 genomes from the pre-ART and ATI timepoints.

Maximum likelihood phylogenies and a tree-based compartmentalisation test (Bayesian Tip-association Significance Testing; BaTS) were used to identify phylogenetic clustering patterns of viral genomes across all timepoints. The presence of cytotoxic T lymphocyte (CTL) and drug-resistance mutations was also assessed.

Results: For non-controllers, we found little evidence for compartmentalisation between the pre-ART and ATI timepoints. For P4 and P5, who exhibited TCVR, we observed that the HIV-1 genomes were genetically-distinct during the ATI timepoints where rebound (R) was delayed. For P4, where rebound was delayed during the second (R2) and third (R3) ATI, there was strong evidence for compartmentalisation within the pre-ART ($p=0.001$) and first ATI (R1: $p=0.001$) timepoints, indicating that sequences from these timepoints are genetically-distinct from each other and from the R2/R3 timepoints.

The R2/R3 timepoint sequences were genetically-similar, with weak evidence for compartmentalisation within these timepoints (R2: $p=0.08$; R3: $p=0.03$). For P5, we observed strong evidence that the virus identified during R3, where rebound was delayed, is genetically-distinct to all earlier timepoints ($p=0.001$). No known CTL-escape or drug-resistance mutations emerged during the ATI timepoints for P4 and P5.

Conclusions: For two participants, we found plasma-derived viral genomes were genetically-distinct during the ATI timepoints where a delay to viral rebound was observed. The emergence of these distinct viral variants during an ATI may be associated with transient virological control. This viral control is not attributed to impaired viral replication caused by known CTL-escape or drug-resistance mutations.

The Rainbow 5-plex digital PCR assay improves quantification of the viral reservoir resulting in a better understanding of the HIV-1 proviral landscape

M. Delporte¹, L. Lambrechts¹, M. Pardons¹, S. De Braekeleer¹, E. Blomme¹, S. Rutsaert¹, W. Trypsteen¹, L. Vandekerckhove^{1,2}

¹HIV Cure Research Center (Ghent University), Ghent, Belgium, ²Ghent University Hospital, Ghent, Belgium

Background: The Intact Proviral DNA assay (IPDA) is considered as the gold standard to quantify the intact viral reservoir in people living with HIV-1 (PLHIV) that are treated with antiretroviral therapy (ART). By amplifying two short HIV-1 sub-genomic regions that are often deleted and/or hypermutated (psi and env), covering only 2.4% of the HIV-1 genome, this assay might overestimate the intact viral reservoir size.

Therefore, we developed the Rainbow 5-plex digital PCR assay that quantifies both the total and intact HIV-1 reservoir by targeting simultaneously 5 HIV-1 sub-genomic regions.

Methods: The Rainbow 5-plex digital PCR assay was used to quantify: a) total HIV-1 DNA (RU5), b) intact HIV-1 DNA, using either 2 regions (psi/env) or 4 regions (psi/env/gag/pol) (n = six chronic ART-suppressed PLHIV; subtype B) on the QiaCuity Four 5-plex platform, with each primer/probe set linked to a different fluorescent probe. Near full-length sequences (NFL) from the same individuals were obtained using the HIV Proviral UMI-mediated long-read sequencing (HIV-PULSE) assay.

Results: An average of 1926 total HIV-1 DNA cp/million CD4+ T cells was measured using the Rainbow assay. When considering 2 versus 4 sub-genomic regions, an average of 207.8 and 176.0 intact HIV-1 DNA cp/million CD4+ T cells were quantified, respectively.

Mapping the respective primers/probe sets from the Rainbow assay against the 510 distinct proviral genomes obtained by HIV-PULSE, we observed that some defective proviruses would be classified as intact in 5/6 participants by the 2-plex dPCR and in 3/6 participants by the 4-plex dPCR. In fact, 3 distinct sequences with frameshifts would be classified as intact by dPCR (either focusing on 2 or 4 regions).

Additionally, 3 distinct sequences harboring inversions or large deletions in the gag/pol region would be considered as intact in the original 2-plex dPCR when correctly identified as defective in the 4-plex dPCR.

Conclusions: Increasing the genomic coverage by including additional sub-genomic regions in dPCR assays provides a closer estimate of the intact proviral reservoir. Indeed, the identification of NFL proviruses with inversions or deletions in the gag/pol regions justifies the design of the Rainbow assay.

TUPEA07

Linking inducible HIV-1 reservoir to rebound after treatment interruption

L. Lambrechts¹, Y. Noppe¹, M. Pardons¹, B. Cole¹, S. Rutsaert¹, S. De Wit², G. Vanham³, E. Florence³, L. Vandekerckhove¹

¹Ghent University, Department of Internal Medicine & Pediatrics, Ghent, Belgium, ²Saint Pierre University Hospital, Brussels, Belgium, ³Institute of Tropical Medicine, Antwerp, Belgium

Background: The origin of viral rebound remains elusive as only a few links between proviral sequences and rebound plasma viruses have been described. Here we characterized the translation- and replication-competent reservoirs of three individuals under ART and compared it to rebound plasma viruses detected during analytical treatment interruption (ATI).

Methods: Peripheral blood CD4 T cells were collected from 3 ART-treated individuals right before ATI. P24-expressing cells were single-cell sorted following latency reversal and near full-length proviral sequencing was performed. Replication-competent viral sequences were isolated from supernatant of positive quantitative viral outgrowth assay (qVOA) wells. During ATI, plasma was collected at first detectable viral load (>1000 copies/mL) and either 5'- or 3'-half viral RNA genomes were isolated through single genome amplification.

Results: We retrieved 20 sequences from positive qVOA wells, 30 proviral genomes from p24+ cells, 89 (median=32) 5'-half and 94 (median=32) 3'-half rebound plasma sequences acquired during ATI. Among distinct sequences retrieved from p24+ cells, 88% displayed defects in the packaging signal (PSI) region and/or major splice donor (MSD) site. Among qVOA and rebound sequences, none had PSI/MSD defects, suggesting their minor role in viral rebound and replication. One overlap between the translation- and replication-competent reservoir was observed, notably between the only p24+ cell with an intact PSI/MSD and one genome-intact qVOA sequence. Moreover, two overlaps were observed between viruses from qVOA wells and 5'-half rebound plasma sequences.

Conclusions: The direct origin of rebounding plasma virus remains hard to identify as only few overlaps were detected by comparing the translation and replication-competent fractions to plasma viruses collected during ATI, with no overlap between the three datasets.

Yet, we report an overlap between an intact qVOA sequence and a provirus from a p24-expressing cell, confirming that some of the translation-competent proviruses are capable of inducing new cycles of replication.

Potent, HIV-specific latency reversal through CRISPR activation delivered by lipid nanoparticles exhibiting a high efficiency of transfecting resting CD4⁺ T cells with minimal toxicity

P.M. Ceva¹, S. Kan², A. Tan², M. Holz¹, D.L. Furtado³, D. Purcell¹, A. Johnston⁴, C. Pouton⁴, T. Payne⁴, W. Zhao², F. Caruso³, J. Symons^{2,5}, M. Roche², S.R. Lewin^{2,6,7}

¹The University of Melbourne at The Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia,

²The University of Melbourne at The Peter Doherty Institute for Infection and Immunity, Department of Infectious Diseases, Melbourne, Australia, ³The University of Melbourne, Department of Chemical Engineering, Melbourne, Australia, ⁴Monash Institute of Pharmaceutical Sciences, Monash University, Melbourne, Australia, ⁵University Medical Center, Translational Virology, Department of Medical Microbiology, Utrecht, Netherlands, ⁶Royal Melbourne Hospital at The Peter Doherty Institute for Infection and Immunity, Victorian Infectious Diseases Service, Melbourne, Australia, ⁷Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia

Background: Activation of HIV transcription through LTR-targeted CRISPR activation (CRISPRa) provides a promising strategy of potentially reversing HIV latency without affecting host-cell transcription. However, the advancement of this novel latency-reversing agent is hampered by the lack of an efficient delivery vehicle for the CRISPRa machinery to resting CD4⁺ T cells.

We hypothesized that mRNA-lipid nanoparticles (LNPs) could be used to advance CRISPRa as a next-generation latency-reversing agent.

Methods: Fluorescently labelled standard and modified LNPs encapsulating reporter mCherry mRNA (mCherry-LNP) or co-encapsulating the dCas9-SAM system – dCas9-VP64 mRNA, MS2-p65-HSF1 mRNA and either LTR-targeting or non-targeting control guideRNA (CRISPRa-LNP) – were formulated through microfluidic mixing. RNA concentration and encapsulation efficiency were determined using a RiboGreen assay.

Transfection efficiency of mCherry-LNPs and viability were assessed in Jurkat cells, non-stimulated or 72h αCD3/αCD28 pre-stimulated primary CD4⁺ T cells from HIV-negative donors using flow cytometry.

Reactivation of LTR-mediated transcription through CRISPRa-LNPs was assessed in J-Lat LTR-Tat-IRES-GFP reporter cells using flow cytometry.

Results: LNPs were formulated reproducibly at sub-100 nm size and exhibited RNA encapsulation efficiencies of >90%. Standard mCherry-LNPs exhibited high transfection efficiency within 24h in Jurkat cells (99%) at <5% toxicity. Transfection efficiency of pre-stimulated CD4⁺ T cells was moderate (mean±SEM mCherry⁺ cells 29±5%) but toxic (43±5% viability) after 72h.

In non-stimulated cells, few cells were transfected (2±0.3%) with lower toxicity (68±8% viability), which coincided with a 20-fold reduction in LNP association. In contrast, transfection of non-stimulated CD4⁺ T cells with modified LNPs resulted in a striking 92±2% efficiency at minimal toxicity (88±3% viability) within 72h.

Similarly, treatment with modified but not standard CRISPRa-LNPs induced potent LTR-mediated transcription with all five targeting guideRNAs, reaching up to 76±13% GFP⁺ J-Lat cells compared with 0.89±0.1% using non-targeting guideRNA, both at viabilities >90%.

Conclusions: We developed a novel LNP formulation capable of delivering nucleic acid-based therapeutics to resting CD4⁺ T cells. The three-component dCas9-SAM CRISPR activation system can be co-encapsulated into one LNP and can induce strong latency reversal in a cell line model for HIV latency.

These results provide compelling justification for the further assessment of CRISPRa-LNP as a 'shock and kill' strategy.

Characterization of the intact and defective HIV-1 subtype C reservoir in South African women and men at baseline and 96 weeks after ART-therapy

N.V. Buchholtz¹, L.E. Hermans², C. Ummakwe², N.A. Kootstra³, D. de Jong¹, J. Symons¹, H.A. Tempelman², A.M. Wensing^{1,4}, M. Nijhuis^{1,5}

¹University Medical Center Utrecht, Translational Virology, Department of Medical Microbiology, Utrecht, Netherlands, ²Ndlovu Medical Center, Research Department, Elandsdoorn, South Africa, ³Amsterdam UMC, Amsterdam Infection and Immunity Institute, Department of Medical Microbiology, Amsterdam, Netherlands, ⁴University of the Witwatersrand, Ezinhsa, Faculty of Health Sciences, Johannesburg, South Africa, ⁵University of Witwatersrand, HIV Pathogenesis Research Unit, Faculty of Health Sciences, Johannesburg, South Africa

Background: To increase equity in HIV cure strategies it is important to study the viral dynamics and reservoir size of the dominant HIV-1 subtype (C) in women and men. The major obstacle to cure is the proviral reservoir. Aim of this study was to investigate impact of time of presentation and gender on immune activation, size and activity of the intact and defective reservoir in people with HIV before and during 96 weeks of antiretroviral therapy (ART).

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor

Methods: 83 participants were included (63% female). Median CD4-count at ART initiation was 315 cells/mm³ and viral load (VL) 169,659 copies/mL. Baseline, 48, and 96 week PBMCs were collected for Intact Proviral DNA Assay (IPDA) (in house adjusted for subtype C) and msRNA to measure reservoir activity. Plasma was used for cytokine analysis.

Results: During treatment, a significant decrease of both reservoirs and msRNA was detected ($p < 0.001$). The decrease of the intact compared to the defective reservoir was significantly more profound after 96 weeks of therapy ($p < 0.001$). msRNA and CD4 were significantly, positive, and inverse correlated respectively, with defective but not with intact provirus at baseline ($p < 0.001$ - $p < 0.05$).

Furthermore, baseline VL was significantly correlated with the intact and defective reservoir, but at 48 and 96 weeks after therapy only the defective reservoir showed a significant correlation ($p < 0.001$ - $p < 0.05$).

MCP1, sCD163 and sCD14 significantly decrease after 48 weeks, IL7 and TNF- α show a continuous decline during 96 weeks ($p < 0.001$). IL2 significantly increases between baseline and 96 weeks ($p < 0.05$).

Conclusions: A more pronounced decline of the intact reservoir was seen at 96 weeks after therapy. Interestingly, levels of msRNA correlate with the large defective viral reservoir rather than the smaller intact reservoir suggesting that the defective reservoir actively produces viral transcripts.

Also, the inverse significant correlation with CD4 cells could indicate that the defective reservoir is one of the drivers of CD4 depletion. Moreover, the significant correlation between the defective reservoir and plasma viral load during therapy could indicate an influence of the defective reservoir to low level viraemia during therapy. Therefore, besides elimination of the intact reservoir removal of the defective reservoir may be important to reduce HIV associated co-morbidities.

Methylseleninic acid induces HIV viral reactivation from latently infected cells *in vitro* and *ex vivo*

R. Shepherd¹, J. Stern^{1,2}, J. Zerbato³, C. Tumpach¹, A. Solomon¹, Y. Kim¹, S. Lewin^{1,3,4}, M. Roche^{1,5}

¹University of Melbourne/The Peter Doherty Institute for Infection and Immunity, Department of Infectious Disease, Melbourne, Australia, ²University of Melbourne/The Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ³Royal Melbourne Hospital, Victorian Infectious Disease Service, Melbourne, Australia, ⁴Monash University/Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia, ⁵Royal Melbourne Institute of Technology (RMIT), School of Health and Biomedical Sciences, Melbourne, Australia

Background: We have previously shown that the circadian proteins CLOCK and BMAL-1 can bind to the HIV long terminal repeat and activate HIV transcription (Chang et al AIDS 2019). As the organic selenium compound Methylseleninic acid (MSA) increases BMAL-1 transcription and enhances apoptosis in cancer models, we investigated MSA as a latency reversing agent (LRA) and whether MSA enhances death of HIV-infected cells alone or combined with other putative LRAs.

Methods: Latent cell lines containing an integrated HIV provirus with a green fluorescent protein (GFP) reporter (J-LAT10.6), and CD4+ T-cells isolated from peripheral blood mononuclear cells from people living with HIV (PL-HIV) on antiretroviral therapy were cultured with 10uM MSA. Viral reactivation was measured by GFP expression or cell-associated unspliced (US) and multiply spliced (MS) HIV RNA in CD4+ T-cells.

Surface expression of activation markers CD38 and CD69 were quantified by flow cytometry. RNA sequencing was performed on MSA-treated CD4+ T-cells isolated from PL-HIV on ART. Synergy with LRAs was measured by Bliss Independence (BI).

Results: MSA potently induced HIV protein in J-LAT10.6 cells (23.12-fold increase in GFP expression cf. unstimulated cells, $p < 0.001$). In CD4+ T-cells from PLHIV MSA induced US HIV RNA (4.4-9 fold-increase $p = 0.016$) but not MS RNA; increased CD69 expression (6.8-52.5 fold-increase, $p = 0.016$) and decreased CD38 expression (4.21-39.6 fold-decrease, $p = 0.016$); RNA sequencing revealed that MSA significantly upregulated pro-apoptotic genes (SMAC, BIM, BAK1) and downregulated anti-apoptotic genes (XIAP, BCL2).

In J-LAT10.6 cells, MSA significantly synergised with the bromodomain inhibitor, JQ1 (BI = 0.09, $p = 0.0418$) and SMAC mimetic, AZD5582 (BI = 0.5, $p = 0.0109$) in the induction of GFP.

Conclusions: MSA increased HIV transcription and translation in latently infected cell lines, as well as initiating viral transcription in primary cells from PLHIV in the absence of sustained T-cell activation. Synergy was observed with MSA and LRAs with diverse mechanisms of action.

Although there was an increase in pro-apoptotic genes, we were unable to determine if this was in all cells or only in HIV-infected cells. MSA potentially reverses latency and may sensitise latently infected cells to apoptosis, showing promise as a dual 'shock and kill' LRA.

TUPEA11

DPP9 inhibitors: a novel class of drugs for clearance of HIV-1 infected cells

K. Clark¹, J. Kim¹, Q. Wang¹, H. Gao¹, R. Presti¹, L. Shan¹

¹Washington University in St. Louis, Infectious Disease, St. Louis, United States

Background: NNRTIs induce targeted cell death of HIV-1 infected cells. We recently reported that this mechanism of cell killing occurs through sensing of HIV-1 protease via the inflammasome sensor CARD8. Due to issues with NNRTI resistance and poor pharmacodynamics, it's essential to identify ways to sensitize the CARD8 inflammasome for sensing HIV-1 protease.

Here we employ chemical inhibitors to block the negative regulator of CARD8, DPP9, to increase NNRTI-mediated killing of HIV-1 infected cells.

Methods: CD4⁺ T cells were isolated from people without HIV, infected with reporter viruses or clinical HIV-1 isolates, and treated with NNRTIs and/or DPP9 inhibitors. Cells were cultured in human serum to identify reductions in efficacy. For in vivo clearance of HIV-1 infected cells, infected CD4⁺ T cells were transfused into MISTRG-6-15 mice and treated with EFV and/or VbP. For HIV latent reservoir clearance, CD4⁺ T cells were isolated from PLWH, plated in limiting dilution for quantitative viral outgrowth assay, and treated with NVP, EFV, or EFV with VbP.

Results: As high micromolar concentrations of NNRTIs are needed for effective clearance of HIV-1 infected cells, we tested DPP9 inhibitors' ability to enhance NNRTI-mediated killing. The DPP9 inhibitor Val-boroPro was able to enhance NNRTI-mediated killing and induced NNRTI-independent cell killing. While human serum reduced NNRTI efficacy, VbP completely restored the EC50 of NNRTIs tested. VbP also increased the killing efficacy of most resistance mutants tested. While EFV had modest effects in vivo, VbP was able to greatly increase cell killing of HIV-1 infected cells in humanized mice eliminating up to ~68% of infected cells. VbP was also able to significantly increase clearance of HIV-1 latent reservoirs from PLWH, eliminating 75% of latent reservoirs.

Conclusions: Here we report a novel class of drugs for potential development of an HIV cure strategy. We show the capacity of this strategy to clear HIV-1 infected cells in vitro, ex vivo, and in vivo.

We also demonstrate this strategy can overcome considerable barriers to clinical implementation proving the broad suitability of this method for the existing genetic variation seen in PLWH. This offers a promising new strategy for putting the kill in "shock and kill".

TUPEA12

Pre-existing immunity restricts plasma and mucosal antibody responses during SARS-CoV-2 Omicron breakthrough infection

A. Chung¹, K. John Selva¹, P. Ramanathan¹, E. Haycroft¹, A. Reynaldi², D. Cromer², L. Downie³, S. Davis¹, R. Purcell¹, H. Kent¹, J. Juno¹, M. Davenport², S. Kent¹

¹University of Melbourne, Doherty Institute, Department of Microbiology and Immunology, Melbourne, Australia, ²Kirby Institute, Kensington, Australia, ³University of Melbourne, Department of Optometry and Vision Sciences, Melbourne, Australia

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the causative agent of COVID-19 disease, remains a challenge to global public health. Antibodies can mediate protection through neutralisation and Fc-mediated functions.

Understanding mucosal antibody responses from COVID-19 infection and/or SARS-CoV-2 vaccination is crucial for the development of new vaccine strategies to generate long term protective immunity against SARS-CoV-2, especially against emerging viral variants.

Methods: We developed a suite of high throughput antibody assays capable of assessing neutralization and the Fc profiles (isotype, subclass, Fc Receptor binding) to an extensive panel of SARS-CoV-2 proteins including variants of concern.

Antibody responses from paired plasma and mucosal (saliva and basal tears, where sufficient volume was available) samples were profiled from 37 COVID-19 vaccinees (vaccinated, uninfected), 22 COVID-19 recovered individuals (infected then vaccinated) and 29 individuals with breakthrough infections (vaccinated then infected) from 3 different COVID-19 waves (Delta, Omicron BA.1 and BA.2).

Results: Saliva from COVID-19 recovered vaccinees displayed improved antibody neutralizing activity, Fc Receptor engagement and IgA over COVID-19 vaccinees. Repeated ancestral spike vaccination narrowed antibody cross-reactivity in COVID-19 recovered vaccinees as vaccine-induced responses favored the imprinted ancestral spike.

Furthermore repeated mRNA vaccination also boosted SARS-CoV2-specific IgG2 and IgG4 responses in both plasma and mucosa (saliva and tears). Antibody responses to breakthrough COVID-19 were also dampened and narrowed to the ancestral strain by increased pre-existing vaccine-induced immunity.

However, despite a more delayed start compared to plasma, salivary antibodies rose rapidly following breakthrough COVID-19, especially following Omicron BA.2 infection.

Conclusions: Our data demonstrates how prior antigen exposure, including number of vaccine doses and/or prior SARS-CoV-2 infection, along with vaccine platform can influence SARS-CoV-2 antibody responses.

Furthermore we highlight how pre-existing immunity shapes both plasma and mucosal SARS-CoV-2-specific antibody responses, which has implications for long term protection from COVID-19.

TUPEA13

Immunological profiles of people living with HIV admitted with acute COVID-19 in Tshwane, South Africa

M.A. van der Mescht¹, Z. de Beer^{1,2}, H.C. Steel¹,
T. Moyo-Gwete^{3,4}, S.I Richardson^{3,4}, P.L Moore^{3,4,5,6,7},

¹University of Pretoria, Immunology, Pretoria, South Africa, ²Tshwane District Hospital, Pretoria, South Africa, ³National Institute for Communicable Diseases, Johannesburg, South Africa, ⁴SAMRC Antibody Immunity Research Unit, Johannesburg, South Africa, ⁵DSI/NRF, Johannesburg, South Africa, ⁶CAPRISA, Berea, South Africa, ⁷Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, ⁸Steve Biko Academic Hospital, Pretoria, South Africa

Background: South Africa has the largest population of PLWH in the world, reporting a prevalence of 18.7% in adults in 2020. PLWH could have worse COVID-19 outcomes due to persistent immune deficiency and dysregulation. This study compared the immunological profiles and clinical outcomes of people living with and without (HIV-) admitted with COVID-19 to hospitals in Tshwane, South Africa.

Methods: In total, 174 SARS-CoV-2 PCR-positive clients with moderate to severe COVID-19 were recruited from April 2020 to November 2021. Whole blood samples were obtained on the first day of hospitalization and T-cell and monocyte phenotyping performed on a CytoFlex flow cytometer.

Data clean up and scaling were done in Kaluza and uploaded to Cytobank for analysis. Cytokine levels were determined in plasma on a Bio-Plex Suspension Array platform.

Results: Thirty-seven clients were PLWH. Median CD4+ T-cell count: 256 (IQR 115-388) cells/ μ L; HIV viral load was suppressed in 76%. They were younger (46 ± 10.9 vs 55 ± 14.4 years $p=0.0064$), more likely to be female (73% vs 42.3% $p=0.0013$) and had higher ROX scores (15.3 [IQR 8.2- 22.1] vs 9.6 ([IQR 4.6-11.4] $p=0.0031$) than HIV- clients. Mortality was similar between the groups: 15.4% vs 13.5% in PLWH ($p=0.7864$).

After adjusting for age and sex, PLWH had increased non-classical ($p=0.0014$) and activated ($p=0.0045$) monocytes as well as the highest expression of PD-L1 ($p=0.0168$).

Differences in CD8+ were: lower effector memory (EM)-1 ($p=0.0127$) and exhausted TEMRA ($p=0.0284$), higher EM-2 ($p=0.0123$), activated central memory ($p=0.0001$), and pre-effector-1 ($p=0.0427$) subsets in PLWH. PLWH had increased concentrations of IL-1Ra ($p=0.0096$), IL-2 ($p=0.0173$), and IL-15 ($p=0.0217$).

Conclusions: PLWH hospitalized with COVID-19 had less severe disease, possibly due to lower levels of inflammation secondary to skewed monocyte subset ratios and CD8+ T-cell maturation, and higher levels of anti-inflammatory and immunoregulatory cytokines.

The interaction of PD-L1 and PD1 promotes immune suppression. HIV predominantly induces IL-1Ra over IL-1 synthesis that drives hyperinflammation in COVID-19. IL-2 and IL-15 both aid in T-cell responses and modulate inflammation by respectively activating and promoting the survival of T-regulatory cells. It is possible that the immune dysregulation seen in HIV could inhibit the hyperinflammatory immune response caused by SARS-CoV-2.

Track B: Clinical science

MOPEB01

Rapid two-phase decay of intact and defective HIV DNA during acute treated HIV infection, which is accelerated with earlier ART initiation

L. Shi¹, R. Hoh², H. Hartig², V. Pae², S. Sarvadhavabhatla², S. Donaire², G. Laird³, M. Peluso¹, J. Martin², F. Hecht², C. Pilcher², T. Henrich², J. Wang¹, H. Hatano², S. Deeks², S. Lee²

¹University of California Berkeley, Biostatistics, Berkeley, United States, ²University of California San Francisco, Medicine, San Francisco, United States, ³AcceleVirDx, Baltimore, United States

Background: The HIV reservoir largely consists of "defective" virus. Several studies now suggest that HIV+ cells harboring "intact" (i.e., potentially replication-competent) provirus decay faster than defective provirus during long-term antiretroviral therapy (ART) suppression. However, there are limited data describing HIV reservoir decay rates during the first few months of treated acute HIV.

Methods: Individuals diagnosed with acute (<100 days) HIV were enrolled in the UCSF Treat Acute HIV study between 2015-2020. Participants were initiated on ART (tenofovir/emtricitabine+dolutegravir) and followed for 24+ weeks. Frequencies of intact vs. defective provirus were quantified using the intact proviral DNA assay (IPDA). Multivariate nonlinear general additive models included covariates for timing of ART initiation, initial CD4+ count, and pre-ART HIV RNA.

Results: A total of 67 (83% of screened) participants were enrolled. The proportions of Fiebig I, II, III, IV, V disease were 12%, 15%, 8%, 17%, and 48%. Median age was 30. The cohort was 98% male; 15% African-American, 30% Latino, 21% Asian, 33% Caucasian. Higher initial CD4+ T cell count (Figure 1a) and lower pre-ART plasma HIV RNA (Figure 1b) predicted more rapid decay of defective and intact HIV DNA. Plasma HIV RNA declined to <40 copies/mL after a median of 31 days of ART. Both intact and defective provirus decayed rapidly in the first 50 days (3.6% vs. 4.3%), followed by a slower decay after 50 days (1.1% vs. 1.8%). Earlier ART initiation (Fiebig I-III) was associated with steeper declines in both intact and defective HIV DNA (Figure 1c). For each day delay in ART initiation, intact and defective HIV DNA decreased by 0.02% vs. 0.03% in the first 50 days and by 0.006% vs. 0.01% after 50 days of ART suppression.

Conclusions: We observed a two-phase decay of intact and defective HIV DNA that was significantly faster for individuals with earlier ART initiation. Decay rates were accelerated with earlier ART initiation.

These findings may reflect virologic (rapid decay after plasma viremia suppression) and/or immunologic (contraction of activated cells to memory cells) phenomena in individuals with very small reservoirs and relatively intact immune responses, which can be leveraged in future cure strategies.

Missed opportunities with symptom-based testing of chlamydia and gonorrhea among men who have sex with men and transgender women attending key population-led clinics in Thailand

N. Thammajaruk¹, S. Thongsuksangcharoen¹, S. Suriwong¹, K. Termvanich¹, A. Phunkron², T. Sangpasert³, T. Pasansai⁴, P. Brutrat⁵, M. Avery⁶, S. Mills⁶, P. Phanuphak¹, N. Phanuphak¹

¹Institute of HIV Research and Innovation (IHRI), Bangkok, Thailand, ²The Service Workers In Group Foundation, Bangkok, Thailand, ³Rainbow Sky Association of Thailand, Bangkok, Thailand, ⁴Mplus Foundation, Chiang Mai, Thailand, ⁵The Service Workers In Group Foundation, Chonburi, Thailand, ⁶FHI 360, Bangkok, Thailand

Background: Many resource-limited settings, including Thailand, have implemented symptom-based screening for *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoeae* (NG). Asymptomatic anorectal and oropharyngeal CT and NG infections limit the usefulness of this practice.

We studied the proportions of CT and NG infections which would be missed if symptom-based screening was implemented among men who have sex with men (MSM) and transgender women (TGW) attending key population (KP)-led clinics for HIV testing and pre-exposure prophylaxis (PrEP) services.

Methods: From July 2020 to September 2021, Thai MSM and TGW aged ≥18 years, with at least one reported HIV risk in the past six months (condomless sex, >5 sexual partners, history of bacterial sexually transmitted infections (STIs), and/or substance use), were enrolled at KP-led clinics and followed up every 3 months for 12 months. STI symptoms were recorded at every visit before specimen collections. Pooled urine, pharyngeal, and rectal samples from each participant were obtained for molecular Xpert CT/NG tests.

Results: We enrolled 1,427 MSM and 138 TGW with a median (IQR) age of 28 (23-34) years. 196 were HIV-positive, 892 started/continued PrEP and 477 refused PrEP. CT was detected in 526/4,074 (12.9%) visits and NG in 359/4,074 (8.8%) visits.

STI symptoms were only reported in 23/526 CT-positive visits (4.4%) and in 15/359 NG-positive visits (4.2%). Urethral symptoms were most common (82.6%), followed by rectal (13.0%), and oropharyngeal (4.4%) symptoms among symptomatic CT infections.

For symptomatic NG infections, symptoms most commonly appeared at the urethra (86.7%), followed by oropharynx (13.3%), and rectum (6.7%). STI symptoms were also reported in 21/3,548 CT-negative visits (0.6%) and in 29/3,715 NG-negative visits (0.8%).

Conclusions: Among MSM and TGW clients of KP-led clinics in Thailand, those exposed to high risk of STIs, CT and NG infections were detected by molecular test in around 10% of their clinic visits. Symptoms were only presented in less than 5% of these CT and NG infections. Use of symptom-based screening would result in 95% missed diagnoses.

Integrating regular STI testing, regardless of symptoms, into these KP-led clinics has high potential as an entry point for STI test and treat strategy aiming at ending STIs by 2030.

MOPEB03

Safety and efficacy of 6-month rifampicin resistant TB regimens in people living with HIV: final analysis

C. Berry¹, M. Dodd², K. Fielding², I. Motta¹, E. Kazounis¹, M. Rassoool³, S. Rajaram³, V. Solodovnikova⁴, R. Moodliar⁵, N. Parpieva⁶, I. Liverko⁶, Z. Tigay⁷, B.-T. Nyang'wa⁸
¹Medecins Sans Frontieres, London, United Kingdom,
²London School of Hygiene and Tropical Medicine, London, United Kingdom, ³Wits Health Consortium, Johannesburg, South Africa, ⁴Republican Scientific and Practical Center for Pulmonology and Tuberculosis, Minsk, Belarus, ⁵THINK TB and HIV Investigative Network, Durban, South Africa, ⁶Republican Specialized Scientific and Practical Medical Center of Phthisiology and Pulmonology, Tashkent, Uzbekistan, ⁷Republican Phthisiological Hospital No. 2, Nukus, Uzbekistan, ⁸Medecins Sans Frontieres, Amsterdam, Netherlands

Background: 6-month regimens for rifampicin resistant tuberculosis (RR-TB) have been recommended by the WHO. People living with HIV (PLHIV) have poorer TB treatment outcomes. In an interim analysis, PLHIV had similar outcomes in both standard care (SoC) and bedaquiline, pretomanid, linezolid and moxifloxacin (BPaLM) arm with a better safety profile in the BPaLM arm.

Methods: Participants with RR-TB were recruited from Uzbekistan, Belarus and South Africa irrespective of HIV status. Participants with negative or unknown HIV status were offered testing. Antiretroviral treatment was offered to all PLHIV. The HIV status subgroup was analysed at week 72 for both efficacy (unfavourable outcome being composite of death, recurrence, treatment failure, early discontinuation and loss-to-follow up) and safety (grade 3 and above/SAE) in the modified intention-to-treat and intention-to-treat populations respectively.

Results: Of the 550 participants in the intention-to-treat population, 153 (27.8%) were HIV positive. 29/153 were newly diagnosed, 23/153 were reinitiated and 101/153 were continuing treatment. 104 participants had a VL taken at baseline and week 24. 54/55 PLHIV remained undetectable at week 24 and 36/49 PLHIV became undetectable by week 24.

79.4% of PLHIV on BPaLM had a successful outcome. The risk difference for the primary efficacy outcome for BPaLM compared with SoC was -3.1% in the HIV positive and -38.7% in the HIV negative population.

This was not maintained across arms. Safety outcome for BPaLM compared with SoC at week 72 were -27.9% (-47.5% to -8.3%) in PLHIV and -24.3% (-36.5% to -12.1%) in the HIV negative population. There were 2 deaths of PLHIV, neither were related to HIV or TB progression.

HIV status	SOC n/N (%)	BPaLM n/N (%)	Risk difference (two-sided 96.6% CI)
Negative	47/99 (47.5)	9/103 (8.7)	-38.7% (-50.9% to -26.6%)
Positive	9/38 (23.7)	7/34 (20.6)	-3.1% (-23.8% to 17.6%)
	SOC n/N (%)	BPaLC n/N (%)	Risk difference (two-sided 96.6% CI)
Negative	47/99 (47.5)	16/84 (19.1)	-28.4% (-42.4% to -14.4%)
Positive	9/38 (23.7)	11/31 (35.5)	11.8% (-11.6% to 35.2%)
	SOC n/N (%)	BPaL n/N (%)	Risk difference (two-sided 96.6% CI)
Negative	47/99 (47.5)	12/75 (16.0)	-31.5% (-45.4% to -17.6%)
Positive	9/38 (23.7)	3/36 (8.3)	-15.4% (-32.9% to 2.2%)

Table 1: Sub-group analysis by HIV status of primary efficacy outcomes for BPaLM, BPaLC and BPaL compared with SoC

Conclusions: PLHIV treated with BPaLM did as well as the HIV negative participants. BPaLM appears to be a safer option for PLHIV.

Background: Human Papillomavirus (HPV) vaccination is key in preventing HPV related disease. This study was conducted in 2021 to identify HPV genotypes in genital swabs of adolescents who received quadrivalent (6, 11, 16 and 18) HPV vaccination.

Methods: This cross-sectional study at Newlands Clinic, Zimbabwe, collected vaginal or penile swabs from 92 participants living with HIV, that received HPV vaccination at least 5 years prior to enrollment. HPV DNA was quantified using the Nanodrop spectrophotometer (Inqaba BiotechTM, South Africa). The HPV Direct Flow CHIP kit (Master Diagnostica, Spain) was used for genotyping.

Results: We present results of 92 participants (44.6% female) vaccinated at median age, 15 years (IQR:12-16). Mean duration since vaccination was 6 years (SD:±0.4). Twenty-seven (29.3%) participants were negative for HPV, whilst from those with a positive test, 52(56.5%) had at least 1 high risk (HR) type. Concomitant high- and low- (LR) risk types were identified in 36 (39%) participants (Figure 1).

	three	1	2	3	2	3	0
	four	0	0	1	0	1	0
	five	0	0	0	0	0	1
	six	0	0	0	1	0	0

Fig 1: Heat map of participant numbers with respective HR and LR types

Fifteen (16.3%) participants (10 of them female) tested positive for HPV 18 (Figure 2).

Four (4.3%), were positive with at least types 6 or 11 with respect to vaccine preventable LR types.

One participant tested positive for HPV 16.

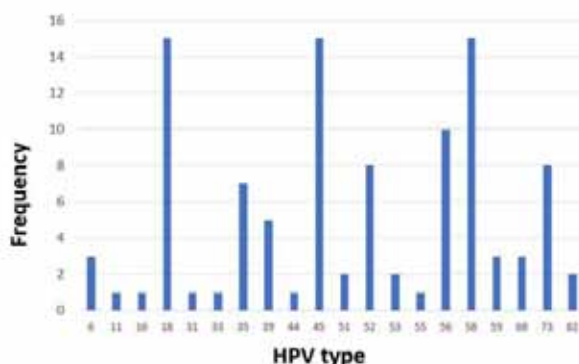

Figure 2: Frequency of vaccine types and all HR genotypes.

Conclusions: HPV 16 and 18 showed differing prevalence suggesting different vaccine efficacy for these types.

Further investigation is needed to determine if a vaccine booster is warranted. Type 45 and 58 were the most prevalent HR types

¹US. Centers for Disease Control and Prevention, Lilongwe, Malawi, ²US. Centers for Disease Control and Prevention, Atlanta, United States, ³USAID, Lilongwe, Malawi, ⁴Malawi Ministry of Health, Lilongwe, Malawi, ⁵Lighthouse Trust, Lilongwe, Malawi, ⁶EGPAF, Lilongwe, Malawi, ⁷ICAP at Columbia University, New York, United States, ⁸ICAP at Columbia University, Lilongwe, Malawi

Background: Malawi has one of the highest cervical cancer (CxCa) burdens globally. CxCa screening and treatment of pre-cancer is an important intervention to eliminate CxCa. The Malawi Population-based HIV Impact Assessment (MPHIA) 2015-16 reported low coverage for CxCa screening among women living with HIV (WLHIV). Since October 2018, President's Emergency Plan for AIDS Relief (PEPFAR) Malawi has supported the provision of CxCa screen-and-treatment services for WLHIV in the highest-burden antiretroviral (ART) facilities in Malawi. We compared the MPHIA 2020-21 screening and treatment data to the MPHIA 2015-16 findings.

Methods: The MPHIA are nationally representative household surveys that include a questionnaire and HIV testing. Women aged 15-64 were asked about CxCa screening, results, and treatment.

We analyzed self-reported CxCa screening data among WLHIV by demographic factors and reported 95% confidence intervals (CI). Results were weighted and accounted for survey design.

Results: In 2015-16 and 2020-21, 1,507 and 1,616 WLHIV were interviewed, respectively. In 2015-16, 16.1% (95% CI: 13.5%-18.8%) reported CxCa screening, compared to 38.4% (95% CI: 35.3%-41.6%) in 2020-21. CxCa screening among WLHIV on ART increased from 17.0% (95% CI: 14.2%-20.2%) to 41.2% (95% CI: 38.0%-44.5%).

Although CxCa screening coverage improved across multiple demographic characteristics, the magnitude of improvement was highest in the lower education and wealth classes. There was an over 3-fold increase in WLHIV with no education (9.0%; 95% CI: 5.6%-14.2% to 30.4%; 95% CI: 24.1%-37.5%). For those in the lowest wealth quintile, screening was almost 7 times more in 2020-21 (3.8%; 95% CI: 1.6%-8.5% to 25.8%; 95% CI: 19.8%-32.9%).

There was greater improvement in CxCa screening coverage in rural settings; 11.7% (95% CI: 9.3%-14.7%) to 36.0% (95% CI: 32.3%-39.9%) compared to 27.5% (95% CI: 22.6%-33.0%) to 46.0% (95% CI: 40.9%-51.1%) in urban.

Same-day treatment for abnormal results was 52.4% (95% CI: 27.0%-76.7%) in 2015-16 and 74.6% (95% CI: 48.7%-90.1%) in 2020-21.

Conclusions: CxCa screening among WLHIV has markedly improved, especially for those on ART and in underserved communities. This suggests that PEPFAR investments and integration of CxCa screening in ART clinics have increased demand and access. However, this can be strengthened by ensuring CxCa screening services are available at all ART facilities.

Liver fibrosis regression measured by transient elastography in people living with HIV successfully treated for hepatitis C using direct acting antivirals

J. Young¹, S. Wang¹, R. Sacks-Davis², A. Stewart², D. Van Santen², M. van der Valk³, J. Doyle², G. Matthews⁴, J. Berenguer⁵, L. Wittkop⁶, K. Lacombe⁷, A. Rauch⁸, M. Stooze², M. Hellard², M. Klein¹

¹Research Institute of the McGill University Health Centre, Montreal, Canada, ²Burnet Institute, Melbourne, Australia, ³Amsterdam University Medical Centre, Amsterdam, Netherlands, ⁴The Kirby Institute, Sydney, Australia, ⁵Gregorio Marañón General University Hospital, Madrid, Spain, ⁶Inserm Research Center Bordeaux Population Health, Bordeaux, France, ⁷Sorbonne University, Paris, France, ⁸Bern University Hospital, Bern, Switzerland

Background: Successful treatment for hepatitis C virus (HCV) reduces liver fibrosis. Transient elastography (TE) has been shown to capture true fibrosis regression after successful HCV treatment, once inflammation abates. It is not clear how fibrosis regression changes with time after treatment ends.

Methods: We used data from eight of 11 cohorts in the International Collaboration on Hepatitis C Elimination in HIV Cohorts (InCHEHC), including data from Australia, Canada, France, the Netherlands, Switzerland and Spain. We selected individuals successfully treated for a primary HCV infection using all oral direct acting antivirals and with at least one TE measured within a year prior to starting treatment. This baseline measurement was used to classify fibrosis stage (F0-F1<7.2, F2-F3≥7.2-<14.6, F4≥14.6 KPa). For those selected, all TE measurements after successful treatment were included in our generalised additive modelling, provided HCV RNA remained undetectable. Our model included a random intercept allowing repeated measures from the same individual and an adaptive spline representing the change in mean over time.

Results: TE measurements were included from 1714 individuals; 513 had a measurement after treatment ended (220 F0-F1, 202 F2-F3, 91 F4) with a median follow-up of 0.8 years. For those with advanced fibrosis (F2-F3) or cirrhosis (F4), the mean response shows a rapid decline in stiffness during treatment as inflammation abates (Figure). Those with advanced fibrosis then regress towards normal (F0-

F1) with the mean response falling below 7.2KPa; those with cirrhosis show early fibrosis regression but this attenuates (Table) and the mean never approaches normal.

Figure. Mean response curves for transient elastography over time in HIV/HCV co-infected participants successfully treated for HCV.

Period	Change in KPa (95% credible interval)			Fibrosis stage when starting treatment		
	F0-F1 <7.2KPa	F2-F3 ≥7.2-<14.6 KPa	F4 ≥14.6 KPa	F0-F1 <7.2KPa	F2-F3 ≥7.2-<14.6 KPa	F4 ≥14.6 KPa
1.5 to 0.5 years before treatment starts	-0.1 (-0.2 to -0.1)	1.1 (0.8 to 1.4)	6.5 (4.8 to 8.2)			
0.5 to 1.5 years after treatment ends	-0.1 (-0.1 to 0.0)	-0.7 (-1.0 to -0.4)	-1.2 (-2.5 to 0.1)			
1.5 to 2.5 years after treatment ends	-0.1 (-0.1 to 0.0)	-0.2 (-0.5 to 0.0)	-0.7 (-1.7 to 0.4)			
2.5 to 3.5 years after treatment ends	-0.1 (-0.1 to 0.0)	-0.1 (-0.4 to 0.2)	0.3 (-1.0 to 1.6)			

Conclusions: Successful HCV treatment leads to meaningful fibrosis regression in those with advanced fibrosis. Those with cirrhosis do not fully recover and need continued surveillance.

Early clinical experience using tecovirimat during the Mpox epidemic in Toronto suggests ongoing clinical equipoise for randomized trials

S. Shah¹, S. Mishra^{1,2,3}, S.A. Myers¹, K. Gough^{2,3}, C. Tan^{2,3}, R. Clarke⁴, S. Walmsley^{4,3}, M. Sharma^{2,3}, A. Chan^{5,3}, J. Leis^{5,3}, D.H.S. Tan^{1,2,3}

¹St. Michael's Hospital, MAP Centre for Urban Health Solutions, Toronto, Canada, ²St. Michael's Hospital, Division of Infectious Diseases, Toronto, Canada, ³University of Toronto, Department of Medicine, Toronto, Canada, ⁴Toronto General Hospital, Division of Infectious Diseases, Toronto, Canada, ⁵Sunnybrook Research Institute, Biological Sciences, Toronto, Canada

Background: Tecovirimat is an anti-smallpox drug used for treating Mpox during the current global outbreak, but randomized controlled trials have not yet been completed.

Methods: We conducted a retrospective observational study of Mpox patients at three Toronto hospitals between MAY-AUG2022. We present a descriptive analysis of those who were prescribed oral tecovirimat 600mg

twice daily x14d for the management of severe manifestations, highlighting adherence, tolerability and clinical outcomes.

Results: Of 54 consenting study participants, 19 (35%) received tecovirimat. All were men who have sex with men, over one-third (37%) were white and 9 (47%) were living-with-HIV, with median (interquartile range) CD4 count 551 (296, 862) cells/mm³ and 8 (89%) having HIV RNA<20 copies/mL.

Median (IQR) age was 38 years (31.5, 41.5). Manifestations at clinical assessment included rash (100%), lymphadenopathy (74%), myalgia (74%), fever (63%), lethargy (63%), headache (42%), pharyngitis (37%), proctitis (32%), low mood (21%), hematochezia (16%), penile swelling (16%), pruritus (5%), conjunctivitis (5%), myocarditis (5%), and urethral discharge (5%). The indication for tecovirimat was symptom severity in 17 (89%) and anatomic site of involvement in 2 (11%).

All patients reported adherence to the full course of drug as prescribed. Tecovirimat was well-tolerated overall, but 1 participant each reported diarrhea, blurry vision, and nocturnal restless legs that resolved with completion of therapy.

At 14-day follow up, most had satisfactory clinical improvement, however, one patient continued to develop new PCR-confirmed Mpox skin lesions on day 8 of therapy with persistent PCR-positivity 6 days after completing treatment; another developed new, small, itchy, folliculitis-like chest pustules on day 14 of therapy resolving within 2 weeks (though not tested for Mpox); and one patient with myocarditis experienced exercise-induced dyspnea and chest tightness with worsening cardiac enzymes on day 11 of therapy, in the context of high-intensity aerobic training.

Conclusions: Early experience treating Mpox with tecovirimat suggests it is safe, well-tolerated and effective, but the occasional finding of ongoing symptoms despite therapy raises questions about limitations to its efficacy. In the context of considerable community demand for the drug, efforts should be made to connect Mpox patients to rigorous randomized controlled trials, given this ongoing clinical equipoise.

MOPEB08

Characterization of mpox in people who live with HIV: a country-wide observational study

I. Núñez^{1,2}, S.E. Ceballos-Liceaga³, L. Sosa-Laso³, J.L. Mosqueda⁴, P.F. Belaunzarán-Zamudio⁵, J. Sierra-Madero⁶, G. Reyes-Terán⁷, A. De la Torre Rosas⁸, S.I. Valdés-Ferrer^{9,10}

Background: Over 85,000 mpox cases have been reported worldwide. A large proportion of them are people who live with HIV/AIDS (PLWHA), some series report percentages over 50%. Mpox has been hypothesized to be more severe in PLWHA.

However, no studies have conclusively shown worse outcomes among PLWHA.

We aim to study the association between HIV and severe mpox.

Methods: We used the national epidemiologic surveillance system in Mexico to obtain data on confirmed-mpox cases.

A case report format was submitted to the General Epidemiology Directorate with clinical data on people with mpox. We used this data to construct logistic regression models using HIV as the main exposure of interest and adjusting for age, gender, and mechanism of HIV transmission. We defined severe mpox as that requiring hospitalization or that resulted in death.

Results: 3291 mpox cases were diagnosed from May-November 2022. 1930 (58.6%) were in PLWHA, 97% were men, and 87% identified as men-who-have-sex-with-men. The epidemiologic curve of mpox cases is shown in *Figure 1*. Logistic regression analyses and the proportion of persons that developed a given outcome or symptom are shown in *Figure 2*.

HIV status was associated with an increased odds of severe mpox, generalized rash, fever, fatigue, vomit, diaphoresis, painful lesions, diarrhea, and lymphadenopathies.

Figure 1.

Figure 2.

Conclusions: Several symptoms, such as fever and fatigue, were more common in PLWHA. Importantly, HIV conferred an increased risk of severe mpox. This underlines the importance of directing preventive measures and clinical trials of therapeutics and preventive interventions towards this population at risk.

PEPFAR tuberculosis preventive treatment coverage and remaining gaps among people living with HIV

S. O'Connor¹, M. Peterson², R. Briceño-Robaugh², M. Desai³

¹US Centers for Disease Control and Prevention (CDC),

Global Tuberculosis Branch, Atlanta, United States, ²US

Agency for International Development, TB Division,

Washington, D.C., United States, ³The Office of the

U.S. Global AIDS Coordinator and Health Diplomacy,

Washington, D.C., United States

Background: In 2018, the President's Emergency Plan for AIDS Relief (PEPFAR) committed to providing tuberculosis preventive treatment (TPT) to all people living with HIV (PLWH) receiving antiretroviral therapy (ART) through PEPFAR-supported programs. During US government fiscal years (FY) 2017–2022, PEPFAR set cumulative targets for 22,275,651 PLWH to complete TPT. We assessed target achievement, TPT completion rates, and remaining gaps in 54 countries where PEPFAR operated in 2022.

Methods: PEPFAR Monitoring, Evaluation, and Reporting (MER) data for FY 2017–2022 were used to report the number of PLWH who started and completed TPT. Target achievement was defined as cumulative number of TPT completions divided by cumulative TPT targets. TPT com-

pletion rates were calculated by dividing the number of TPT completions by initiations, and differences in age, sex, and whether ART had been initiated recently were examined.

To estimate the number of PLWH who may remain eligible for TPT, cumulative TPT completions were subtracted from the number of PLWH currently on ART in PEPFAR-supported programs.

Results: Overall, 11,307,593 TPT completions were reported, representing 51% target achievement. The overall TPT completion rate was 78%. No major differences were noted by age or sex. TPT completion among those initiating TPT within six months of ART initiation was 72%, versus 83% among those on ART for longer than six months when TPT was initiated. By FY22, PEPFAR was providing ART to 19,238,096 PLWH, suggesting that up to 7,930,503 (41%) PLWH currently in PEPFAR-supported programs may remain eligible for TPT (Figure 1).

Conclusions: Though progress has been made in providing lifesaving TPT to PLWH, gaps remain across PEPFAR. Improved active TB case finding, surge and sustain campaigns, shorter TPT regimens, and enhanced reporting and recording systems may expand TPT coverage. Lower TPT completion rates among clients new to ART warrant interventions to improve adherence.

Performance of rifampicin resistant TB regimens used as standard-care in the TB-PRACTECAL clinical trial

C. Berry¹, M. Dodd², I. Motta¹, K. Fielding², R. Moodliar³, M. Rassool⁴, S. Rajaram⁴, V. Solodovnikova⁵, N. Parpieva⁶, I. Liverko⁶, Z. Tigay⁷, B.-T. Nyang'wa⁸

¹Medecins Sans Frontieres, London, United Kingdom,

²London School of Hygiene and Tropical Medicine, London, United Kingdom, ³THINK TB and HIV Investigative Network, Durban, South Africa, ⁴Wits Health Consortium, Johannesburg, South Africa, ⁵Republican Scientific and Practical Center for Pulmonology and Tuberculosis, Minsk, Belarus, ⁶Republican Specialized Scientific and Practical Medical Center of Phthisiology and Pulmonology, Tashkent, Uzbekistan, ⁷Republican Phthisiological Hospital No. 2, Nukus, Uzbekistan, ⁸Medecins Sans Frontieres, Amsterdam, Netherlands

Background: In December 2022, the WHO recommended 6-month regimens containing bedaquiline, pretomanid, linezolid and moxifloxacin (BPaLM) for the treatment of most people with rifampicin-resistant tuberculosis (RR-TB). The WHO 2019 guidelines phased out use of second-line injectables (SLI), recommending 9-12 month, all oral, short regimens or 18-20 month longer regimens and these regimens remain in practice in most settings.

We aim to show the efficacy and safety of the standard care (SoC) regimens used in TB-PRACTECAL trial and compare them to outcomes of contemporaneously recruited participants treated with BPaLM.

Methods: Participants with RR-TB were recruited from Uzbekistan, Belarus and South Africa, irrespective HIV status. Participants allocated to the standard of care (SoC) regimen were categorised into pre-2019 or post-2019 recommendations according to adoption in country and shorter (36-48 week regimens) or longer regimens (72-96 week regimens). The proportion satisfying the primary composite outcome (unfavourable outcome comprising death, early treatment discontinuation, lost-to-follow-up, treatment failure and recurrence) in each of these categories was summarised in the modified intention-to-treat (mITT) population. In the intention-to-treat population (ITT), grade 3 and above/serious adverse events (SAE) were also summarised.

Sensitivity analyses were performed comparing BPaLM to the SoC, excluding participants recruited before implementation of the 2019 guidelines.

Results: 151 participants were recruited into the SoC arms from 2017 to 2021, of which 94 and 105 were post-implementation of the 2019 WHO guidelines and met criteria for the mITT and ITT populations respectively. Unfavourable outcomes were demonstrated in 17/29 (58.6%) participants in long pre-2019 regimens; 7/13 (53.8%) short pre-2019 regimens; 24/57 (42.1%) long post-2019 regimens and 8/38 (21.1%) short post-2019 regimens. The sensitivity analysis showed a risk difference of -19.1% (-31.9% to -6.3%) favouring BPaLM regimens.

Grade ≥ 3 and SAE affected 63.6%; 53.8%; 37.5% and 48.8% of the long pre-2019, short pre-2019; long post-2019 and short post-2019 cohorts respectively. The sensitivity analysis showed a risk difference of -17.9% (-31.4% to -4.3%) favouring BPaLM regimens.

Conclusions: The short post-2019 regimen was the most efficacious of the SoC regimens. Post-2019 RR-TB regimens were both less efficacious and less safe than BPaLM, despite not having injectable agents. TB programs should transition to BPaLM regimens.

Impact of HIV during standard first-line tuberculosis treatment on the risk of subsequent rifampicin-resistant TB in the Western Cape Province, South Africa

N. Zinyakatira^{1,2}, M. Smith^{3,2}, A. Heekes^{3,2}, A. Boulle^{1,2}, N. Tiffin⁴, H. Cox⁵

¹University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, ²Western Cape Government, Department of Health, Health Intelligence Directorate, Cape Town, South Africa, ³University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health and Family Medicine, Cape Town, South Africa, ⁴University of the Western Cape, South African National Bioinformatics Institute, Cape Town, South Africa, ⁵University of Cape Town, Division of Medical Microbiology, Faculty of Health Sciences, Cape Town, South Africa

Background: Multi-drug or rifampicin-resistant tuberculosis (MDR/RR-TB) is a major threat to people living with HIV (PLHIV). Evidence suggests that PLHIV, particularly those with advanced HIV, may be more likely to acquire rifampicin-resistance during first-line TB treatment; in turn driving the MDR/RR-TB epidemic in high burden countries like South Africa.

We aimed to assess the risk of subsequent MDR/RR-TB diagnosis in individuals with rifampicin-susceptible TB (RS-TB) disease starting first-line TB treatment.

Methods: This was a retrospective cohort analysis including individuals with laboratory confirmed RS-TB, of all ages, who started first-line TB treatment between 2007 and 2016 inclusive, attending public health facilities in the Western Cape (WC) Province, South Africa. This routinely collected data is amalgamated by the WC Provincial Health Data Centre. Participants were followed-up through the data centre to describe subsequent diagnosis of TB. We report preliminary analysis of this very large cohort.

Results: A total of 139,540 were included; 59,994 (43%) were females and 52,428 (38%) were PLHIV (Figure 1). The median age was 34.4 (IQR, 26.3-44.4). Overall, 14,662 (28%) of PLHIV and 20,870 (24%) HIV-negative individuals had a subsequent episode of TB identified, with rifampicin drug susceptibility testing (DST) available for 8,920 (61%) and 15,098 (72%) HIV-positive and HIV-negative individu-

als respectively. PLHIV had a higher risk of a subsequent TB episode compared to HIV-negative individuals (OR 1.23, 95% CI, 1.20 - 1.26), while PLHIV were nearly twice as likely to be diagnosed with RR-TB if they had a subsequent TB diagnosis (OR 1.92, 95% CI, 1.76 - 2.11).

When restricting to 12 months follow-up after starting first-line TB treatment, PLHIV were still more likely than HIV-negative individuals to experience a subsequent TB episode (OR 1.16, 95% CI, 1.09 - 1.24). Within 12 months, PLHIV were more than three times more likely to be diagnosed with RR-TB, given a subsequent TB diagnosis (OR 3.14, 95% CI, 2.52 - 3.94).

Conclusions: These data suggest that PLHIV are at substantially higher risk of developing MDR/RR-TB during first-line TB treatment than those who are HIV negative. Further analysis of this very large cohort will assess potential contributing factors, such as the provision of antiretroviral treatment and CD4 status.

Unit, Bristol, United Kingdom

Background: HIV infection is associated with lower bone density, increasing the risk of fracture. We investigated how bone density changes over one year in peripubertal children living with HIV (CWH) compared to HIV-uninfected children (CWOH) in Zimbabwe.

Methods: From 2018-2020, CWH from public sector HIV clinics aged 8-16 years on antiretroviral therapy (ART) for at least two years, and CWOH of similar ages from nearby schools were recruited in Harare. At baseline and 12 months, dual X-ray absorptiometry was performed and Z-scores calculated. Bone measures included height-adjusted total-body less-head bone mineral content for lean mass (TBLH-BMC^{LB}) Z-score and size-adjusted lumbar spine bone mineral apparent density (LS-BMAD) Z-score. Linear regression models compared longitudinal changes in bone outcomes by HIV status adjusting for age, pubertal stage (by Tanner), baseline bone measurements and time since first visit.

Results: Of 609 participants recruited at baseline, 19% were lost-to-follow-up (no deaths) leaving 244 CWH (mean±SD 13.0±2.3 years, 119 (48.8%) girls) and 248 CWOH (12.9±2.4 years old, 126 (50.8%) girls) at follow-up.

Among CWH, 82% were virally suppressed (<1000 copies/ml). The prevalence of stunting (height-for-age Z-score <-2) at follow-up among CWH was 28.1% compared to 8.7% among CWOH (p<0.001).

Among girls, bone density gains over a median 35 months were similar between CWH and CWOH: adjusted mean differences in LS-BMAD (0.05[95%CI -0.06,0.16], p=0.35) and TBLH-BMC^{LB} (0.11[-0.02,0.25], p=0.11).

Male CWH gained less TBLH-BMC^{LB} (-0.15[-0.31,0.09], p<0.001) compared to CWOH, whilst LS-BMAD gains were similar (0.06[-0.44,0.55], p=0.85). HIV was associated with delayed bone mass gains, particularly among older boys who appeared to be still gaining bone at the end of study follow-up (Figure 1).

Figure 1. Best fit plot for the association between age and TBLH-BMC (grams) at follow-up stratified by sex and HIV status.

Conclusions: Unlike girls, boys living with HIV experience reduced bone mass gain over one year. Despite ART, bone growth is perturbed during adolescence which has implications for future fracture risk. Strategies to address this are warranted.

Background: The link between fatty liver diseases and cognitive impairment (CI) among people living with HIV (PLWH) remains unclear. We investigated the association

of non-alcoholic fatty liver (NAFLD), advanced liver fibrosis and non-alcoholic steatohepatitis (NASH) with significant activity and liver fibrosis [HKB1] with CI [HKB2] among well-suppressed PLWH in a Thai cohort.

Methods: PLWH ≥ 50 years old on stable antiretroviral therapy (ART) were included. The Thai-validated version of Montreal Cognitive Assessment (MoCA) was used to evaluate cognitive performance and a cut-off of $< 25/30$ was used to define CI. Liver stiffness and controlled attenuation parameters were measured using FibroScan. NAFLD and advanced liver fibrosis was defined as CAP value ≥ 248 dB/m and liver stiffness ≥ 9.5 kPa, respectively. The outcome was NASH with significant activity and liver fibrosis which was defined as FibroScan-AST (FAST) score ≥ 0.67 .

Multivariable logistic regression was employed to investigate the association of CI with NAFLD, advanced liver fibrosis and FAST score ≥ 0.67 .

Results: A total of 319 PLWH (63.3% male) with a median age of 54.4 (interquartile range [IQR], 51.7-59.6) years were included. The median duration of HIV was 18.6 (IQR, 15.3-20.9) years, and 98% had HIV RNA < 50 copies/mL. 74 (38%) participants had NAFLD and 33 (10%) had advanced liver fibrosis.

FAST score ≥ 0.67 was present in 66 (20.1%) participants. 192 (60.2%) participants had CI. In multivariable analysis, FAST score ≥ 0.67 was significantly associated with CI (adjusted odds ratio, aOR=2.11, 95% CI 1.09-3.90, $p=0.027$), after adjusting for age, sex, BMI, employment status, education, income level, smoking alcohol use, diabetes mellitus and hypertension.

After additional adjustment for HIV-related covariates such as CD4/CD8 ratio, HIV duration and ART regimen, FAST score ≥ 0.67 was still associated with CI (aOR=2.01, 95% CI 1.02-3.98, $p=0.04$). The association between NAFLD or advanced liver fibrosis and CI was not statistically significant (p -values > 0.1).

Conclusions: NASH with significant activity and liver fibrosis was associated with lower cognitive performance in a group of virally suppressed PLWH, even after controlling for demographics and HIV disease parameters. Additional research is needed to better understand this association.

Background: Depression is the most common neuropsychiatric disorder in people living with HIV (PLHIV), with harmful and potentially life-threatening consequences. Screening for depression remains a priority for PLHIV in care. The 9-item Patient Health Questionnaire (PHQ-9) is a widely used depression screening tool, but with limited accuracy when applied across cultural contexts, particularly in sub-Saharan Africa.

We aimed to evaluate the performance of an alternative PHQ-9 scoring algorithm in Sub-Saharan African PLHIV.

Methods: Adult PLHIV were enrolled in five HIV programs in Cameroon, the Republic of Congo, Côte d'Ivoire, Kenya and Senegal, that are part of the leDEA collaboration. Trained study nurses or social workers administered the PHQ-9; a blinded clinical evaluation was then performed by a psychiatrist.

We compared the performance of the standard PHQ-9 algorithm (cut-off ≥ 10) to a new algorithm including:

- The presence of at least one mood symptom (PHQ-9 items 1&2) combined with at least three other symptoms listed in the PHQ-9, and;
- A simplified recoding of each 4-response item in two categories (absence/presence). Sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV), and area under the curve (AUC) were assessed against the psychiatric diagnosis.

Results: Overall, 723 participants were included [Cameroon (n=289), Congo (n=113), Côte d'Ivoire (n=141), Kenya (n=82), Senegal (n=98), female: 53%, median age: 43 years (IQR 35-50)]. Eighty were diagnosed with depression by a psychiatrist (11%). With the new scoring algorithm, Se (0.85 [95% CI: 0.75-0.92]) and NPV (0.98 [95% CI: 0.96-0.99]) were significantly increased compared to those of the standard PHQ-9 cut-off (0.46 [95% CI: 0.35, 0.58] and 0.93 [95% CI: 0.91, 0.95], respectively) (Table1).

The AUC of the new scoring algorithm was higher compared to the standard one: PHQ-9 cut off (0.85 [95% CI: 0.81, 0.90] vs 0.71 [95% CI: 0.66, 0.77]).

Conclusions: As a primary screening test, the new scoring algorithm appeared to improve the accuracy of the PHQ-9 to identify depression across settings. Recoding should also facilitate PHQ-9 administration by simplifying the response scale. This alternative PHQ-9 scoring approach might be considered to identify PLHIV in need of referral for further diagnostic evaluations.

¹Makerere University-Johns Hopkins University Research Collaboration, Kampala, Uganda, ²University of Zimbabwe, Harare, Zimbabwe, ³Centre for AIDS Programme of Research in South Africa, Durban, KwaZulu-Natal, South Africa, ⁴Johns Hopkins Bloomberg School of Public Health, Blantyre, Malawi, ⁵Centre for AIDS Programme of Research in, Durban KwaZulu-Natal, South Africa, ⁶University of the Witwatersrand, Johannesburg, South Africa, ⁷University of North Carolina Project, Lilongwe, Malawi, ⁸Harvard T.H. Chan School of Public Health, Boston, United States, ⁹Johns Hopkins Bloomberg School of Public Health, Kampala, Uganda, ¹⁰Johns Hopkins University Bloomberg School of Public Health, Baltimore, United States, ¹¹Johns Hopkins University, Baltimore, United States, ¹²Johns Hopkins University School of Medicine, Baltimore, South Africa

Background: In the IMPAACT PROMISE 1077BF study, we found that postpartum declines in bone mineral density (BMD) during breastfeeding were greater in African women living with HIV (WLWH) receiving TDF-based ART compared to those not on ART. We describe postpartum BMD changes in breastfeeding African women in the PROMISE trial who then enrolled in the PROMOTE observational cohort.

Methods: In four African countries, former PROMISE participants were enrolled in the PROMOTE study. Total hip and lumbar spine (LS) BMD were assessed by Dual Energy X-ray Absorptiometry (DXA) after delivery (week 0) and at postpartum week 74 in PROMISE, then at PROMOTE entry.

Country-specific Z-scores were created by internal standardization to the PROMISE DXA result at delivery. Linear mixed models adjusted for country were used to estimate the average 5-year change in hip and LS BMD Z-scores after postpartum week 74.

Results: At PROMOTE entry, 459 women had available DXA data from PROMISE. Median (IQR) age was 32 (29-36), BMI 24.6kg/m² (22.0-29.3), parity 3 (2-4), months on ART in PROMISE 24.8 (14.2-34.7). HIV-1 viral load was <1000 copies/mL in 93%, 92% were on TDF-ART. In the median 3.3 (2.2-3.7) years since postpartum week 74, 19% had a new pregnancy and 13% were still lactating at PROMOTE entry. At entry, mean (SD) BMD was 0.96 (0.12) for LS and 0.95 (0.12) g/cm² for hip. LS BMD Z-scores increased by 31% per 5 years (95%CI: 22%, 40%) and hip by 8% per 5 years (1%, 16%), adjusted for country. Compared to women without, women with new pregnancies had lower annualized rate of change in BMD: mean difference (95%CI) LS = -0.057 (-0.078,-0.035) and hip = -0.032 (0.053,-0.011).

Figure 1. Relative change (%) in spine and total hip BMD from week 0 and 74 in the PROMISE to the first measurement in PROMOTE Study.

The relative change at each PROMISE time point was calculated as ((PROMOTE entry measurement - PROMISE measurement) / PROMISE measurement) x 100. Values >0 indicate that the BMD values at PROMOTE entry are greater than the BMD values measured in PROMISE (red line represents the mean).

Conclusions: Compared to women who had new pregnancies, WLWH who had no new pregnancies had greater LS BMD recovery, but not hip, in the 3 years after week 74 postpartum.

Background: The association of HIV acquisition with increased cardiometabolic risk is attributed to heightened and chronic inflammation in people living with HIV (PLWH) and/or the effects of antiretroviral therapy (ART). However, empirical evidence of the association of HIV-related factors with hypertension and diabetes is inconsistent.

We assessed the association of HIV-related factors with hypertension and type 2 diabetes mellitus among PLWH.

Methods: This cross-sectional study included 14,119 adult PLWH from Cameroon enrolled in the International epidemiology Databases to Evaluate AIDS (IeDEA) during 2016 through 2021. Hypertension was defined as Systolic Blood Pressure $\geq 140/90$ mmHg and/or current use of antihypertensive medication; diabetes was defined as Fasting Blood Sugar ≥ 126 mg/dL and/or use of antidiabetic medications.

Univariable and multivariable multinomial logistic regression analysis examined factors associated with hypertension alone; diabetes alone; and both outcomes together, with clients with neither condition as the reference group. Both univariable and multivariable models were fit.

Results: Of 14,119 participants, 9177 (65%) were women. The median age (25th-75th percentiles) was 42 years (35-51) years. Compared with those aged 19-29 years, age >50 years was associated with: hypertension alone (aOR: 5.62; 95%CI: 3.18, 9.95); diabetes alone (aOR: 7.07; 95% CI: 1.57, 32.0), and both (aOR: 8.52; 95% CI: 1.07, 67.8). Men had higher odds of having both conditions together (aOR: 2.41; 95%CI: 1.22, 4.77). Overweight (aOR: 2.07; 95%CI: 1.10, 3.90) and obesity (aOR: 3.46; 95%CI: 1.81, 6.64) were predictors of hypertension alone, compared with being underweight.

WHO stage II (aOR: 0.57; 95%CI: 0.41, 0.79) and WHO stage III (aOR: 0.67; 95%CI: 0.50, 0.90) were inversely associated with hypertension alone. The odds of diabetes alone were lower with ART use (aOR: 0.44; 95%CI: 0.22, 0.87). CD4 count >350 cells/mm³ and viral load ≤ 200 copies/mL were not associated with any of the conditions.

Conclusions: These findings indicate that traditional cardiovascular risk factors, including older age, male sex, overweight and obesity, are strongly associated with hypertension among PLWH. Further research examining associations between HIV disease stage and ART use with hypertension and diabetes is warranted.

MOPEB17

Renal safety parameters after switch to doravirine/islatravir (DOR/ISL 100/0.75mg) once-daily: week 48 results from 2 randomized, active-controlled phase 3 trials, MK8591A-017 (P017) and MK8591A-018 (P018)

F.A. Post¹, J.-M. Molina², A.M. Mills³, K. Lacombe⁴, J.K. Rockstroh⁵, C.J. McMullan⁶, Y.-P. Zhou⁶, A. Grandhi⁶, F.-H. Su⁶, A.J. Kim⁶, M.C. Fox⁶, T.A. Correll⁶
¹King's College Hospital NHS Foundation Trust, London, United Kingdom, ²University of Paris Diderot and St-Louis Hospital, Paris, France, ³Men's Health Foundation, Los Angeles, United States, ⁴INSERM IPLESP, St. Antoine Hospital, AP-HP, Sorbonne Université, Paris, France, ⁵Medizinische Klinik und Poliklinik, University of Bonn, Bonn, Germany, ⁶Merck & Co., Inc., Rahway, United States

Background: Certain antiretroviral drugs may affect renal function. The objective of this post-hoc analysis was to evaluate renal safety parameters after 48 weeks in 2 phase 3 DOR/ISL (100/0.75mg) switch trials.

Methods: P017 (NCT04223778) was an open-label switch from any oral 2- or 3-drug regimen, with randomization stratified by baseline antiretroviral therapy (bART). P018 (NCT04223791) was a double-blind switch; bART was bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF). Adults with HIV-1 were randomized 1:1 to switch to DOR/ISL (100/0.75mg) once-daily or continue bART.

Participants with creatinine clearance ≤ 30 mL/min were excluded. Renal safety parameters were assessed, including estimated glomerular filtration rate (eGFR) using CKD-Epi Cystatin-C equation to avoid reliance on creatinine-based eGFR confounded by inhibition of renal creatinine secretion by several antiretroviral agents.

Results: 658 participants switched to DOR/ISL (100/0.75mg); 655 remained on bART, of which 319 remained on B/F/TAF in P018. In P017, bART was INSTI-based in 52%, PI-based in 14%, and Other in 34% of participants; 30% of bART included TDF, 39% included TAF, and 28% included other NRTIs. No differences in mean change from baseline between treatment arms were observed for cystatin-C or urine albumin/creatinine ratio in either trial at 48 weeks. An increase in cystatin-C based eGFR and a decrease in urine retinol-binding protein/creatinine ratio (URBP/UC)

was observed in P017 for participants switched to DOR/ISL; a similar effect was not present in P018 (Table). Renal and urinary adverse events (RUAEs) were infrequent and similar between groups: P017 DOR/ISL 3.9%, bART 2.4%; P018 DOR/ISL 2.2%, B/F/TAF 3.4%; no participants switched to DOR/ISL had serious RUAEs or discontinued treatment due to RUAEs.

A randomized controlled trial of (5R)-5-hydroxytryptolide in HIV INRs receiving ART

W. Cao¹, X. Liu², Y. Han¹, X. Song¹, L. Lu¹, X. Li¹, J.-P. Routy³, M. Zuo⁴, T. Li^{1,2}

¹Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Department of Infectious Diseases, Beijing, China, ²Tsinghua University, School of Medicine, Beijing, China, ³McGill University Health Centre, Montreal, Canada, ⁴Shanghai Pharmaceuticals Holding Co., Ltd., Shanghai, China

Background: Therapeutic approaches to HIV-suppressed immunological non-responders (INRs) remain unsettled. We previously reported the efficacy of Chinese herbal Tripterygium wilfordii Hook F in INRs. Its derivative (5R)-5-hydroxytryptolide (LLDT-8) on CD4⁺ T cell recovery was assessed.

Methods: The phase II, double-blind, randomized, placebo-controlled trial was conducted in adult patients with long-term suppressed HIV infection and suboptimal CD4 recovery, at eight hospitals in China. The patients were

1:1:1 assigned to receive oral LLDT-8 0.5mg or 1mg daily, or placebo combined with antiretroviral therapy for 48 weeks. All study staff and participants were masked. The primary endpoints include change of CD4⁺ T cell counts and inflammatory markers at week 48.

This study is registered on ClinicalTrials.gov (NCT04084444) and Chinese Clinical Trial Register (CTR20191397).

Results: A total of 149 patients were enrolled from Aug 30, 2019, and randomly allocated to receiving LLDT-8 0.5mg daily (LT8, n= 51), 1mg daily (HT8, n= 46), or placebo (PL, n= 52). The median baseline CD4⁺ T cell count was 248 cells/mm³, comparable among three groups. LLDT-8 was well tolerated in all participants.

At 48 weeks, change of CD4⁺ T cell counts was 49 cells/mm³ in LT8 group (95% confidence interval [CI]: 30, 68), 63 cells/mm³ in the HT8 group (95% CI: 41, 85), compared to 32 cells/mm³ in the placebo group (95% CI: 13, 51). LLDT-8 1mg daily significantly increased CD4⁺ T cell count compared to placebo (P=0.036), especially in participants over 45 years old.

The mean change of serum interferon-γ-induced protein 10 (IP-10) was -72.1 mg/L (95% CI -97.7, -46.5) in the HT8 group at 48 weeks, markedly decreased compared to -22.8 mg/L (95% CI -47.1, 1.5, P=0.007) in the placebo group. Treatment-emergent adverse events (TEAEs) were reported in 41 of 46 (89.1%) participants in the HT8 group, 43 of 51(84.3%) in LT8, and 42 of 52 (80.7%) in the PL group. No drug-related serious adverse events (SAEs) were reported. **Conclusions:** LLDT-8 enhanced CD4 recovery and alleviated inflammation in long-term suppressed INRs, providing them a potential therapeutic option.

Weight gain among people living with HIV in Zambia transitioning to dolutegravir-based antiretroviral regimens containing tenofovir alafenamide versus tenofovir disoproxil fumarate

E. Heilmann^{1,2}, S. Sivilie^{3,4}, J.Z. Hines², D. Engamba⁴, K. Mwebo², M. Mwitumwa⁴, A. Mwila², D. Kampamba³, L. Chirwa⁴, C. Siangenda³, M. Itoh², L. Mulenga^{3,4}

¹Public Health Institute, Oakland, United States, ²U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, ³Ministry of Health, Lusaka, Zambia, ⁴University Teaching Hospital, Lusaka, Zambia

Background: Dolutegravir (DTG)-based antiretroviral therapy (ART) might be associated with weight gain, particularly in combination with tenofovir alafenamide (TAF) versus tenofovir disoproxil fumarate (TDF). We compared weight changes among PLHIV who switched to a DTG-based regimen using data from electronic health records in Zambia.

Methods: We conducted a retrospective cohort study of PLHIV aged ≥20 years at ART initiation with ≥2 recorded weights before and after ART switch between 2017 and August 2022. We estimated weight change over time using linear mixed effects models adjusting for age, sex,

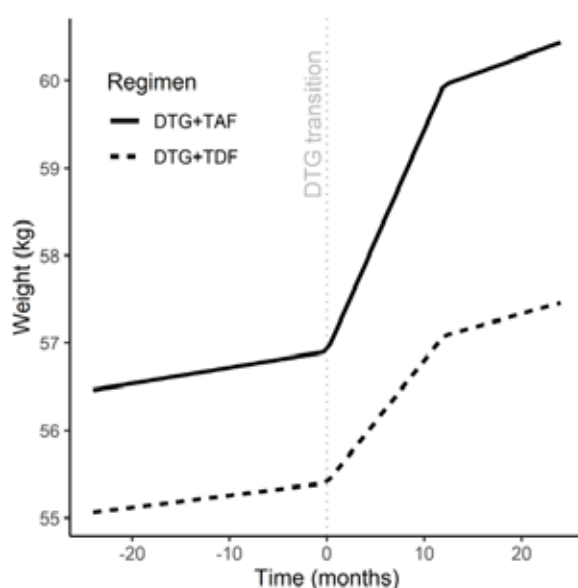

and body mass index and viral load at time of switch with participants as random intercepts and linear splines with knots at time of switch and 12-months post-switch.

Results: We analyzed 140,816 records (15.1%) of PLHIV transitioned to a DTG-based regimen; 97.9% switched to DTG+TDF while 2.1% received DTG+TAF. PLHIV on DTG+TAF were older (46 vs. 39 years, $p<0.001$) and more were female (68.8% vs. 66.7%, $p=0.016$) than PLHIV on DTG+TDF.

Trends in weight gain were greater among PLHIV on DTG+TAF versus DTG+TDF during all 3 time periods (before switch: $\beta=0.31$, 95% confidence interval [CI]=0.01-0.61; ≤ 1 year post-switch: $\beta=1.67$, 95% CI=1.40-1.94; >1 year post-switch: $\beta=2.19$, 95% CI=1.30-3.08).

Model-estimated changes in weight for PLHIV on DTG+TAF were 0.22kg/year before switching, 3.05kg in the first year after switching, and 0.49kg in the second year while for PLHIV on DTG+TDF, weight gain was 0.16kg, 1.68kg, and 0.38kg during the same periods (Figure).

Conclusions: PLHIV on ART experienced weight gain which was highest during the first year after transitioning to DTG-based regimens and in combination with TAF. Our findings provide real-world evidence of DTG- and TAF-associated weight gain from a large PLHIV population in Zambia. Given the rising burden of noncommunicable diseases among PLHIV, weight management counseling and screening for metabolic syndrome are needed for holistic clinical management of PLHIV.

Sedative drug burden is associated with concurrent physical frailty in people aging with HIV in Canada: findings from the Positive Brain Health Now Study (+BHN)

H.U. Michael^{1,2}, M.-J. Brouillette^{3,4}, R. Tamblyn^{5,6,7}, L. Fellows⁸, N. Mayo^{1,2,9}

¹McGill University, Experimental Medicine, Montreal, Canada, ²Research Institute of McGill University Health Center Research Institute (RI-MUHC), Center for Outcomes Research and Evaluation (CORE), Montreal, Canada, ³McGill University, Department of Psychiatry, Montreal, Canada, ⁴McGill University Health Centre (MUHC), Chronic Viral Illness Service, Montreal, Canada, ⁵McGill University, Division of Experimental Medicine, Montreal, Canada, ⁶McGill University, Department of Epidemiology, Biostatistics & Occupational Health, Montreal, Canada, ⁷McGill University, Department of Medicine, Montreal, Nigeria, ⁸Montreal Neurological Institute, McGill University, Department of Neurology and Neurosurgery, Montreal, Canada, ⁹McGill University, School of Physical and Occupational Therapy, Montreal, Canada

Background: Medications with sedative activity are widely prescribed for anxiety, pain, insomnia, muscle spasms, and seizures. However, sedatives have been linked to adverse outcomes such as frailty.

This study aimed to know the extent to which sedative burden is associated with concurrent physical frailty in people aging with HIV.

Methods: A cross-sectional study of people living with HIV aged ≥ 35 years, living with HIV for at least a year, enrolled in the Positive Brain Health Study recruited across five clinical sites in Canada with baseline visits between 2014 and 2016. Medication data were collected from personal interviews and chart reviews. The sedative burden was estimated using the Sedative Load Model (SLM) and the sedative list of the Anticholinergic and Sedative Burden Catalog (ACSBC-SL).

The physical frailty indicator phenotype (FIP) was adapted from Fried's criteria using validated self-report items for exhaustion, low physical activity, slow gait speed, and low grip strength. A count of $\geq 3/5$ of the FIP criteria was defined as frail.

A multivariable logistic regression model was used to estimate the association between sedative burden and physical frailty. Final models were fully adjusted for demographics, polypharmacy, and comorbidities.

Results: 824 people living with HIV (85% male, 92% virologically suppressed, mean age 53 years) were included. 102 men (15%) and 26 women (21%) were identified as frail. The overall prevalence of frailty was 16% (128). 39% of participants were using ≥ 1 medication with a sedative effect, while 16% and 23% were prescribed primary sedatives using the SLM and ACSBC-SL, respectively.

Using the ACSBC-SL tool, the Sedative burden score ($OR=1.35[1.09-1.68]$), use of any sedative ($OR=1.84[1.02-3.22]$), use of a primary sedative ($OR=1.74[1.01-2.93]$), number of

sedatives (OR=1.57[1.15-2.14]), and the number of primary sedatives (OR=1.74[1.01-2.93]) were associated with frailty. Using the SLM, only the number of sedatives was associated with physical frailty (OR=1.40[1.03-1.90]).

Conclusions: The sedative drug burden estimated using the ACSBC-SL was associated with physical frailty independent of comorbidities. Longitudinal studies are needed to understand if reducing the sedative drug burden in people aging with HIV prevents or reverses physical frailty.

MOPEB21

Disability in people living with HIV (PLWH) in Asia: a prospective multi-centre case-control study

G.C.Y. Lui¹, Y. Chen², P.L. Wong³, C.-C. Hung⁴, C.-S. Wong⁵, R. Rajasuriar³

¹The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong, SAR of China, ²Chongqing Public Health Medical Center, Chongqing, China, ³University of Malaya, Kuala Lumpur, Malaysia, ⁴National Taiwan University, Taipei, Taiwan, ⁵National Centre for Infectious Diseases, Singapore, Singapore

Background: The burden of disability among PLWH varies temporally and spatially. Understanding the burden of disability and the associated factors would improve healthcare support planning to improve quality of life.

Methods: We performed a prospective case-control study in five Asian cities. PLWH aged ≥ 35 years and age- and sex-matched HIV-uninfected controls were enrolled. We collected demographic and clinical data, and measured frailty, mood (PHQ-9 and DASS-21 for depression, anxiety and stress) and cognitive function (International HIV Dementia Scale/IHDS and Montreal Cognitive Assessment/MoCA).

The primary endpoint was moderate disability, defined as WHODAS 2.0 ≥ 2 . Secondary endpoints were complex score of WHODAS and domain-specific dichotomous scores. We compared the prevalence of moderate disability and WHODAS score between cases and controls, and determined whether HIV was independently associated with disability using multivariate binary logistic regression and linear regression models.

Results: We enrolled 695 PLWH and 228 controls. PLWH had mean (\pm standard deviation) age of 53.3 \pm 10.0 years, 561(81%) were male HIV diagnosis for 9.3 \pm 7.4 years, 82% had HIV RNA < 50 copies per mL, and current CD4 was 520 \pm 296 cells/mm³, 52% was taking integrase inhibitor-based, and 41% non-nucleoside reverse transcriptase inhibitor-based regimens. Compared with controls, PLWH had higher burden of frailty, polypharmacy, depression, anxiety, stress, and loneliness, and poorer social support. Moderate disability was present in 357(51.4%) PLWH and 112(49.1%) controls respectively. WHODAS complex score was higher in PLWH (9.58 \pm 11.93 vs. 7.06 \pm 8.25, $p < 0.001$). Among the WHODAS domains, PLWH had a trend of more impairment in participation (75.0% vs. 68.4%, $p = 0.052$).

Moderate disability was independently associated with frailty, PHQ-9 score, stress score, MoCA, and loneliness, after adjusting for age, sex and study site, but not with HIV. Complex WHODAS score was independently associated with frailty, PHQ-9, stress and anxiety scores, IHDS, MoCA, and loneliness, but not with HIV, after adjusting for age, sex and study site. Among PLWH, moderate disability was independently associated with frailty, PHQ-9 score, stress and anxiety scores, loneliness, and MoCA.

Conclusions: Compared with age- and sex-matched HIV-uninfected controls, PLWH had higher prevalence of frailty, depression, stress, anxiety and loneliness, but not that of moderate disability in Asian cities.

TUPEB01

Association of antiretroviral therapies with adverse perinatal outcomes in pregnant women living with HIV: systematic review and meta-analysis

K. Beck¹, I. Cowdell¹, C. Portwood¹, H. Sexton¹, M. Kumarendran¹, Z. Brandon¹, S. Kirtley², J. Hemelaar¹

¹University of Oxford, National Perinatal Epidemiology Unit, Infectious Diseases Epidemiology Unit, Oxford Population Health, Oxford, United Kingdom, ²University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: The World Health Organization recommends integrase strand transfer inhibitor (INSTI) dolutegravir (DTG)-based antiretroviral therapy (ART) as first-line regimen in pregnant women living with HIV (WLHIV). Non-nucleoside reverse transfer inhibitor (NNRTI)-based ART and protease inhibitor (PI)-based ART are recommended as second- and third-line regimens. The impact of different ART regimens on perinatal outcomes is uncertain. We aimed to assess the comparative risk of adverse perinatal outcomes in WLHIV receiving different classes of ART.

Methods: We conducted a systematic literature review by searching PubMed, CINAHL, Global Health, and EMBASE for studies published between Jan 1, 1980, and September 20, 2022. We included studies reporting on the association of pregnant WLHIV receiving different classes of ART with 11 perinatal outcomes: preterm birth (PTB), very PTB, spontaneous PTB, low birthweight (LBW), very LBW (VLBW), term LBW, preterm LBW, small for gestational age (SGA), very SGA (VSGA), stillbirth, and neonatal death. Pairwise random-effects meta-analyses compared the risk of each adverse perinatal outcome among WLHIV receiving INSTI-ART, NNRTI-ART, PI-ART, and nucleoside reverse transfer inhibitor (NRTI)-based ART, and compared specific 'third drugs' from different ART classes. Subgroup and sensitivity analyses were conducted based on country income status and study quality. The protocol is registered with PROSPERO, number CRD42021248987.

Results: 30 cohort studies including 222,312 pregnant women met the eligibility criteria. Random-effects meta-analyses showed that INSTI-ART is not associated any ad-

verse perinatal outcomes compared to NNRTI-ART and PI-ART. PI-ART is associated with a significantly increased risk of SGA (Relative Risk (RR) 1.28, 95% CI 1.09-1.51) and VSGA (1.41, 1.08-1.83), compared to NNRTI-ART.

Specifically, lopinavir/ritonavir (LPV/r) was associated with an increased risk of SGA (1.40, 1.18-1.65) and VSGA (1.84, 1.37-2.45), compared to efavirenz (EFV), but not compared to nevirapine (NVP). We found no evidence that any class of ART or specific 'third drug' was associated with an increased risk of PTB.

Conclusions: Our findings support the recommendation of INSTI-ART as first-line ART regimen for use in pregnant WLHIV. However, the increased risks of SGA and VGSA associated with PI-ART, compared to NNRTI-ART, may impact choice of second- and third-line ART regimens in pregnancy. These findings should inform clinical guidelines.

TUPEB02

Efficacy of dolutegravir plus lamivudine in treatment-naïve people living with HIV without baseline drug-resistance testing: week 24 results of the randomized D2ARLING study

E. Cordova¹, J. Hernandez Rendon¹, V. Mingrone¹, P. Martin¹, G. Arevalo Calderon¹, J. Ballivian¹, S. Seleme¹, N. Porteiro¹

¹Fundacion IDEAA, Research Department, Buenos Aires, Argentina

Background: DTG-3TC dual therapy regimen is indicated for treatment-naïve people living with HIV (PLHIV). However, some concerns remain about its use when no information of baseline HIV-1 drug-resistance testing is available due to potential transmitted resistance. Efficacy data in this scenario is scarce.

Methods: D2ARLING is a randomized, open-label, phase IV study, designed to assess the efficacy and safety of DTG+3TC in treatment-naïve PLHIV with no available baseline HIV-1 resistance testing. Participants were randomized 1:1 (stratified by screening plasma HIV-1 RNA and CD4+ T-cell count) to DTG+3TC or DTG+TDF/XTC. Per protocol a genotypic drug-resistance test was performed at day 1 and remained double-blinded throughout the study. Primary endpoint: proportion of participants with plasma HIV-1 RNA <50 copies/mL at week 48 (ITT-exposed analysis, snapshot algorithm, non-inferiority 95%CI margin=10%). Week-24 analysis is reported here (ClinicalTrials.gov: NCT04549467).

Results: Out of 244 subjects screened, 214 were randomized to receive DTG+3TC (n=106) or DTG+TDF/XTC (n=108).

Baseline characteristics were similar between arms. Median age 31 years (IQR 26-39), 22.9% female, 30.8% HIV-1 RNA >100,000 copies/mL, and 19.7% CD4+ T-cell count <200 cells/mL.

At week 24, in the ITT-exposed snapshot 94.34% of participants on DTG+3TC arm and 95.37% on DTG+TDF/XTC arm achieved HIV-1 RNA <50 copies/mL (difference -1.03%;

95%CI -7.89% to 5.82%, $p=0.97$). Proportion of participants with HIV-1 RNA ≥ 50 copies/mL at week 24 was 0.94% (n=1) and 1.85% (n=2) in the DTG+3TC and DTG+TDF/XTC arms, respectively. One subject in the DTG+TDF/XTC arm met protocol-defined virological failure. No treatment-emergent mutations to any of the study drugs were observed in the virological failure genotypic resistance test. AEs overall rates were similar between arms (DTG+3TC n=36, DTG+TDF/XTC n=38), with low rates of withdrawals due to AEs for both DTG+3TC (<1%) and DTG+TDF/XTC (0%).

All serious AE were not related: DTG+3TC (1.9%) vs. DTG+TDF/XTC (4.6%). Median weight change was 2kg (IQR 0.5-4.25) and 0kg (IQR -1.5-3) in the DTG+3TC and DTG+TDF/XTC arms, respectively.

Conclusions: At week 24, DTG+3TC was non-inferior to DTG+TDF/XTC in treatment-naïve PLHIV without baseline resistance testing. Confirmation of these results at week 48 will provide strong evidence about DTG+3TC efficacy in resource-limited settings where pretreatment resistance testing is not always available.

TUPEB03

Efficacy and safety of switching older adults (≥ 60 years) from first-line art to B/F/TAF in Kenya - a randomized clinical trial (the B/F/TAF elderly study)

L.A. Ombajo^{1,2}, J. Penner³, J. Nkuranga^{1,2}, M. Mburu¹, E. Otieno^{1,2}, J. Mecha¹, S. Wahome⁴, R. Wanjohi⁵, F. Ndinya⁶, S. Bhagani⁷, A. Pozniak⁸

¹University of Nairobi, Clinical Medicine and Therapeutics, Nairobi, Kenya, ²University of Nairobi, Center for Epidemiological Modelling and Analysis, Nairobi, Kenya, ³University of British Columbia, Family Practice, Vancouver, Canada, ⁴Kenyatta National Hospital, Comprehensive care clinic, Nairobi, Kenya, ⁵The Nairobi Hospital, Radiology, Nairobi, Kenya, ⁶Jaramogi Oginga Odinga Teaching and Referral Hospital, Medicine, Kisumu, Kenya, ⁷Royal Free London Foundation Trust, Infectious Diseases/HIV Medicine, London, United Kingdom, ⁸London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Age-related comorbidities overlap with ARV-related adverse events (AEs), limiting treatment options for aging populations of people living with HIV (PLWH). We evaluated the efficacy and safety of switching older PLWH from first-line treatment to bicitgravir/emtricitabine/tenofovir alafenamide (B/F/TAF).

Methods: This open-label, randomized, active controlled, non-inferiority trial is being conducted at two sites in Kenya. Eligible participants were PLWH ≥ 60 years on a first line regimen with HIV RNA <50 copies/mL for at least 12 weeks. Participants were randomized 1:1 to switch to B/F/TAF or continue current ARV regimen (CAR).

Primary endpoints are proportion of participants with plasma HIV-1 RNA ≥ 50 copies/mL at week 48 in the intention-to-treat-exposed (ITT-E) population using the FDA Snapshot algorithm with a non-inferiority margin of 4%,

Index

and percentage change in lumbar spine bone mineral density (BMD) at 48 weeks. We present pre-specified week 24 analysis.

Results: Between February and May 2022, 520 participants were randomized (260 B/F/TAF, 260 CAR). Of these, 296 were enrolled into the BMD monitoring population (143 B/F/TAF, 153 CAR). All participants were black, median age 64 years (range 60–80), 267 (51.4%) were female, with baseline characteristics balanced between arms. At baseline, 495 (95.2%) participants were on TDF and 177 (59.8%) of the BMD population had osteoporosis. At the week 24, 1.5% in the B/F/TAF arm and 1.9% in the CAR arm had HIV-RNA ≥ 50 copies/mL (difference [95% CI], -0.4% [-2.63 to 1.86]), meeting non-inferiority criteria. The mean percentage change in lumbar spine BMD was +0.73% (SD 5.5) in the B/F/TAF arm and +0.11% (SD 5.1) in the CAR arm (difference [95% CI], 0.62% [-0.59 to 1.84]). Grade 3 or 4 AEs were uncommon (1.2% on B/F/TAF; 0.8% on CAR) with no treatment-related serious AEs. Grade 3 to 4 laboratory abnormalities were similar between arms (16.9% on B/F/TAF; 16.5% on CAR); renal AEs were more common with CAR (12.7% on CAR; 7.7% on B/F/TAF) and low-density lipoprotein abnormalities more common with B/F/TAF (5.0% on B/F/TAF; 1.9% on CAR).

Conclusions: Switch to B/F/TAF was non-inferior to CAR in this older African population; at week 24 the improvement in BMD in B/F/TAF was not significantly better than CAR.

TUPEB04

Similar inflammatory markers after switching to cabotegravir + rilpivirine long-acting vs. continuing bicitegravir/emtricitabine/tenofovir alafenamide: data from the Phase 3b SOLAR study

E. Elliot¹, D.A. Baker², E. Adachi³, J. Rodriguez⁴, M. Montero Alonso⁵, G. Rizzardini^{6,7}, P. Patel⁸, C.L. Latham⁸, D. Sutherland-Phillips⁸, R. Urbaityte⁹, K. Sutton⁸, H.P. Garges⁸, K. Smith⁸, B. Baugh¹⁰, R. D'Amico⁸, J. van Wyk¹

¹ViiV Healthcare, Brentford, United Kingdom, ²East Sydney Doctors, Darlinghurst, Australia, ³The University of Tokyo Hospital, Tokyo, Japan, ⁴Global Research Institute, California, United States, ⁵Hospital Universitario y Politécnico La Fe, Valencia, Spain, ⁶Fatebenefratelli Sacco Hospital, Milan, Italy, ⁷University of the Witwatersrand, Johannesburg, South Africa, ⁸ViiV Healthcare, Durham, United States, ⁹GSK, London, United Kingdom, ¹⁰Janssen Research & Development, Titusville, United States

Background: Cabotegravir + rilpivirine (CAB+RPV) administered every 2 months (Q2M) is the only complete long-acting (LA) regimen for the maintenance of HIV-1 suppression. Here, we present changes from baseline to Month (M) 6 and M12 in key inflammatory markers from the Phase 3b SOLAR study, overall and by subgroups.

Methods: SOLAR (NCT04542070) is a randomized (2:1), open-label, multicenter, noninferiority study assessing virologically suppressed adults switching to CAB+RPV LA

Q2M vs. continuing daily bicitegravir/emtricitabine/tenofovir alafenamide (BIC/FTC/TAF). Subgroup analyses were carried out by sex at birth, age (<35, 35–<50, ≥ 50 years), and body mass index (BMI; ≥ 30 , <30 kg/m²). Key inflammatory markers (platelet-poor plasma D-dimer, serum interleukin-6 [IL-6], serum C-reactive protein [CRP], CD4/CD8 ratio, serum soluble (s) CD14, and sCD163) were measured at baseline, M6, and M12, and were compared between treatments and subgroups.

Results: Overall, 454 participants received CAB+RPV LA and 227 received BIC/FTC/TAF; 18% of the total population were female, 20% were aged ≥ 50 years, and 22% had a BMI ≥ 30 kg/m².

Overall, at M12, CAB+RPV LA demonstrated noninferior virologic efficacy vs. BIC/FTC/TAF (HIV-1 RNA ≥ 50 copies/mL, 1% [n=5/447] vs. <1% [n=1/223]) (presented elsewhere). There were no significant differences between CAB+RPV LA and BIC/FTC/TAF in change from baseline to M6 or M12 for key inflammatory markers (treatment geometric mean ratio [CAB+RPV LA:BIC/FTC/TAF; 95% confidence interval]): D-dimer, M6: 0.98 (0.94–1.02), p=0.258, M12: 1.00 (0.96–1.05), p=0.826; IL-6, M6: 0.94 (0.84–1.05), p=0.256, M12: 0.96 (0.84–1.10), p=0.574; CRP, M6: 0.96 (0.83–1.11), p=0.582, M12: 0.99 (0.84–1.17), p=0.927. Changes in CD4/CD8 ratio, sCD14, and sCD163 were similar between treatment groups. Changes in inflammatory parameters were similar across key subgroups for CAB+RPV LA (Table).

	Overall		Sex at birth				Age (years)							
	CAB+RPV LA n=447	BIC/FTC/TAF n=223	CAB+RPV LA		BIC/FTC/TAF		CAB+RPV LA		BIC/FTC/TAF		CAB+RPV LA		BIC/FTC/TAF	
			Female n=176	Male n=271	Female n=112	Male n=111	<35 n=173	35–<50 n=174	≥ 50 n=100	<35 n=112	35–<50 n=111	≥ 50 n=100	<35 n=112	35–<50 n=111

Table. SOLAR Key Inflammation Marker Changes from baseline by Treatment Groups and Key Subgroups.

Conclusions: Over 12 months, CAB+RPV LA administered Q2M demonstrated noninferior virologic efficacy vs. daily oral BIC/FTC/TAF, with similar changes in inflammatory markers overall and by subgroups.

TUPEB05

Evaluation of therapeutic concentrations of anti-HIV antibodies 3BNC117/teropavimab and 10-1074/zinlirvimab through PK-PD modeling and prediction of the washout duration in HIV cure studies

Y. Zheng¹, S. Guzy², M. Caskey³, Q. Ma⁴, S.E. Collins¹, D. Sen Gupta¹, R. Palaparthi¹

¹Gilead Sciences, Inc., Foster City, United States,

²POP_PHARM, Rishon LeZion, United States, ³The Rockefeller University, New York, United States, ⁴University at Buffalo, State University of New York, Buffalo, United States

Background: 3BNC117 and 10-1074 are potent broadly neutralizing antibodies (bNAbs) against HIV envelope glycoproteins isolated and cloned from people with HIV (PWH). Teropavimab (3BNC117-LS) and zinlirvimab (10-1074-LS) are recombinant, fully human monoclonal antibodies derived from 3BNC117 and 10-1074, respectively, with two amino acid substitutions in the Fc domain to prolong their half-lives. 3BNC117/teropavimab and 10-1074/zinlirvimab have been shown to induce rapid decline in viremia in PWH, as well as delay the time-to-viral rebound in suppressed PWH during analytical treatment interruption (ATI). The purpose of this study is to evaluate the therapeutic concentrations of the bNAbs through pharmacokinetic-dynamic (PK-PD) modeling.

Methods: Population PK-PD models were developed based on concentration and/or viral dynamic data from 6 studies that evaluated their antiviral activity in 45 viremic and 49 suppressed PWH during ATI, and 3 PK studies of 3BNC117/teropavimab and 10-1074/zinlirvimab. The PK of the bNAbs were modeled by two-compartment linear PK models. The PD model describes viral replication using logistic growth function, and viral elimination by the bNAbs using first-order kinetics, with a saturable nonlinear relationship between bNAb concentrations and viral elimination rates.

Distinct viral populations sensitive or resistant to each bNAb were modeled to capture the mechanism of resistance selection in treated participants.

Simulations were performed to evaluate different washout durations of teropavimab and zinlirvimab to predict time-to-viral rebound during ATI.

Results: The PK-PD models adequately described the PK and viral dynamic data from all studies analyzed. The estimated half-lives of teropavimab and zinlirvimab in suppressed PWH are ~62 and 77 days, respectively. The estimated mean (95% CI) serum concentrations corresponding to 20% maximum drug effect of 3BNC117/teropavimab and 10-1074/zinlirvimab were 6.3 (4.9-8.2) and 8.1 (2.5-26) µg/mL, respectively.

Simulations predicted that after a washout period of ≥48 weeks following single dose combination of 30 mg/kg teropavimab and 10 or 30 mg/kg zinlirvimab, these bNAbs would have minimal effects on the time-to-viral rebound during ATI.

Conclusions: The PK-PD modeling analyses provided insights to the minimal therapeutic serum concentrations and washout durations of the long acting bNAbs to help define their efficacy in HIV cure studies.

Patient-reported outcomes after 12 months of maintenance therapy with cabotegravir + rilpivirine long-acting compared with bictegravir/emtricitabine/tenofovir alafenamide in the Phase 3b SOLAR study

V. Chounta¹, C. Mussini², C. Cazanave³, E. Adachi⁴, B. Eu⁵, M. Montero Alonso⁶, G. Crofoot⁷, K. Sutton⁸, D. Sutherland-Phillips⁹, R. Urbaityte⁹, A. Ehmann¹⁰, J. Scherzer¹¹, P. de los Rios⁸, R. D'Amico⁸, W.R. Spreen⁸
¹ViiV Healthcare, Brentford, United Kingdom, ²University of Modena and Reggio Emilia, Modena, Italy, ³Pellegrin Hospital, University Hospital of Bordeaux, Bordeaux, France, ⁴The University of Tokyo, Tokyo, Japan, ⁵Prahan Market Clinic, Melbourne, Australia, ⁶Hospital Universitario y Politécnico La Fe, Valencia, Spain, ⁷The Crofoot Research Center, Houston, United States, ⁸ViiV Healthcare, Durham, United States, ⁹GSK, London, United Kingdom, ¹⁰GSK, Ballston Spa, United States, ¹¹ViiV Healthcare, Munich, Germany

Background: The SOLAR (NCT04542070) Phase 3b study demonstrated noninferior virologic efficacy of switching to cabotegravir+rilpivirine long-acting (CAB+RPV LA) dosed Q2M from daily oral bictegravir/emtricitabine/tenofovir alafenamide (BIC/FTC/TAF) vs. continuing BIC/FTC/TAF over 12 months in suppressed ART-experienced people living with HIV-1. Patient-reported outcomes (PROs) from SOLAR are presented herein.

Methods: PRO endpoints included a treatment preference questionnaire; overall treatment satisfaction and satisfaction with treatment flexibility, convenience, and willingness to continue treatment (HIV Treatment Satisfaction Questionnaire status version [HIVTSQs]); acceptability of injections (Perception of Injection questionnaire); and three single-item questions exploring an individual's fear of disclosure, anxiety relating to adherence requirements, and daily reminder of their HIV status (FAD questions).

Results: Of 670 participants, 447 (67%) switched to LA therapy and 223 (33%) continued BIC/FTC/TAF (2:1 randomization). After 12 months of treatment (or at withdrawal), most (90%) questionnaire respondents preferred LA injectable treatment vs. daily oral therapy (5%); the remaining 5% reported no preference. The top reason for preferring LA therapy was not having to worry about taking HIV medicine (85%).

A statistically significant increase from baseline favoring CAB+RPV LA vs. BIC/FTC/TAF was reported in overall treatment satisfaction, and satisfaction with treatment flexibility, treatment convenience, and willingness to continue treatment after 12 months of therapy (Table).

Acceptability of injections improved after 12 months of treatment. At baseline (prior to randomized treatment), 49% (n=218/447) of participants in the CAB+RPV LA arm and 43% (n=97/223) in the BIC/FTC/TAF arm reported "always"/"often" to at least one FAD question.

After 12 months of therapy, a higher proportion of respondents in the CAB+RPV LA group reported improvements in all three FAD questions compared with respondents receiving BIC/FTC/TAF.

Table.

Conclusions: Switching to CAB+RPV LA Q2M was associated with improved treatment satisfaction, preferred by 90% of participants, while also providing emotional well-being benefits including relief from the fear of disclosure and anxiety surrounding adherence.

TUPEB07

Pharmacokinetic bridging with oral Lenacapavir for missed subcutaneous Q6M dosing

V. Jogiraju¹, M. Shelton¹, N. Shaik¹, D. Bhakta¹, J. Ling¹, H. Wang¹, H. Dvory-Sobol¹, M. Rhee¹, R. Palaparthi¹, R. Singh¹

¹Gilead Sciences, Inc., Foster City, United States

Background: Lenacapavir (LEN) is currently approved for multidrug-resistant HIV-1 infection in combination with other antiretrovirals for heavily treatment-experienced individuals.

In ongoing Phase 2/3 studies (CAPELLA and CALIBRATE), participants receive oral LEN loading (600 mg on Days 1 and 2; 300 mg on Day 8) followed by 927 mg SC given every 6-months (Q6M) starting from Day 15.

In these studies, mean trough concentrations >15.5 ng/mL, which is inhibitory quotient-4 (IQ4; ie, 4-fold in-vitro protein binding-adjusted 95% effective concentration), are associated with high rates of virologic suppression. In participants temporarily unable to receive SC LEN during its clinical hold, oral bridging (300 mg QW) was used until SC dosing was resumed.

Our objective was to evaluate the pharmacokinetics (PK) of LEN during oral bridging (OB) period to assess the adequacy of 300-mg oral QW LEN for maintaining therapeutic concentrations between missed SC LEN doses.

Methods: During OB period, sparse PK samples were collected at the start (of OB period) and every ~10-12 weeks (without regard to a prespecified time since dose) until SC

LEN was resumed. LEN plasma concentrations were summarized during OB period in the CAPELLA (N=57) and CALIBRATE (N=82) studies.

Results: In both studies, mean LEN concentration and the lower-bound 90% confidence interval (CI) were maintained above the efficacy target of IQ4 at all OB period visits (Table 1).

At the time of SC LEN resumption, mean (lower-bound 90% CI) predose concentrations in CAPELLA (74.4 ng/mL [56.2 ng/mL]) and CALIBRATE (50.7 [43.6]) exceeded IQ4.

Study	Concentration	OB Day 1	OB Week 10	OB Week 20	OB Week 30
CAPELLA	Mean, ng/mL	46.1 (n=56)	76.2 (n=57)	74.8 (n=36)	41.7 (n=39)
	90% CI	40.3, 51.9	66.1, 86.3	50.4, 99.3	29.9, 53.5
CALIBRATE	Mean, ng/mL	27.8 (n=76)	54.9 (n=68)	52.5 (n=60)	50.1 (n=6)
	90% CI	25.3, 30.4	47.1, 62.8	43.7, 61.4	24.4, 75.7

Table 1. Plasma LEN Concentrations During OB Period With LEN 300 mg QW

Conclusions: Mean LEN concentrations and the lower-bound 90% CIs were maintained above IQ4 from the first oral LEN bridging visits until SC LEN was resumed in both studies. These results indicate that LEN 300 mg oral QW provides adequate concentrations to bridge LEN dosing in participants who may miss their Q6M SC injection.

Suicidal behaviors among Thai adolescents and young adults living with HIV

T. Sudjaritruk^{1,2}, O. Mueangmo^{1,2}, J. Saheng^{1,2}, W. Wongjak², T. Chaito², P. Nantarat², J.L. Ross³, A.H. Sohn³, C.A. Mellins^{4,5}

¹Faculty of Medicine, Chiang Mai University, Department of Pediatrics, Chiang Mai, Thailand, ²Faculty of Medicine, Chiang Mai University, Clinical and Molecular Epidemiology of Emerging and Re-emerging Infectious Diseases Research Cluster, Chiang Mai, Thailand, ³TREAT Asia/amfAR, The Foundation for AIDS Research, Bangkok, Thailand, ⁴NY State Psychiatric Institute, HIV Center for Clinical and Behavioral Studies, New York City, United States, ⁵Columbia University, New York City, United States

Background: Suicide is the fourth leading cause of death in adolescents and young adults worldwide. Suicidality can negatively impact quality of life and HIV treatment outcomes. This study aimed to describe suicidal ideation and behaviors among Thai adolescents and young adults living with HIV (AYA-HIV).

Methods: A cross-sectional study was conducted among Thai AYA-HIV aged 15-24 years who were aware of their HIV status, and attended an HIV clinic in Chiang Mai, Thailand. Participants were interviewed about lifetime and recent suicidal ideation and behaviors by well-trained staff, using a cross-culturally validated Thai version of the Columbia-Suicide Severity Rating Scale (C-SSRS). The C-

SSRS's questions are divided into 4 subscales:

1. Suicidal ideation;
2. Intensity of ideation;
3. Suicidal behaviors;
4. Lethality of suicide attempts.

Results: Of 150 AYA-HIV enrolled, 101 (67%) were male, 90 (60%) had perinatally acquired HIV, 85 (57%) were heterosexual, and the median age was 21 (interquartile range [IQR]: 19-23) years. At enrollment, 66 (45%) had graduated with bachelor degree or higher, and 126 (84%) had monthly incomes <500 USD. All AYA-HIV were on combination antiretroviral treatment (cART), of which 70% of regimens included non-nucleoside reverse transcriptase inhibitor, and the median self-reported adherence to cART was 95% (IQR: 90-100%). The median CD4 count was 547 (IQR: 378-747) cells/mm³; 79% had viral load <50 copies/mL. Overall, 44 (29%) AYA-HIV reported lifetime suicidal ideation, 8 of whom (18%) reported symptoms within the past month.

Additionally, 16 (11%) AYA-HIV reported having suicidal behaviors during their lifetime, 2 (13%) within the previous 3 months. The characteristics of suicidal ideation and behaviors among our Thai AYA-HIV are summarized in Table 1.

Suicidality characteristics*	Lifetime (n=44)	Recent† (n=8)
Subscale 1: Suicidal ideation		
Type of suicidal ideation		
Non-specific active suicidal thoughts	35 (79.5)	8 (100)
Active suicidal ideation without intent to act	23 (52.3)	4 (50.0)
Active suicidal ideation with intent to act	12 (27.3)	1 (12.5)
Active suicidal ideation with specific plan and intent	8 (18.2)	1 (12.5)
Subscale 2: Intensity of suicidal ideation		
Frequency		
Less than once a week	20 (45.5)	4 (50.0)
Once a week	5 (11.4)	2 (25.0)
2-5 times in week	7 (15.9)	0 (0)
Daily or almost daily	10 (22.7)	2 (25.0)
Many times each day	2 (4.5)	0 (0)
Reason for suicidal ideation		
Completely to get attention/revenge/reaction from others	3 (6.8)	0 (0)
Mostly to get attention/revenge/reaction from others	2 (4.5)	1 (12.5)
Equally to get attention/revenge/reaction from others and to end/stop pain	8 (18.2)	1 (12.5)
Mostly to end/stop pain	12 (27.3)	1 (12.5)
Completely to end/stop pain	7 (15.9)	2 (25.0)
Non-specific reasons	12 (27.3)	3 (37.5)
Subscale 3: Suicidal behavior		
Type of suicidal behavior		
Actual suicide attempt	12 (27.3)	2 (25.0)
Interrupted attempt	8 (18.2)	1 (12.5)
Aborted or self-interrupted attempt	9 (20.5)	0 (0)
Preparatory acts or behavior	2 (4.5)	0 (0)
Subscale 4: Intensity of suicidal attempt† (n=12)		
Intensity of suicidal attempt	The most severe	The most recent
No or very minor physical damage	2 (16.7)	2 (16.7)
Minor physical damage	6 (50.0)	6 (50.0)
Moderate physical damage	3 (25.0)	3 (25.0)
Severe physical damage	1 (8.3)	1 (8.3)

*Data were presented as number (percent, %).

†Within 1 month for suicidal ideation, and within 3 months for suicidal behavior.

‡Among participants with actual suicidal attempt (n=12).

Table 1. Characteristics of suicidal ideation and behaviors among Thai adolescents and young adults living with HIV.

Conclusions: Suicidal ideation and behaviors were prevalent in Thai AYA-HIV in our study cohort. Screening for suicidality in primary HIV clinics could help with earlier detection and linkage to appropriate management for this population.

Detectable viral load among virally suppressed adolescents on multi-month antiretroviral drug refills in four regions of the mainland of Tanzania

T. Samatta¹, G. Ngoda¹, F. Chisonjela¹, D. Temba¹, J. Mwakisambwe¹, L. Machumi¹, G. Msalale², F. Kibaba³, P. Pagali⁴, A. Kibao⁵, W. Mauka¹, E. Matiko⁶, L. Shija⁶, M. Swaminathan⁶, D. Sando¹, G. Lyatuu¹

¹Management and Development for Health, Dar es Salaam, Tanzania, United Republic of, ²Office of the Regional Administrative Secretaries, Tabora, Tanzania, United Republic of, ³Office of the Regional Administrative Secretaries, Geita, Tanzania, United Republic of, ⁴Office of the Regional Administrative Secretaries, Kagera, Tanzania, United Republic of, ⁵Office of the Regional Administrative Secretaries, Dar es Salaam, Tanzania, United Republic of, ⁶Tanzania Country Office, U.S. Centres for Disease Control and Prevention, Dar es Salaam, Tanzania, Dar es Salaam, Tanzania, United Republic of

Background: About half of the adolescents in HIV care in Tanzania receive their antiretroviral therapy (ART) through multi-months dispensing (MMD) at three- and six-monthly intervals. While undetectable HIV viral load (HVL) is a pre-requisite for enrolment in MMD, it's unclear whether adolescents on MMD maintain their undetectable viral load status. We assessed detectable HVL among adolescents on MMD and associated factors across four regions of Tanzania.

Methods: We identified adolescents aged 10-19 years with HIV on ART enrolled on MMD in routine healthcare in Dar-es-Salaam, Kagera, Geita and Tabora regions of Tanzania. These adolescents were followed up via their routine three/six monthly clinical visits per their MMD schedules until 30th September 2022. Our primary outcome was detectable plasma HVL (≥50 copies/mL) at their one-year HVL follow-up test since MMD enrolment.

We used Poisson estimation of the binomial regression with robust error variance, controlling for age, sex, and other clinical characteristics to investigate risk factors of detectable HVL reporting adjusted risk ratio (aRR) and 95% CI.

Results: We identified 3,439 adolescents newly enrolled on three (2,828, 82.2%) and six (611, 17.8%) monthly MMD between April and June 2021 across 395 health facilities. Among these adolescents, 1,744 (50.7%) were aged 10-14 years and 1,872 (54.4%) were females. At baseline, 1,972/3,018 with data (65.3%) were classified as WHO clinical stage 3 or 4, 215 (6.3%) were on second-line ART, and 3,340 (97.1%) had been on ART for at least a year.

At the one-year viral load follow-up test, 434 (12.6%) adolescents were found to have detectable HVL. The risk of having detectable HVL did not vary by age (p=0.31), sex (p=0.32), WHO stage (p=0.24), or ART duration (p=0.07). However, those on second-line ART regimen were twice as likely to have detectable HVL compared to those on first-line regimen (aRR 2.43, 95%CI 1.94-3.04).

Conclusions: Detectable HVL remains a clinical concern among adolescents with HIV on MMD, which may suggest sub-optimal ART adherence or drug resistance mutations. There is need to remain vigilant in monitoring the risk of detectable HVL and strengthen adherence support to prevent subsequent virologic failure and drug resistant mutations.

of Munich (LMU), Munich, Germany, ⁶German Center for Infection Research (DZIF), partner site Munich, Munich,

Germany

Background: In 2021, only 65% of Mozambican children on antiretroviral therapy (ART) were virologically suppressed. Poor adherence is the principal driver of ART failure, and a deeper understanding of underlying causes is needed for improved treatment support, particularly for infants who have even lower suppression rates. Data from intensified adherence support visits for HIV-positive neonates and infants enrolled in the LIFE study in Mozambique were analyzed to address this knowledge gap.

Methods: Infants with positive point-of-care virologic tests at birth or post-natal visits initiated ART and were followed up to 18 months of age, with routine viral load monitoring. Information from adherence interventions was extracted from narrative reports and merged with clinical data.

Results: A total of 117 recruited infants tested HIV-positive. DTG-based ART was initiated in 2 (1.7%) infants and 39 (33.3%) transitioned from LPVr to DTG-based ART. At 6, 12, and 18-month study visits, 70.3%, 72.7%, and 63.6% of caregivers reported no ART interruptions in the past week. Virologic suppression rates for the same study visits were 31.1%, 47.0%, and 50.9%. Qualitative adherence data was available for 62.4% (73/117) of participants.

The percentage of infants with reported barriers by category were:

1. Paternal-related, 72.6% (53/73);
2. Maternal-related, 60.3% (44/73);
3. Socioeconomic, 42.5% (31/73);
4. Medication-related, 32.9% (24/73); and
5. Provider-related, 5.5% (4/73).

Non-disclosure to the father was a noted adherence barrier for 28.8% (21/73). Excluding infants with missing data, 33.7% (28/83) of mothers had not disclosed their serostatus to the father by the first adherence intervention, and 75.0% (21/28) of them lived with the father.

Fear of abandonment was the most common reason for non-disclosure to fathers, reported for 67.9% (19/28) of mothers.

Conclusions: Medication-related adherence barriers were common, and most children received LPVr-based ART. It was not possible to quantify in this analysis, but the recent introduction of dispersible DTG tablets, allowing for once-daily dosing, has the potential to improve the unacceptably low virologic suppression rates observed.

However, the impact of optimized pediatric ART will be minimized without intensified and proactive efforts to identify and address family-specific barriers that adversely impact adherence, with particular attention to paternal factors and serostatus disclosure.

TUPEB11

Cause of death among infants by HIV status in Zambia, 2020-2021

W. Sichembe¹, K. Mwebo¹, A. Mwila¹, P. Kapombe², M. Cheelo², N. Kancheya¹, P. Minchella¹, J. Hines¹

¹US Centers for Disease Control and Prevention, Lusaka, Zambia, ²Ministry of Health, Lusaka, Zambia

Background: Although mortality is higher among HIV positive infants compared to those without HIV, optimized pediatric antiretroviral treatment (ART) has improved survival.

We explored the causes of death (COD) and survival-time by HIV status among deceased infants in Zambia from 2020-2021.

Methods: We analyzed the Zambian Ministry of Health mortality surveillance data from 2020-2021. Verbal autopsies (VA) are conducted on persons who die in the community or within 48 hours of arrival at health facilities in 27 districts representing ~50% of Zambia's population. Trained officers collect past medical history and circumstances proximal to death from close relatives/associates using a standardized World Health Organization questionnaire.

Responses are analyzed by a validated algorithm that assigns probable CODs. We analyzed CODs and survival-time by HIV status among infants (<1 year old) using R.

Results: VAs were conducted for 2,446 infants from 2020-2021. Sixty-six (2.7%) infants were HIV positive (with 50% on ART), 1,372 (56.1%) were HIV negative and 1,008 (41.2%) had unknown HIV status. Among HIV positive and negative infants, the probable CODs were mainly indeterminate or infectious.

Birth asphyxia, prematurity and neonatal sepsis were the leading probable CODs among infants with unknown HIV status, who died younger than those with known HIV sta-

tus (median days: 2 vs. 136; $p < 0.01$). Survival-time did not differ for HIV positive compared to HIV negative infants (median days: 136.5 vs 136; $p = 0.45$). Among HIV positive infants, survival-time did not differ by ART status ($p = 0.74$).

Rank	HIV Positive (n = 68) cause (%)	HIV status HIV Negative (n = 1572) cause (%)	Unknown HIV status (n = 3000) cause (%)
1	Indeterminate (27.9)	Indeterminate (25.9)	Birth Asphyxia (31.5)
2	Meningitis and Encephalitis (19.2)	Diarrheal diseases (29.8)	Prematurity (28.1)
3	Unspecified infectious diseases (12.1)	Unspecified infectious diseases (12.3)	Neonatal sepsis (11.3)
4	Diarrheal diseases (12.1)	Meningitis and Encephalitis (14.2)	Neonatal Pneumonia (9.2)
5	Cardiac disease (8.1)	Cardiac disease (14.4)	Fresh stillbirth (6.9)

*Cause of death determined by verbal autopsy

Table 1. Top five causes of death among infants by HIV status in Zambia, 2020-2021.

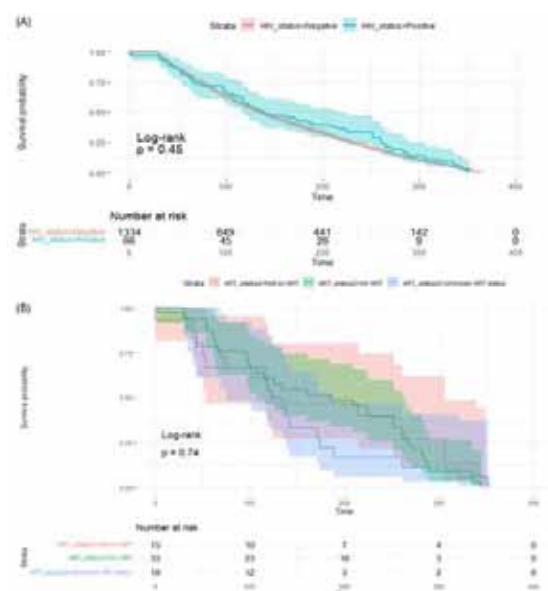

Figure 1. Survival time of infants from birth (A) HIV positive and HIV negative (B) HIV positive by ART status.

Conclusions: The lack of difference in survival-time among deceased infants by HIV status could be because other infectious diseases highly affect this age group. Infants with unknown HIV status died younger from complications of pregnancy and delivery. Improved neonatal care, diagnostics for the indeterminate COD and management of infectious diseases can improve infant outcomes. Prompt ART initiation can also improve survival of HIV positive infants.

TUPEB12

Increased dolutegravir coverage is associated with increase in viral load coverage and suppression among children living with HIV in Togo

Y.K. D'Almeida¹, A.N. Moussa¹, E. Kokoloko¹, D. Hillah¹, J.P. Tchupo¹, D. Messan¹, J. Mandala², C. Casalini²

¹FHI 360, Lome, Togo, ²FHI 360, Durham, United States

Background: Though a UNAIDS 2021 report shows that, between 2010 and 2020, Togo halved AIDS-related deaths in children ages 0-14, available data show low dolutegravir coverage (DTG-C) and viral load suppression (VLS) among children living with HIV (CLHIV). This analysis presents data and solutions to improve DTG-C, viral load

coverage (VLC), and VLS among CLHIV at selected public health facilities. The work was supported by the PEPFAR- and USAID-funded EAWA project, which is implemented by FHI 360.

Description: Routinely collected data were analyzed for CLHIV ages 14 and younger from October 2019 through September 2022. We assessed the proportion of CLHIV on antiretroviral therapy (ART) who received a dolutegravir-based regimen; VLC, calculated as CLHIV with a documented viral load test result (VLTR) among those on ART; VLS, calculated as CLHIV with a documented VLTR below 1,000 copies among those with a VLTR. Between October 2019 and September 2020, only half were on a dolutegravir-based regimen, less than half had a documented VLTR, and 64% reached VLS. A team was tasked with implementing solutions based on roots cause analysis: Eligible CLHIV were line listed and contacted for starting/transitioning to dolutegravir and collecting viral load samples; ART adherence support was provided; monthly dolutegravir stock monitoring was conducted; pending test results were tracked through a laboratory focal person; VLTR were documented; and CLHIV were informed within one week from test result. Granular data were used to prioritize technical assistance to sites with lowest DTG-C, VLC, and VLS.

Lessons learned: From October 2019–September 2020, October 2020–September 2021, and October 2021–September 2022, an increase was observed in the following indicators among CLHIV: DTG-C from 52% to 64% to 71%, respectively; VLC from 48% to 85% to 90%, respectively; and VLS from 64% to 70% to 82%, respectively. A positive trend in indicators was observed when disaggregated by age (Table 1).

	Oct 2019 - Sep 2020				Oct 2020 - Sep 2021				Oct 2021 - Sep 2022			
	0-4	5-9	10-14	total 0-14	0-4	5-9	10-14	total 0-14	0-4	5-9	10-14	total 0-14
Current on ART	406	600	717	1,723	428	693	807	1,928	510	841	1,046	2,397
Dolutegravir-based regimen	30%	91%	33%	52%	47%	99%	43%	64%	68%	97%	46%	71%
Documented VLTR	115 (32%)	248 (40%)	432 (62%)	795 (48%)	272 (80%)	507 (87%)	620 (85%)	1,399 (85%)	372 (95%)	676 (87%)	834 (90%)	1,882 (90%)
Virally suppressed	75 (65%)	156 (63%)	276 (64%)	507 (64%)	177 (65%)	353 (70%)	444 (72%)	974 (70%)	294 (79%)	542 (80%)	701 (84%)	1,537 (82%)

Table 1. Dolutegravir, viral load coverage, and viral load suppression by age band, by year, Togo

Conclusions/Next steps: Solutions that address root causes and granular data use were successful in increasing DTG-C, which resulted in increased VLC and VLS among CLHIV. Such approaches should be scaled up and become national standard of care.

⁶CENSIDA, Mexico City, Mexico, ⁷CCINSHAE, Mexico City,

Mexico

Background: Antiretroviral therapy (ART) among children and adolescents living with HIV (C/ALHIV) frequently includes drugs considered obsolete among adults. Since 2019, Mexico implemented a national optimization program, based on the use of second-generation integrase inhibitors (INSTIs) –mainly co-formulated BIC/TAF/FTC– as preferred regimens for ART initiation and switch. We aimed to evaluate this rollout program among children and adolescents.

Methods: Data were obtained from SALVAR (National System for Antiretroviral Surveillance and Administration). We included information of C/ALHIV between 8 to 17 years, who started on ART or switched to BIC/TAF/FTC, from June 2019 to June 2021. We categorized them as "started BIC/TAF/FTC" (G1), "switched to BIC/TAF/FTC" (G2), or "started other than BIC/TAF/FTC" (G3). We calculated the proportion of C/ALHIV with viral suppression (VS) (<40 copies/ml) after six months of ART initiation or switch and durability of the regimen, defined as maintaining VS on the same ART versus other outcomes.

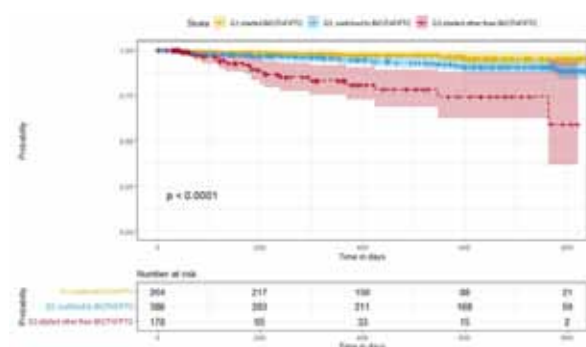

Figure 1. Probability of keeping the same ART regimen.

Results: A total of 828 C/ALHIV were included; the median follow-up was 447 days (IQR 182-702); 264 (32%) were classified as G1, 386 (47%) as G2, and 178 (21%) as G3. The median age was 17 (IQR: 16 -18), 15 (IQR: 12-17), and 16 (IQR: 14 -17) years (p-value<0.01); and 23%, 48% and 67% of participants were cisgender women for G1, G2, G3 (p-value<0.01). The last regimen used before ART switch in G2 was mainly based on protease inhibitors (PIs) in 64%, followed by NNRTIs in 20%. Within G3, 49% were started on NNRTIs, other

INSTIs in 37%, and PIs in 11%. After six months of initiation or switch, VS was present in 86%, 96% and 86% of G1, G2 and G3. The durability of ART regimen in each group is shown in Figure 1.

Conclusions: In this real-life experience analysis, second-generation INSTIs showed highly effective and long-lasting performance in Mexican children and adolescents.

TUPEB14

Recommendations for missed oral lenacapavir loading doses using population-pharmacokinetics-based simulations

R. Singh¹, N.A. Shaik¹, F. Bellanti², C. Comisar², K. Polireddy²,

M. Rhee¹, R. Palaparthi¹

¹Gilead Sciences, Inc., Foster City, United States, ²Certara,

Inc., Princeton, United States

Background: Lenacapavir (LEN) is currently approved for the treatment of multidrug-resistant HIV-1 in combination with other antiretrovirals for heavily treatment-experienced (HTE) individuals. In the ongoing pivotal Phase 2/3 study (CAPELLA), participants received oral LEN loading (600 mg on Days 1 and 2; 300 mg on Day 8) followed by 927 mg SC Q6M starting from Day 15 (Phase 2/3 regimen). Current data indicate that a mean trough LEN concentration of 15.5 ng/mL (inhibitory quotient-4 [IQ4]) is associated with high antiviral activity. Given the importance of oral loading doses in achieving and maintaining concentrations >IQ4, it is imperative to consider options to manage missed oral loading doses. We used a population-pharmacokinetic (PopPK) model to simulate various dosing scenarios to guide missed oral loading-dose recommendations for the HTE population.

Methods: A previously developed 2-compartment PopPK model with 1st-order absorption and linear elimination was used to simulate plasma concentrations following missed oral LEN doses to provide recommendations for different scenarios of missed doses, and identify alternative dosing options.

Results: Recommendations for missed oral loading dose scenarios in Phase 2/3 regimen are shown (Table 1). In all scenarios, the recommended alternative dosing option maintained LEN concentrations >IQ4. Figure 1 shows a scenario in which the Day 2 oral dose is missed by ≥6 days, with alternative dosing options on Days 8 and 15.

Loading Dose Day	Missed Dose Scenario	Recommendation
Day 2	Day 2 oral dose missed by <6 days	Participant should take 600 mg PO dose as soon as possible
	Day 2 oral dose missed by ≥6 days	Participant should take 600 mg instead of 300 mg on Day 8 and 300 mg on Day 15 (along with SC injection)
Day 8	Day 8 oral dose missed by <6 days	Participant should take 300 mg PO dose as soon as possible
	Day 8 oral dose missed by ≥6 days	Participant should take 300 mg on Day 15 (along with SC injection)

Table 1. Summary of Missed Dose Recommendations for Oral LEN Loading in Phase 2/3 Dosing Regimen.

Ruxolitinib-mediated HIV-1 reservoir decay in A5336 phase 2a trial

M.D. Reece¹, Z. Zhang¹, S. Pereira-Ribeiro¹, R. Sekaly¹, D.A. Kulpa¹, J. Yoon¹, E. White¹, R.F. Schinazi^{2,3,4}, V.C. Marconi^{5,6}, C. Gavegnano^{1,7,8,9,10}

¹Emory University, Department of Pathology and Laboratory Medicine, Atlanta, United States, ²Emory University, School of Medicine, Atlanta, United States, ³Emory University, Department of Pediatrics, Atlanta, United States, ⁴Center for ViroScience and Cure, Atlanta, United States, ⁵Emory University, Division of Infectious Diseases, Atlanta, United States, ⁶Emory University, Department of Global Health, Atlanta, United States, ⁷Emory University, Department of Pharmacology and Chemical Biology, Atlanta, United States, ⁸Emory University, Center for Human Health, Atlanta, United States, ⁹Atlanta Veterans Affairs Medical Center, Department of Pathology, Decatur, United States, ¹⁰Harvard University, Center for Bioethics, Boston, United States

Background: Ruxolitinib is FDA approved for myelofibrosis, polycythemia vera, atopic dermatitis and chronic graft-versus-host disease. We evaluated the impact of ruxolitinib on the peripheral HIV-1 reservoir and key immunomodulatory events driving HIV-1 persistence in people with HIV-1 (PWH) in an AIDS Clinical Trial (ACTG) sponsored open-label randomized Phase 2a multi-site trial (n=60).

Methods: Inclusion criteria: ≥ 18 age ≤ 75 , background ART regimen (NNRTI or INSTI without cobicistat for ≥ 2 years), continuously virologically suppressed, CD4⁺ T-cell count >350 cells/mm³; no significant medical condition besides HIV or hypertension. Participants were randomized to

ruxolitinib 10 mg bid plus ART (n=40) or ART alone (n=20) from week 0 through 5. Both groups were observed through week 12. Cellular markers (flow-cytometry), soluble cytokine (Mesoscale), intDNA and IPDA were measured on peripheral blood from weeks 0, 5, and 12. Sequential series of Mann-Whitney U tests were performed to understand how biomarker changes across weeks impact reservoir decay.

We evaluated:

1. Biomarkers within the ruxolitinib-treated group which were significantly ($p < 0.05$) different between weeks 5 and 12,
2. Which markers determined in test 1 were significantly ($p < 0.05$) different *versus* control group, and;
3. Which of these were trending towards significance ($p < 0.1$) between participants with high reservoir decay and those with no decay.

Significance was further confirmed through Benjamini-Hochberg testing to minimize the false discovery rate.

Results: IntDNA and IPDA reservoir measurements were highly correlated to one another ($r^2 0.86$). HIV-1 reservoir significantly decayed in the ruxolitinib group by week 12 *versus* control.

Decay correlates included decrease in activation and expansion markers (week 5), leading to reservoir decay by week 12 (CD127⁺/CD4⁺ T_N and CD127⁺/CD8⁺ T_{TD}, CD39⁺/CD4⁺ T_{EM}, and CD69⁺ in B cells). Reservoir decay by week 5 associated with change at week 5 (IL10), and change at week 12 (BCL2⁺/CD8⁺ T_{CM}).

Conclusions: Ruxolitinib decays the HIV-1 reservoir and re-sets immune balance in PWH on ART. Based on reservoir decay during treatment (week 0 to 5), our model predicts a 99.99% decay in 2.5 years, should rates of decay remain constant. These data are foundational for further human trials with Jak 1/2 inhibitors such as ruxolitinib towards HIV-1 elimination.

Bioengineering, Seattle, United States, ²University of

Washington, Pharmaceuticals, Seattle, United States,

³University of Washington, Pharmaceuticals and Medicine,

Seattle, United States, ⁴University of Washington,

Pediatrics, Seattle, United States, ⁵University of

Washington, Medicine, Seattle, United States

Background: Introduction of long-acting Cabenuva, containing two HIV drugs, cabotegravir and rilpivirine, in two-intramuscular injections for HIV treatment is a significant step toward addressing adherence and pill fatigue. However, clinical and programmatic issues limit *Cabenuva* uptake worldwide. WHO has an on-going initiative to distribute a short-acting oral product called TLD (tenofovir, lamivudine & dolutegravir). Advantages to dolutegravir in TLD include its higher barrier to resistance than cabotegravir, but oral TLD requires daily dosing. Thus, the goal of this study is to develop a Next-Gen long-acting TLD 3-drug combination treatment in a single subcutaneous injection.

Methods: Previously, we reported on biocompatible lipid-exipients and a process to stabilize multiple HIV drugs with disparate physical-chemical (including water solubility) properties. This technology enables transformation of current HIV drugs (including water-insoluble lopinavir, ritonavir, efavirenz, atazanavir and water soluble tenofovir, lamivudine) into drug-combination nano-particulate (DcNP) products that are stable in suspension. Employing the DcNP process, lipid excipients composed of distearoyl-phosphatidyl-choline (DSPC) and distearoyl-phosphatidyl-ethanolamine derivatized with polyethylene-glycol (MW=2000) or mPEG₂₀₀₀-DSPE were systematically tested to produce a stable, sterile TLD suspension for non-human-primate (NHP) studies. *M. nemestrina* (~5-8 kg, n=8) were given a single subcutaneous injection of TLD in DcNP (6.2/5/10 mg/kg) and a plasma time-course was determined.

Results: TLD-DcNP product was prepared by:

1. Dissolving TLD with lipid-exipients in hydrated-alcohol, followed by controlled solvent-removal process to produce TLD-DcNP powder;
2. The particle-size of TLD-DcNP in saline suspension was reduced (d~60-80 nm) resulting in a stable- injectable TLD product, suitable for subcutaneous dosing.

Compared to the free-and-soluble form for which TLD concentrations fell below detectable levels within a few hours as previously reported, the DcNP formulation demonstrated a long-acting plasma time-course for all

3-drugs when given as a single subcutaneous dose. While NHP plasma TLD levels for DcNP dosage-forms were different for each drug substance, at the dose tested, all 3 drugs sustained concentrations above EC₅₀ > 4 weeks. These data were reproducible in making TLD-DcNP product and in NHP pharmacokinetic profile.

Conclusions: We have successfully developed a process that transforms short-acting to long-acting TLD into an all-in-one subcutaneous injection product for consideration of clinical development.

and Laboratory Medicine, New Orleans, United States

Background: Long-acting HIV treatment could improve pediatric outcomes through simplified dosing. ARV-eluting implants offer advantages over monthly injections including retrievability and extended duration. Here, we apply a pharmacokinetic/pharmacodynamic (PK/PD) modeling approach to support development of a reservoir-style, biodegradable, ARV-delivery implant system for young children.

Methods: Plasma PK of islatravir (ISL), emtricitabine (FTC) and bictegravir (BIC) was characterized over 30 hours following IV dosing in rabbits (5, 30, and 0.75 mg/kg, respectively) and used to fit a PK model for estimating each drug's unit impulse response (UIR). This UIR was used to deconvolve subcutaneous (SQ) absorption from plasma PK measured over 1 year in 8 rabbits with SQ ISL-, FTC-, and BIC-eluting implants. An HIV-IIIB challenge model with TZM-bl reporter cells was used to characterize the concentration-response relationship for ARV (alone or combined) with a 43.6-fold protein-binding adjustment for BIC. The inhibitory form of the Hill equation and competitive-inhibition interaction models were fit to estimate PD parameters. Continuous-infusion PK models with literature reference values were used to predict plasma concentrations from deconvolved absorption (as µg/day dose) for 2-year-olds at 50th percentile of weight. The PD model was applied to predict percent maximal inhibition from the combination of these concentrations.

Results: Two-compartment, macro-parameter models with log-additive error fit the IV PK. All ARVs were quantifiable for >1 year in rabbit plasma. Model estimates and

Especialidad del Bajío, General Direction, Leon, Mexico

Background: Until 2018, first line ART in Mexico was mainly based on efavirenz containing regimens; despite reports of pre-treatment HIV drug resistance (HIVDR) levels to non-nucleoside reverse transcriptase inhibitors (NNRTIs) reaching 10% or more. Since June 2019, a national strategy using BIC/TAF/FTC as the preferred single tablet regimen for ART initiation and switch was implemented. We evaluated patterns of resistance among individuals who initiated or switched to BIC/TAF/FTC.

Methods: National System for Antiretroviral Surveillance and Administration database was used for the analysis. We searched for archived plasma samples of adults who started or switched to BIC/TAF/FTC, from June 1st 2019 to June 30th 2021; and had viral loads over 1,000 copies/ml at least six months after BIC/TAF/FTC initiation. Protease,

reverse transcriptase and integrase were sequenced using standard next generation sequencing methods (Illumina). Reads were aligned and consensus sequences obtained with HyDRA. HIVDR was estimated using the Stanford HIVdb tool (V9.4), using both 5% (assessing low-frequency variants) and 20% (Sanger-like) consensus sequences. HIVDR was defined as a Stanford score of ≥ 315 to the drug of interest.

Results: We included 666 sequences: 208 from ART initiators and 458 from persons who switched from other regimens. Using 20% consensus sequences, resistance to any INSTI was observed in 4 (1.9%) and 5 (1.1%) initiation and switch samples, respectively (Figure 1).

INSTI resistance increased to 2.9% and 3.1% in initiators and switching, respectively, when using 5% consensus sequences. At 20% threshold, 4 INSTI Surveillance Drug Resistance Mutations (SDRM) were observed among initiators: E138AKT (0.5%), Y143CHRS(0.5%), S230R (0.2%), and R263 (0.5%). Among persons switching, 2 SDRM were observed: E138AK T (0.2%), R263K (0.2%).

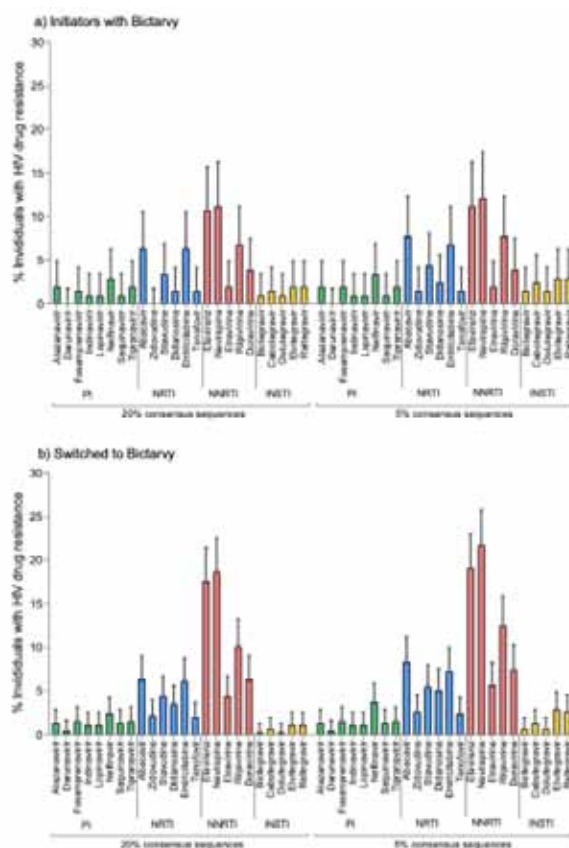

Figure 1. HIV drug resistance by drug.

Conclusions: After two years of a national rollout strategy using second-generation INSTIs in Mexico, resistance mutations to these drugs are found in a very small proportion of subjects. Nevertheless, continuous HIVDR surveillance is warranted in the country.

Doravirine Resistance Patterns Identified through week 192 in the DRIVE-FORWARD and DRIVE-AHEAD Phase 3 clinical trials

C. Orkin¹, D. Kuritzkes², C. Katlama³, F.-H. Su⁴, V. Teal⁴, R. Plank⁴, R. Lahoulou⁵, E. Asante-Appiah⁴

¹Queen Mary University of London, London, United Kingdom, ²Brigham and Women's Hospital, Harvard Medical School, Boston, United States, ³Paris-Sorbonne University, Paris, France, ⁴Merck & Co., Inc., Rahway, United States, ⁵MSD France, Puteaux, France

Background: Doravirine (DOR) is a novel non-nucleoside reverse transcriptase (RT) inhibitor (NNRTI) approved for the treatment of HIV-1. DOR was rationally designed to address limitations associated with other NNRTIs, particularly resistance from HIV-1 variants bearing common NNRTI resistance-associated substitutions in RT such as K103N, Y181C, or G190A.

Methods: Resistance to DOR was assessed through Week 192 of two phase 3 clinical trials, DRIVE-FORWARD (MK-1439-018) and DRIVE-AHEAD (MK-1439A-021), in participants randomized to DOR (100mg) for the 96-week double-blind studies followed by 96-week open-label study extensions, and in participants who switched from the comparator (darunavir/r or efavirenz) to DOR in the extensions.

Resistance testing was performed by Monogram Biosciences in participants who met criteria for protocol-defined virologic failure (PDVF; non-response or rebound) or discontinued (d/c) early with HIV-1 RNA >400 copies/mL.

suppressed after PDVF. Resistance testing was performed in 51 participants (34 PDVF, 17 d/c); DOR-associated mutations were detected in 12 and phenotypic resistance in 10, mainly before Week 96 (Table).

The most common RT substitutions were V106A/I/M and F227C. In the study extensions, 502 participants switched from comparator to DOR; 26 (5.2%) had PDVF (including 9 with HIV-1 RNA ≥50 and <200 copies/mL), and 12 of 26 re-suppressed after PDVF. Resistance testing was performed in 9 switch participants (6 PDVF, 3 d/c); DOR-associated mutations were detected in 4 and phenotypic resistance in 3 (Table). Common NNRTI substitutions including K103N, Y181C and G190A were not detected.

Conclusions: In DRIVE-FORWARD and DRIVE-AHEAD, the development of DOR resistance-associated substitutions in RT was uncommon (16/1249; 1.3%) and occurred mainly during the first year of treatment. Overall, the DOR RT substitutions observed were distinct from those of other NNRTIs.

Table. Genotypic and phenotypic resistance detected in participants with PDVF (n=109) or early discontinuation (n=271) through week 192 in DRIVE-FORWARD & DRIVE-AHEAD (N=1249)

Results: 747 ART-naïve participants received DOR in DRIVE-FORWARD and DRIVE-AHEAD; 83 (11.1%) had PDVF (including 29 with HIV-1 RNA ≥50 and <200 copies/mL), and 33 of 83 re-

Background: Tanzania and other resource-limited settings in sub-Saharan Africa have reported progress in scaling up ART usage. However, treatment success

among people living with HIV (PLHIV) has not been fully appreciated. In March 2019, Tanzania introduced a WHO-recommended dolutegravir-based combination therapy to its ART program.

Therefore, we investigated HIV viral suppression rates, associated factors, and the burden of HIV drug resistance (HIVDR) among PLHIV a year after the introduction of dolutegravir in Tanzania.

Methods: We conducted a national representative cross-sectional survey from September to December 2020. Adults and children PLHIV from 36 HIV care and treatment centres in Tanzania were recruited. Blood samples, demographic and clinical information were obtained. HIV viral load (HVL) was estimated using the COBAS 8800 TaqMan (Roche Molecular system). Viral suppression was defined at HVL<1000 copies/mL.

Independent factors associated with viral suppression were identified using regression analyses ($p<0.05$). HIVDR genotyping was performed from samples with HVL \geq 1000 copies/mL. HIV genes (reverse transcriptase, protease, and integrase) were amplified by PCR and directly sequenced. The Stanford HIVDR database was used for HIVDR analysis.

Results: A total of 2039 PLHIV were recruited, with 57.5% being adults and 64.7% of them were females; whereas children contributed 42.5% and 53.5% were females. The viral suppression rates were 96.1% and 89.1%, in adults and children, respectively.

Hereby, adults and children on the dolutegravir-based regimen recorded the highest viral suppression rates of 96.4 % and 91.3%, respectively; while the lowest suppression rates were observed in PLHIV on protease inhibitor-based regimen at 78.8% and 85.4%, respectively. In addition, factors including marital status, initial HVL, the current ART regimen, and treatment adherence were independently associated with viral un-suppression status ($p<0.05$).

Furthermore, HIVDR was detected in 71.5% of PLHIV with high viremia (HVL \geq 1000 copies/mL). Importantly, 5.8 % of participants had dolutegravir drug resistance mutations, including the major drug resistance mutations; Q148K, E138K, G118R, G140A, T66A, and R263K.

Conclusions: The present findings indicate that dolutegravir-based regimens show promise for treating HIV in Tanzania. However, there are still barriers to optimal treatment outcomes, such as the emergence of dolutegravir HIVDR and adherence among PLHIV in Tanzania.

CMV-Specific IgG changes during severe COVID-19 suggestive of acute reactivation

G.C. Ambayec¹, H. Pickering², M. Peluso¹, F. Chan¹, G. Beck-Engeser¹, K. Wick¹, M. Matthay¹, C. Calfee¹, J. Martin¹, S. Deeks¹, S. Iyer³, T. Henrich¹, S. Lee¹, E. Reed², P. Hunt¹

¹University of California, San Francisco, San Francisco, United States, ²University of California, Los Angeles, Los Angeles, United States, ³University of California, Davis, Davis, United States

Background: During acute SARS-CoV-2, CMV is associated with an increased risk of hospitalization, and in non-human primates, reactivates to a greater degree in tissues than in blood. We hypothesized that CMV reactivation during severe COVID-19 might disrupt the steady-state of CMV-specific IgG production and clearance via antigen-antibody complexes, leading to dynamic CMV-specific IgG changes.

Methods: Serum from participants with PCR-confirmed COVID-19 were sampled from a hospitalized cohort with severe acute COVID-19 (COMET/IMPACC), a non-hospitalized cohort with acute mild COVID-19 (CHIRP), and a convalescent cohort of participants who had recovered from COVID-19 at least 30 days earlier (LIINC), and assessed CMV-specific IgG index using a commercial assay. Changes in those with acute COVID-19 were assessed up to 28 days later.

Results: Hospitalized participants (n=442) tended to have a higher median age than the 11 non-hospitalized acute COVID-19 participants (58 vs. 47) and the 327 LIINC participants who previously recovered from COVID-19 (44).

While the majority of hospitalized participants were CMV-seropositive or indeterminate, a much larger proportion had low (0.4-0.9) or indeterminate (0.9-1.1) CMV IgG index values than in the convalescent cohort (34% vs 21%, $P<0.001$, Panel A).

Among those with "negative" or "indeterminate" CMV IgG indices at hospital admission, CMV-specific IgG titers increased significantly over a median of just 14 days ($P<0.0001$), with many rising into the "positive" range. No change in CMV IgG index was observed in the non-hospitalized participants with acute COVID-19 over 28 days ($P=0.65$).

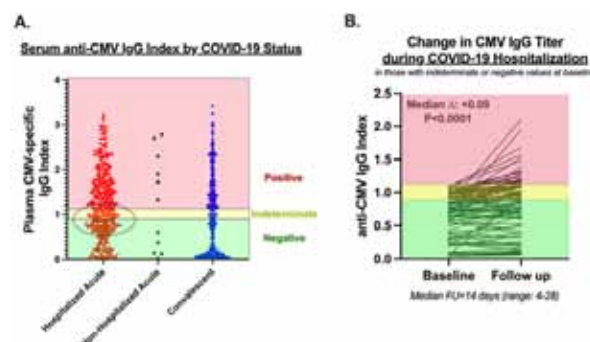

Figure.

Conclusions: Hospitalized people with acute COVID-19, while more likely CMV-seropositive, have lower serum CMV-specific IgG levels than non-hospitalized and recovered people with COVID-19, which subsequently rise during hospitalization. These findings support the hypothesis that severe acute COVID-19 induces tissue CMV re-activation, transiently clearing CMV-specific antibodies from circulation via antigen-antibody complexes before increasing B cell production.

Track C: Epidemiology and prevention science

Race, place, and substance use continue to impact HIV incidence among Sexual Minority Men: active surveillance of HIV seroconversion from the UNITE Longitudinal Cohort study

J. Malone¹, S.S. Jones¹, A. Talan¹, H.J. Rendina^{1,2}

¹Whitman Walker Institute, Research, Washington D.C., United States, ²George Washington University, Milken Institute School of Public Health, Washington D.C., United States

Background: Sexual Minority Men (SMM) continue to be disproportionately impacted by the U.S. HIV epidemic. We calculated the HIV incidence rate and incidence rate ratios on a large, population-based cohort of SMM in the U.S. to identify factors associated with HIV seroconversion.

Methods: UNITE is a prospective cohort study aimed at identifying biopsychosocial factors associated with HIV seroconversion among SMM. There were 7,956 participants enrolled into the cohort, recruited using geospatial, social networking apps. Enrollment occurred between November 2017 and September 2018. Individuals were eligible if they were at least 16 years of age, identified as male at enrollment, reported HIV-negative or unknown status, and were willing to conduct at-home HIV and STI testing. We conducted Poisson regression models with robust variance to identify factors associated with seroconversion, adjusting for baseline age, race, substance use, adverse childhood experiences (ACE), PrEP use at baseline, self-perceived PrEP indication, any health insurance, and condom use frequency.

Results: There were 121 seroconversions after 24 months of follow-up. 6,304 participants completed the 12-month follow-up, while 4,957 completed the 24-month follow-up with individuals contributing between 0-2 years of follow up time. Accounting for varying person-time, the incidence rate was 10.3 cases/1000 PY. Black race [compared to White (aIRR: 2.89, 95%CI: 1.84, 4.57), Asian (aIRR: 2.89, 95% CI: 1.04, 8.13), or Multiracial race (aIRR: 2.31, 95% CI: 1.20, 4.44)], not knowing if you had health insurance (aIRR: 4.19 95% CI: 1.83, 9.60), any drug use within 3 months of study enrollment (aIRR: 2.33, 95% CI: 1.44, 3.76), living in the Southern U.S. (aIRR: 2.26, 95% CI: 1.18, 4.31), and a higher frequency of no condom use at baseline (aIRR: 1.004, 95% CI: 1.002, 1.007) were all positively associated with HIV seroconversion. Older age (aIRR: 0.975, 95% CI: 0.96, 0.996) and reporting uncertainty about self identifying as having PrEP indication (aIRR: 0.57, 95% CI: 0.34, 0.98) were associated with lower HIV incidence.

Conclusions: These findings on a large sample of SMM highlight that Black SMM, those living in the Southern U.S., and those using illegal substances remain vulnerable to higher rates of HIV seroconversion, requiring socially and politically driven interventions.

Demographic and clinical characteristics of mpox among people living with HIV/AIDS (PLWHA) during the 2022 outbreak in Brazil: an observational study

A.R. Pascom¹, G. Dias¹, I.M. Souza¹, R.d.S. Oliveira¹,
A.C. Ferreira¹, A.E. Miranda¹, G.F. Pereira¹

¹Ministry of Health of Brazil, HIV/AIDS/TB/HV/STI
Department, Brasília, Brazil

Background: The new mpox outbreak extending world-wide is mostly affecting gays and other men who have sex with men, and people living with HIV/AIDS (PLWHA). There are limited data on mpox and PLWHA. This study aims to describe and compare the demographic and clinical characteristics of mpox cases according to HIV/AIDS status in Brazil.

Methods: We conducted a cross-sectional study using data obtained from the mpox and HIV/AIDS MoH national databases in Brazil. We included confirmed and probable mpox cases aged 15 and over reported to the MoH systems between June 7th and December 31st, 2022, according to the case definition adopted in the country. Descriptive statistics and Chi-square tests were used to compare sociodemographic and clinical characteristics for PLWHA, and HIV-negative people or unknown status (HIV-).

Results: As of December 2022, 10,046 confirmed and probable mpox cases were included in this study, out of those 46%(4,657) were HIV positive. The median age was 32 (IQR:27-38), 73%(7,235) were cisgender males, and 64% were gays and other men who have sex with men (MSM). Among those PLWHA, the median age was slightly higher (34yo,IQR:29-38), 79% (3,620) were cisgender male, and 70%(3,232) were MSM. STIs were more frequent among PLWHA (n=710;15%) than HIV- people (n=372;7%) (p-value<0.001); 9%(416) PLWHA were diagnosed with syphilis at mpox notification, and 3%(165) among HIV- cases. Signs and symptoms were also significantly more prevalent among PLWHA: 93% presented at least one sign or symptom, and 58% presented rashes; among HIV- cases proportions were 90% and 51%, respectively. 5.3%(246) PLWHA and 4.5%(243) HIV- or unknown-status cases were hospitalized. Twelve deaths due to mpox and 13 due to other causes were registered; 11 and five, respectively, among PLWHA.

Conclusions: This study has shown a high frequency of HIV/AIDS among mpox cases reported in Brazil. PLWHA had more STIs, signs and symptoms, complications, hospitalization, and deaths. These results highlight the importance of reorganizing health services and investing in professional capacity building to face the mpox outbreak, especially in HIV/AIDS and other STI services. Furthermore, it reinforces the need to plan prevention strategies, including vaccination against mpox, specifically targeted at this population.

Prevalence and correlates of dual mood disorders among PLHIV-PWUD in a Canadian setting

S. Taheri^{1,2}, M.J. Milloy^{1,2}, J. Choi¹, N. Fairbairn^{1,2},
M.E. Socías^{1,2}

¹BC Centre on Substance Use, Vancouver, Canada,

²University of British Columbia, Department of Medicine,
Vancouver, Canada

Background: Mental disorders are pervasive among people living with HIV (PLHIV) and have been shown to impact clinical outcomes; however, little is known about correlates of mood disorders (particularly dual diagnoses) among PLHIV. This study aims to explore the prevalence and correlates of dual mood disorder symptoms among PLHIV who use drugs (PLHIV-PWUD).

Methods: Data were obtained from the ACCESS study, an ongoing prospective community-recruited cohort study of PLHIV-PWUD in Vancouver, Canada. Using multivariable generalized linear mixed-effects models, we evaluated factors associated with comorbid moderate/severe anxiety and depressive symptoms (dual mood disorders) as measured by the PROMIS instrument.

Results: Between December 2016 and November 2021, 577 PLHIV-PWUD contributed 3356 observations. 87 (15%) participants reported moderate/severe dual mood disorder symptoms at baseline. Multivariable adjusted analysis showed significant and positive associations between moderate/severe dual mood disorder symptoms and daily injection drug use (Adjusted Odds Ratio [AOR] = 1.40; 95% Confidence Interval [CI]: 1.06-1.85), daily use of stimulants (AOR = 1.61; 95% CI: 1.21-2.13) or opioids (AOR = 1.53; 95% CI: 1.14-2.05), persistent/major pain (AOR = 1.85; 95% CI: 1.44-2.37), high school level education or higher (AOR = 1.31; 95% CI: 1.01-1.68), recent incarceration (AOR = 3.57; 95% CI: 1.77-7.20), and homelessness (AOR = 2.05; 95% CI: 1.23-3.40).

Conclusions: In this cohort of PLHIV-PWUD, dual mood disorders were common and associated with several substance-use and social-structural vulnerabilities. This highlights the need for further understanding the determinants of dual diagnoses in order to improve mental health outcomes among this population.

MOPEC04

Molecular and phylodynamic approaches to the characterisation of HIV-1 transmission: a genomic epidemiological study in Victoria, Australia

G. Tairaroa^{1,2}, D. Chibo², S. Herman³, D.J. Price^{1,4}, E. Steinig¹, J. Prestedge^{1,2}, S. Duchene³, S.R. Lewin^{1,5,6}, D.A. Williamson^{1,2}

¹The University of Melbourne, Department of Infectious Diseases, Melbourne, Australia, ²The Royal Melbourne Hospital, Victorian Infectious Diseases Reference Laboratory, Melbourne, Australia, ³The University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, ⁴The University of Melbourne, Centre for Epidemiology and Biostatistics, Melbourne, Australia, ⁵Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia, ⁶The Royal Melbourne Hospital, Victorian Infectious Diseases Service, Melbourne, Australia

Background: In Australia, the incidence of HIV has declined steadily in recent years, although the virtual elimination of HIV transmission will require additional interventions. The use of molecular approaches to identify putative HIV-1 transmission networks may complement traditional surveillance, and could support timely contact tracing, as well as the targeted administration of pre-exposure prophylaxis (PrEP) to efficiently reduce further transmission. The efficacy and acceptability of these methods have yet to be examined thoroughly in an Australian context.

Here, to understand the public health potential of HIV-1 molecular epidemiological approaches in our setting, we analysed a comprehensive longitudinal collection of HIV-1 sequences from plasma from newly diagnosed people with HIV in Victoria, Australia.

Methods: De-identified HIV-1 *pol* gene sequences generated between 2000 and 2020 were analysed. Sequences were subtyped, and surveillance drug-resistance mutations (SDRMs) identified. Assessment of molecular transmission networks was performed using HIV-TRACE (0-4-4), and phylodynamic assessment of network growth using BEAST (2-6-6).

Additional demographic data were integrated with these molecular findings, allowing for a description of the transmission dynamics of HIV in this setting over the past two decades. Ethical approval for this project was obtained and engagement of communities in this work and its interpretation is ongoing.

Results: Based on our genetic thresholds, 70% of HIV-1 *pol* sequences were part of a putative transmission network, as defined through HIV-TRACE. SDRMs were identified in 375 people living with HIV (10.7%), becoming increasingly uncommon in recent years, with sustained transmission of these limited to a subset of smaller networks. Transmission networks showed changing patterns in epidemic growth, stabilisation and decline, providing further detail to support the control of these distinct although overlapping sub-epidemics; while many networks have

maintained an effective reproductive number (R_e) of less than 2.0, others show periods of epidemic growth reaching R_e values greater than 4.0.

Conclusions: This study provides a detailed, longitudinal view of HIV-1 transmission in Victoria, Australia. These findings provide local data to inform the ongoing discussions of the acceptability and place of molecular approaches in clarifying HIV-1 transmission and guiding public health responses in Australia.

MOPEC05

Silent transfer determination using HIV recency testing in Lusaka Province of Zambia: experience from the Catholic Relief Services Epidemic Control 90-90-90 (EpiC 3-90) project

L.M. Chibesa¹, M.J. Chaila¹, D. Moyo², W. Mumba², T. Mfunne¹, S. Mwape¹, N. Muhongo¹, P. Saili¹, B. Mukanyimi¹, F. Mwape², C. Chungu¹, C. Mwale²

¹Catholic Relief Services, EpiC 3-90 Project, Lusaka, Zambia,

²Ministry of Health, Lusaka Provincial Health Office, Lusaka, Zambia

Background: People living with HIV (PLHIV) who silently transfer from one health facility to another, present a challenge in the correct estimation of the burden of HIV in the population, as they may be classified as recently identified in the destination facility.

An additional challenge, is the estimation of attrition, thus affecting HIV programming. The HIV recency testing programme has provided an opportunity to identify clients who have a suppressed VL result (<1,000 copies/ml) prior to ART initiation.

We utilized HIV recency programme data to identify silent transfers and design interventions tailored to mitigate this challenge.

Methods: Newly identified eligible PLHIV, (≥15 years old), were enrolled in the programme which identified recent HIV-1 acquisition using an algorithm that combined rapid test for recent HIV acquisition (RTRI) with HIV viral load (VL) testing. PLHIV who had a suppressed HIV VL result (<1000 copies/mL) before ART initiation were classified as silent transfers.

We present findings from Lusaka Province health facilities for the period January 2020 to December 2022.

Results: During the period under review, we collected 33,855 samples and received 93%(n=31,503) VL results. Approximately 35% (n=10,891) of the 31,503 results received had a suppressed VL (<1000 copies/mL) and were categorised as silent transfers from 2020 to 2022. The silent transfers were 34% (663/1,938) in 2020; 34% (3,512/10,445) in 2021 and 35%(6,716/19,120) in 2022.

Out of the 6 districts in the province, Lusaka accounted for 82%(8,889/10,891) of all the silent transfers and therefore requires prioritization in addressing this problem.

Figure 1. Recency results consolidated by year and district.

Conclusions: Strategies to curb the "silent transfers" must be employed to optimize the continuity of care. These cause inaccuracies in the number of newly identified PLHIV and in data-driven decision-making for HIV epidemic control in Zambia. Mitigation may include client education, effective use of HIV screening tools, and introduction of biometric identification systems.

MOPEC06

New metrics for understanding trends in undiagnosed HIV among key populations

R. Gray¹, H. Camara¹, L. Khawar¹, A. Grulich¹, R. Guy¹, S. McGregor¹, N. Medland¹

¹Kirby Institute, UNSW Sydney, Sydney, Australia

Background: We investigated novel epidemiological metrics for understanding trends in undiagnosed HIV among key populations in Australia.

Methods: We produced estimates for the number of people living with undiagnosed HIV and the number of new HIV infections using national HIV surveillance data and the European Centre for Disease Prevention and Control (ECDC) HIV modelling tool. Using these estimates, we calculated:

1. The Total Diagnosed Fraction, the proportion of all people with HIV who have received a diagnosis;
2. The Yearly Diagnosed Fraction, the proportion of people who have not yet received a diagnosis who received a diagnosis during each year, and;
3. The Case Detection Rate, which is the term used for the annual ratio of the number of new HIV diagnoses to the number of new HIV infections each year; from 2008 to 2019.

In MSM, we calculated this in Australian-born and overseas-born individuals. In heterosexual people we report this in women and men.

Results: Each metric for Australian-born MSM improved consistently over the period. In contrast, the metrics for the overseas-born group worsened (Total Diagnosed Fraction: 85.0% to 81.9%, Yearly Diagnosed Fraction: 23.1% to 17.8%, and Case Detection Rate: 0.74 to 0.63)—meaning the number of undiagnosed overseas-born MSM is growing and it will take longer to diagnose everyone at current testing rates. In heterosexuals, both women and men had consistent increasing trends for the Total Diagnosed

Fraction and Yearly Diagnosed Fraction but with women having consistently higher values. Heterosexual men had a declining Case Detection Rate (below one since 2011), compared to an increase for women (above one since 2009). Meaning the number of heterosexual women with undiagnosed HIV has been falling while the number of undiagnosed heterosexual men has been increasing.

Conclusions: The additional metrics provide important information on Australia's progress towards achieving national and international targets. The more dynamic changes seen in the undiagnosed population highlight diverging trends for key populations not seen in the Total Diagnosed Fraction. The decreasing metrics for overseas-born MSM highlight the challenges in ensuring equity of HIV prevention, testing and care among all key populations.

MOPEC07

Establishing HIV-1 recent infection surveillance using a point-of-care test for recent infection among persons newly diagnosed with HIV infection in Thailand

K. Srithanaviboonchai^{1,2}, T. Yingyong³, T. Tasaneeyapan⁴, S. Suparak⁵, S. Jantaramanee³, B. Roudreo³, S. Tanpradech⁴, J. Chuayen¹, A. Kanphukiew⁴, T. Naiwatanakul⁴, S. Aungkulanon⁴, M. Martin⁶, C. Yang⁶, B. Parekh⁷, S.C. Northbrook⁸

¹Chiang Mai University, Research Institute for Health Sciences, Chiang Mai, Thailand, ²Chiang Mai University, Faculty of Medicine, Chiang Mai, Thailand, ³Ministry of Public Health, Department of Disease Control, Nonthaburi, Thailand, ⁴U.S. Centers for Disease Control and Prevention, Division of Global HIV/ TB, Nonthaburi, Thailand, ⁵Ministry of Public Health, Department of Medical Sciences, Nonthaburi, Thailand, ⁶U.S. Centers for Disease Control and Prevention, Division of Global HIV/ TB, Atlanta, United States, ⁷U.S. Centers for Disease Control and Prevention, Division of Global HIV/ TB, Atlanta, Thailand, ⁸Centers for Disease Control and Prevention, Division of Global HIV/ TB, Nonthaburi, Thailand

Background: Recent HIV infection surveillance can be used to identify areas and groups with potential for HIV acquisition. A new surveillance model using the point-of-care test for recent HIV infection (RTRI) was integrated into routine HIV testing services in 14 of 76 provinces representing all health administrative regions in Thailand. We describe characteristics of recent HIV infections reported from April to August 2022.

Methods: All hospitals in 14 provinces, 12 high and 2 low burden HIV provinces (defined as <5,000 annual HIV diagnoses for low burden provinces), were invited to participate in the new surveillance activity. One hundred thirty-nine hospitals were trained to offer RTRI to newly diagnosed PLHIV who were at least 15 years of age and treatment naïve or on ART <1 month after diagnosis. Left-over blood specimens of consenting clients were tested by RTRI

(Asanté™ HIV-1 Rapid Recency® Assay) and linked to case surveillance data to remove re-testers and those already on treatment. Descriptive and multivariate analyses were conducted using SAS v 9.4 to characterize epidemic profile of recent infections.

Results: Of 139 public hospitals who volunteered to participate, 69 reported that newly diagnosed PLHIV had been identified (ranging from 17-260 clients per facility) during the surveillance period. Of 1,053 newly diagnosed PLHIV, 106 (10.1%) tested RTRI-recent, after correction with case surveillance data. The highest proportion of recent infections were seen among 15-19 year old (males:19.0%, females:11.6%), transgender women (18.0%), and men who have sex with men (11.4%). Two northeastern provinces reported the highest proportion of recent infections (21.0% and 19.0%) compared to other provinces. PLHIV <20 years old had a higher risk for recent infection than others in multivariate analysis (Adjusted odds ratio: 2.7, 95% CI 1.4-5.3).

Conclusions: National recent infection surveillance using RTRI was successfully implemented and identified younger age, key populations and two northeastern areas to be at higher risk for HIV acquisition. When triangulated with other program and surveillance data sources, recency data may provide better understanding of current epidemiologic trends. Targeted interventions to prevent new infections among youth, transgender and MSM may help interrupt ongoing transmission.

MOPEC08

ZAMPHIA 2021 showed reduction in advanced HIV disease (AHD) prevalence but further scale up of AHD screening and management needed

M. Itoh¹, S. Sivilie², A. Mwila¹, K. Mweebo¹, L. Mwiinga¹, D. Chanda², K. Stafford³, K. Dzekedzeke³, M. Charurat³, M. Bronson⁴, S. Birhanu⁴, H. Patel⁴, J.Z. Hines¹, L.B. Mulenga²

¹Centers for Disease Control and Prevention, Lusaka, Zambia, ²Zambia Ministry of Health, Lusaka, Zambia, ³University of Maryland, Baltimore, Baltimore, United States, ⁴Centers for Disease Control and Prevention, Atlanta, United States

Background: Reducing HIV-related mortality from advanced HIV disease (AHD) through timely diagnosis and management is a critical aspect of a successful HIV program. We analyzed the nationally representative Zambia Population-based HIV Impact Assessment (ZAMPHIA) 2021 data to assess the population-level AHD prevalence.

Methods: We determined AHD prevalence among people living with HIV (PLHIV) aged 15-59 years by their awareness and ART status and calculated the arithmetic mean difference with ZAMPHIA 2016 using z-scores. Participants completed a questionnaire and whole blood was collected. Awareness of HIV-positive status and treatment status were based on self-report or having detectable ART in one's blood. CD4+ testing was done for all who tested

HIV positive, with AHD defined as a CD4 count of <200 cell/mm³. Analyses were weighted and accounted for survey design.

Results: AHD prevalence was 7.0% in 2021, compared to 13.9% in 2016 (Table 1). Among PLHIV who were unaware of their status, AHD prevalence was 18.8% in 2021. Among those aware of their status and on ART, AHD prevalence was 4.8% compared to 37.9% among those aware but not on ART. While those who were aware but not on ART only comprised 1.8% (CI: 1.2-2.3%) of PLHIV, they represented 9.7% (CI: 4.5-14.9%) of those with AHD; among them, 74.3% were female, average diagnosis was 3.9 years ago and 37.1% had ever taken ART (Table 2).

Year	Overall, % (95% CI)*	Unaware HIV, % (95% CI)	Aware, on ART, % (95% CI)*	Aware, not on ART, % (95% CI)
2021	7.0 (5.7-8.5)	18.8 (13.5-25.1)	4.8 (3.5-6.3)	37.9 (20.6-57.7)
2016	13.9 (12.5-15.3)	17.7 (15.0-20.6)	10.9 (8.3-11.8)	22.8 (17.4-29.1)
p-value for mean difference	<0.01	0.74	<0.01	0.13

Table 1: Weighted proportion PLHIV aged 15-59 years with advanced HIV disease (CD4+ count <200) by awareness status in Zambia – 2016 (N = 2,446) versus 2021, (N = 2,045)

Characteristic	Overall (n=148)	Unaware of HIV (n= 46*)	Aware, currently on ART (n=88)	Aware, currently not on ART (n=14*)
Time since HIV diagnosis, mean years (95% CI)	6.1 (4.7-7.6)	n/a	6.4 (4.8-8.1)	4.1 (2.0-6.1)
Mean age, years (95% CI)	40.3 (38.7-41.9)	41.2 (38.9-43.5)	40.1 (37.8-42.5)	38.8 (35.1-42.5)
Female sex, % (95% CI)	51.6 (41.6-61.5)	51.1 (34.4-67.6)	48.1 (35.1-61.4)	74.3 (45.5-92.9)

Table 2: Characteristics of PLHIV aged 15-59 years with advanced HIV disease (CD4+ count <200) by awareness status in Zambia, 2021

(*Analyses with sample size <50 participants should be interpreted with caution)

Conclusions: The population-level burden of AHD has decreased in Zambia since 2016, likely reflecting achievements of Zambia's universal test-and-treat strategy (started in 2016). Approximately one-third of PLHIV aware of their HIV status but not on ART had AHD but they only represent ~10% of the total AHD burden.

Addressing AHD in Zambia will involve identifying the remaining undiagnosed PLHIV in addition to screening for AHD among those aware of their status, especially if they have disengaged from care.

MOPEC09

Increasing prevention coverage among Australian gay and bisexual men but elevated HIV risk among younger and bisexual men: analysis of national behavioural surveillance data 2017-21

M. Holt¹, T. Broady¹, C. Chan², J. MacGibbon¹, L. Mao¹, J. Rule³, P. Whatley⁴, B. Bavinton²

¹UNSW Sydney, Centre for Social Research in Health, Sydney, Australia, ²UNSW Sydney, The Kirby Institute, Sydney, Australia, ³National Association of People with HIV Australia, Sydney, Australia, ⁴Australian Federation of AIDS Organisations, Sydney, Australia

Background: Gay and bisexual men (GBM) in Australia increasingly use biomedical prevention methods. Rising 'net prevention coverage' (the use of any effective strategy e.g. condoms, PrEP or undetectable viral load, UVL) is associated with declining HIV infections. However, disparities in prevention coverage are believed to exist. We analysed variations in prevention coverage to identify opportunities for intervention.

Methods: Behavioural surveillance data were collected during 2017-21 from gay venues, events and online in seven states/territories. Trends in net prevention coverage and HIV risk (condomless anal sex with casual partners unprotected by PrEP or UVL) were assessed with logistic regression, stratifying by age, country of birth, sexual orientation and the proportion of gay residents in participants' residential suburbs.

Results: 25,865 survey responses from participants with casual male partners were included. The mean age was 37.6 years, 69.8% were Australian-born, 88.2% gay-identified, and 9.7% living with HIV. Net prevention coverage increased from 69.8% in 2017 to 75.1% in 2021 ($p < .001$), and HIV risk declined from 30.2% to 24.9% ($p < .001$), influenced by rising PrEP use (15.6% to 33.9%, $p < .001$). Participants aged <25 years were the most likely to consistently use condoms (33.5% in 2017 to 25.4% in 2021, $p = .02$), but also reported the highest levels of HIV risk (42.2% in 2017 to 40.8% in 2021, $p = .01$). 25-44 year olds were the most likely to use PrEP (18.7% to 39.0%, $p < .001$) and 45 year olds the most likely to use/report UVL (13.6% to 11.8%, $p = .02$). In 2021, net prevention coverage was lower among Australian-born vs. overseas-born men (73.5% vs. 78.9%, $p < .001$), and higher among gay vs. bisexual/other-identified participants (77.7% vs. 63.4%, $p < .001$). During 2017-21, net prevention coverage increased more in suburbs with 10% gay residents (73.4% to 88.3%, $p < .001$) and less in suburbs with <10% gay residents (68.9% to 73.7%, $p < .001$).

Conclusions: Recent increases in HIV prevention coverage are concentrated among older GBM and suburbs with more gay residents. Younger men and bisexual men remain more at risk of HIV, more reliant on condoms, and less likely to use PrEP or UVL. Encouraging greater prevention coverage in these groups is necessary to further reduce HIV risk in Australia.

MOPEC10

Disruptions to services for people who inject drugs in Ukraine: modelling the impact of Russia's invasion on HIV and hepatitis C virus transmission

J. Stone¹, A. Trickey¹, T. Saliuk², N. Semchuk², Y. Sazonova², O. Varetska², F.L. Altice³, P. Vickerman¹

¹University of Bristol, Bristol Medical School, Bristol, United Kingdom, ²Alliance for Public Health, Kyiv, Ukraine, ³Yale University, New Haven, United States

Background: People who inject drugs (PWID) in Ukraine have a high burden of HIV and HCV infection. We estimated the impact of disruptions to non-governmental organization (NGO) activities, opioid agonist therapy (OAT) and anti-retroviral therapy (ART) following Russia's invasion of Ukraine.

Methods: We utilised an existing dynamic HIV/HCV transmission model among PWID in Ukraine. The model assumed 4-5% OAT coverage, 35-48% ART coverage and 37-49% NGO coverage in 2017, with NGO contact reducing injecting risk and increasing condom use and OAT/ART recruitment. We estimated the 1 and 10-year impact of ceasing NGOs, OAT and/or ART from March 2022 for 12 months in terms of additional HIV/HCV infections and impact per person-year (pyr) of closure.

Using national programmatic data, we estimated the pyrs of each intervention lost since Russia's invasion by comparing monthly numbers of PWID engaged in each intervention in 2022 with 2020/21. Combining these estimates with model projections, we estimated the impact of disruptions to services since March 2022.

Results: Ceasing all services for 1 year would have resulted in an additional 2,939 (95% credibility interval: 1,954-4,112) new HIV infections and 2,501 (1,668-3,578) new HCV infections in 2022. Even if services reopened after that year, there would be an additional 19,057 (13,449-25,938) new HIV infections and 9,409 (6,134-14,290) new HCV infections by 2032, increases of 39.6% and 6.1%, respectively. For each 100pyrs of closures, there would be an additional 3.6 (2.5-4.9) new HIV infections and 1.8 (1.2-2.7) new HCV infections over 2022-2032.

The national number of PWID accessing ART and OAT has remained stable (or increased) since Russia's invasion, although reductions occurred in Eastern Ukraine. However, there were 6,187 fewer pyrs of NGO contact (compared to 2020/21), which model projections suggest will result in an additional 36 (23-53) and 84 (56-113) new HIV and HCV infections in 2022, respectively, and 144 (102-198) and 156 (108-205) by 2032.

Conclusions: Disruptions to services since the war may have had limited impact on HIV and HCV transmission among PWID. However, considerable detrimental impact could occur with larger disruptions, emphasising efforts to continue services have been crucial for maintaining recent gains.

MOPEC11

Impact and cost-effectiveness of 3 different long-acting pre-exposure prophylaxis products in 3 African countries: a mathematical modelling study

D. Kaftan¹, D. Resar², M. Milali¹, J. Campbell², A. Olowu²,

I. Platais¹, H.-Y. Kim¹, S. Jenkins², A. Bershteyn¹

¹NYU Grossman School of Medicine, Department of Population Health, New York, United States, ²Clinton Health Access Initiative, Boston, United States

Background: HIV incidence remains high in sub-Saharan Africa (SSA) despite treatment scale-up. Oral pre-exposure prophylaxis (PrEP) is effective when taken as directed, but has had limited impact in SSA, in part due to challenges with daily dosing. Long-acting PrEP (LA-PrEP) formulations that may ameliorate these challenges include:

1. Two-monthly injections (cabotegravir),
2. Six-monthly injections (lenacapavir), and;
3. Monthly oral pills (islatravir and its potential successors).

We estimated the potential impact of each LA-PrEP formulation and maximum cost per dose delivered to be cost-effective in western Kenya (Nyanza region), South Africa, and Zimbabwe.

Methods: We adapted an HIV network transmission model, EMOD-HIV, to estimate:

1. Impact of scaling each LA-PrEP product on when incidence falls below 1 per 1,000 adults per year,
2. Doses required to avert 1 HIV acquisition or disability-adjusted life-year (DALY), and;
3. Maximum per-dose cost to avert 1 DALY for US\$500 over 20 years.

We assumed PrEP introduction in 2025, coverage rising to 5-20% of adults by 2030, and HIV risk reduction by 95% while using injectable PrEP and 67% while using monthly oral PrEP (to account for sub-optimal adherence with self-dosing).

We performed a bounding analysis on user risk profiles:

1. Equal distribution among sexually active adults, and;
2. "Risk-prioritized" distribution from highest-risk (sex workers) to lowest.

Results: Two-monthly or six-monthly injectable PrEP with 20% risk-prioritized coverage could reduce incidence to <1 per 1,000 per adult per year in western Kenya by 2030 (2034 for monthly oral) and Zimbabwe by 2034 (2039 for monthly oral).

In South Africa, incidence remained >1 per 1,000 for 20 years, but LA-PrEP was more efficient than in western Kenya and Zimbabwe, requiring 5-7x fewer doses to avert 1 HIV acquisition. LA-PrEP could be cost-effective if delivered at ≤\$24 (two-monthly injectable), ≤\$70 (six-monthly injectable), and ≤\$7 (monthly oral) per dose in the most efficient setting (South Africa) and scenario (5% risk-prioritized coverage).

Results were sensitive to prioritization: 1 risk-prioritized dose averted as many HIV acquisitions as 2 non-risk-prioritized doses.

Conclusions: LA-PrEP has the potential to significantly accelerate HIV incidence declines in SSA. Low-cost suppliers and delivery models will be required for LA-PrEP to be cost-effective.

MOPEC12

HIV risk among men who have sex with both men and women in Australia: findings from national behavioural surveillance surveys

B. Bushby¹, C. Chan¹, J. MacGibbon², S. Spencer³, L. Mao², T. Broady², M. Holt², B.R. Bavinton¹

¹Kirby Institute, UNSW Sydney, Sydney, Australia, ²Centre for Social Research in Health, UNSW Sydney, Sydney, Australia, ³Sydney Bi+ Network, Sydney, Australia

Background: Men who have sex with men and women (MSMW) have not been prioritised in HIV prevention and research, despite increased HIV risk compared to the general population. We examined characteristics of MSMW (last 6 months) compared to men who have sex with men only (MSMO) from Australian behavioural surveillance.

Methods: We recruited men across Australia at LGBTQ venues/events and online. We included data from the last available round for all participating jurisdictions (2021-2022) and restricted the sample to those with ≥1 male sex partner in the last 6 months. MSMW and MSMO were compared using chi-square/t-tests.

Results: 6,447 responses were included (MSMW=7.0%, MSMO=93.0%). MSMW were more likely to be recruited online than MSMO (63.0% versus 54.7%, p=0.001). Among MSMW, 6.2% were HIV-positive, 73.8% HIV-negative and 20.0% were untested/unknown, compared to 6.8%, 85.6%, and 7.6% among MSMO (p<0.001). While 89.2% of MSMO self-identified as gay and 6.4% as bisexual/pansexual, 63.0% of MSMW identified as bisexual/pansexual and 21.7% as gay (p<0.001).

MSMW were more likely to be transgender (6.2% versus 0.8%, p<0.001) and non-binary (13.1% versus 2.5%, p<0.001). 29.7% of MSMW reported >10 male partners in the last 6 months compared to 17.5% of MSMO (p<0.001). 54.3% of MSMW had 1 female partner and 34.4% had 2-5 in the last 6 months. 50.1% of MSMW reported recent condomless anal intercourse with casual male partners (CLAIC) compared to 42.2% of MSMO (p=0.001).

When taking biomedical prevention in the participant into account, 30.4% of MSMW and 12.5% of MSMO reported having CLAIC without pre-exposure prophylaxis (PrEP) or undetectable viral load (p<0.001).

Among non-HIV-positive participants (n=6,010), MSMW were less likely to have ever tested for HIV (80.1% versus 97.0%, p<0.001) or used PrEP (26.7% versus 38.6%, p<0.001). Among those reporting CLAIC (n=2,490), the disparity in PrEP use was greater (39.9% versus 68.6%, p<0.001).

Conclusions: We found important differences between MSMW and MSMO. MSMW reported higher numbers of male partners and CLAIC, and lower PrEP use and HIV testing. Research is needed to understand these dispari-

⁵Instituto Nacional de Salud Pública (INSP), Cuernavaca, Mexico, ⁶Ministério da Saúde, Brasília, Brazil

Background: Number of HIV cases continues to rise among young (18-30 years) gay, bisexual, and other men who have sex with men (MSM) and transgender women (TGW) in Latin America. ImPrEP was a PrEP implementation study conducted in Brazil, Peru, and Mexico.

We describe characteristics of HIV seroconversions in Im-PrEP by country.

Methods: Eligible MSM and TGW (HIV-negative, ≥18 years, reporting 1+ risk criteria) were screened and enrolled on the same day and received a 30-day oral TDF/FTC PrEP supply.

Follow-up visits were scheduled 4 weeks post-enrolment and quarterly thereafter. HIV rapid testing was performed at all visits.

We compared demographic (at enrollment) and behaviour (last visit prior to seroconversion) characteristics using chi-square or exact tests for the contingency tables and Kruskal Wallis tests for medians.

Results: From February 2018-June 2021, 9509 MSM/TGW were enrolled (Brazil: 3928 [41.3%]; Mexico: 3288 [24.6%]; Peru: 2293 [24.1%]); 104 were diagnosed with HIV during 12,185.25 person-years of follow-up.

Overall, 76.0% were young, 82.7% non-white, and 71.3% completed secondary education or more. The median number of partners was 5 (IQR:2-15); 70.2%, 92.2% and 85.6% reported receptive condomless anal sex, inconsistent condom use and incomplete PrEP adherence, respectively.

The median number of days between the first PrEP dispensation and HIV diagnosis was 360 days, higher in Brazil (541 days) and lower in Mexico (242 days).

The median HIV viral load after diagnosis was 12,257 copies/mL, lower in Mexico (3680 copies/mL) and higher in Peru (50100 copies/mL). Viral mutations detected were: 1 (1.8%) K70 and 6 (10.5%) M184V/I (Table).

	All N = 104 n (%)	Brazil N = 24 n (%)	Mexico N = 18 n (%)	Peru N = 62 n (%)	p-value
Gender (cisgender men)	93 (89.4)	22 (91.7)	18 (100.0)	53 (85.5)	0.29

Inconsistent condom use	43 (41.4)	13 (54.2)	5 (27.8)	25 (40.3)	0.27
Risky drinking	13 (12.5)	4 (16.7)	4 (22.2)	5 (8.1)	0.16
Stimulant use	89 (85.6)	20 (83.3)	12 (66.7)	57 (91.9)	0.03
Incomplete self-reported PrEP adherence (missed any PrEP pills in the past 30 days)	360 (186-581)	541 (244-770)	242 (108-331)	360 (245-560)	0.02
Days from first PrEP dispensation to HIV diagnosis, Median (IQR)	12,257	7227	3680	50,100	0.02
First HIV viral load after diagnosis, Median (IQR) copies/mL	(851-114,118)	(387-54,311)	(700-80,750)	(1070-156,000)	0.12
HIV genotyping with valid results	37 (54.8)	11 (45.8)	7 (38.9)	39 (62.9)	0.12
Mutations (valid results)	1 (1.8)	1 (9.1)	0 (0.0)	0 (0.0)	0.32
K70	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	—
M184V/I	6 (10.5)	1 (9.1)	2 (28.6)	3 (7.7)	0.23

Table. Characteristics of HIV seroconversion in the ImPrEP study by country.

Conclusions: We observed poor adherence among MSM and TGW who seroconverted during the ImPrEP study. Long-acting PrEP may be an appropriate strategy to overcome adherence barriers observed among young MSM and TGW in Latin America.

MOPEC14

Comparing PrEP initiation rates by service delivery models among adolescent boys and young men in KwaZulu-Natal, South Africa: preliminary findings from a population-based prospective study

M. Hlongwa^{1,2}, W. Basera^{1,3}, S. Aheron⁴, N. Naqvi⁴, J. Drummond⁴, M. Cheyip⁴, C. Mathews¹, E. Nicol^{1,5}

¹South African Medical Research Council, Cape Town, South Africa,

²University of KwaZulu-Natal, Durban, South Africa, ³University of Cape Town, Cape Town, South Africa,

⁴Centers for Disease Control and Prevention, Pretoria, South Africa,

⁵University of Stellenbosch, Cape Town, South Africa

Background: Pre-exposure prophylaxis (PrEP) is an HIV prevention strategy that can reduce the risk of HIV acquisition by more than 90% if taken consistently. South Africa started rolling out PrEP in 2016, initially for selected population groups before expanding access to more people. However, there is a dearth of research focused on PrEP among adolescent boys and young men (ABYM), despite them acquiring HIV at high rates. To address this gap, we compared PrEP initiation rates by service delivery points (SDPs) among ABYM in KwaZulu-Natal, South Africa.

Methods: We conducted a population-based prospective study in 22 SDPs from July 2021 to June 2022 in uMgungundlovu – a district with 24% HIV prevalence among males aged 15-49 years in KwaZulu-Natal province. Sexually active ABYM aged 15 – 35 years who tested HIV negative were recruited at purposively selected PrEP SDPs (i.e., healthcare facilities, secondary schools and Technical Vocational Education and Training (TVET) colleges, and community-based youth zones). We defined PrEP initiation according to national guidelines. We described baseline characteristics using summary statistics and reported PrEP initiation proportions overall and by SDPs. PrEP initiation for each participant was extracted against local medical records.

Index

Results: The study included 1 078 ABYM were recruited from 22 SDPs, with more than half aged 15-24 years ($n=590$, 55%) and 45% ($n=488$) aged 25-35 years. Among 1 078 participants who were eligible for PrEP, 13% ($n=141$) were started on PrEP.

Among the participants who were started on PrEP, more than half (52%, $n=74$) were from high schools and TVET colleges, compared with community-based youth zones (26%, $n=37$) and healthcare facilities (21%, $n=30$). Participants were 18.4 (95% CI: 4.79 – 9.18) and 32.6 (95% CI: 6.49 –16.4) times more likely to initiate PrEP in youth zones and schools, respectively, compared to clinics ($p<0.001$).

Conclusions: PrEP initiation rates were low among AYBM in KwaZulu-Natal, South Africa. Providing PrEP in high schools and TVET colleges, and community-based SDPs resulted in improved PrEP initiation rates when compared with traditional facility-based model. High schools and TVET colleges, and community-based SDPs could serve as important additional models to the traditional facility-based model for improving PrEP accessibility and initiation among ABYM.

MOPEC15

Peer influence on Latino sexual minority men's motivation to use PrEP in Miami, Florida

E. Rodriguez¹, C.H. Shrader², L. Craker¹, A. Johnson³, J. Skvoretz⁴, M. Kanamori¹

¹University of Miami, Public Health Sciences, Miami, United States, ²Columbia University, New York, United States,

³University of Miami, Medicine, Miami, United States,

⁴University of South Florida, Tampa, United States

Background: Respondents in this study, implemented in Miami-Dade County, Florida, a majority-minority community and a US HIV epidemic hotspot, are Latino sexual minority men (LSMM), a group at elevated risk for HIV.

Despite the beneficial effects of pre-exposure prophylaxis (PrEP), LSMM continue to experience disparities in PrEP uptake and subsequent increased HIV vulnerability- which could perhaps be due to their social environment.

The Motivational PrEP Cascade (MPC) describes the stages of change individuals undergo in achieve PrEP adherence; however, the model lacks consideration of the social context, including peer influence.

Methods: To measure peer influence, we conducted a sociocentric network autocorrelation model to identify how a respondent's position in the MPC is associated with their social network members' position in the MPC based on their friendship status, emotional attachment, frequency of interaction, or frequency of interaction weighted by emotional attachment.

Results: Eleven seeds and their 12 friendship network members ($n=143$ LSMM) were recruited into our study. The majority of participants were in PrEP Pre-Contemplation ($n=44$); and almost one-third of our sample reported using PrEP ($n=38$).

There was a positive correlation between a participant's cascade position and their alters' cascade position that varied depending on how the ties to alters are measured: friendship, emotional attachment, frequency of interaction, or frequency of interaction weighted by emotional attachment.

As visualized in Figure 1, each network varies in density and contains individuals at various stages of the MPC. Results from a network autocorrelation model found that LSMM's MPC position was associated with the positions of their friendship network members.

Figure 1. Visualization of LSM friendship networks and MPC position.

Conclusions: By increasing PrEP uptake, LSMM may serve as models to their peers and increase the likelihood of PrEP use. HIV prevention interventions to progress LSMM along the MPC should embrace the utility of friendship networks.

MOPEC16

Voluntary medical male circumcision and incident HIV acquisition among men who have sex with men: a randomized controlled trial

Y. Gao¹, Y. Sun¹, L. Yang¹, Z. Guo¹, W. Zhang¹, Y. Li¹, H. Zou¹

¹Sun Yat-sen University, School of Public Health, Shenzhen, China

Background: Meta-analyses and systematic reviews of observational studies suggest that voluntary medical male circumcision (VMMC) may reduce the risk of HIV acquisition among men who have sex with men (MSM), especially in men who primarily engage in insertive anal sex. We conducted a randomized controlled trial (RCT) to assess the efficacy of VMMC in reducing incident HIV acquisition among MSM.

Methods: This RCT was conducted in eight cities in China. Uncircumcised, HIV-negative men aged 18-49 years who predominantly practiced insertive anal sex and had two or more male sex partners in the past 6 months, were randomized to either intervention (immediate circumcision) or control (delayed circumcision) arms.

HIV testing was repeated at 3, 6, 9, and 12 months. HIV incidence was estimated in intention-to-treat (ITT) and per protocol (PP) analyses. HIV incidence rate ratio (IRR) and 95% confidence intervals (CIs) were calculated. This trial was registered at Chictr.org (ChiCTR2000039436).

Results: A total of 247 MSM were enrolled: 124 in the intervention arm and 123 in the control arm. Baseline characteristics of participants in the intervention and control groups were comparable. Retention rates in both arms were similar during follow-up. The two arms contributed 116 and 117 person-years of follow-up, respectively. Zero and five HIV seroconversion cases were observed in the intervention (HIV incidence rate, per 100 person-years: 0.00, 95% CI:0.00–3.18) and control (4.27, 1.38–9.97) arms. IRR was 0.00 (95% CI: 0.00–1.08) and 0.00 (0.00–1.13) in the ITT and PP analyses. All adverse events related to VMMC were mild and resolved quickly. Follow-up is ongoing and the final results will be available by July 2023.

Conclusions: This is the first RCT to demonstrate the efficacy of VMMC in preventing HIV among MSM. VMMC is very likely to be efficacious in preventing incident HIV acquisition among MSM who predominantly practice insertive anal sex. Large-scale RCTs with long-term follow-up may be necessary to further confirm this efficacy.

MOPEC17

Same-day initiation of emtricitabine-tenofovir disoproxil succinate in a demedicalized model of oral pre-exposure prophylaxis (PrEP) in Mexico: a real-world data analysis

M. Gomez Zepeda¹, R.A. Cruz Flores², A. Gonzalez Rodriguez³, E. Rodriguez-Nolasco⁴, R.S. Niño Vargas⁴, M.E. Zghaib Rivero⁵, I. Macías González⁶, S.-M. Juan Gerardo⁷

¹Clinica Especializada Condesa, Prevention Cordination, Mexico, Mexico, ²Clinica Especializada Condesa, Epidemiology, Mexico, Mexico, ³Clinica Especializada Condesa, Executive Direction, Mexico, Mexico, ⁴Clinica Especializada Condesa, Monitoring and Analysis Unit, Mexico, Mexico, ⁵Clinica Especializada Condesa, Clinical Research Unit, Mexico, Mexico, ⁶Clinica Especializada Condesa, Diagnosis and Counseling, Mexico, Mexico, ⁷Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, HIV Clinic, Mexico, Mexico

Background: To evaluate the feasibility of PrEP initiation at the first visit under a demedicalized delivery model implemented by Mexico City HIV Program as a strategy to expand PrEP access.

Methods: We analyzed data of 2,980 people who started PrEP in 2022 within the Mexico City HIV Program (90% cisgender men, 8% trans and non-binary people, and 2% cisgender women), with an average age of 31.9 years (S.D. 7.9). Same-day start (SDS) was defined as provision on the first visit simultaneously with risk assessment and testing, and delayed start (DS) as the provision on subsequent days.

Results: Most users (98.8%) received assessment and follow-up by non-medical health workers. PrEP was provided in 3 public units (PU) (67.2%), 3 community centers (CC) in Mexico City and 1 CC in Guadalajara. Entry routes were spontaneous request (82.1%), request for readmission

6.9%, referral at the end of Post Exposure Prophylaxis (PEP) 6.1%, sexually transmitted infections (STIs) care 2.5% and MPOX 2.4 %. 84.7% of people started PrEP on SDS mode and 15.3% on DS (Median 10 days). No differences were found between PU and CC, age, chemsex, crystal-meth or anabolic supplements use. The factors associated with DS were assessment by physicians (OR 6.1 [3.7, 9.9]), cisgender women (OR 3.9 [2.2, 6.9]), referral at the end of PEP (OR 3.8 [2.7, 5.2]) or STI care (OR 3.8 [2.4, 6.2]).

Loss to follow-up at first PrEP follow-up appointment (1 month) was 10.7% in SDS and 18.8% in DS ($p = 0.001$) and 15.3% in the SDS and 20.4% in DS for the second follow-up appointment 4 months after ($p < 0.042$). At baseline, 24 (0.8%) users with eGFR < 60 ml/min were detected, 10 the first month, and 5 in subsequent visits (incidence of 1 per 200), with no difference between SDS and DS ($p = 0.3072$). Three people living with HIV were detected at baseline in SDS group, 4 the first month and 1 incident acquisition in subsequent visits (incidence of 1.2 per 10,000 PrEP users-month).

Conclusions: Same-day initiation of PrEP by non-medical professionals in a large-scale delivery model is feasible and safe.

MOPEC18

Looking beyond the facility to reduce HIV vertical transmission among HIV positive pregnant women: making a case for TBA model in selected local government areas of Taraba State, Nigeria

A.N. Dadi¹, G. Yisa¹, E. Okeke², G. Omoregie¹, J. Anyanti², D. Garba³

¹Society for Family Health, Programmes, Abuja, Nigeria, ²Society for Family Health, Monitoring and Evaluation, Abuja, Nigeria, ³Taraba State AIDS Control Agency, Programmes, Jalingo, Nigeria

Background: The prevention of mother-to-child transmission (PMTCT) of HIV has taken a pivotal role in HIV management with the target of ending new infection in children by 2030. Vertical transmission is the leading route for HIV transmission among children globally. Nigeria has an estimated 83,000 women needing PMTCT, 38,234 (46%) were identified and 34,472 (42%) are on ART. Taraba State has only 34% PMTCT Coverage which is suggestive of high rates of vertical transmission. To improve and strengthen community interventions, existing structures such as Traditional Birth Attendants (TBAs) were identified to look beyond the facility to reduce vertical transmission of HIV among children. The aim of the study was to assess the contributions of TBA model to PMTCT.

Methods: Eight local government areas (LGAs) were selected based on high rates of TBA patronage in Taraba State. TBAs were selected randomly based on their willingness to participate in the study and trained. Documented data for pregnant women enrolled for PMTCT in facility and cohort registers between August of 2020 and July 2022, were analyzed using quantitative methods to

assess the contribution of TBAs in identifying and linking pregnant women who acquired HIV to health care facilities.

Results: The results indicated that between August 2020 and July 2022 a total of 62,376 clients were referred for HIV testing service (HTS), 57,827 were tested, of these 304 tested HIV positive and 289 were linked to treatment. TBAs referred 20,686 (33.2%) pregnant women for HTS, 19,244 (33.3%) tested, 110 (36.2%) identified as HIV positive and all enrolled for PMTCT (100% linkage). Within the period, TBAs linked 73 infants (0-12 months) for early infant diagnosis (EID).

Conclusions: The TBA model has contributed to identifying and linking people living with HIV that are pregnant, thus recording significant reductions in vertical transmissions which emphasizes the benefits of using community structure such as TBA to improve case identification at the community.

Comprehensive training and capacity building for TBAs is key to strengthening community structure and referral system for PMTCT and ending vertical transmission of HIV among children.

MOPEC19

HIV PrEP continuation among clients formerly engaged in PrEP services at private pharmacies participating in a pilot study in Kenya

V. Omollo¹, S. D. Roche², P. Mogere³, P. Ongwen⁴, M. Asewe¹, P. Banjeree^{2,2}, G. Rota¹, P. Otieno¹, G. Maina⁵, R. Malen², K. Owari¹, J. Odoyo¹, D. Were⁴, E. A. Bukusi^{1,6,7}, K. Ngure⁸, K. F. Ortblad²

¹Kenya Medical Research Institute, Centre for Microbiology Research, Nairobi, Kenya, ²Fred Hutchinson Cancer Center, Public Health Sciences Division, Seattle, United States, ³Novartis Pharmaceuticals, Basel, Switzerland, ⁴Jhpiego, Nairobi, Kenya, ⁵Kenya Medical Research Institute, Centre for Clinical Research, Nairobi, Kenya, ⁶University of Washington, Global Health, Seattle, Kenya, ⁷University of Washington, Obstetrics and Gynecology, Seattle, Kenya, ⁸Jomo Kenyatta University of Agriculture and Technology, School of Public Health, Nairobi, Kenya

Background: HIV pre-exposure prophylaxis (PrEP) delivery at private pharmacies is a novel and promising differentiated service delivery model that could address access barriers to public clinic-based PrEP delivery. We measured post-study PrEP continuation (i.e., linkage to clinic-based PrEP services) among individuals who initiated PrEP at one of 12 private pharmacies participating in a six-month pilot study in Kisumu and Kiambu Counties, Kenya.

Methods: During the pilot study (January-July 2022), clients that met the PrEP eligibility criteria were dispensed a 1-month PrEP supply at initiation and a 3-month supply at refill visits by trained pharmacy providers. Three months following pilot completion (October 2022), we followed up with participants who had initiated pharmacy PrEP services.

In our follow-up phone surveys, former study participants reported on their current PrEP use, and, if applicable, location of PrEP access and/or reasons for discontinuation. We reported descriptive statistics.

Results: We called 667 clients who initiated PrEP at pharmacies and reached 74% (492/667) of the participants called. The median age was 25 years (IQR 22-31), 43% (211/492) were male, and 76% (372/492) were unmarried. During the pilot study, most surveyed participants refilled PrEP at least once (79%, 388/492). Three months post-study completion, the majority of participants had stopped PrEP use (59%, 291/492).

Reasons for stopping PrEP included: not wanting to get PrEP from a clinic (60%, 175/291), no longer feeling at HIV risk (22%, 64/291), and testing HIV positive (4%, 13/291). Among the 201 clients still using PrEP, most obtained PrEP from a public clinic (59%, 118/201) and some from a private clinic (13%, 27/201). PrEP use three months post-study completion was greater among those who refilled PrEP at least once at the pharmacy (46%, 180/388) compared to those who never refilled PrEP at the pharmacy (20%, 21/104).

Conclusions: Stopping the delivery of PrEP services at private pharmacies following completion of a pilot study resulted in more than half of eligible users discontinuing use because they were not interested in clinic-delivered PrEP services. More research is needed to understand whether and how private pharmacies can be leveraged and sustained as PrEP service delivery points in Kenya and similar settings.

MOPEC20

Expanded peer outreach approach on PrEP uptake amongst key population in Nakuru County, Kenya

W. Opudo¹, H. Malava², R. Kiuna³, D. Wandina⁴, A. Kahiga⁵, L. Matu⁶, M. Kithika⁷, N. Gitahi⁸

¹GoldStar Kenya, HIV Prevention, Care and Treatment, USAID Tujenge Jamii Project, Nairobi, Kenya, ²Delloite, Senior Technical Officer- GBV and Key Population, Nakuru, Kenya, ³Nakuru County Department of Health, County AIDS and STI Control Program, Nakuru, Kenya, ⁴GoldStar Kenya, HIV Prevention, USAID Tujenge Jamii Project, Nairobi, Kenya, ⁵Delloitte, Senior Technical Officer- HIV Care and Treatment, Nakuru, Kenya, ⁶GoldStar Kenya, Deputy Chief of Party - USAID Tujenge Jamii, Nakuru, Kenya, ⁷Delloite, Chief of Party - USAID Tujenge Jamii Project, Nakuru, Kenya, ⁸GS Kenya, Executive Director, Nairobi, Kenya

Background: Effective strategies to increase pre-exposure prophylaxis (PrEP) uptake and continuation among men who have sex with men (MSM) and female sex workers (FSW) who engage in sex work or transactional sex are sparsely reported. We aimed to describe the available evidence on strategies for improving the uptake and continuation of PrEP among men who have sex with men and female sex workers or otherwise are at high risk of acquiring HIV, and report their implementation outcomes.

Description: In FY 22 between March 2022 to September 2022, USAID Tujenge Jamii initiated Expanded Peer Outreach Approach to increase PrEP utilization /Uptake amongst the key population targeting the MSMs and FSWs within Nakuru county.

This approach entailed capacity building of Peer educators/navigators and outreach workers on PrEP Module. the PrEP modules majored on demand creation, Follow up Schedule, Myths and Miss conception, Side Effects, Community PrEP Refills and PrEP Champions also identified. This was followed by referrals and linkages to the 5 DICES within hotspots for PrEP delivery by the Clinicians. Data was then collected and reviewed monthly using PrEP MOH Registers and tabulated in Excel sheets.

Lessons learned: A total of 35 MSMs and 2562 FSWs were Screened (New and Restart Clients) with 77% (27/35) of the MSM and 89% (2284/2562) of the FSWs screened being eligible for PrEP. Of those eligible, 81% (22/27) and 24% (539/2284) of eligible MSMs and FSWs were initiated on PrEP. A total of 45 MSMs and 576 FSWs were continuing with PrEP of which 2 (4%) MSMs and 28(5%) FSWs were PrEP restarts.

Of the clients who had month one refills, 100% (4/4) of the MSM were tested for HIV with no seroconversions whilst 73% (82/112) of the FSWs had a HIV test done with 7% (6/82) seroconverting. 6% (5/82) FSWs were diagnosed and treated for STI while on PrEP with no cases reported amongst the MSMs. 9% (7/82) FSWs reported Inconsistent or no condom use during intercourse for the review period.

Conclusions/Next steps: Expanded Peer Outreach Approach is a public health approach with great potential for reaching new populations and ensuring and enhancing demand creation for PrEP delivery both at facility and community settings.

MOPEC21

Using Common Elements Treatment Approach (CETA) to improve access to mental health services among people living with HIV in Rwenzori region in Western Uganda

C. Mwanje¹, T. Ngabirano¹, M. Banura¹, M. Ndifuna¹, S. Atugonza¹, L. Tumuhairwe¹, S. Ongom¹, B. Wackenreuter², C. Figge³, H. Lukwata Ssentongo⁴

¹Jhpiego, Programs, Kampala, Uganda, ²Jhpiego, Programs, Baltimore, United States, ³John Hopkins University, Global Mental Health, Baltimore, United States, ⁴Ministry of Health, Mental Health and Control of Substance Use, Kampala, Uganda

Background: With an estimated 1.4 million people living with HIV/AIDS in Uganda, HIV-positive individuals are three times more likely to develop mental health disorders. With funding from Health Resources and Services Administration (HRSA), Jhpiego Uganda working with Ministry of Health and John Hopkins University used the Common Elements Treatment Approach (CETA) model to scale up integration of Mental health services in HIV care

clinics in three health facilities in Western Uganda. CETA is a system of care that allows trained providers to assess symptom severity, create a treatment plan and deliver psychotherapeutic care for common mental health problems.

Description: 35 health workers from mental and HIV clinics of three high volume health facilities were selected, trained, mentored, and supported to provide psychoeducation, screening, group support therapy (for mild conditions) and individualized psychotherapy (for moderate and acute conditions) in the routine HIV care and management. Program data was collected using Client Monitoring Forms (CMF) and HIV client cards.

Lessons learned: From August to December 2022, 463 clients including 60% (282) HIV-positive individuals received mental health services through CETA providers. 73% of these benefited from a group-based care that includes psychoeducation, mental health screening, and group sessions. 27% (77) of the HIV-positive individuals presented moderate and acute symptoms and received individualized psychotherapy ranging from 8-12 sessions. 58% of clients requiring individualized sessions were improving and continuing with care while 35% had fully recovered, and 8% had stopped care due to relocation, transport challenges, and stigma.

Recipients of individualized sessions improved in adherence and appointment keeping for HIV care from 52% to 82% and 59% to 76% respectively. Improvements in HIV care outcomes were directly proportional to the reduction in mental ill health symptoms in clients. Integrating psychoeducation and screening in routine HIV/AIDS care activities increased demand for mental health care services at health facilities.

Conclusions/Next steps: Achievement of the last UNAIDS 90-target on viral load suppression requires increasing access to mental health services for HIV populations. The next phase of the program is supporting its full adoption and integration into existing differentiated service delivery (DSD) models, and scaling it up to other facilities serving big HIV-populations.

MOPEC22

PrEP versus improved HIV Care Cascade: which best drives HIV decline? A mathematical modelling study

K. Ryan^{1,2}, M. Traeger¹, M. Stoové^{1,2}, N. Scott^{1,2}, V. Cornelisse², D. Murphy^{2,3}, E. Wright^{2,1,4}

A comparison of acceptability of HPV self-sampling for cervical cancer screening among women living with and without HIV in Lagos University Teaching Hospital, Nigeria

A. Adejimi^{1,2}, K. Okunade³, A. Faturoti¹, A. Akanmu⁴,
A. Banjo⁵, F. Omokhodion²

¹University of Lagos, Nigeria, Department of Community Health and Primary Care, Lagos, Nigeria, ²University of Ibadan, Nigeria, Department of Community Medicine, Ibadan, Nigeria, ³University of Lagos, Nigeria, Department of Obstetrics and Gynecologic, Lagos, Nigeria, ⁴University of Lagos, Nigeria, Department of Haematology and Blood Transfusion, Lagos, Nigeria, ⁵University of Lagos, Nigeria, Department of Anatomic and Molecular Pathology, Lagos, Nigeria

Background: Women living with HIV have higher risk of persistence Human Papillomavirus (HPV) infection and developing cervical cancer compared to women in the general population. As part of self-care interventions, HPV testing with self-collected genital samples and timely follow-up care has the potential to improve the prevention of cervical cancer among women.

The aim of this study was to assess and compare the acceptability of HPV self-sampling method for cervical cancer screening among women living with and without HIV in Lagos University Teaching Hospital (LUTH), Lagos, Nigeria.

Methods: A comparative cross-sectional study was conducted and participants were selected using a systematic sampling technique. Data were collected using a semi-structured interviewer-administered questionnaire and analyzed using SPSS. Chi-square statistics was used at the level of significance was set at 5%.

Results: The mean age of the respondents was 42.4 years \pm 7.3SD and 64.8% were married. Awareness of HPV was low (33.6%) and this was significantly lower among women living with HIV (18.5%) than women living without HIV (50.2%). However after a brief information on HPV and cervical cancer, a significantly higher proportion of women living with HIV (92.8%) compared to women without HIV (83.6%) accepted HPV self-sampling method for collection of genital samples ($p < 0.0001$).

Awareness of HPV was significantly associated with the acceptance of HPV self-sampling method for the collection of genital samples.

Age, marital status, level of education and previous Pap test were not significantly associated with the acceptance of HPV self-sampling among the women in the two groups.

Conclusions: Acceptance of HPV self-sampling method for early detection of high-risk genital HPV infection and prevention of cervical cancer especially among women living with HIV can be achieved by increasing the awareness about HPV and HPV self-sampling method for the collection of genital samples.

Around this time concurrent increases in ART coverage and more rapid post-diagnosis ART initiation occurred, and this period coincided with declines in notifications of HIV incident infections in gay and bisexual men (GBM). We sought to determine the relative contributions of PrEP and improvements in the HIV Care Cascade to this decline.

Methods: We used a population-level, deterministic compartmental model of HIV transmission in GBM in Victoria calibrated to HIV notifications. We modelled four scenarios of PrEP uptake and improvements in key HIV Care Cascade indicators (HIV treatment uptake and virological suppression) including a status quo scenario (PrEP use and HIV Care Cascade levels taken from national reports) (Table). The annual number of HIV diagnoses and HIV incident infections from 2010 to 2019 were projected for each scenario. Each of the three counterfactual scenarios is described in the Table.

Results: Compared to the pre-PrEPX period, the number of HIV infections post-PrEPX declined 21.8% in scenario 1 (status quo), and increased by 11.2%, 18.9% and 63.7% in scenarios 2-4, respectively. The number of infections in scenario 1 was 278 less than in scenario 2 (relative reduction of 32.3% due to PrEP). The number of infections in scenario 1 was 342 less than in scenario 3 (relative reduction of 37.0% due to improvements in the HIV Care Cascade). The number of infections in scenario 1 was 740 less than in scenario 4 (relative reduction of 55.9% due to PrEP and improvements in the HIV Care Cascade combined), (Table).

	Projected number of incident HIV infections 2014-2016	Projected number of incident HIV infections 2017-2019	% Change: 3 years-post PrEPX (intervention) vs 3-years pre-PrEPX (control)	Estimated number of additional HIV infections during intervention period (2017-2019) in each counterfactual scenario vs status quo	Estimated relative increase in HIV infections during intervention period (2017-2019) in each counterfactual scenario vs status quo
Scenario 1: Status quo	746	583	-21.8%		
Scenario 2: No PrEPX or PBS PrEP uptake	774	861	11.2%	278	32.3%
Scenario 3: No improvement in HIV Care Cascade from 2015 onward	778	925	18.9%	342	37.0%
Scenario 4: No PrEPX or PBS PrEP uptake and no improvement in HIV Care Cascade from 2015 onward	808	1323	63.7%	740	55.9%

Conclusions: PrEP and improvements in HIV Care Cascade indicators each contributed an estimated one-third decline in incident HIV infections during 2017-2019 in Victoria, Australia. These findings emphasise the importance of combination biomedical HIV prevention strategies to reduce incident HIV infections.

TUPEC02

Implementing cervical cancer screening tools to identify serotypes of human papillomavirus (HPV) among women living with HIV, Cuilapa Guatemala 2022

L. Leon Pineda¹, R. Pineda¹, L. Aguirre¹, J. Abdo¹, Y. Villaseñor¹, W. Lopez¹, I. Escobar²

¹IntraHealth International, Guatemala, Guatemala,

²IntraHealth International, Epidemiologist, Guatemala, Guatemala

Background: Low- and middle-income countries (LMICs) have the highest rate of cervical cancer incidence and mortality. Women living with HIV have a six-fold increased risk of cervical cancer compared with women without HIV by acquiring human papillomavirus (HPV). Guatemala has a cervical cancer prevalence of 17%. Yet the Ministry of Health has limited access to screening tools and reagents for risk assessment of cervical cancer.

IntraHealth International's USAID-funded HIV Care and Treatment Project supports eight HIV clinics in Guatemala, providing integrated services including sexual reproductive health services to women living with HIV.

Description: The Project and another NGOs joined interventions to identify Guatemalan women at risk of cervical cancer. In 2022, one Project-supported HIV clinic (Cuilapa) screened 69 women between the ages of 25–49 for cervical cancer.

The Project provided programmatic assistance, subsidized travel costs, and followed-up on patient results in order to ensure timely interventions. Screening was performed using GeneXpert testing and strain identification to categorize women according to cancer risk.

Among the 55% with a HPV-DNA result (35/69), follow-up was performed using colposcopy and biopsy of cancer lesions. Of those 35 women, 6% were diagnosed with cancer (2/35) and received additional treatment at referral facilities.

Age Group	# screened	Total VPH DNA n(%)	HPV16 n(%)	HPV18 n(%)	Other high-risk	Colposcopy	Invasive Cancer
25 - 29	16	10(63%)	3(19%)	0	7(44%)	10	0
30 - 34	11	8 (73%)	4(36%)	0	6(55%)	8	0
35 - 39	10	6(60%)	2(20%)	0	4(40%)	6	0
40 - 44	15	4(27%)	1(7%)	1(7%)	3(20%)	4	0
45 - 49	17	10 (59%)	2(12%)	3(18%)	8(47%)	10	2(6%)
Total	69	35(55%)	12(17%)	4(6%)	28(41%)	35	2(6%)

Table. Cervical cancer screening of women living with HIV, Hospital Regional de Cuilapa, Guatemala 2022.

Lessons learned: We learned that inter-institutional coordination for the implementation of preventive tools is key to reduce comorbidities in people living with HIV, identifying type and population. This served as a milestone for new preventive strategies for women in Guatemala.

Conclusions/Next steps: We successfully integrated a cervical cancer screening program into routine HIV care at a HIV care center in Guatemala using HPV DNA testing. We observed high screening yield with a preponderance

of non-16 or 18 HPV types. Screening in Guatemala should be linked to treatment, focused on younger women and those with more advanced immunosuppression.

TUPEC03

Adoption of the *Malkia Klabu* prevention intervention in Tanzania for young women: distribution of HIV self-test kits and contraceptives at girl-friendly drug shops

E. Anderson¹, A. Mnyippembe², L. Sheira¹, C. Solorzano-Barrera¹, C. Chiu¹, K. Hassan², J. Allan², J. Msasa², A. Sabasaba², L. Packer¹, S. McCoy¹, J. Liu³

¹University of California, Berkeley, Berkeley, United States,

²Health for a Prosperous Nation, Dar es Salaam, Tanzania, United Republic of, ³University of California, San Francisco, San Francisco, United States

Background: In a cluster-randomized trial (NCT05357144), we are evaluating the effectiveness of *Malkia Klabu* ("Queen's Club"), a youth-centered intervention in Tanzania delivering HIV self-test (HIVST) kits and sexual and reproductive health (SRH) products to adolescent girls and young women (AGYW) through girl-friendly drug shops. At *Malkia Klabu* shops, AGYW can join a customer loyalty program to get free SRH products and earn punches for other shop purchases, redeemable for small prizes. We analyzed product distribution to assess initial adoption of the scaled intervention.

Methods: We examined 6 months of electronic sales data to female patrons (age 15–24) from 72 shops in the Shinyanga Region. We assessed time trends and heterogeneity across shops in the distribution of:

- SRH study products (HIVST kits, oral and emergency contraception, condoms, pregnancy tests) between arms, and;
- Membership cards and prizes among intervention shops. Control shops also distribute free HIVST kits to AGYW but sell other SRH products as per usual.

Results: From July 2022–January 2023, intervention shops (N=37) distributed 8,114 SRH products and HIVST kits to AGYW compared to 2,538 from control (N=35) shops. Intervention shops distributed more condoms (1648 vs. 100), emergency contraception (837 vs. 2), oral contraceptives (1487 vs. 37), and pregnancy tests (1653 vs. 193) than control shops. Distribution of HIVST kits in intervention shops was initially more rapid than among controls, but converged by 6 months (2489 vs. 2206).

Mean monthly products distributed per shop varied widely, with many intervention shops achieving several fold increases in customer transactions over their control counterparts.

At intervention shops, 2,255 AGYW joined *Malkia Klabu* (median 66 per shop; IQR=36–88), engaging in 8,221 transactions (median 159 per shop; IQR=80–380).

Conclusions: HIVST kit distribution rapidly increased in both arms, while substantially more SRH products were distributed among *Malkia Klabu* shops. These differences

largely accord with price differentials (free HIVST kits in both arms, only free contraceptives in the intervention arm), underscoring AGYW's price sensitivities.

Monitoring the trajectory of HIVST kit distribution through 24 months of the trial will determine to what extent *Mal-ika Klabu* may additionally appeal to AGYW beyond lowering cost barriers.

TUPEC04

Prevalence of sexually transmitted infections and bacterial vaginosis in South African adolescent girls and adult women at high risk of HIV acquisition

A.G. Abrahams^{1,2}, C. Mehrou-Loko², N. Radzey^{1,2}, R. Harryparsad², B. Meyer², M.T. Manhanza², H. Humphries^{3,4}, P. Gumbi⁴, F. Busakwe⁵, N. Ahmed⁵, F. Fortune⁵, L.-G. Bekker^{2,5}, J.-A.S. Passmore^{2,3,6}, H.B. Jaspan^{2,7}, L. Masson^{2,3,8,9}

¹Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Department of Integrative Biomedical Sciences, Cape Town, South Africa,

²Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Department of Pathology, Cape Town, South Africa, ³Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, ⁴School of Life Sciences, University of KwaZulu-Natal, Pietermaritzburg, South Africa, ⁵Desmond Tutu HIV Centre, Cape Town, South Africa, ⁶National Health Laboratory Service, Cape Town, South Africa, ⁷Seattle Children's Research Institute, University of Washington, Department of Biochemistry, Washington, United States, ⁸Burnet Institute, Life Sciences Discipline, Melbourne, Australia, ⁹Central Clinical School, Monash University, Carlton, Australia

Background: Young South African adolescent girls and young women (AGYW) are at a higher risk for HIV infection than older women. Sexually transmitted infections (STIs) and bacterial vaginosis (BV) have been associated with increased inflammation in the female genital tract (FGT), which in turn increases HIV susceptibility.

The aim of this study was to compare the prevalence of STIs/BV in AGYW versus older South African women, as well as associated risk factors, to understand the high rates of HIV infection seen in young women in this setting.

Methods: Vaginal swabs were collected from 106 AGYW (14-19 years old) and 51 older women (25-35 years old) in Cape Town, South Africa, enrolled in our National Institutes of Health funded Mucosal Injury from Sexual Contact study. Swabs were tested for STIs, *Chlamydia trachomatis* (CT), *Neisseria gonorrhoeae* (NG) and *Trichomonas vaginalis* (TV) by real-time PCR.

Vaginal smears were Gram-stained for BV diagnosis by Nugent scoring.

Results: CT was the most prevalent STI (37.6%), followed by NG (12.1%) and TV (10.2%). CT and NG prevalence was higher in AGYW than in 25-35-year-olds (51.9% versus 23.5% and 15.1% versus 3.9%, $p=0.0008$ and $p=0.0396$, respectively).

A total of 47% had BV, while 14% had intermediate microbiota and 39% were BV negative. BV prevalence was similar between AGYW (46.4%, $n=97$) and older women (48.9%, $n=47$), however, the vaginal pH of older women was lower than AGYW ($p=0.0101$).

NG positive women reported significantly fewer vaginal sexual acts in the preceding month than those who tested negative ($p=0.0009$).

Nugent score correlated positively and vaginal pH correlated negatively with the number of reported vaginal sexual acts ($\rho=0.1903$, $p=0.0209$ and $\rho=-0.2286$, $p=0.0236$, respectively).

The proportion of AGYW (57.6%) who reported male condom use was similar to older women (51.0%). In addition, the majority of STI/BV cases were asymptomatic.

Conclusions: STIs/BV prevalence is high among young South African women, with CT and NG particularly prevalent in AGYW compared to older women, potentially increasing the risk for HIV acquisition. Strategies such as point-of-care screening for FGT inflammation and STI/BV, as well as pre-exposure prophylaxis are urgently needed to reduce HIV susceptibility in this population.

TUPEC05

Medroxyprogesterone acetate and levonorgestrel levels are positively correlated with immune mediators

N. Radzey¹, A. Abrahams¹, D.W. Erikson², R. Harryparsad¹, B. Meyer¹, P.L. Chen³, X. Gao³, O. Taku¹, A.-L. Williamson¹, C. Mehrou-Loko¹, F. Lefebvre d'Helencourt³, G. Buck⁴, J. Smit⁵, J. Strauss⁶, K. Ahmed⁷, M. Beksinska⁵, M. Serrano⁴, V. Bailey⁷, C. Morrison³, J. Deese⁸, K. Nanda⁸, L. Masson⁹

¹University of Cape Town, Institute of Infectious Diseases & Molecular Medicine, Cape Town, South Africa, ²Oregon National Primate Research Center, Beaverton, United States, ³FHI 360, Durham, United States, ⁴Virginia Commonwealth University, Department of Microbiology and Immunology and Center for Microbiome Engineering and Data Analysis, Richmond, United States, ⁵MatCH Research Unit (Wits MRU), Department of Obstetrics and Gynaecology, Durban, South Africa, ⁶University of Pennsylvania, Department of Obstetrics and Gynaecology, Philadelphia, United States, ⁷Setshaba Research Centre, Tshwane, South Africa, ⁸Consultant, Durham, United States, ⁹Burnet Institute, Disease Elimination Program, Life Sciences Discipline, Melbourne, Australia

Background: The injectable depo-medroxyprogesterone acetate (DMPA-IM) is the most popular form of hormonal contraception among South African women, while the levonorgestrel (LNG) implant is gaining popularity. Pharmacokinetic studies show that medroxyprogesterone acetate (MPA) and LNG levels vary among individuals using these methods. Little is known about the impact of hormone levels on immune mediators previously linked to sexually transmitted infection (STI) and HIV risk in the female genital tract (FGT).

Methods: We randomly assigned 160 South African women to DMPA-IM, copper intrauterine device (IUD), or LNG implant in the Evidence for Contraceptive Options and HIV Outcomes (ECHO) trial.

Eleven cytokines and antimicrobial peptides were measured in vaginal swabs in duplicate using Luminex and ELISA at baseline, one (M1) and three months (M3) following contraceptive initiation. Systemic concentrations of estradiol, progesterone, MPA and LNG were measured in serum samples using liquid chromatography-mass spectrometry at each timepoint.

Changes in systemic hormone levels over time for each arm were assessed using Mann-Whitney U test; and associations between serum hormone levels and vaginal immune mediator concentrations using Spearman correlations.

Results: At baseline, serum hormone levels were similar across arms. Younger women (age 15-24) had higher levels of progesterone ($p=0.012$) compared to older women (age ≥ 25). Estradiol levels were higher in copper IUD users compared to women using DMPA-IM at M1 ($p=0.0380$) and both estradiol and progesterone levels were higher in copper IUD users at M3 compared to women using DMPA-IM ($p=0.006$ and $p=0.010$, respectively) and the LNG implant ($p=0.001$ and $p=0.010$, respectively).

MPA levels in DMPA-IM users positively correlated with IL-6 ($p=0.040$) and fold changes in IL-8 ($p=0.040$), MIP-1 α ($p=0.003$) and MIP-3 α ($p=0.006$) at M1. In LNG implant users, LNG levels positively correlated with IL-6 ($p=0.045$), IL-1 β ($p=0.040$), IL-8 ($p=0.029$), MIP-1 α ($p=0.023$) and MIP-3 α ($p=0.030$) at M3. Progesterone levels were positively correlated with IL-6 ($p=0.013$) at M1 and IL-8 at M1 and M3 ($p=0.049$ and $p=0.046$, respectively) in the LNG implant arm.

Conclusions: MPA and LNG levels at M1 and M3 positively correlated with immune mediators in their respective arms, suggesting that individual-level metabolism of these contraceptive steroids may differentially influence immune profiles associated with HIV acquisition risk.

TUPEC06

High prevalence rates of chlamydia and gonorrhea among adolescent men who have sex with men (AMSM) and transgender women (ATGW) enrolled in a PrEP cohort in Salvador, Northeast Brazil

C. Oliveira¹, L. Marques¹, G. Campos¹, D. Medeiros¹, V. Salgado¹, L. Magno², F. Soares³, Á. Silva¹, H. Brito¹, P. Nascimento³, T. Fonseca³, M. Westin⁴, A. Grangeiro⁵, I. Dourado³

¹Federal University of Bahia, Multidisciplinary Institute for Health, Vitória da Conquista, Brazil, ²University of Bahia, Department of Life Sciences, Salvador, Brazil, ³Federal University of Bahia, Collective Health Institute, Salvador, Brazil, ⁴Federal University of Minas Gerais, Faculty of Medicine, Belo Horizonte, Brazil, ⁵University of São Paulo, Faculty of Medicine, São Paulo, Brazil

Background: *Neisseria gonorrhoeae* (NG) and *Chlamydia trachomatis* (CT) are among the sexually transmitted infections (STIs) with high rates worldwide. These infections disproportionately affect AMSM and ATGW. This population's prevalence rates by anatomical site, sociodemographic and behavioral data (SBD) are scarce in Brazil and elsewhere.

Methods: PrEP1519 is a prospective, multicenter, open-label PrEP demonstration cohort study of AMSM and ATGW aged 15-19. For this analysis, we included 246 adolescents who enrolled in PrEP1519 between April 2019-February 2021 in the city of Salvador, Northeast Brazil. They were tested for NG and CT by qPCR using swabs collected from oral, anal, and urethral anatomical sites. We assessed the association between SBD and the prevalence of STIs by Pearson's chi-squared test or Fisher's exact test. Poisson regression with robust variance was used to estimate the adjusted prevalence ratio (PR) and 95% confidence interval (95%CI).

Results: The prevalence of STIs by anatomical site is summarized below:

STI	Any site		Oral (n=245)		Anal (n=210)		Urethral (n=213)	
	n (%)	95%CI	n (%)	95%CI	n (%)	95%CI	n (%)	95%CI
N. gonorrhoeae	37 (17.9)	13.21-23.74	23 (9.4)	6.31-13.76	16 (7.6)	4.71-12.11	4 (1.9)	0.70-4.92
C. trachomatis	12 (5.9)	3.36-10.10	3 (1.2)	0.39-3.75	5 (2.4)	0.99-5.62	4 (1.9)	0.70-4.92
Coinfection	1 (0.5)	0.06-3.47	-	-	1 (0.5)	0.06-3.47	-	-

Table. Prevalence of *N. gonorrhoeae* and *C. trachomatis*. PrEP1519, Northeast Brazil, 2019-2021

Factors associated with NG was a lower level of schooling (PR=2.08; 95%CI 1.07-4.04) and engaging in receptive anal sex in the last three months (PR=2.45; 95%CI 0.91-6.65). Condomless oral sex in the previous three months was associated with CT (PR=3.75; 95%CI 1.28-11.00) and lower level of schooling (PR=3.00; 95%CI 0.90-9.98), but the 95%CI was wide and imprecise.

Conclusions: We found a high prevalence of NG and CT acquisition among AMSM and ATGW, especially in extra-genital sites. These findings highlight the need for test-

ing in multiple anatomical sites among HIV-vulnerable populations. The association between education, receptive anal sex and condomless oral sex with STIs expresses the role social and behavioral factors play in the greater vulnerability of MSM and ATGW to these infections.

Therefore, inclusive and comprehensive sexual health and behavior counseling tailored for these populations, especially those who are more willing to engage in riskier sexual practices, could further improve HIV and STI prevention and care.

TUPEC07

Just how far off target are we? Measuring unmet pre-exposure prophylaxis (PrEP) need among men who have sex with men (MSM) and transgender women (TGW) in Asia

K.E. Green¹, C. Chan², M.M. Cassell³, J. Ong^{4,5,6}, D. Fraser², L. Zhang⁷, M. Poonkasetwattana⁸, N. Suwandi⁸, N. Phanupak⁹, H. Boonyapisompan¹⁰, B.R. Bavinton², H.-M.A. Schmidt^{11,12}

¹PATH, Hanoi, Vietnam, ²University of New South Wales, Kirby Institute, Sydney, Australia, ³FHI 360, HIV Department, Hanoi, Vietnam, ⁴Alfred Health, Melbourne Sexual Health Centre, Melbourne, Australia, ⁵Monash University, Central Clinical School, Melbourne, Australia, ⁶London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom, ⁷School of Public Health, Xi'an Jiaotong University Health Science Center, China-Australia Joint Research Centre for Infectious Diseases, Xi'an, China, ⁸Asia Pacific Coalition on Male Sexual Health, Bangkok, Thailand, ⁹Institute of HIV Research and Innovation, Bangkok, Thailand, ¹⁰Asia Pacific Transgender Network, Bangkok, Thailand, ¹¹UNAIDS Regional Office for Asia and the Pacific, Bangkok, Thailand, ¹²World Health Organization, Global HIV, Hepatitis and STIs Programme, Geneva, Switzerland

Background: Despite recent efforts to expand oral pre-exposure prophylaxis (PrEP) access in Asia, uptake has lagged significantly behind the regional 2025 target, with only 3% of the 4 million goal achieved.

We aimed to measure unmet PrEP need among men who have sex with men (MSM) and transgender women (TGW) in Asia to inform scale-up strategies.

Methods: We implemented an online cross-sectional survey among MSM and TGW across 15 and 11 countries or territories in Asia, respectively, from May to November 2022. Participants were asked about potential HIV risk, PrEP use history, and PrEP product and service preferences. We defined unmet PrEP need as those who had:

1. Heard of and wanted to take PrEP but had never taken it;
2. Never heard of PrEP but had HIV risk factors indicating need;
3. Taken oral PrEP but preferred a different PrEP product (e.g., long-acting PrEP), or;
4. Had temporarily discontinued oral PrEP due to a barrier (side effects, not liking pills, cost) but still needed it.

We generated descriptive statistics and used multivariable logistic regression models to identify factors associated with unmet PrEP need.

Results: Among 17,032 MSM and 1,260 TGW surveyed, 10,195 (59.9%) MSM and 598 (47.5%) TGW were found to have unmet PrEP need:

1. 6,130 (60.1%) MSM and 202 (33.8%) TGW were PrEP-naïve but wanted to take it;
2. 1,368 (13.4%) MSM and 134 (22.4%) TGW were unaware of PrEP but reported risk factors indicative of need;
3. 2,004 (19.7%) MSM and 182 (30.4%) TGW were taking oral PrEP but preferred using a different product;
4. 693 (6.8%) MSM and 80 (13.4%) TGW had temporarily discontinued PrEP due to a barrier.

Knowing fewer people who took PrEP (aOR=1.85; 95%CI:1.72-2.00), condomless anal sex in past 6 months (aOR=1.64 95%CI:1.54-1.75), and younger age (aOR=1.02 95%CI:1.01-1.02) were positively associated with unmet PrEP need.

Conclusions: We identified substantial unmet PrEP need among MSM and TGW respondents, in the largest known regional study on PrEP in Asia. Urgent investment is needed to increase PrEP awareness and service access, accompanied by a wider selection of products, that best align with what TGW and MSM need and want.

TUPEC08

Accuracy of indirect adherence measures among adolescent men who have sex with men (aMSM) and transgender women (aTGW) in Brazil: a longitudinal analysis

D.R. Zeballos Rivas¹, L. Magno², F. Soares¹, J.A. Pinto Junior³, L. Amorim⁴, D. Greco⁵, A. Grangeiro⁶, I. Dourado¹, The PrEP1519 study group

¹Universidade Federal da Bahia, Instituto de Saúde Coletiva, Salvador, Brazil, ²Universidade do Estado da Bahia, Departamento de Ciências da Vida, Salvador, Brazil, ³Universidade Federal Fluminense, Departamento de Estatística, Niterói, Brazil, ⁴Universidade Federal da Bahia, Instituto de Matemática e Estatística, Salvador, Brazil, ⁵Universidade Federal de Minas Gerais, Faculdade de Medicina, Belo Horizonte, Brazil, ⁶Universidade de São Paulo, Departamento de Medicina Preventiva da Faculdade de Medicina, São Paulo, Brazil

Background: Oral PrEP has been offered free of charge in the health services of the Brazilian National Health System since 2017. In 2022, the updated Brazilian PrEP guidelines included adolescents who are at high HIV risk. Adherence evaluation is crucial for monitoring PrEP users, and indirect measures are used during clinical follow-up. We aimed to assess the accuracy of indirect PrEP adherence measures using longitudinal data and drug concentrations in dried blood spots (DBS).

Methods: PrEP1519 is a prospective, multicenter, open-label PrEP demonstration cohort study conducted with aMSM and aTGW aged 15-19. A diagnostic accuracy analysis was performed comparing a direct measure of adher-

ence - tenofovir diphosphate (TFV-DP) concentrations in DBS- with three indirect measures: medication possession ratio (MPR), pill count, and self-report. Generalized estimating equations (GEE) were used to assess the accuracy of each indirect measure through the computation of the Area Under The Curve (AUC) and their 95% Confidence Interval (95%CI) using the ROC (Receiver Operating Characteristics) curve analysis.

We considered the repeated (longitudinal) measures for the same participants, and we used the reference of protective TFV-DP levels $\geq 800\text{fmol/punch}$ equivalent to 4 pills weekly or more. We also analyze the combination of different methods to assess adherence.

Results: We selected a sample of 302 DBS corresponding to 188 participants. Most were aMSM (78.7%), 18-19 years old (80.3%), and non-whites (72.9%). Matched data for MPR was 294, for self-report 274, and pill count 104. AUC was 0.59 (95%CI: 0.53 - 0.66) for MPR, 0.69 (95%CI: 0.58 - 0.80) for pill count, and 0.75 (95%CI: 0.69 - 0.81) for self-report.

We observed that the combination of the three methods for evaluating adherence yielded an AUC= 0.72 (95%CI: 0.62 - 0.83) and we obtained a better performance with MPR and self-report combined (AUC = 0.77; 95%CI: 0.70 - 0.83).

Conclusions: The three indirect measures discriminated participants with drug levels equivalent to four pills weekly at different time points, indicating that these are valuable methods for monitoring PrEP use. Using more than one indirect method for adherence yields better patient adherence information.

TUPEC09

A client-centered approach to eliminate mother-to-child transmission of HIV: outcomes from a large ART program in Kisumu County, Kenya

F. Odhiambo¹, R. Onyango¹, E. Mulwa¹, M. Aluda¹, L. Otieno¹, E.A. Bukusi^{1,2}, C.R. Cohen², P.M. Murname³

¹Kenya Medical Research Institute, Centre for Microbiology Research, Research Care and Training Program, Nairobi, Kenya, ²University of California San Francisco, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, ³University of California San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States

Background: Elimination of Mother-to-Child Transmission of HIV remains a global health priority. In a large ART program in western Kenya, we introduced several novel prevention of mother-to-child transmission (PMTCT) interventions to identify and support pregnant and breastfeeding women living with HIV. Here we report key outcomes before and after the introduction of these interventions.

Methods: Between October 2016-September 2021, Family AIDS Care & Education Services (FACES), provided PMTCT services across 63 facilities in Kisumu County, Kenya. In 2019,

we implemented individualized client-centered PMTCT interventions in addition to standard of care. The interventions included:

1. Women considered at-risk of poor care engagement (e.g., adolescent mothers, unstable support system, prior history of a treatment interruption) attended visits on a designated day to enable multidisciplinary team review of cases and social networking for teens,
2. Case management for 1:1 psychosocial support and close monitoring; and,
3. Mobile app-based module to facilitate adherence support and mother-baby pair tracking.

We conducted pre-post analyses of PMTCT outcomes before the intervention (Oct 2016- Sep 2018) versus after (Oct 2020-Sep 2021). These included ART initiation, virologic suppression, and infant outcomes following the end of breastfeeding (HIV acquisition by 18 months of age, death, loss to follow-up, or transferred out).

Results: Among 81,740 pregnant women who attended ANC at FACES-supported clinics in Kisumu County between October 2016 and September 2021, HIV prevalence was 16% with little variation over time. The proportion receiving ART during pregnancy increased from 82.4% in 2017 to 99.4% in 2021 ($p<0.001$).

Similarly, the proportion achieving viral suppression increased from 63.5% to 97.2% during pregnancy and 74.0% to 97.3% during breastfeeding (both $p<0.001$). Consequently, perinatal transmission by 18 months of follow-up declined from 5.7% (100/1752) to 2.2% (48/2156) ($p<0.001$). Moreover, loss to follow-up declined from 12% (268/2332) to 2.5% (59/2393; $p<0.001$) while the proportion who transferred out declined from 9.5% (212/2332) to 7.4% (178/2393; $p<0.02$).

Conclusions: Following the implementation of novel client-centered interventions, we observed clinically significant declines in MTCT and loss to follow-up of pregnant and postpartum women on ART. Tailored, client-centered approaches to PMTCT are essential for the achievement of elimination targets.

TUPEC10

Adolescent PrEP initiation at clinics participating in a randomized trial of a standardized client actor training intervention in Kisumu, Kenya

M. Vera¹, J. Sila², B.A Richardson¹, F. Otieno², G. Owiti², V. Kemunto², K. Beima-Sofie¹, A. Larsen¹, J. Pintye¹, G. John-Stewart¹, J. Kinuthia², P. Kohler¹

¹University of Washington, Seattle, United States, ²Kenyatta National Hospital, Kisumu, Kenya

Background: Adolescent girls and young women (AGYW) in Kenya experience high risk of HIV acquisition. AGYW have low PrEP initiation rates due, in part, to stigmatizing interactions with healthcare providers. Our recent randomized trial of a standardized client actor (SC) training intervention for AGYW providers found higher quality of

Late-breaker
abstractsAuthor
Index

PrEP service delivery at intervention sites. However, it was unknown whether higher quality care improved AGYW PrEP initiation.

Methods: This secondary analysis of the Priya-SP cluster randomized trial used routine clinic data from 12 control and 12 intervention health facilities in western Kenya. The intervention aimed to improve health provider adherence to Kenyan national guidelines and communication skills when offering PrEP to AGYW. Record sources included the MoH 731 Plus tool (and its older iterations) and facility-level PrEP registers from May 2019-June 2021.

Mirroring trial timelines, we defined May-December 2019 as the baseline period and December 2020-June 2021 as the post-intervention outcome assessment period.

We analyzed data at the facility level and used linear regression with percent initiating as the outcome, intervention and baseline initiation rates as covariates, and the number eligible during post-intervention at each facility as frequency weights.

Results: In total, 1,375 PrEP-eligible AGYW presented to PriYA-SP sites and were included in this analysis (baseline: n=706, post-intervention: n=669). Among 706 PrEP-eligible AGYW in the baseline period, 441 were at intervention sites and 265 at control sites. Overall, 410 (58.3%) initiated PrEP at baseline: n=203 (46.0%) at intervention sites and n=207 (78.1%) at control sites. Among 669 PrEP-eligible AGYW in the post-intervention period, 360 were at intervention sites and 309 at control sites.

Overall, 591 AGYW (88.3%) initiated PrEP at post-intervention: n=335 (93.9%) at intervention sites and n=256 (82.8%) at control sites. Adjusted for baseline initiation proportions, there was 12.1% higher PrEP initiation among AGYW presenting to intervention sites compared to control sites ($p < 0.001$, 95% Confidence Interval: 0.09-0.15).

Conclusions: Our study found a significant improvement in PrEP initiation among AGYW who presented to facilities that had been randomized to SC training. SC training interventions that improve quality of service delivery could lead to enhanced PrEP coverage.

TUPEC11

Implementation of Community-based HIV-Self-Testing (CB-HIVST) to improve awareness on HIV exposure: lessons learned and implications for the National AIDS Control Program of the Haitian Ministry of Health

M.L. Excellent^{1,2}, M. Laguerre¹, E. Emmanuel¹, C. Orélus¹, D. Lauture¹, J.W. Domercant¹

¹Institut pour la Santé, la Population et le Développement (ISPD), Pétion-Ville, Haiti, ²University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States

Background: In Haiti, HIV blood test was for decades the only way to objectively determine someone's exposure to HIV. Given the testing requirements, the burden of stigma and fear of needles, many individuals were left out. However, through the lens of health equity, HIV self-testing

(HIVST), which is an oral test was introduced in community settings (CB-HIVST) to help fill the gaps in HIV testing services (HTS).

Description: In January 2019 we collaborated with the National AIDS Control Program of the Ministry of Health to develop HIVST guidelines, data reporting tools and training package. We designed an HIVST assessment tool to identify high-risk eligible individuals. We conducted training sessions for community health workers in collaboration with the National Public Health Laboratory to ensure that CHWs accurately assist eligible clients perform the HIVST, interpret the results and advise them on follow-up. Anyone with reactive HIVST received assistance to freely access HIV-blood test to confirm HIV status at a facility of their choice.

We conducted community-based sensitization sessions targeting priority populations: male/sex workers/public transportation drivers/migrants/homeless/pregnant women without prenatal-care. We partnered with faith-based leaders and offered HIVST at Voodoo temples/Churches. We participated in interviews to disseminate knowledge about the value/limitations of HIVST.

Lessons learned: The integration of CB-HIVST into the prevention package has helped people become aware of potential HIV-exposure and confirm their HIV-status in stigma-free and confidential environment.

In FY22 (October 2021 - September 2022), 6834 HIVST were performed with assistance including 45% (3087/6834) females and 55% (3747/6834) males. Seven percent [7% (492/6834)] of HIVST performed were reactive from which 60% (298/492) females.

Overall, the data reported higher HIVST reactivity among females (10%, N=298) than males (5%, N=194). Eighty-eight percent [88% (434/492)] of HIVST reactive clients accepted the standard HIV-blood test, 84% (363/434) were confirmed HIV-positive from which 99% (360/363) initiated ART.

Despite being a screening oral-test, targeted HIVST outreach approach increased individuals access to comprehensive healthcare by addressing major barriers: transportation fees, waiting time, stigma, blood test.

Conclusions/Next steps: CB-HIVST has helped bring services to individuals unaware of HIV-exposure. That strategy is relevant to reaching the 95-95-95-UNAIDS goals and needs to be readily available at all of our borders crossing points and in more rural areas nationwide.

TUPEC12

Using the young people and adolescent peer supporters (YAPS) model as a mechanism to decentralize HIV testing services and enhance linkage among adolescents and young people in Uganda

A. Dennis¹, E. Magongo Namusoke¹, T. Geoffrey¹, T. Evarest², B. Hudson¹

¹Ministry of Health, AIDS Control Program, Kampala, Uganda, ²The Clinton Health Access Initiative, Infectious and Non Communicable Diseases, Kampala, Uganda

Background: In Uganda, progress across 95 95 95 treatment cascade for adolescents and young people (10-24) lags behind adults. By December 2019, 66% of adolescents and young people (10-24) knew their HIV status, 66% were on antiretroviral treatment (ART) and viral load suppression was 77%. This was largely attributed to absence of a differentiated peer led approach for adolescents and young people. The ministry of Health (MOH) adapted the Zvandiri CATS Model from Zimbabwe into the Young People and Adolescent Peer Supporter (YAPS) model for Uganda. This was premised on World Health Organization guidelines on Adolescents. This started as a pilot in 9 districts later scaled to 81 districts. Between July 2019-March 2020, 50% of Adolescents and Young Persons (AYPs) who received pre-test counselling by YAPS did not receive an HIV test. This created missed opportunities for identification of Adolescents and Young People Living with HIV (AYPLHIV).

Description: MOH decentralized HIV Testing Services (HTS) using YAPS model by reviewing National HIV testing policy to include YAPS as key service providers to screen, test and link AYPs into care. Extensive Consultations were conducted by MOH to collect views that informed policy.

MOH developed HTS training manual for YAPS. Training of Trainers for 30 National YAPS resource persons was conducted. MOH piloted training of the YAPS as HTS lay testers for 5 days in the 9 pilot districts with high HIV burden among adolescents 10-24 Years.

Training topics included promoting HIV testing among adolescents, HIV Self Testing among adolescents, counselling in the context of HIV testing, Linkage to care and Assisted Partner notification. Regular mentorships and support supervision were also conducted by the ministry.

Lessons learned: By March 2022 AYPs tested for HIV by YAPS was 57,215 compared to 68,213 in 2020 march. HIV positivity yield was at 2,14% compared to 1.48% in 2019, AYPs initiated into care increased from 79% in 2020 to 94% in 2022 and Linkage increased from 93% in 2020 to 95% in 2022.

Conclusions/Next steps: The YAPS model when scaled up can be utilized as an approach for decentralizing HTS and contribute to closing the gap on the 1st 95.

TUPEC13

Promoting uptake of HIV self-testing (HIVST) in the private sector through conceptual bundling: a practice of advertising HIVST along with Sexual and Reproductive Health products in Abuja, Nigeria

D. Ukaga¹, D. Aizobu¹, S. Malaba², G. Omoregie¹, O. Idogho¹, J. Anyanti¹, B. Adesina¹, O. Akpabio¹, N. Nnannah¹, P. Omodele¹

¹Society for Family Health, Abuja, Nigeria, ²Population Services International, Nairobi, Kenya

Background: In Nigeria, HIV self-testing (HIVST) is still at its nascent stage with low-awareness, demand, and uptake in the private sector. Conceptual bundling is the practice of introducing additional product to an existing customer as a single package of offer. It is a common practice in the private sector such as community pharmacies and patent proprietary medicine vendor (PPMV) outlets.

To improve the uptake of HIVST in Nigeria, we implemented conceptual bundling of HIVST with sexual and reproductive health (SRH) self-care products.

Description: The Strengthening HIVST in the Private Sector (SHIPS) Project from April – December 2022 piloted implementation of conceptual bundling strategy using SRH products to promote sales of HIVST as additional benefits for potential clients in Abuja, Nigeria. 66 community pharmacies were selected based on the following: membership with pharmacy council of Nigeria, willingness to stock HIVST, and willingness to promote conceptual bundling. We accessed product uptake for SRH commodities, and HIVST product independently, and both products together as a bundle.

Lessons learned: For the period of implementation, only 7 bundled products were sold (3 HIVST kits with condom and 4 HIVST kits with emergency contraceptives). However, when products were sold independently as either HIVST or SRH, high number of sales were recorded: HIVST (1,974), condoms (172,057), Emergency contraceptives (67,905), and lubricants (10,580).

60% of providers were unwilling to promote conceptual bundling. Providers reported reasons such as low risk perception of client to HIV, stigma, and cost of HIVST. However, 95% of providers reported that clients will be interested to purchase HIVST with another SRH product if physically packaged together, and at a reduced price.

Additionally, 80% of pharmacies reported that conceptual bundling helped to increase awareness on HIVST among SRH products users.

Conclusions/Next steps: While conceptual bundling helped to improve awareness on HIVST among SRH products users, it failed to promote uptake of HIVST. A physical packaging of HIVST and SRH products together with a price reduction is encouraged to improve uptake of HIVST.

TUPEC14

Secondary distribution of HIV self-test kits from males to their female sexual partners in two fishing communities in rural Uganda: results from the PEST4MEN pilot study

J.K. Matovu¹, A.T. Namwama¹, L. Kemigisha², L. Bogart³, N. Fakier⁴, P. Olupot-Olupot¹, D. Serwadda², G. Taasi², J. Musinguzi⁵, R.K. Wanyenze²

¹Busitema University Faculty of Health Sciences, Mbale, Uganda, ²Makerere University School of Public Health, Kampala, Uganda, ³RAND Corporation, California, United States, ⁴European and Developing Countries Clinical Trials Partnership, Cape Town, South Africa, ⁵Ministry of Health, Kampala, Uganda

Background: Secondary distribution of HIV self-test kits from females to males has increased HIV testing rates in men in most settings but little evidence exists on the potential for secondary HIV self-test kits distribution from males to females.

We assessed the acceptability of secondary HIV self-test kits distribution from the male fisherfolk to their female sexual partners in a fishing community context.

Methods: This analysis used data from the **PEer-led HIV Self-Testing intervention for MEN** (PEST4MEN), an ongoing pilot intervention in Buvuma and Kalangala island districts in central Uganda. At the baseline visit (July 2022), data were collected from 400 male fisherfolk (15+ years) who self-reported a HIV-negative or unknown HIV status and had not tested for HIV 3+ months prior to enrolment. After enrolment, men were requested to obtain two oral HIV self-test kits from a male distributor in the community. At the first follow-up visit (September 2022), men were asked about the number of kits that they received, if they gave out any kits to anyone, and, if they did, whether or not those who received them self-tested for HIV. Data were analyzed using STATA version 16.0.

Results: Of 361 men interviewed at follow-up, 98.3% (355) received at least one kit; 79.7% (283) received two kits. Of those that received two kits, 88.0% (181) gave the second kit to someone else; almost all recipients (97.8%, n=177) accepted the kits.

Seventy-five per cent of the men (74.6%, 132/177) gave the second kit to their primary/steady or other female sexual partners. Eighty-three per cent (147/177) reported that the person that they gave the second kit to used it to self-test for HIV. Of these, 8.2% (12/147) reportedly tested HIV-positive; among female sexual partners, 5.3% (7/132) tested HIV-positive. Only 33.3% (4/12) of the HIV-positive self-testers reportedly linked to HIV care.

Conclusions: Secondary distribution of HIV self-test kits from males to their female sexual partners was well accepted and identified a significant proportion of HIV-positive self-testers. However, linkage to HIV care was sub-optimal, calling for innovative approaches to improve linkage to HIV care following secondary HIV self-test distribution in this setting.

Addressing HIV testing gaps in Zimbabwe in the midst of health system and socioeconomic stressors

R. Golin^{1,2}, N. Kruse-Levy³, R. Malaba⁴, O. Maguwu³, T. Maphosa⁴, A. Peterson⁴, N. Zender¹

¹U.S. Department of State, Office of the Global AIDS Coordinator and Health Diplomacy, Washington, United States, ²U.S. Agency for International Development, Office of HIV/AIDS, Washington, United States, ³U.S. Agency for International Development, Harare, Zimbabwe, ⁴U.S. Centers for Disease Control and Prevention, Harare, Zimbabwe

Background: Zimbabwe has achieved 96/96/93 against UNAIDS three 95 benchmarks. Communicable disease outbreaks and socioeconomic strain have resulted in high levels of health care worker attrition, challenging the HIV program's achievements and progress.

PEPFAR/Zimbabwe supports >90% of the national HIV treatment cohort, and has an overarching goal to support the government to end HIV/AIDS as a public health threat by 2030. PEPFAR/Zimbabwe's HIV testing services (HTS) are focused on closing the testing gaps and supporting timely linkage to prevention and treatment services. The largest HIV case finding gaps exist among children and key populations.

Description: PEPFAR/Zimbabwe collaborated with the Ministry of Health and Child Care, Global Fund, and implementing partners to support facility- and community-based HTS.

From October 2021 - September 2022 (fiscal year [FY]22), the program directly supported 17 testing modalities in facilities and communities, including modalities where HTS is routinely recommended (e.g., PMTCT and tuberculosis [TB] service delivery points).

Targeted community testing and HIV self-test distribution helped decentralize HIV testing services. Mentoring and direct technical support was provided.

Lessons learned: From PEPFAR/Zimbabwe data, the program achieved 99% (67,195/67,777) of the FY22 case-finding target; 57% of these achievements were from women 15-49 years old. Provider-initiated HIV testing and counseling services drove case-finding (45% contribution).

The highest testing positivity was in community index testing and TB clinics (33% and 29%, respectively). 99.6% of pregnant women had a known HIV status at their first antenatal care appointment (including women who knew their status prior to the visit), and 93% of individuals with new or relapsed TB had a documented HIV status during the reporting period. 389,012 HIV self-tests were distributed in FY22; 40% were distributed to adults 20 - 29 years old. The program's estimated linkage to treatment was 96% (64,289/67,195).

Additionally, 75,371 individuals initiated HIV pre-exposure prophylaxis and 134,668 males received voluntary medical male circumcision

Conclusions/Next steps: Zimbabwe continues to overcome challenges and is positioned to sustain HIV epidemic control through concerted efforts to achieve annual case finding targets and support linkage to treatment and prevention services. Additional effort is required to maximize HTS in TB clinics and linkage to treatment services.

HIV self-testing in real-world use, a tool to end HIV in Thailand

K. Termvanich¹, T. Amatsombat¹, K. Rurkukos¹, P. Mingkwanrungruang¹, M. Bucha¹, T. Phattanathawornkool¹, J. Sripanjakun¹, P. Sittisatid¹, S. Jittjang², S. Mills², N. Phanuphak¹

¹Institute of HIV and Research Innovation, Bangkok, Thailand, ²FHI 360, Bangkok, Thailand

Background: Although the use of HIV self-tests (HIVST) is a key strategy fully endorsed by the National AIDS Committee to end AIDS in Thailand, progress towards its wide-scale implementation has been extremely slow.

We aimed to investigate the uptake, reactive testing yield, and linkages to antiretroviral treatment (ART) and PrEP of a real-world online HIVST service in Bangkok.

Methods: In May 2022, with the support from USAID Epic program, Pribta-Tangerine Clinic – a private sexual health clinic in Bangkok, Thailand, distributed free blood-based HIVST kits.

Online demand creation began one month before service availability, linking potential clients to clinic staff for risk assessment through telehealth.

Clients received an HIVST via mail, and were able to submit their result to the clinic electronically.

Clients with non-reactive results were offered PrEP, those with reactive results were linked to confirmatory testing. Same-day ART initiation was offered to those with confirmed HIV-positive status.

Results: From May–November 2022, the clinic distributed HIVST kits to 320 clients, 106 (33.1%) were first-time HIV testers. Test results were submitted by 251 (78.4%) clients, of which 18 were reactive.

Of these, 11 were confirmed positive and all initiated same-day ART, three were negative upon confirmation testing, and four did not confirm their result.

Overall confirmed HIV-positive rate was 4.4%. Among 233 non-reactive clients, 41 (17.6%) accepted PrEP services and 27 (11.6%) received sexually transmitted infection (STI) screening. Among 77 first-time HIV testers with returned results, 3 (3.9%) were confirmed positive (Figure 1).

Conclusions: HIVST delivered through telehealth successfully engaged clients with HIV in treatment, including those who never had an HIV-test before. Furthermore, non-reactive clients who otherwise might not enter prevention services, were linked to PrEP and STI services. Scale-up of this online HIVST service model is needed to optimize its potential in ending HIV in Thailand.

Figure 1. HIVST results returning from the clients.

HIV self-testing education on TikTok: a content analysis

R. Oladele^{1,2}, M. Adesina^{1,2}, I. Olufadewa¹, A.-P. Ilochonwu¹, M. Imadojiemu¹, M. Akande¹, K. Fatola¹, O. Asaolu¹, A. Adekunle¹, M. Akinwola¹, T. Adene¹, A. Abdullah¹, F. Olayonwa¹, F. Akintunde¹, A. Akinbode¹

¹Slum and Rural Health Initiative, Ibadan, Nigeria,

²University of Ibadan, Ibadan, Nigeria

Background: In 2016, the World Health Organization officially recommended HIV self-testing (HIVST) to promote privacy and encourage more people to test for their HIV status. Despite the availability of this service, there are more than 5.4 million people living with HIV who don't know their status. With over 990 million users, TikTok is a platform that has been used to educate and promote HIVST. Hence, this study conducted content analysis of HIVST education videos on TikTok.

Methods: We searched for videos on TikTok using keywords such as 'HIV self-testing', 'HIV', among others. This search was conducted between the 24th December 2022 and 5th January, 2023. Videos in languages other than the English language were not eligible for this study.

We extracted the basic information of each included video, including the URL, release date, uploader's type (individual or organization), source, diagnostic specimen, country, self-kit name, and views. The Medical Quality Video Evaluation Tool (MQ-VET) was used to evaluate the content of the videos.

Results: We extracted 108 videos that were uploaded between October 2020 and January 2023. Out of these videos, 78 videos met our inclusion criteria. Most of the videos (78.2%) provided information mainly on how to use the HIVST kit, while 21.4% of the videos also provided awareness of HIV and HIV symptoms, debunked myths and misconceptions about HIV, and fought stigmatization in addition to HIVST education. The sources of the videos were: TikTok influencers (47%), healthcare professionals (10%), non-governmental organizations (7%), the Ministry of Health (1%), PLWHIV, and persons on ART (6%). The mean MQ-VET scores for the videos were 42.38 ± 16.37 .

Conclusions: This study revealed that non-governmental organizations and healthcare professionals who have sound knowledge, expertise, and understanding of HIVST

were not actively involved in the dissemination of HIVST education on TikTok. Therefore, this widely used platform should be leveraged by experts in partnership with influencers to push accurate and simplified information on HIV self testing.

Empowering adolescent school girls with SKILLZ: 6-month follow-up results from a cluster randomized trial in Lusaka, Zambia

C. Chiu¹, C. Mulubwa², B. Mkandawire³, M. Musonda³, N. Katota², J. Chipungu², C. Bolton², J.X. Liu⁴

¹University of California, Berkeley, Berkeley, United States,

²Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, ³Grassroot Soccer, Lusaka, Zambia, ⁴University of California, San Francisco, San Francisco, United States

Background: Adolescent girls are disproportionately at high risk for HIV and unintended pregnancy, which lead many to drop out of school. Effective interventions to address risky sexual behavior and increase their uptake of HIV and contraceptives are urgently needed.

Methods: In a cluster-randomized controlled trial across 46 schools in Lusaka, Zambia, we evaluate the impact of SKILLZ, a peer-led demand generating sports-based program for empowering adolescent girls, implemented by Grassroot Soccer. SKILLZ consists of:

- 12 after school sessions of comprehensive sexuality and sexual and reproductive health (SRH) education delivered by trained young adult mentors ("Coaches"),
- a large community "graduation" soccer event where HIV testing and contraception are available, and;
- community-based distribution of HIV self-testing and contraceptives from Coaches and referrals to youth-friendly clinic services as required. We randomly sampled 2,154 Grade 11 girls from school rosters and surveyed them at baseline (March – December 2021), 6, and 12 months to measure self-reported SRH knowledge and uptake of HIV/SRH products and services.

We estimated linear difference-in-difference models on our primary outcomes: uptake of HIV testing and any contraceptive method within the last 6 months. Further, we disaggregated contraceptive uptake by method, and examined impact on new adoption and discontinuation separately.

Results: About 90% of surveyed girls in treatment arm schools participated in SKILLZ, attending a mean of 6.59 (SE: 4.30) sessions. From a baseline of 37%, SKILLZ increased HIV testing by 27 percentage points (95% CI: 0.201, 0.340), increased new adoption of HIV testing by 20 percentage points (95% CI: 0.157, 0.251) and reduced testing discontinuation by 4 percentage points (95% CI: -0.066, -0.012). From 20% at baseline, SKILLZ increased contraception uptake by 12 percentage points (95% CI: 0.049, 0.195). New adoption of contraception increased by 7 percentage points (95% CI: 0.022, 0.118) and discontinuation decreased by 2 percentage points (95% CI: -0.035, -0.001).

Conclusions: SKILLZ substantially increased both uptake of HIV testing and contraception among adolescent girls at 6 months. Additional evaluation of behavior maintenance at 12 months and related implementation processes are underway, and will better characterize how holistic, integrated demand-and supply interventions may achieve meaningful change.

HIV treatment outcomes among people who inject drugs: a global systematic review and meta-analysis

K. Kipkoech^{1,2}, J. Stone¹, H. Fraser¹, J. Cheema³,

A. McNaughton⁴, A. Trickey¹, A. Artenie¹, J. Ambia¹, A. Lim¹, L. Gordon¹, G. Mola¹, A. Scheibe^{5,6}, N. Martin³, L. Johnson⁷, P. Vickerman^{1,8}

¹University of Bristol, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom, ²University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, ³University of California San Diego, Division of Infectious Diseases and Global Public Health, San Diego, United States, ⁴University of Oxford, Pandemic Sciences Institute, Oxford, United Kingdom, ⁵TB HIV Care, Cape Town, South Africa, ⁶University of Pretoria, Community Oriented Primary Care Research Unit, Department of Family Medicine, Pretoria, South Africa, ⁷University of Cape Town, Centre for Infectious Disease Epidemiology and Research, University of Cape Town, Cape Town, South Africa, Cape Town, South Africa, ⁸University of Bristol, NIHR Health Protection Research Unit in Behavioural Science and Evaluation, Bristol, United Kingdom

Background: People who inject drugs (PWID) are frequently assumed to have worse HIV treatment outcomes than other population groups, but data on this has never been synthesised. We aimed to quantify HIV treatment outcomes (retention in care and viral suppression) among PWID globally and compare outcomes with other population groups (general population, men who have sex with men (MSM) and female sex workers (FSW)).

Methods: We searched MEDLINE, Embase, and PsycINFO databases for studies published between 01/01/2010 – 16/02/2021, that either assess:

1. Retention in care/on antiretroviral therapy (ART) for PWID on HIV treatment;
2. Levels of viral suppression for PWID on HIV treatment or PWID living with HIV, or
3. Effect measures for how these outcomes differ compared to other population groups.

We pooled outcome data using random-effects meta-analyses. Proportions retained in care/on ART were converted into a 12-month retention estimate, assuming an exponential retention decay. Proportions virally suppressed were converted to a <1000 copies/mL threshold, using a validated Weibull distribution model of viral loads in ART patients.

Oral
abstracts

Poster
exhibition

E-posters

Late-breaker
abstracts

Author
Index

Results: 133 studies met the inclusion criteria, with 116 and 36 studies having data on viral suppression and retention in care/on ART (26 studies presented data on both outcomes) from 35 and 15 countries, respectively.

Globally, about two-thirds of PWID were retained in care/on ART at 12 months (65.6%, 95% confidence interval [CI] 58.0-73.3%), with retention being significantly lower than for MSM (odds ratio [OR] 0.61, 95%CI 0.42-0.91; 20 studies), but not for FSW or the general population.

Globally, a third of PWID living with HIV (33.0%, 95%CI 30.0-36.1%) and half of those on ART (52.8%, 95%CI 46.2-59.3%) were virally suppressed.

Viral suppression among PWID living with HIV on ART was lower compared to general population (OR 0.57, 95%CI 0.50-0.64; 30 studies) and MSM (OR 0.50, 95%CI 0.43-0.59; 26 studies), as was viral suppression among PWID living with HIV (general population OR 0.61, 95%CI 0.49-0.76, 28 studies; MSM OR 0.56, 95%CI 0.47-0.67, 35 studies).

Conclusions: Retention in care/on ART and viral suppression among PWID are suboptimal and much lower than for other population groups. Focussed interventions are urgently required to improve HIV treatment outcomes among PWID.

TUPEC20

Long-term retention in HIV care up to six years following enrolment in prevention of mother-to-child transmission: a prospective cohort study among women living with HIV in Dar es Salaam, Tanzania

R. Urrio¹, G. Lyatuu¹, D. Sando¹, M. Mahande¹, E. Philipo¹, H. Naburi², P. Lyaruu¹, A. Kimonge¹, K. Mayogu¹, B. Simba¹, A. Kibao³, M. Msangi⁴, Z. Zeebari⁵, G. Biberfeld⁵, A.M. Ekstrom⁵, C. Kilewo⁶, P. Rwehumbiza⁷, A. Kagesten⁵

¹Management and Development for Health, Program, Dar es Salaam, Tanzania, United Republic of; ²Muhimbili University of Health and Allied Sciences, Paediatric and Child Health, Dar es Salaam, Tanzania, United Republic of; ³Office of Regional Administrative Secretary, Dar es Salaam, Tanzania, United Republic of; ⁴Ministry of Health, Dodoma, Tanzania, United Republic of; ⁵Karolinska Institutet, Global Public Health, Stockholm, Sweden; ⁶Muhimbili University of Health and Allied Sciences, Obstetric and Gynaecology, Dar es Salaam, Tanzania, United Republic of; ⁷US Center for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania

Background: To prevent mother-to-child transmission of HIV (PMTCT) during pregnancy/breastfeeding and ensure healthy mothers and children, pregnant women with HIV must remain on antiretroviral treatment (ART) for life. However, motivation to remain on ART may decline beyond the PMTCT period.

We assessed retention in ART care among women with HIV up to 6 years after PMTCT enrolment in Dar es Salaam, Tanzania.

Methods: A cohort of 22,631 pregnant women with HIV were enrolled in PMTCT care between 01/01/2015 and 31/12/2017 and followed-up to 31/07/2021.

Data were extracted from national electronic routine HIV care database. Kaplan Meier was used to estimate time to ART attrition (death, stopped ART, or lost to follow-up [no show ≥90 days since scheduled appointment]) and the proportion retained in care.

Predictors of ART attrition were estimated using Cox regression.

Results: The median follow-up was 3 years (IQR 0.1-4). The number (proportions) of women retained were 13,819 (78%), 11,233 (69%), 9,787 (63%), 7,234 (60%), 3,723 (57%) and 1,036 (56%) at years 1, 2, 3, 4, 5 and 6, respectively.

The overall attrition rate (95% CI) per 100 person-years was 13.8 (13.5-14.1), highest in the first year at 27.1 (26.3-27.9), thereafter declining to 9.5 (8.9-10.1) in year three and 2.7 (2.1-3.5) in year six.

ART attrition was higher in women aged <20 years versus 30-39 years (adjusted HR 1.63, 95% CI 1.38-1.92), women enrolled in the third versus first trimester (1.29, 1.16-1.44), and women enrolled in 2017 versus 2015 (1.28, 1.13-1.46).

In contrast, attrition was lower in women ≥40 years (0.89, 0.79-1.00), women initiating ART before versus during the index pregnancy (0.71, 0.65-0.77) and women attending health centres versus dispensaries (0.81, 0.76-0.86).

Marital status, ART regimen, entry point at HIV diagnosis, or health facility ownership (public/private) had no significant association with retention.

Conclusions: ART attrition among women with HIV enrolled in lifelong ART remains highest in the first year of PMTCT enrolment, and declines markedly after completion of the standard 24-month PMTCT period.

Targeted interventions are needed to mitigate ART attrition throughout the continuum of care from PMTCT to chronic HIV care.

TUPEC21

Care to deliver: managing HIV care cascade among HIV positive pregnant women lead to improved outcomes- Results from Global Fund supported Ahana project in 13 states of India

K. Biswas¹, S. Kanoujia¹, M. Singh¹, R. Rana¹, S. Dasgupta¹, M. Jain¹, A. Shukla¹

¹Plan International (India Chapter), Global Fund Department, New Delhi, India

Background: Integration with vast Indian public health infrastructure witnessed HIV testing service expanded till the village level ensuring increased access to HIV testing services among pregnant women. With this there was increased identification of HIV positive pregnant women needed HIV treatment & C&S while care and support services was remotely available.

Ahana project supported by The Global Fund aims to ensure ART linkage & adherence and manage cascade towards EMTCT.

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor

Description: Four pronged customized strategy adopted to converge service access at a very large scale and with a peripheral access of HIV treatment- care and support services for HIV positive pregnant women

A. Integration and engagement with the public health facilities for new case finding,

B. Ensuring early testing and engaging ART centre to early linkage,

C. Formation of community support group of PPWs to promote self-care and ensure treatment adherence and EMTCT outcome,

D. Capacity building of general health system and information system convergence to streamline and to facilitate one national data reporting for EMTCT.

Lessons learned: Expansion in service access led to early HIV testing and resulted in identification of more than 18 thousand HIV positive pregnant women; linkage to ART services improved from 86% during 2016-17 to 99.7% during April-Dec, 22. Institutional deliveries among HIV positive pregnant women increased from 90% during 2016-17 to more than 94% in April-Dec, 23.

While linkages of HIV exposed infants with EID testing within 2 months improved from 55% during 2016-17 to 90% in April-Dec, 22, HIV testing among spouses of PPWs increased from 74% during 2018-19 to 97% during April-Dec, 22. HIV testing at 18 months confirmed that transmission has been averted among more than ten thousand HEIs.

Conclusions/Next steps: The above results suggest that large scale successful outreach is better achievable through a community-led intervention. Strengthening of capacities of the community groups leads improved outreach and quality sustainable service delivery in the community.

With communities across 307 districts in 13 states empowered and started providing the services at the village level, Ahana project demonstrate the roadmap for the EMTCT in India.

TUPEC22

The impact of mentor mothers psychosocial groups towards optimized PMTCT services uptake among HIV positive pregnant women attending ANC: experience from 10 regions of Tanzania

M. Ngowa¹, A. Maro¹, N. Makyao², A. Nyirenda³, F. Ngalesoni¹, H. Sasya¹, A. Muya⁴

¹Amref Health Africa, Monitoring and Evaluation, Dar Es Salaam, Tanzania, United Republic of, ²Amref Health Africa, Program Advisory, Dar Es Salaam, Tanzania, United Republic of, ³Amref Health Africa, Program Director, Dar Es Salaam, Tanzania, United Republic of, ⁴Amref Health Africa, Head of Programs, Dar Es Salaam, Tanzania, United Republic of

Background: In Tanzania antenatal care (ANC) services are entry point for HIV testing and linkage to PMTCT services. Tanzania HIV impact survey of 2016-2017 shows that 98.7% of pregnant women attended ANC, 92.4% know their

HIV status at first ANC visit, 51.9% were newly initiated on Antiretroviral therapy (ART) during pregnancy and 46.1% were already on ART prior to pregnancy. Despite that significant progress has been made in scaling up PMTCT services to pregnant positive women attending ANC there is a need to strengthen community interventions to tackle the fears of social discrimination and stigma that prevent positive pregnant women accessing HIV treatment and adherence to ART for PMTCT.

Description: Amref Health Africa in collaboration with Christian Social Services CSSC under Global Fund is implementing a PMTCT program in 10 regions of Tanzania, the program initiated community model called Mentor Mother "Mama Kinara" aiming at reaching HIV positive pregnant women with PMTCT services information at community level through psychosocial support groups (PSSG).

Mama Kinara are HIV positive pregnant or breastfeeding women with strong adherence to ART trained on PMTCT services at community level, the program trained 692 Mama Kinara who facilitate linkage between community and facility and provide PMTCT services education through PSSG. In a group of 5-10 positive pregnant women, Mama Kinara provide ANC information, psychosocial support to improve partners status disclose confidence and reduce self-stigma and discrimination, educate on early maternal ART initiation, encourage ART adherence and retention to care.

Lessons learned: In a period of 2021 to 2022, A total of 172 psychosocial groups were formed by 1,681 PMTCT positive members. Among 179,454 attended ANC, 100% were newly tested for HIV where by 0.92% were tested HIV positive and 97% were newly initiated on ART.

Among those attended ANC 1,738 new their HIV status prior to pregnancy which make 98.9% of total HIV positive women on ART at first ANC.

Conclusions/Next steps: The government of Tanzania to ensure Mama Kinara model through psychosocial groups is adopted and scaled up in other remaining regions to ensure women utilize the platform for fully disclosure and elevate confidence levels of accessing PMTCT services.

Track D: Social and behavioural sciences

MOPED01

Application of information-motivation-behavioural skills (IMB) HIV prevention model on hepatitis B virus infection prevention among pregnant women in Central Uganda: a baseline for a comparative interventional study on HIV/HBV prevention

I.B. Afolabi¹, N.O. Atulomah¹, A.B. Aremu², L.A. Maidoki¹

¹Cavendish University Uganda, Public Health, Kampala, Uganda, ²Islamic University In Uganda, Human Anatomy, Kampala, Uganda

Background: The ever-increasing impact of HIV infection on the natural history of hepatitis B virus infection (HBV) pathogenesis has drastically amplified the risk of liver-related morbidity and mortality, particularly in developing countries. However, despite the transmission potential and infectivity of HBV infection known to be more than 50 to 100 times that of HIV, efforts to tackle the lingering chronicity of HIV/HBV mono or co-morbidity in developing countries like Uganda need to focus on predictors of the often neglected health behaviours of vulnerable populations such as pregnant women that contribute overwhelmingly to the mother-to-child-transmission of both infections.

We employed information-motivation-behavioural skills diagnostic model to elucidate the dynamics of HBV prevention behaviors among pregnant women attending antenatal care in Central Uganda as a baseline for a comparative interventional study geared at reducing the burden of both infections and breaking the chain of materno-foetal transmission of the infections.

Methods: A baseline health facility-based cross-sectional study capturing quantitative data using the constructs of IMB model was conducted among 385 randomly selected expectant mothers between September and October 2020. From the pilot of the instrument, 7.8 and 8.4 scores for Cronbach's internal consistency and test-retest reliability coefficient were respectively obtained. Transformation into weighted aggregate scores was done for the derived data using SPSS version 26. The study hypotheses were ascertained with ANOVA and Linear regression analysis with ($p \leq 0.05$) level of significance

Results: The respondents' mean age was 25.69 (25.33 \pm 26.05). Predominantly, most had secondary education (42.3%, 95% CI= 37.31 \pm 47.41). In corroboration with IMB model of HIV prevention, all-round positive linear associations exist between the inadequacy of HBV-related information (5.97 \pm 6.61; $B=0.57$; $p<.001$), the moderate motivation (17.10 \pm 18.31; $B=0.97$; $p=.014$), the good behavioral skills (12.39 \pm 13.37; $B=0.56$; $p<.001$) towards preventive behaviours, and the underwhelming extent of prevention practices (15.03 \pm 16.20) demonstrated by the respondents.

Conclusions: The validity of the imperativeness of IMB model for HIV-like infectious disease is evident from this novel study. Therefore it has underscored the focus points

for the comparative interventional study to be built on promoting positive behaviours towards HIV/HBV and reducing the infection magnitude among obstetric populations in low-and middle-income countries.

MOPED02

Decoding HIV science – designing an experience-based gamified intervention to understand viral diversity and latency

K. Goyal¹, S. ul Hadi², M. Ahmad², D.L. Bose², J. Mukherjee², P. Saha², S.P. Shewale³, A. Jadhav³, S. Sahay⁴

¹DCT Mindlinks, New Delhi, India, ²IAVI, New Delhi, India, ³Krishna Institute of Medical Science Deemed to be University, Karad, India, ⁴ICMR - National AIDS Research Institute, Pune, India

Background: In order to enhance equitable, reciprocal and sustained community participation in research, it is important that participants gain better understanding of not just the 'how' but also the 'why' behind HIV research. This enhanced sense of knowledge can motivate them to actively engage in and contribute to research. However, community conversations around HIV science are often prescriptive and jargon-laden, making them difficult to comprehend.

Towards this, experiential interventions to explain viral diversity and latency were co-created and piloted among key populations in India.

Methods: 8 co-design workshops between key community representatives and researchers, across geographies in India (Delhi, Kerala, Maharashtra), helped identify key messages to be communicated around HIV science and vaccine research.

Gamified interventions were co-created and piloted with 380 key community members in rural Maharashtra to enhance understanding of hidden viruses, need for regular testing (latency) and identification of common targets across diverse strains of HIV to develop effective vaccines (diversity, conserved epitopes).

The scientific quest was simulated using lab coats, coloured inks, droppers, forceps etc. Impact of the intervention was analysed through pre- and post-game questionnaires and community conversations.

Results: Community insights from the workshops revealed that the intervention should:

- Communicate complexities of science rather than HIV awareness;
- Be participatory and engaging by playing on participants' competitive spirit.

The pilot intervention, informed by the above, generated an overall positive response from the community.

- The Intrinsic playfulness and pleasantness drove likability with 72% and 76% participants enjoying the diversity and latency games respectively. They expressed feeling more confident to understand the science behind the research when explained through games;

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

- 78% participants correctly answered questions around the scientific concepts conveyed through the games. Participants felt more appreciative of the complexities of the science and better equipped to understand their role in the research.

Conclusions: The use of gamification for meaningful and inclusive community engagement helps potential participants feel more involved and engaged in the research process.

Simulating the experience of stepping into the shoes of the scientists helped create an 'HIV competent Community' which empowered them to better understand and take ownership of their role in HIV prevention research.

MOPED03

Couple dynamics, risk perception and interest for a multipurpose prevention product for HIV and pregnancy prevention

J. Etima¹

¹Makerere University-Johns Hopkins University Research Collaboration, Psychosocial Support, Kampala, Uganda

Background: Multipurpose Prevention Technologies (MPTs), also referred to as Dual Purpose Technologies (DPTs), are innovative products for HIV and Pregnancy prevention currently under development. Interest in MPTs may be influenced by the individual's or couple's HIV risk perception, as well as how couples relate to one another. The aim of this study was to explore couple dynamics, Risk perception and their influence on interest for MPTs.

Description: This analysis uses data from 400 couples enrolled in the Microbicide Trials Network (MTN) 045/CUPID (Couple User Preferences in Dual Purpose Prevention products) study to assess influence of couple dynamics and HIV risk perception on interest for MPTs. Specifically, we assessed:

1. The influence of couple dynamics like communication, relationship efficacy, fidelity and support on interest for MPTs and
2. Whether HIV risk perception determined interest in MPTs. We used data from In-depth interviews conducted with couples (CIDI) or individuals (Female FIDI, Male MIDI), the Behavioral Demographic Questionnaire (BDQ) and Couples observation tool.

Lessons learned: Overall couples showed high interest in MPTs (91%) and had healthy couple dynamics, 67% of couples contributed equally to conversations about MPTs, with 91% males & 90% women demonstrating engagement. This was corroborated during CIDI_2178 [Uganda], "Our relationship is good we talk or plan about something together, we make decisions together so generally we do everything together".

71% females and 81% males disagreed that their partner's sexual behavior gives them a chance of getting HIV. Couples had a low HIV risk perception scoring 2 on the HIV Risk Score (0-7); Balkus 2018 (modified).

However, despite the low risk score 50% females; 35% males did not know if their partner had other sexual partners thus the interest in MPTs.

Conclusions/Next steps: Couples who had good communication, partner support, and high fidelity showed high interest in MPTs. Couples underestimate their HIV risk, nonetheless they appreciate some aspects of risk like the uncertainty of their partners having other sexual partners. It is therefore critical to develop strategies to support couples understand their HIV risk.

These findings underscore the importance of healthy couple dynamics, and risk perception in decision making about HIV and pregnancy prevention technologies.

MOPED04

Exploring the role of social determinants of health and their potential relationship in affecting dimensions of stigma and health-related quality of life in people living with HIV

J.M Lo Hog Tian^{1,2}, J.R Watson¹, S.B Rourke^{1,3}

¹Unity Health Toronto, MAP Centre for Urban Health Solutions, Toronto, Canada, ²University of Toronto, Institute of Medical Science, Toronto, Canada, ³University of Toronto, Department of Psychiatry, Toronto, Canada

Background: HIV stigma is still prevalent in Canada, negatively impacting the health of people living with HIV. Social determinants of health also have a significant impact on health, yet there is little work examining how these determinants play a role in how stigma may impact health. This study uses moderation analysis to examine how social determinants of health affects the relationship between enacted, internalized, and anticipated stigma and health-related quality of life physical and mental health dimensions.

Methods: The study used a two-wave panel design with quantitative survey data collected on 339 participants in Ontario, Canada at baseline (t_1) between August 2018 and September 2019 and follow-up (t_2) between February 2021 and October 2021. Moderation models were constructed with each type of stigma at t_1 as antecedents predicting physical and mental health at t_2 as the outcome.

Separate models were created with each social determinant of health (age, years since HIV diagnosis, gender, sexual orientation, ethnicity, geographic region, education, employment, and basic needs) acting as the moderator.

Results: For age, those of older age had a significant negative relationship between internalized ($b = -5.20$, 95% CI: -7.81, -2.59) and enacted ($b = -3.31$, 95% CI: -5.87, -0.75) stigma and mental health. For those who live in the Greater Toronto Area, enacted ($b = -3.96$, 95% CI: -6.56, -1.37) and anticipated stigma ($b = -5.26$, 95% CI: -8.60, -1.94) had a negative impact on mental health.

For the gay/lesbian group, anticipated stigma had a negative impact on mental health ($b = -3.43$, 95% CI: -6.60, -0.26). Lastly, for those who never lacked basic needs, en-

acted ($b = -4.43$, 95% CI: -7.25 , -1.62) and anticipated ($b = -4.17$, 95% CI: -7.38 , -0.95) stigma had a negative impact on mental health. None of the models with physical health as the outcome had significant moderators.

Conclusions: Our findings demonstrate that the relationship between stigma and mental health can change based on an individual's social determinants of health. Moreover, intervention strategies to reduce stigma may be more effective if they are tailored to and consider the social determinants of health.

MOPED05

The correlates and experiences of HIV-related intersectional stigma among caregivers of adolescents living with HIV in KwaZulu Natal, South Africa: results from a mixed method study

N.Z. Sithole¹, Z. Mkhwanazi¹, S. Carries¹, L. Sigwadhi², D. Govindasamy¹

¹South African Medical Research Council, Health Systems Research Unit, Durban, South Africa, ²Stellenbosch University, Epidemiology and Biostatistics, Cape Town, South Africa

Background: Stigma is a formidable barrier to HIV treatment outcomes and wellbeing. Caregivers play a critical role in promoting HIV adherence and mental health among adolescents living with HIV (ALHIV). However, caregivers themselves encounter multiple stigmas that intersect with HIV-stigma, namely poverty and gender identities, and these together have substantial impact on their health and wellbeing. If we can understand the drivers of HIV-related intersectional stigma, we can develop targeted strategies to improve HIV and wellbeing outcomes among caregivers and ALHIV.

The objectives of this study were to understand the factors associated with and lived experiences of HIV-related intersectional stigma among caregivers of ALHIV.

Methods: We conducted a mixed-method study drawing on baseline data from an economic incentive trial (PACT no: PACTR202203585402090, <https://pactr.samrc.ac.za/>) that was implemented between March 2021-September 2022 with caregivers of ALHIV (10-19-year-olds) consecutively sampled from peri-urban clinics in Durban, KwaZulu Natal, South Africa.

Caregivers completed a baseline questionnaire that examined household socio-economic status, mental health, wellbeing, and stigma using the Everyday Discrimination Scale. These topics were further explored through in-depth interviews with 8 purposively sampled caregivers. Descriptive statistics and a linear regression model to assess correlates of HIV-related intersectional stigma was conducted using STATA (V17). Qualitative data were analysed thematically using NVivo.

Results: Of the N=100 caregivers enrolled in the trial, 86% were female, the median age was 42 years (IQR:34-50), and 89% were living with HIV. Factors associated with HIV-related intersectional stigma include: depressive symp-

toms ($\beta=4.36$, $p=0.01$), caregiver burden ($\beta=5.62$, $p=0.003$), caregivers happiness ($\beta=4.28$, $p=0.02$). Key themes that shaped HIV-related intersectional stigma included unemployment, food insecurity, negative coping strategies, lack of self-acceptance and isolation, ill-treatment from healthcare workers and community members due to their HIV-positive status and inability to fulfil gendered roles.

Conclusions: Findings indicate that caregivers of ALHIV encounter HIV-related intersectional stigma at multiple levels which impacts their mental health and wellbeing. Multi-sectoral interventions such as group-based mental health and economic empowerment programs that address internalized and externalized HIV-stigma, poverty and gender norms could mitigate these effects.

MOPED06

Depression, violence and stigma among people living with HIV at public sexual health clinics in urban Lima, Peru: converging syndemics in need of urgent attention

C. Contreras¹, R.A. Errea², C. Chavez², E. Gonzales², M. Aguilar¹, J.T. Galea³, L. Lecca^{2,2}

¹Socios En Salud, Mental Health, Lima, Peru, ²Socios En Salud, Lima, Peru, ³University of South Florida, Social Work, Tampa, United States

Background: In Peru, approximately 100.000 persons live with HIV and despite free access to antiretrovirals (ARV), morbidity and mortality rates due to HIV remain high, often complicated by social and mental health issues which not been well described in service settings.

Socios En Salud (SES), a nonprofit health organization Lima which works to strengthen publicly delivered health services, collaborated with the Peruvian National HIV program to assess the social and mental health barriers to ARV adherence experienced by people with HIV (PWH) to assess the prevalence of common social and mental health barriers to HIV care services and ARV adherence.

Methods: From July 2022 – December 2022, persons attending two public sexual health clinics or identified by venue-based outreach campaigns in northern Lima, Peru were invited to complete a questionnaire which included questions on mental health, violence and stigma. Data were cleaned, analyzed and descriptive tables produced.

Results: A convenience sample of 246 persons were invited to complete the questionnaire of which 194/246 (78%) accepted. Mean participant age was 32 years (range 19-62). 89% were male, 11% female, 1% identified and transgender. 43% of participants were newly-diagnosed with HIV of which 30% were awaiting ARV initiation.

Regarding mental health, 54% reported a current mental health problem of which 92% reported depression and/or anxiety. Experiences of interpersonal violence was reported by 43% of participants and stigma (HIV and/or sex/gender-based) reported by 98% of participants.

Conclusions: Though limited in size and generalizability, high levels of mental health morbidity, stigma and violence were experienced by PLW in Lima Peru which like converge to create a syndemic of barriers that synergize to hamper access to and continuation of HIV care services.

These data will help leverage our work to improve HIV services in Peru by addressing these social and mental health problems in an integrated way at the point of HIV service delivery.

MOPED07

Intersectionality of gender, ethnicity, and sexual orientation identities and HIV stigma in people living with HIV in Canada

J.M Lo Hog Tian^{1,2}, A. McFarland^{1,2}, L. Penny¹, T. Bennett¹, K. Musumbulwa¹, J.R Watson¹, A.J Odhiambo³, S. Baral⁴, C. Worthington⁵, K. Monteith⁶, B. Oliver⁷, M. Payne⁸, S.B Rourke^{1,9}

¹Unity Health Toronto, MAP Centre for Urban Health Solutions, Toronto, Canada, ²University of Toronto, Institute of Medical Science, Toronto, Canada, ³University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, ⁴Johns Hopkins University, Department of Epidemiology, Baltimore, United States, ⁵University of Victoria, School of Public Health and Social Policy, Victoria, Canada, ⁶COCQ-SIDA, Montreal, Canada, ⁷University of Calgary, Faculty of Health, Community and Education, Calgary, Canada, ⁸Nine Circles Community Health Centre, Winnipeg, Canada, ⁹University of Toronto, Department of Psychiatry, Toronto, Canada

Background: HIV stigma remains a challenge to excellent health for people living with HIV. This is especially significant for individuals who are disproportionately affected by HIV and who occupy intersecting racial, sexual, or sociocultural identities. Studies have examined the individual impact of various identities on one's experience of HIV stigma; however, little is known about how these identities may intersect to impact how an individual experiences stigma.

This study aims to examine the impact of intersecting ethnicity, gender, and sexual orientation identities on levels of internalized, enacted, and anticipated stigma in people living with HIV from three provinces in Canada.

Methods: Participants were recruited in Ontario, Alberta, and Québec (n=1,064) to complete the People Living with HIV Stigma Index study, a survey tool which collected various demographic information and contained externally validated quantitative scales measuring different types of stigma. Regression analysis was used to separately examine the impact of ethnicity, gender, and sexual orientation on rates of internalized, enacted, and anticipated stigma. We constructed two-way and three-way interaction models by creating interaction terms with each permutation of ethnicity, gender, and sexual orientation variables and examined how they predicted each type of stigma.

Results: In the multiple regression, the gay/lesbian group had significantly lower internalized stigma than the heterosexual group ($b=-0.13$, $p=0.02$), whereas the African, Caribbean, and Black group had significantly greater anticipated stigma than the Caucasian group ($b=0.22$, $p<0.01$). In the two-way model, gender x sexual orientation was the only significant interaction with the lesbian group having greater internalized stigma ($b=0.32$, $p=0.06$). In the three-way model, the lesbian African, Caribbean, and Black group had greater internalized stigma ($b=0.80$, $p=0.09$), whereas the lesbian Indigenous group had both greater enacted ($b=1.24$, $p=0.01$) and anticipated stigma ($b=0.71$, $p=0.09$).

Conclusions: Overall, we found that levels of HIV stigma were consistent and high across most population groups, with a few intersections including lesbian African, Caribbean, Black people and lesbian Indigenous people experiencing greater levels of stigma.

These findings suggest that it may be important in developing stigma reduction strategies that are tailored to the needs of specific population groups, which may be under-represented in research and HIV programming.

MOPED08

Stigma, social support, and symptoms of depression, anxiety, and suicidal ideation or self-harm among people with HIV with irregular interaction with the health care system in KwaZulu-Natal Province, South Africa

L.M. Filiatreau¹, F. Musiello², A. Mody³, E.H. Geng³, A. van Heerden^{2,4}

¹Washington University, Department of Psychiatry, St. Louis, United States, ²Human Sciences Research Council, Centre for Community Based Research, Pietermaritzburg, South Africa, ³Washington University, Division of Infectious Diseases, St. Louis, United States, ⁴University of the Witwatersrand, MRC/Wits Developmental Pathways for Health Research Unit, Johannesburg, South Africa

Background: People with HIV (PWH) in Africa are at heightened risk of poor mental health, including self-harm and suicidal ideation. Understanding drivers of poor mental health (e.g., stigma, low social support), particularly among those with irregular interaction with the healthcare system, is critical to righting these disparities and closing the mental health treatment gap for PWH in Africa.

Methods: We randomly sampled 150 individuals who had accessed care in a peri-urban clinic in KwaZulu-Natal Province, South Africa in the prior two years who had no record of a clinic visit in the prior three months (i.e., had transferred out, died, or were lost to care). We located and interviewed 100 of these individuals or their kin to ascertain true clinical outcomes and explore individuals' psychosocial well-being. We estimated the prevalence of depression (Patient Health Questionnaire-9 scores >9) and anxiety symptoms (Generalized Anxiety Disorder-7

scores > 9) and thoughts of suicidal ideation or self-harm in the prior two weeks, and explored the relationship between high internalized, anticipated, and enacted stigma (HIV Stigma Mechanisms Measure), and low social support from friends, family, and significant others (Multidimensional Scale of Perceived Social Support) and each mental health measure using separate, unadjusted log-binomial regression models.

Results: Eighteen individuals had died (18.0%), 51 (51.0%) had reinitiated care, and 31 (31.0%) were out of care. Of the 82 individuals interviewed, 37 (45.7%), 24 (29.6%), and 18 (22.2%) reported symptoms of depression, anxiety, and thoughts of suicidal ideation/self-harm, respectively. The prevalence of depression, anxiety, and suicidal ideation/self-harm was higher among PWH reporting high anticipated and enacted stigma compared to others (Table). The prevalence of anxiety was higher among PWH reporting low family support compared to others (Table).

	Depressive disorder symptoms PR (95% CI)	Anxiety disorder symptoms PR (95% CI)	Suicidal ideation PR (95% CI)
High Stigma (scale scores > 48 = referent)			
Internalized (sub-scale scores > 12 = referent)	0.9 (0.5, 1.7)	1.5 (0.7, 3.1)	1.3 (0.5, 3.4)
Anticipated (sub-scale scores > 18 = referent)	2.0 (1.4, 3.1)	2.2 (1.1, 4.1)	2.8 (1.3, 5.9)
Enacted (sub-scale scores > 18 = referent)	2.4 (1.6, 3.4)	2.7 (1.5, 5.0)	4.8 (2.4, 9.6)
Low Social Support (scale scores < 36 = referent)			
Friends (sub-scale scores < 12 = referent)	0.7 (0.4, 1.1)	0.6 (0.3, 1.2)	0.8 (0.4, 1.8)
Family (sub-scale scores < 12 = referent)	1.4 (0.9, 2.2)	2.7 (1.4, 5.0)	1.4 (0.6, 3.3)
Significant Other (sub-scale scores < 12 = referent)	0.5 (0.2, 1.1)	0.3 (0.1, 1.3)	0.5 (0.1, 1.8)

Table. Crude associations between stigma and social support and symptoms of depression, anxiety, and suicidal ideation/self-harm in people with HIV with irregular contact with the healthcare system in KwaZulu-Natal Province, South Africa.

Conclusions: Community-level interventions that aim to minimize HIV-related stigma and increase access to mental health care are urgently needed to improve the well-being of PWH in South Africa.

MOPED09

Internalized HIV stigma compromises retention in care amongst people living with HIV in Umlazi, South Africa

E. Crittendon¹, C. Moe^{2,3}, M. Krows², S. Govere⁴, M.Y. Moosa⁵, C. Celum^{1,2}, P. Drain^{1,2,3}

¹University of Washington, Medicine, Seattle, United States,

²University of Washington, Global Health, Seattle, United States, ³University of Washington, Epidemiology, Seattle, United States, ⁴AIDS Healthcare Foundation, Durban, South Africa, ⁵University of KwaZulu-Natal, Infectious Diseases, Durban, South Africa

Background: HIV stigma remains a major barrier to care for people living with HIV (PLWH), but the impact has not been well characterized in high-prevalence resource-limited countries. Internalized stigma is a dimension of HIV stigma in which PLWH attribute negative beliefs and attitudes associated with HIV and AIDS towards themselves. We assessed the impact of internalized HIV stigma on care outcomes after diagnosis in Umlazi Township, South Africa.

Methods: We conducted a prospective cohort study with adults (>=18 years) who were diagnosed with HIV from September 2013 to April 2017. Stigmatizing beliefs were measured using validated scales at the enrollment visit and before HIV diagnosis, and again 12 months later. We constructed logistic regression models to determine independent predictors of internalized HIV stigma 12 months post-HIV diagnosis. Test associations between stigma, social characteristics, and negative health outcomes were estimated using Poisson regression.

Results: Among 3,105 PLWH, the mean age was 33 years and 57.13% were female. At enrollment, 34% reported stigmatizing beliefs, and 19% (n=578) reported internalized stigma 12 months after HIV diagnosis.

In the unadjusted analyses, baseline characteristics associated with 12-month stigma included male sex, higher educational attainment, not attending church, middle income-earning, and perceived HIV risk pre-diagnosis (Figure 1).

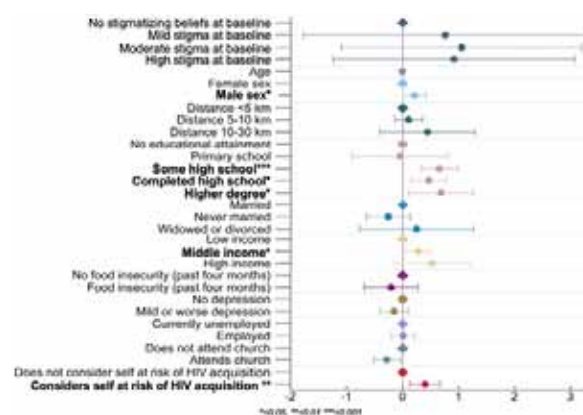

Figure 1. Associations between internalized stigma at 12 months and baseline characteristics, univariate logistic regression.

At 12 months, lacking a supportive partner (incremental risk ratio [IRR] 1.13, 95% CI 1.10-1.17, $p < 0.001$) and not disclosing one's HIV status (IRR 1.07, 95% CI 1.04-1.09, $p < 0.001$) were associated with perceiving stigma. In the adjusted multivariate analysis, 12-month stigma was associated with a significantly higher incidence of not being retained in care (IRR 1.39, 95% CI 1.10-1.78, $p < 0.007$).

Conclusions: Internalized stigma remains common among PLWH after engagement in HIV care for one year, and leads to higher rates of dropping out of care. Routinely monitoring internalized HIV stigma and providing more social support, when needed, may help improve HIV treatment outcomes.

MOPED10

HIV disclosure experience, resilience and viral suppression among PLHIV in Ghana

M.A. Roach¹, T. Loeb², A. Rao², G. Turpin², O. Syarif³, P. Looze³, K. Lalak³, J. Anoubissi³, L. Sprague⁴, C. Garcia de Leon Moreno⁴, D. Matyushina⁴, E. Ayeh^{3,5,6}, S. Baral², K. Rucinski¹

¹Johns Hopkins University Bloomberg School of Public Health, Department of International Health, Baltimore, United States, ²Johns Hopkins University Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, ³Global Network of People Living with HIV (GNP+), Amsterdam, Netherlands, ⁴UNAIDS, Geneva, Switzerland, ⁵Pan African Positive Women's Coalition (PAPWC), Kadoma, Zimbabwe, ⁶Ghana Network of Persons Living with HIV, Accra, Ghana

Background: Disclosure of HIV status is an important life event for people living with HIV (PLHIV). Disclosure experience may establish a foundational relationship with care and impact treatment adherence. Further, given adversities faced by PLHIV, resilience may establish behaviors that promote positive relationships with treatment. However, it is not well understood how disclosure experience and resilience interact to impact viral suppression among PLHIV.

Methods: Study implementation was led by NAP+, networks of PLHIV in Ghana through the Stigma Index 2.0 in partnership with GNP+, ICW, and UNAIDS. PLHIV completed a questionnaire to assess demographics, experiences of HIV and non-HIV related stigma and discrimination, resilience-factors, and other self-reported outcomes including viral suppression. Participants were also asked to evaluate their experiences of disclosure with friends and family. Multivariable log-binomial models were used to estimate prevalence ratios (PR) for the association between disclosure experience and viral suppression. Subgroup analysis assessed a dichotomized measure of resilience as a potential modifier.

Results: Among 1827 PLHIV, the median age was 39 (IQR 30-48) and 65.3% (n=558) of respondents identified as cis-gender women. Those with an overall positive disclosure

experience were more likely to have achieved viral suppression than participants with a negative disclosure experience (PR 1.09, 95% CI: 1.00-1.19). The magnitude of this association increased among participants with lower resilience scores (PR 1.33, 95% CI: 1.11-1.60). Among participants with higher resilience scores, the association between disclosure experience and viral suppression was attenuated (PR 1.03, 95% CI: 0.94-1.14).

	Prevalence Ratio	95% CI	p-value
Overall association	1.09	1.00-1.19	0.04
Stratified by resilience score**			
Less Resilient	1.33	1.11-1.60	<0.01
More Resilient	1.03	0.94-1.14	0.53

*Adjusted for age, gender, sexual orientation, sex worker status, years knowing HIV status, HIV support group
**Resilience developed from a composite score of ten items. The score was dichotomized with negative scores indicating less resilient and positive scores and scores of zero indicating more resilient.

Table. Adjusted prevalence ratios for the association of positive disclosure experience and viral suppression among PLHIV in Ghana.*

Conclusions: Among PLHIV in Ghana, people with a positive disclosure experience were more likely to report viral suppression suggesting the importance of early interactions for sustained engagement in treatment. The experience of disclosing one's HIV status might be particularly critical for more marginalized PLHIV with lower levels of resilience. Optimizing treatment may necessitate multi-level interventions that increase resilience resources for PLHIV in Ghana.

MOPED11

Discordance between HIV risk perception, sexual behavior, and PrEP adherence among young sexual and gender minorities in the United States: an ATN 142 analysis

N.K. Kelly¹, M. Rosso², C. Ranier², K. Claude², K.E. Muessig², L. Hightow-Weidman²

¹University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, ²Florida State University, Institute on Digital Health and Innovation, College of Nursing, Tallahassee, United States

Background: Pre-exposure prophylaxis (PrEP) is a crucial component of ending the global HIV epidemic; however, PrEP use has lagged among key populations, including young sexual and gender minorities. One common belief posits that young people struggle to take daily oral PrEP due to their developing decision-making skills, yet quantitative evidence of this assumption is limited.

This study sought to examine whether individual-level decision-making factors, such as HIV risk perception and sexual behavior, predicted PrEP adherence in a randomized controlled trial of sexual and gender minority youth in the United States (U.S.).

Methods: In 2019-2021, the Adolescent Medicine Trials Network for HIV Interventions (ATN) 142 study randomized 225 HIV-negative PrEP users (ages 16-24) throughout the U.S. to either a smartphone app to improve PrEP adherence, the app plus text-based adherence coaching, or stand-

ard of care. Poisson regression with robust standard errors was used to estimate the associations between HIV risk perception (using a modified version of the Perceived HIV Risk Scale, range: 5,28), sexual behavior (any condomless anal sex in the past 3 months), and self-reported daily oral PrEP adherence (≥ 4 pills in the past week) at the same time point (baseline) and longitudinally (3 months), controlling for potential confounders.

Results: At baseline, 86.2% (N=194/225) self-reported high PrEP adherence, 55% (N=124/225) recently had condomless anal sex, and the median HIV risk perception score was 13 (interquartile range: 10,15). Baseline HIV risk perception (RR: 0.93, 95% CI: 0.83,1.04) and sexual behavior (RR: 1.09, 95% CI: 0.97,1.24) were not associated with PrEP adherence at the same time point and did not predict 3-month PrEP adherence (RR: 0.95, 95% CI: 0.83,1.08; RR: 1.05, 95% CI: 0.92,1.20, respectively).

Additionally, baseline HIV risk perception was not associated with sexual behavior at either time point (baseline RR: 1.12, 95% CI: 0.93,1.34; 3-month: RR: 1.09, 95% CI: 0.89,1.34).

Conclusions: In this national trial, HIV risk perception and sexual behavior did not predict PrEP adherence.

These findings suggest that addressing individual-level perceptions and behaviors may be insufficient for impacting PrEP use among young people at risk of HIV.

Future PrEP interventions for youth should target multi-level adherence barriers, such as community- and partnership-level barriers.

MOPED12

Integrated chronic medicine pick-up points enabled by Amazon Smart Lockers, destigmatizes the collection of antiretroviral medication and promotes adherence to treatment

S. Hendriks¹, E. Arnachellam¹

¹Right ePharmacy, Centurion, South Africa

Background: The fifth decade of the HIV/AIDS pandemic has seen significant advancements in antiretroviral therapy, with HIV recognized as a manageable chronic disease. However, the stigma associated with the disease in most parts of Africa raises important questions about access to medication and the allocation of resources to clients living with HIV.

Stigma can create barriers to adherence and may result in discrimination and marginalization of people living with HIV.

Description: Collect & Go Smart Lockers have been implemented in South Africa, Botswana, Eswatini and Lesotho to create convenient pick-up points for chronic medication in rural and remote regions in Sub-Saharan Africa. In South Africa, a collaboration between the National Department of Health and health innovation provider Right ePharmacy, created a facility for chronic stable clients to collect their medication, including ART and other chronic disease medication. The Central Chronic Medicine Dispensing and Distribution (CCMDD) programme, enabled

by Amazon Collect & Go smart lockers, provides a safe, convenient, integrated mechanism for clients to collect their chronic medication discretely.

Lessons learned: Integrated chronic disease programmes can help improve adherence by providing convenient and discreet access to medication. Effective treatment of HIV requires collaboration between National Health and Innovation partners. Addressing the stigma associated with HIV is critical for improving access to treatment and adherence. Integrated programs can help address stigma by providing discreet pick-up points for medicine collections.

Conclusions/Next steps: By integrating chronic disease medicine programmes with the use of Amazon Collect & Go Smart lockers, the stigma associated with collecting antiretroviral medication can be reduced significantly, thereby improving treatment adherence. Pick-up points for integrated chronic medicine, provides a convenient and discreet way for clients to access their medication, potentially leading to higher adherence and better health outcomes.

MOPED13

Factors of age-appropriate services that influence virological suppression in children and adolescents with HIV

A. Terefe¹, D. Delele², D. Ketema³

¹Addis Ababa University, Population Studies/ Demography, Addis Ababa, Ethiopia, ²Addis Ababa University, Medical Sciences-Black Lion, Addis Ababa, Ethiopia, ³Addis Ababa, Public Health, Addis Ababa, Ethiopia

Background: Viral load suppression in children and adolescents with high viral loads receiving ART is influenced by a variety of factors. A few research has revealed services that are favorably influencing re-suppression. We conducted this study as part of the USAID Family-Focused HIV Prevention Care and Treatment OVC activity, which was implemented in 16 towns in Ethiopia's Oromia region. The objective was to identify key case management services that contribute to viral re-suppression in patients with C&ALHIV who are receiving treatment but have a high viral load.

Methods: We followed 180 C&ALHIV who were virally unsuppressed for a minimum of 6 months from October 2020 to August 2022. Case management was done to

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

identify adherence barriers and a care plan was developed to address these barriers. Binary logistic regression was used to determine the magnitude by which health and socio-economic service factors were associated with viral load re-suppression. The outcome variable was viral re-suppression with 12 months of documented initial high viral load. A P-value of less than 0.05 was used to determine the statistical significance.

Results: Viral re-suppression at 12 months was 85.6% ($n = 154$). Participating in peer support groups ($OR = 2.62$; $p = 0.037$), enhanced adherence counseling ($OR=1.56$; $p=0.05$), receiving economic strengthening interventions ($OR = 1.35$; $P = 0.050$), and being linked to age-appropriate sexual and reproductive health services ($OR = 1.51$; $P = 0.042$) were all associated with an increased risk of viral load re-suppression among C&ALHIV.

Conclusions: The findings revealed that case management services provided at a community level can make a difference in achieving viral re-suppression among C&ALHIV with high viral load. Among others, receiving enhanced adherence, participating in peer support groups, linkage to sexual and reproductive health services, and engaging primary caregivers in economic strengthening interventions (e.g., cash transfer, VSLA) were associated with viral load re-suppression.

MOPED14

Testing the impact of stigma focused interventions on PrEP use and mental health by age groups among Black sexual diverse men

L. Eaton¹, R. Watson¹, T. Huedo-Medina², V. Earnshaw³, M. Kalichman², R. Driver⁴, C. Chandler⁵, J. Kalinowski⁵, S. Kalichman²

¹University of Connecticut, Human Development and Family Sciences, Mansfield, United States, ²University of Connecticut, Storrs, United States, ³University of Delaware, Newark, United States, ⁴Columbia University, New York City, United States, ⁵Vanderbilt University, Nashville, United States

Background: Elevated rates of HIV/STI among sexual diverse Black men (SDBM) are not attributable to sexual-risk taking factors, and therefore, approaches to ameliorating HIV/STI incidence among SDBM must include addressing structural and social factors.

It is known that stigma undermines HIV prevention efforts for SDBM and therefore interventions grounded in stigma dissolution are needed.

Methods: Using a randomized controlled trial design, we evaluated the impact of both a structural intervention (providing all HIV testing services virtually) and a counseling intervention (using stigma focused content) to increase health care access and HIV prevention behaviors over short (3 and 6 month) and long term (12 month) outcomes with $N = 474$ participants. Participants resided in the southeastern US and data were collected from 2017-2019. Participants reported HIV negative status at

baseline. Participants also received rectal and urethral sexually transmitted infection (STI) testing for *Chlamydia trachomatis* (CL) and *Neisseria gonorrhoeae* (GN).

Results: Rectal and urethral CL and GH at baseline were found to be elevated relative to the general population (16.7% for rectal and 3.1% for urethral tests across both STI) and rates of STI were higher among younger participants (<30 , 30.7%) relative to older participants (≥ 30 , 12.9%). PrEP use at baseline was low with $N = 18$ (3.7%) of the sample reporting use.

Post intervention rates of PrEP use at follow ups were significantly higher among participants who had received the stigma focused counseling intervention compared to the control, time matched counseling condition ($aOR = 0.35$; 95% CI = 0.13,0.95; $p < .05$). Intervention effects, however, were stronger for younger participants than older participants.

Further, providing HIV prevention services virtually resulted in a 13% increase in the likelihood of attending HIV prevention appointments.

Conclusions: Results from the current study demonstrate the importance of addressing factors relating to stigma as a means of improving health related outcomes. Participants in the current study were at elevated risk for HIV (based on STI data), however, important changes in health behavior occurred post intervention that could have a considerable impact on prevention.

Results varied by age suggesting that interventions, both structural and counseling, need to adapt for age cohort related factors.

MOPED15

Improving access to social support and household economic strengthening intervention among children living with HIV in southern Nigeria: translating evidence to practice

E. Nwanja¹, O. Toyo¹, U. Akpan¹, C. Nwangeneh², A. Enwongo³, Q. Emeyi¹, A. Idemudia², A. Adeoye¹, O. Onyedini¹, D. Ogundehin⁴, E. James⁴, A. Eyo¹

¹Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, ²FHI 360, Abuja, Nigeria, ³Achieving Health Nigeria Initiative (AHNI), Abuja, Nigeria, ⁴USAID, Abuja, Nigeria

Background: Social determinants of health account for 30-55% of the treatment outcome, and children living with HIV (CLHIV) face significant risks and vulnerability. To reduce health inequality and optimize treatment outcomes among CLHIV, PEPFAR through USAID facilitated collaboration between its treatment program and the Orphan and Vulnerable Children (OVC) program in Akwa Ibom and Cross Rivers States, Nigeria. This paper describes how this collaboration improved the enrollment of CLHIV in the OVC program.

Description: Several meetings were held between the treatment partners (ECEWS) and the OVC partners in Akwa Ibom to identify areas of collaboration and im-

prove synergy. CLHIV (< 17 years) were referred for OVC enrolment after initiating antiretroviral therapy. Caregivers who consented were enrolled on the OVC program at the community, household enrollment number of caregivers returned to the facility, and documented on the electronic medical record.

The OVC program provided community-based adherence support, financial support for clinic visits (drug refills and viral load tests) and medical emergencies, nutritional counselling and supplements, and household economic strengthening to enrolled households. They also supported the treatment program on case identification and linkage to treatment. Joint visits by case workers from the treatment and OVC partners were conducted to CLHIV for service delivery. Joint monthly meetings were held and used to address data discrepancies. For this paper, viral load outcome assessed for children enrolled on the OVC program include viral suppression (<1000cps/mls) and undetectable viral load levels (<50cps/mls).

Lessons learned: A total of 4,840 (F:2513, M:2327) children were enrolled on the OVC program as of September 2022 representing 75% (4840/6482) of all CLHIV on treatment. Of these children enrolled, 98.8% (4637/4691) of those eligible for viral load test, had viral test done, 98.4% (4564/4637) were virally suppressed and 92.6% (4293/4637) had undetectable viral load levels.

Conclusions/Next steps: Systematic collaboration between the treatment and OVC programs improved access of children living with HIV on ART to other socioeconomic services provided by the OVC program.

MOPED16

Differences between sexual risk behaviours, HIV care utilization, and experience of stigma and violence between cisgender and transgender men who have sex with men: findings from Biobehavioural Surveys in Ukraine

S. Aijaz Khan¹, D. Gillespie², J. Nicholls³, K. Hood², P. Vickerman¹, J. Stone⁴

¹University of Bristol, Bristol medical School, Bristol, United Kingdom, ²Cardiff University, Centre for Trials Research, Cardiff, United Kingdom, ³Cardiff and Vale Sexual Health Service, Cardiff, United Kingdom, ⁴University of Bristol, Bristol Medical School, Bristol, United Kingdom

Background: Men who have sex with men (MSM) and transgender persons are at high risk for HIV in Ukraine. Transgender MSM may be more vulnerable to HIV infections than cisgender MSM due to several individual, social, and structural factors, with ~10 % of transgender persons reporting avoiding HIV services due to stigma. We assessed differences in HIV risk, intervention uptake and stigma/violence experience between cisgender and transgender MSM in Ukraine.

Methods: We analysed data from three national Integrated HIV Bio-behavioural Surveys (2013, 2015, 2018) which recruited MSM using respondent-driven sampling,

with an overall sample size of 18,621. We evaluated the differences in HIV prevalence, sexual risk behaviours, HIV testing and treatment seeking, and lifetime experiences of stigma and violence (2018 only) between cisgender and transgender MSM using multivariable regression modelling.

Results: Compared to cisgender MSM (n=18,102), transgender MSM (n=503) were more likely to be clients of non-governmental organizations (aOR = 1.37, 95%CI: 1.09-1.70), receive free condoms (last 12 months; aOR = 1.49, 95%CI: 1.24-1.78), to procure commercial sex (last month; aOR = 2.06, 95% CI:1.35-3.14), provide commercial sex (last month; aOR = 2.30, 95% CI:1.88-2.82) and engage in sexualised drug use (last month; aOR = 1.57, 95% CI: 1.11-2.21). However, we found no difference in HIV prevalence (last month; 5.61% vs 4.75%, p=0.497), HIV testing uptake in past year (73.75% vs 70.25%, p=0.395) or ART use (among HIV positives; 66.67% vs 72.12%, p=0.835) between cisgender and transgender MSM. In 2018, transgender MSM were more likely to report facing stigma from family and friends (aOR = 3.58, 95%CI: 2.54-5.04) general social stigma (aOR = 3.13, 95%CI: 2.22-4.41), anticipated healthcare stigma (aOR = 3.63, 95%CI: 2.53-5.16), physical assault (aOR = 2.73, 95%CI: 1.85 – 4.03) and coercive sex (aOR = 3.01, 95%CI: 1.99-4.55) than cisgender MSM.

Conclusions: Transgender MSM in Ukraine may engage in more high-risk practices than cisgender MSM. Whilst elevated levels of stigma against transgender MSM are concerning, higher levels of access to HIV prevention could subdue the influence of stigma on HIV transmission in transgender MSM. Stigma and harm reduction interventions for MSM should be tailored based on transgender status.

Complexities of managing survivors of Gender-based Violence: experiences from Beitbridge, Zimbabwe

M. Majachani¹, J. Murungu²

¹Chinhoyi University of Technology, Development Studies, Chinhoyi, Zimbabwe, ²University of Zimbabwe, Medicine, Harare, Zimbabwe

Background: In Zimbabwe, about 1 in 3 women aged 15-49 have experienced physical violence and about 1 in 4 women have experienced sexual violence since the age of 15. This is perpetuated by socio-cultural and religious practices that normalise sexual violation of women and girls.

We sought to determine the impact of GBV on new HIV acquisition in Beitbridge district, Zimbabwe where harmful practices such as child marriages are prevalent.

Methods: Data collected from 2020-2022 on survivors subjected to gender-based violence (GBV) at the Family Support Trust (FST) clinic, were analysed in python software to determine the extent to which GBV impacts HIV incidence. Data were filtered to retain those tested for

abstractsAuthor
Index

HIV because of the risk and further filtered to retain the number of survivors tested for at least 3 times in line with the national guidelines with a final positive HIV test result after having tested negative on the initial test. This was calculated against the total number of those at risk of contracting HIV as a result of GBV to determine the HIV incidence rate.

Results: Of the 3220 survivors who received post GBV medical and psychosocial services at FST, 68% were sexually violated women and girls of all age groups (median age 14 years) and of those, 40% were survivors of harmful traditional practices. 93.6% (2,838) of the survivors were tested for HIV. Already on ART (10) and knowing one's status were the reasons for not testing for HIV.

Among the 2,834 that tested HIV negative, 70% presented after 72 hours and were ineligible for post-exposure prophylaxis. 511 presented already pregnant. 41 survivors had a new HIV positive result on follow-up testing at three months translating to an incidence rate of 2.1% amongst GBV survivors. Self-reported none adherence was the reason for 2 seroconversions among PEP users.

Conclusions: GBV prevention, screening and management should be integrated with combination HIV prevention services. A multifaceted and multisectoral approach to the prevention and management of GBV targeting harmful practices, legal factors, literacy on HIV prevention, early presentation and PEP adherence and linkage to PrEP is indicated.

The effect of a conditional cash transfer program on AIDS morbidity and mortality in the poorest daughters and mothers: a cohort study of 12.6 million women in Brazil

A.F. Silva^{1,2}, I. Lua^{1,2}, G.S. Jesus^{2,3}, P.F. Pinto^{1,2}, C.A. Santos², M.Y. Ichihara², M.L. Barreto², L. Magno⁴, L.E. Souza¹, J. Macinko⁵, I. Dourado¹, D. Rasella^{1,2,6}

¹Collective Health Institute, Federal University of Bahia (UFBA), Salvador, Brazil, ²Center for Data and Knowledge Integration for Health (CIDACS), Gonçalo Moniz Institute, Oswaldo Cruz Foundation (FIOCRUZ), Salvador, Brazil,

³Faculty of Medicine, Federal University of Bahia (UFBA), Salvador, Brazil, ⁴Department of Life Sciences, State University of Bahia (UNEB), Salvador, Brazil, ⁵Departments of Health Policy and Management and Community Health Sciences, UCLA Fielding School of Public Health, Los Angeles, United States, ⁶ISGlobal, Hospital Clinic - Universitat de Barcelona, Barcelona, Spain

Background: Poverty is a social determinant known as one of the main risk factors for a wide range of diseases and health problems, including HIV/AIDS. However, available scientific evidence is still inconclusive for the impact of conditional cash transfer programs (CCT) on HIV/AIDS, specifically for women. We evaluated the effects of one of the largest CCTs in the world, the *Bolsa Família Program* (PBF), on sequential AIDS outcomes, incidence and mor-

talidity, among women (daughters and mothers) beneficiaries and head of household, using data from a nationwide cohort of the poorest Brazilian people on the Unified Registry for Social Programs (*Cadastro Único*).

Methods: We analyzed a cohort of 12.6 million low-income Brazilian women from 2007 to 2015, comparing BFP beneficiaries and non-beneficiaries, using a quasi-experimental impact evaluation design.

We used inverse probability of treatment weighting (IPTW) to adjust for selection into receipt of PBF benefits and then fitted multivariable Poisson regressions, adjusted for all relevant socioeconomic, demographic, and healthcare confounding variables -at the individual and municipal level- to estimate the effect of PBF on AIDS incidence and mortality rates. We also evaluated PBF effects for different subpopulations to per capita wealth, age, race/ethnicity and education.

Results: PBF exposure was associated with a lower AIDS incidence (RR: 0.63; 95% CI: 0.52-0.76) and mortality (RR: 0.57; 95% CI: 0.40-0.81) for daughters and lower AIDS incidence (RR: 0.58; 95% CI: 0.55-0.61) and mortality (RR: 0.57; 95% CI: 0.53-0.63) for mothers. PBF associations were significantly stronger among women living in extreme poverty (RR: 0.58 for incidence and RR: 0.53 for mortality among daughters; RR: 0.49 for incidence and RR: 0.53 for mortality among mothers). PBF impact was also stronger among brown/black, adolescents and young and with lower education women.

Conclusions: Conditional cash transfers could significantly reduce AIDS morbidity and mortality in PBF beneficiary women, especially among the extremely poor. During the current dramatic rise in global poverty, due to the COVID-19 pandemic, CCT investments could protect against potential increases in the HIV/AIDS burden and contribute towards achieving AIDS-related Sustainable Development Goals (SDGs).

MOPED19

Displacement-related challenges faced by internally displaced persons in northern Mozambique and their implications for HIV testing: a qualitative study

C. Chantre¹, K. dos Santos², M. Xaria², T. Zacarias², P. Fortunato dos Santos³, J.L. Davis¹, J. Mootz⁴

¹Yale School of Public Health, Epidemiology of Microbial Diseases, New Haven, United States, ²Mozambican Ministry of Health, Nampula, Mozambique, ³Mozambican Ministry of Health, Maputo, Mozambique, ⁴Columbia University/ New York Psychiatric Institute, Psychiatry, New York, United States

Background: Exposure to traumatic events such as forced displacement is associated with an increased risk for HIV. However, HIV testing among internally displaced populations (IDPs) is difficult, with scant literature documenting barriers to HIV testing among this group, particularly in southern Africa. Northern Mozambique has one of the

highest HIV incidence rates in sub-Saharan Africa. Our study investigated how displacement experiences were tied to risk of HIV acquisition and explored HIV awareness and testing for young adult IDPs settled in Nampula City, Mozambique.

Methods: We used a purposive sampling strategy to conduct six focus group discussions with IDPs, district representatives, and community leaders and three key informant interviews with policymakers and humanitarian personnel. We used thematic analysis to analyze the data.

Results: The study included (n=51; 29.4% Female, 21.6% under 25) participants and sampled until saturation was met. Participants reported that displaced young adults, especially young women were highly vulnerable to HIV acquisition due to transactional sex, early marriage, and sexual violence.

However those parous had at least previously engaged in HIV testing services, with young men mentioning less frequent engagement. IDPs and key stakeholders noted that for IDPs, financial, linguistic, and geographic barriers impeded engagement with health services and cited competing priorities between understanding one's HIV status, and more basic needs like food, security, and livelihood. Interrupted education and conversations around HIV stigma demonstrated potential constraints to HIV testing among displaced youth. Other challenges mentioned were the lack of interventions promoting HIV testing that previously existed in IDPs' communities of origin (i.e., HIV lay counselors and mobile clinics).

Stakeholders identified structural barriers to HIV testing, describing primary health care centers as unable to respond to the past years' influx of IDPs, and IDPs citing the need for government facilities to enable linkage to health services within their communities.

Conclusions: Although displaced young adults occupy an environment highly vulnerable to HIV acquisition, several displacement-related challenges create barriers for HIV testing. IDPs mentioned HIV testing interventions that had proven helpful in the past, demonstrating that tailoring said interventions to the needs and context of displaced young adults may prove substantive in future HIV programming.

MOPED20

The need to contextualise HIV risk reduction approaches for MSM in Indonesia: results from socioecological risks latent class analysis

L. Nevendorff^{1,2,3}, A. Pedrana⁴, A. Bourne⁵, M. Traeger⁴, M. Stoové⁴

¹Burnet Institute, Public Health, Melbourne, Australia,

²Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia, ³HIV AIDS Research

Center Atma Jaya Chatolic University Indonesia, Jakarta, Indonesia, ⁴Burnet Institute, Disease Elimination Program, Melbourne, Australia, ⁵Australian Research Centre in Sex, Health & Society, La Trobe University, Melbourne, Australia

Background: Most HIV prevention education and behavioural change programmes for men who have sex with men (MSM) focus on reducing individual-level risks. However, HIV risk is also shaped by contextual social and structural factors that shape MSM's sexual risk behaviour but often lie outside an individual's control.

This study aimed to identify patterns of HIV-related risk and their relationship with socioecological factors.

Methods: Using national online survey data from the community-led Chemsex-INA study (n=1314), we determined individual HIV risk patterns among MSM using latent class analysis with posterior probability to predict subgroup membership classifications. Multinomial logistic regression was used to assess the relationship between group membership and covariates representing potential socioecological risk factors.

Results: We identified three unique subgroups: *Sexual Explorative*, *Navigating Complexities*, and *Social Normative* with distinct patterns of individual-level HIV risks that occurred alongside social/networks-level and community-level risks.

Using the *Social Normative* as the reference group, the *Sexual Explorative* group had greater odds of reporting online methods to meet sexual partners (adjusted risk ratio; aRR 4.3; 95%CI 2.1-8.9), using social media and gay-specific dating platforms (aRR 2.6; 95%CI 1.9-3.6), engaging in group sex (aRR 10.9; 95%CI 4.5-25.4), engaging in selling or buying sex (aRR 1.6; 95%CI 1.2-2.2), and experiencing homosexual-related assaults (aRR 1.4; 95%CI 1.1-1.9).

The *Navigating Complexities* group had lower odds of reporting a monthly income of >USD 669 (aRR 0.5; 95%CI 0.3-0.8), receiving HIV/STI information (aRR 0.7; 95%CI 0.5-0.9), and attending STI-related services (aRR 0.6; 95%CI 0.4-0.8), and greater odds of reporting a lack of social support (aRR 1.6; 95%CI 1.1-2.5), not disclosing their sexuality (aRR 1.4; 95%CI 1.1-1.9), reporting sex with multiple men (aRR 6.1; 95%CI 2.5-14.5), having a higher internalised homonegativity index score (aRR 1.2; 95%CI 1.1-1.4) and experiencing homosexual-related assaults (aRR 1.4; 95%CI 1.1-1.9).

Conclusions: By identifying a range of socioecological contexts associated with individual-level HIV risk patterns, our study provides a clearer understanding of the factors that shape HIV risk in Indonesia that need to be

considered when designing HIV prevention and support programs. HIV differentiated care and approaches are required to support a diverse MSM population in Indonesia.

MOPED21

I am not at HIV transmission risk: reasons for sexually active Eswatini adolescents for refusing PrEP

T.J. Matsebula¹

¹Pact Eswatini, Strategic Information, Mbabane, Eswatini

Background: Evidence have shown that HIV pre-exposure prophylaxis (PrEP) is highly effective when taken correctly and consistently by individuals at substantial risk of HIV infection. Due to the high HIV incidence among the general population of Eswatini, PrEP for HIV-exposed individuals is recommended. The Triple-R project is supporting the government of Eswatini to prevent new HIV infections and reducing the HIV vulnerability for orphans and vulnerable children, adolescent girls and young women (AGYWs).

As part of the project, AGYWs are assessed for their health needs and then linked to health services as per identified needs including PrEP. Even though awareness on PrEP has been raised in the country, PrEP uptake remains very low.

Objective: To understand the reasons for Eswatini AGYWs for refusing PrEP as an HIV prevention Strategy.

Methods: Secondary data analysis of routine data collected within ongoing project implementation was explored to assess the needs of AGYWs. Trained Mentors recruit and complete needs assessment where AGYW's HIV risks and health needs are assessed. About 4300 AGYWs were assessed, 2500 were at HIV risk in which 929 of those AGYWs indicated that they are not willing to take PrEP. The 929 clients formed the study sample.

Results: About 90% of the 929 AGYWs do not consistently use condoms during sex. The median age of AGYWs was 22 years. About 50% AGYWs did not view themselves as being sufficiently at risk of HIV to warrant PrEP use.

There was also a 23% consistent belief that sexual partners will not approve PrEP as they will think they are HIV positive and on ART.

About 17% cited lack of interest in PrEP and taking the treatment daily. "It's stressful to take medication every-day when not sick", "Eish, "it will be like I am taking ARVs". Lastly, a few were scared of PrEP side effects.

Conclusions: There is need for programs to address the stigma surrounding taking ART medication and to expand PrEP messaging for both men and women to increase uptake.

Finally, there is urgent need for tailored counseling before PrEP initiation to help PrEP users identify HIV risk periods.

MOPED22

Hoping to adhere? Examining the relationship between hope and PrEP willingness and adherence among adolescent girls and young women enrolled in HIV Prevention Trial 082

M. Gichane¹, S. Hosek², J. Vellozo³, G. Beauchamp⁴, P. Anderson⁵, S. Delany-Moretlwe⁶, C. Celum⁷

¹University of California San Francisco, Obstetrics, Gynecology, and Reproductive Sciences, San Francisco, United States, ²Stroger Hospital of Cook County, Department of Psychiatry, Chicago, United States, ³University of California San Francisco, Division of Global Health and Infectious Disease Epidemiology, San Francisco, United States, ⁴Fred Hutchinson Cancer Center, Seattle, United States, ⁵University of Colorado Denver - Anschutz Medical Campus, Denver, United States, ⁶University of the Witwatersrand, Wits RHI, Faculty of Health Sciences, Johannesburg, South Africa, ⁷University of Washington, Departments of Global Health, Medicine, and Epidemiology, Seattle, United States

Background: Hope is a powerful psychological construct which is linked to positive health outcomes including improved HIV treatment and quality of life among people living with HIV. Less is known about the role of hope in biomedical HIV prevention product uptake and adherence. We assessed the relationship between hope for the future and oral pre-exposure prophylaxis (PrEP) willingness and adherence among African adolescent girls and young women (AGYW).

Methods: HIV Prevention Trial (HPTN) 082 was an open-label, interventional, randomized trial of AGYW (aged 16-25 years) conducted in South Africa and Zimbabwe from October 2016 to October 2018.

We analyzed a short version of the Hope for the Future Scale, a six-item instrument (6-30, 30= highest hope) and seven-item PrEP willingness subscale of the HIV Prevention Readiness Measure (6-36, 36= highest willingness) collected at baseline. PrEP adherence was measured via tenofovir-diphosphate (TFV-DP) concentrations in dried blood spots at follow-up weeks 13, 26, and 52, among participants who accepted PrEP.

We conducted linear regression to assess the relationship between hope and willingness to use PrEP at baseline and generalized estimating equations (GEE) to examine the longitudinal relationship between baseline hope and high PrEP adherence (TFV-DP concentrations ≥ 700 fmol/punch) at follow-up.

Results: Participants (n=451) reported moderate levels of hope (median=20, interquartile range [IQR]: 15-24) and PrEP willingness (mean=21, IQR 15-28). High adherence (TDF/FTC ≥ 700 fmol/punch) was observed in 25% (13-weeks), 21% (26 weeks), and 9% (52-weeks).

At baseline, hope was positively associated with PrEP willingness ($\beta=0.30$, 95% CI: 0.24, 0.36) but was not significantly associated with high PrEP adherence (RR=0.99, 95% CI: 0.95, 1.02) at follow-up.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Conclusions: Having higher levels of hope was positively associated with willingness to use PrEP, but not with high adherence. Hope may operate differently in HIV prevention adherence. Further research is needed to examine resilience and other factors which may promote PrEP adherence.

MOPED23

Homelessness and its relationship with HIV prevention and treatment among men who have sex with men: results from the American Men's Internet Survey, 2017-2021

A. Rao¹, T. Sanchez², J.M. Wiginton¹, W. Edwards², K. Willis¹, T. Eden³, T. Willie³, S. Murray³, S. Baral¹

¹Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, ²Emory University, Department of Epidemiology, Atlanta, United States, ³Johns Hopkins Bloomberg School of Public Health, Department of Mental Health, Baltimore, United States

Background: Men who have sex with men (MSM) are disproportionately affected by housing insecurity across the US, secondary to individual-level and structural stigmas. There are limited data characterizing the relationship between homelessness and HIV-related outcomes.

Methods: 44,559 cisgender MSM who participated from 2017-2021 in the American Men's Internet Survey (AMIS), an annual cross-sectional online survey in the US, were included.

Homelessness was defined as living on the street, a shelter, a Single Room Occupancy hotel, or a car in the past 12 months. Associations between sociodemographic characteristics and homelessness were tested using chi squared and t-tests.

Multivariable Poisson regressions with robust variance estimation assessed associations between homelessness and:

1. Current use of antiretrovirals among people living with HIV (PLWH) and;
2. PrEP in the past 12 months among non-PLWH. Interactions between self-reported race and homelessness were examined.

Results: The median age of participants was 30 years old (IQR: 22-49). Approximately 9% of those included reported living with HIV (n=3,894). Living in the South, having less than a high school education, younger age, and not having health insurance were associated with recent homelessness (p<0.001). Participants identifying as Black and PLWH were 4.34 times as likely to be homeless compared to non-Black, non-PLWH (95%CI: 3.59-5.24).

Homelessness was associated with less PrEP use [aPR: 0.82, 95%CI (0.69, 0.98)] but was not associated with antiretroviral use. Black individuals experiencing homelessness were less likely to have used PrEP than non-Black individuals with no recent homelessness.

Other/multiple	1.53 [1.33, 1.76]	1.23 [1.13, 1.35]

Table 1. Results of a multivariable Poisson regression with robust variance estimation assessing the relationship between homelessness and 1. Use of PrEP among those not living with HIV and 2. Use of antiretrovirals among those living with HIV among men who have sex with men participating in the American Men's Internet Survey, 2017-2021.

Conclusions: Social determinants of health, including homelessness and inadequate health insurance, may impede HIV service uptake. Homelessness among cisgender MSM in the US is disproportionately experienced by Black men, along with those with lower educational attainment, those in the South, and younger individuals. In 2023, HIV prevention programs that fail to address social contexts, including housing insecurity and structural racism, may continue to inadequately address the needs of those at greatest risk.

HÉROS: A community- and person-centered design of healthcare service for GBMSM engaging in chemsex in Taiwan

C. Strong¹, J.-H. Hsu¹, A.-C. Chung^{2,3}, M.-T. Wu^{2,3}, Y.-H. Wu³, K.-W. Lo³, S.-T. Hsu^{3,4}, N.-Y. Ko^{2,3,5}

¹National Cheng Kung University, Department of Public Health, Tainan, Taiwan, ²Taiwan Love and Hope Association, Kaohsiung, Taiwan, ³Healing, Empowerment, Recovery of Chemsex (HERO) Health Center, HÉROS, Kaohsiung, Taiwan, ⁴Kaohsiung Municipal Kai-Syuan Psychiatric Hospital, Department of Community Psychiatry, Kaohsiung, Taiwan, ⁵National Cheng Kung University, Department of Nursing, Tainan, Taiwan

Background: In response to the rise of chemsex globally and in Taiwan, an integrated care model Healing, Empowerment, Recovery of Chemsex Health Center (HERO) was established in the year 2017. It transformed from a model that was located within a regional hospital to a new social enterprise approach of one-stop center (HÉROS) in May 2022. It is now independently located within the community, cooperated with a pharmacy and clinic in an urban neighborhood more accessible for people who engaged in chemsex.

HÉROS aimed to provide comprehensive care including sexual health, HIV/STI prevention and treatment, psycho-social therapy, substance use counseling and referral services for people who engaged in chemsex.

Description: Integrated medical care was provided by the clinic to reduce physical symptoms and psychological discomforts due to chemsex. The pharmacy provided home delivery services and designed customized-centered consultations helping chemsex users to reduce their carving and maintain their well-being.

In addition, HÉROS provided a series of mental health integrated services for chemsex individuals, including psychiatric outpatient clinics, individual psychological counseling, and multiple types of chemsex recovery and supporting groups for people engaging in chemsex.

The three major types of groups for chemsex include the early relapse prevention that helps participants to identify triggers and develop skills for early prevention, the 12-step group, and the interpersonal skills group designed for individuals at the maintenance stage.

Lessons learned: Less than six months after HÉROS was moved to the community in 2022, more than 2000 people visited HÉROS clinic and half of them received pharmacy services. More than 40 chemsex recovery and support groups were held and 70 GBMSM engaged in chemsex have participated. For some GBMSM, chemsex is the results of social isolation and loneliness and can benefit from interventions with a mental health focus provided by psychosocial therapy and support groups.

Conclusions/Next steps: As an integrated one-stop center rooted in the community, HÉROS incorporates a broad array of operational and ideological approaches toward care planning and delivery for people affected by chemsex.

HÉROS exists to facilitate differentiated and simplified chemsex care services which emphasizes a person- and community-centered approach of HIV/STIs, PrEP and chemsex care service delivery.

TUPED02

What do we know about bisexual behaviours and condomless sex with women among men who have sex with men in Sub-Saharan Africa? A systematic review and meta-analysis

M. Fiorentino¹, R. Gravier-Dumoncau Mazelier¹, N. Yanwou^{1,2}, A. Eubanks¹, P. Roux¹, C. Laurent³, B. Spire¹
¹Aix Marseille Univ, IRD, Inserm, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France, ²ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, ³TransVIHMI, Univ Montpellier, IRD, INSERM, Montpellier, France

Background: In Sub-Saharan African (SSA), the HIV dynamic in different regions varies between generalized and mixed epidemics. Prevalence is high in men who have sex with men (MSM), a population that experiences strong social stigma and pressure to have female partners. This suggests that MSM could be a bridging group for HIV transmission to women. We provided an overview of the proportions of bisexual MSM and MSM who have condomless sex with women in various SSA regions.

Methods: Following the PRISMA guidelines, we conducted a systematic review of published peer-reviewed articles containing the following data on MSM: self-reported bisexuality, recent sex (i.e., previous 12 months or 1 month depending on the region), and condomless sex with female partners. We performed a meta-analysis, separately for each region, when the proportion was reported in at least four studies (Figure 1).

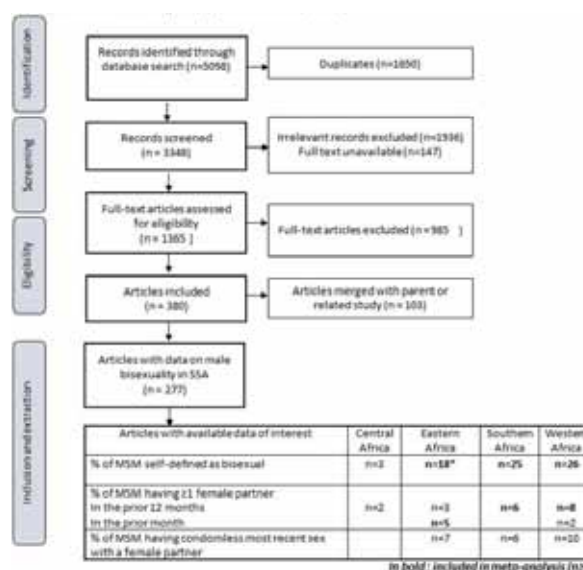

Figure 1. PRISMA flow diagram (systematic review process)

Pooled proportions were calculated using a random-effects model.

Results: The pooled proportion of self-declared bisexual MSM was 22% (95% CI [16;19]) in Southern Africa, 36%[29;43] in Eastern Africa, and 51%[45;56] in Western Africa. In Southern and Western Africa, 29%[22;38] and 47%[36;58] of MSM had ≥ 1 female partner in the prior 12 months, respectively. In Eastern Africa, 23%[9;47] of MSM had ≥ 1 female partner in the prior month.

The pooled proportion of condomless most recent sex with a female partner was 27%[21;35] in Southern Africa, 30%[10;63] in Eastern Africa, and 20%[13;28] in Western Africa.

Conclusions: A significant proportion of MSM in SSA reported bisexual orientation, especially in Western Africa. Condomless sex with female partners was frequent in all three regions, which highlights the risk of HIV bridging to this population.

HIV research, prevention, and care programmes, as well as community-based support for MSM, should be adapted to MSM who have female partners, in order to reduce the HIV bridging risk to the general female population.

TUPED03

The effects of childhood trauma and mental health symptoms on adherence among youth living with HIV in Botswana

K. Molebatsi¹, V. Ntantsana², M.J Brooks³

¹University of Botswana, Psychiatry, Gaborone, Botswana,

²University of KwaZulu Natal, Durban, South Africa,

³University of Pennsylvania Perelman School of Medicine, Philadelphia, United States

Background: Research findings have highlighted the evidence of co-occurring mental health problems in young people living with HIV (YLWHIV) which may be explained by high rates of exposure to trauma in this population. Mental health problems increase risk of poor treatment adherence and participation in risky behaviors which may precipitate poor health and quality of life outcomes. To inform interventions that improve quality of life, and decrease risky behaviors for youth, it is critical to understand the extent to which childhood trauma, mental health problems, and poor adherence occur and coexist. This study examined the associations between childhood trauma, mental health problems and adherence to anti-retroviral treatment (ART) among HIV infected youth in Botswana.

Methods: The study was conducted at an HIV clinic of a public hospital located 38 kilometers from the capital city of Botswana among youth (15-24 years) using a cross sectional design.

Childhood trauma questionnaire, CRAFFT 2.1, Depression, Anxiety, Stress Scale were used to collect data on childhood trauma, problematic substance use and common mental health symptoms respectively.

Adherence to ARTs was assessed objectively and subjectively using the most recent viral load and the simplified medication adherence questionnaire respectively.

Multivariate logistic regression was subsequently performed controlling for variables found to be significantly associated with childhood trauma on bivariate analysis.

Results: Of the 119 youth recruited, 51.26% were adherent to their ART and 87.39% were virologically suppressed. Childhood trauma was reported by 47% of the sample, with physical neglect being the most reported subtype. The prevalence of depression, anxiety, and problematic substance 34.45%, 41.18% and 23.53%.

Exposure to childhood trauma was significantly associated with depression, anxiety, problematic substance use, and non adherence. Sexual trauma and emotional abuse had the highest odds to predict non-adherence (OR = 3.85 and 2.30 respectively).

Conclusions: Promoting adherence and overall well-being must include an emphasis on trauma exposure and mental health. Further studies should explore the longitudinal relationship between these factors in the lives of YLWHIV to see if there are any causal mechanisms that can be explored.

Additionally, a study of protective factors would also provide targets to promote in psychosocial support programs for these youth.

TUPED04

Risk network referral and enhanced peer outreach approach (social network strategy): HIV case identification strategy for female sex workers in Kilifi county - ICRHK key population program

S. Mwangi¹, G. Manguro¹, L. Baya¹, M. Kazungu¹, D. Muchiri¹, A. Vose¹, M. Ogutu¹, D. Kobags¹

¹International Centre for Reproductive Health - Kenya (ICRHK), Health, Mombasa, Kenya

Background: Female sex workers (FSWs) remain disproportionately affected by HIV, with a prevalence estimate of 45.1%[1] among FSWs in Kilifi as compared to 2.3% [2] among the general population in Kilifi counties respectively.

The National HIV program objective is to have 95% of Kenyans to know their status, however, only over 79.5% of Kenyans living with HIV are aware of HIV status which is detrimental to HIV prevention, care and treatment.

ICRHK implemented Risk Network Referral (RNR) a strategy that systematically facilitates referrals from HIV-positive FSW to their social network with a High risk of HIV/STI infection for HIV testing services and connects HIV-negative peers to services that will help them remain negative. ICRHK also implemented EPOA, an innovation that uses performance-based incentives and works through social and sexual networks to improve HIV case-finding outcomes.

Methods: ICRHK conducted a retrogressive data analysis of Key population data for 3 years (2020 to 2022). We analyzed facility-level HIV Data to determine trends of HIV positive Case identification among female sex work-

ers. This data was compared to different models of HIV testing both at the outreach and static sites. Risk network Referrals (RNR) and EPOA as part of the Social Network Strategy (SNS) were analyzed comparatively against conventional key population HIV testing at the static and outreach sites.

Results: The analysis showed that RNR and EPOA produce high HIV positivity rates of case identification among female sex workers in Kilifi County as compared to outreach and static HIV testing methods.

Kilifi County a total of 4644 tests were done among FSWs between October 2019 and June 2022. Among those done through EPOA (1146), 8% turned positive. Out of 2229 tests done through RNR, 169(8%) turned positive while 2% of the through conventional outreach tests turned positive.

Conclusions: To achieve UNAIDS 2030 target, there's a need to scale effective HIV services with high impact. With an ongoing dynamic change in HIV programming for the Key populations, it is prudent that key population implementers adopt high-impact strategies that are sustainable and cost-effective.

TUPED05

Risk characteristics, risk perception, and long-acting PrEP awareness and interest among Black and Hispanic men: a national survey

T. Poteat¹, S. Sarkar², L. Ragone², D. Bogan², MK. Rawlings², A. Rinehart², K. Gallington³, K. Coyne³, P. Daniele³, V. Vannappagari²

¹University of North Carolina at Chapel Hill, Chapel Hill, United States, ²ViiV Healthcare, Durham, United States,

³Evidera, Bethesda, United States

Background: Black and Hispanic people accounted for 70% of new HIV diagnoses but only 31% of HIV pre-exposure prophylaxis (PrEP) users in the US between 2015 and 2019. This data demonstrates the severe inequities in PrEP access and use in historically underserved racial and ethnic groups in the US. Alternative PrEP options, such as long-acting (LA) injectable PrEP, serve a critical role in addressing these gaps.

This study focused on awareness and interest in using LA-PrEP among US Black and Hispanic men by risk characteristics and risk perception.

Methods: Cisgender men were recruited between November 2021-March 2022 through targeted ads on social media platforms to complete an online, self-administered survey. Eligible participants were: 18+ years, current US residents, self-reported Black race and/or Hispanic/Latino ethnicity, reported penetrative (anal or vaginal) sex in the past six months and unknown or negative HIV status.

The survey included questions on demographics, sexual health and behavior, awareness of LA-PrEP prior to survey, and interest in using LA-PrEP after reading a brief product description. Descriptive statistical analyses were conducted using SAS v9.4.

Results: 1,728 Black and Hispanic men completed the survey (median age: 29 years; US geography: South – 53.2%, West – 30.8%, Northeast – 10.1%, Midwest – 5.8%; sexual orientation: heterosexual/straight – 61.3%, gay – 28.7%, bisexual – 5.7%, another orientation – 4.3%).

Half of participants had heard of LA-PrEP prior to survey start; three-quarters expressed interest in using LA-PrEP after reading the description. LA-PrEP awareness and interest were highest among participants who reported: STI diagnosis in the past two years, multiple male partners, injection drug use in the past year, and inconsistent condom use with male partners.

Although LA-PrEP awareness varied by participant characteristics, interest in using LA-PrEP was high across subgroups.

Figure. Awareness and interest to use long-acting PrEP among black and hispanic men by select characteristics.

Conclusions: These results illustrate high interest for LA-PrEP among Black and Hispanic men and the need to increase LA-PrEP awareness in this population.

TUPED06

Factors associated with frequency of drug use among people who inject drugs enrolled in HIV prevention program in Eastern Nepal

K. Dhakal¹, R. Bhattarai², P. Shakya², A. Pun²

¹Save The Children International, Program, Biratnagar, Nepal, ²Save The Children, Program, Kathmandu, Nepal

Background: Harm reduction services are one of the key components of HIV prevention program in Nepal. The frequency of drug injection is an important factor which is related with mental health status and harms related to injecting behavior. However, little is known about the factors which influence the frequency of drug injection among PWID in Nepal.

Thus, we examined the socio-economic and injecting behavior factors associated with frequency of drug injection among PWID enrolled in HIV prevention program in Eastern Nepal.

Methods: We conducted a cross-sectional study with secondary analysis of the routine program data. We included a total of 2653 PWID clients enrolled in the harm reduction program during 2020/2021.

We measured socio-demographic variables, drug injecting behaviors such as age of initiation, types and frequency of drug use and body sites for injection. We used multi-variable linear regression model to analyze the data.

Results: Out of 2653 participants, 6% were women. The mean age was 25.8 years (SD 4.2), 27% were married. More than half of the participants had only primary level of education. The mean age of first injecting drug use was 19.7 years (SD 3.1). The mean frequency of drug use per week was 8.1 times (SD 3.3). Around 89% of the participants inject drugs in groin region and rest others in upper arm. Around 96% of the participants mix more than one type of drug during injection.

Women were more likely to inject drugs frequently per week than men ($\beta=4.10$, $p<0.001$). Those who initiate drug injecting behavior at later age were more likely to inject drugs frequently per week ($\beta=0.18$, $p<0.001$). Those who mix multiple drugs while injecting were more likely to inject drugs frequently per week ($\beta=1.58$, $p<0.001$). Those who inject drugs in groin region were more likely to inject drugs frequently per week ($\beta=1.31$, $p<0.001$) than those who inject in upper arm.

Conclusions: The frequency of drug injection is associated with gender, age of first drug injection, mixing multiple drugs and injecting site in the body. Such evidence is helpful while designing interventions for harm reduction program among PWID in Nepal.

TUPED07

Abstinence from the perspective of men who have sex with men and live in Padang, a religious city in Indonesia

M. Mahathir¹, B.P. Wenny², R. Sabri¹, S. Berlian³

¹Universitas Andalas, Community Health Nursing, Padang, Indonesia, ²Universitas Andalas, Mental Health Nursing, Padang, Indonesia, ³Universitas Andalas Hospital, Medical Surgical Nursing, Padang, Indonesia

Background: HIV prevention efforts in various parts of Indonesia still focus on the central values of culture and religion. The way of life in the most religious semi-urban/urban areas expects abstinence to be the most important method promoted in HIV prevention efforts.

Various kinds of behavioral and other biomedical prevention efforts that have also proven effective in suppressing HIV transmissions, sometimes face many barriers in their implementation, especially in areas where traditional cultures, norms and religion have higher value.

This study explores the perspective of men who have sex with men on abstinence in Indonesia.

Methods: The study was conducted by carrying out phenomenological research. Data were collected between June-September 2022. In-depth interviews were conducted with 20 MSM in Padang, Indonesia by using semi structured questions.

The data analysis in this study used the Stevick-Colaizzi-Keen data analytical method.

Results: Five essential themes were found, the themes were: sex is a basic human-need, abstinence is only temporary, importance of alternative options to sex during

temporary abstinence, MSM will limit who they share their sexual preference with and expectations of other prevention options. Relying on HIV prevention by focusing solely on promoting abstinence is therefore questionable.

In practice, we face a series of behavioural challenges in implementing abstinence, and the key population itself cannot carry out this type of prevention effectively. This should be considered during the strategic planning of such programs to strengthen the acceptance and implementation of more optimal abstinence behavior so that it can significantly reduce the transmission rate.

In Indonesia, there are still few available options for HIV prevention programs based on a behavioural or biomedical approaches compared to developed countries. The limited options and outreach is even worse in under-developed, rural, and suburban areas, yet the discrimination and stigma are still the biggest barriers of all.

Conclusions: Focusing on abstinence only could increase the likelihood of risky behaviors. Being oppressed and discriminated against, the MSM group faces limited options, knowledge, and awareness to apply behavior to prevent transmission. Strengthening prevention efforts in key MSM groups must be specific and unique to identify behavioral needs that can be most effectively implemented.

TUPED08

Archetypes of PrEP discontinuation among transgender women in the United States: a longitudinal, mixed methods cohort study

E.E. Cooney^{1,2}, H.T. Saleem¹, M. Stevenson², R. Aguayo-Romero^{3,4,5}, K.N. Althoff², T.C. Poteat⁶, S.W. Beckham⁷, D. Adams², A. Radix⁸, A.J. Wawrzyniak⁹, C.M. Cannon¹⁰, J.S. Schneider¹¹, J.S. Haw¹¹, A.E. Rodriguez⁹, K.H. Mayer^{4,5}, C. Beyrer¹², S.L. Reisner^{3,4}, A.L. Wirtz², American Cohort to Study HIV Acquisition among Transgender Women (LITE) Study Group

¹Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, ²Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, ³Brigham and Women's Hospital, Boston, United States, ⁴Harvard Medical School, Boston, United States, ⁵The Fenway Institute, Boston, United States, ⁶University of North Carolina Chapel Hill, Social Medicine, Chapel Hill, United States, ⁷Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States, ⁸Callen-Lorde Community Health Center, New York, United States, ⁹University of Miami, Miami, United States, ¹⁰Whitman Walker Institute, Washington, D.C., United States, ¹¹Emory University, Atlanta, United States, ¹²Duke University, Durham, United States

Background: Transgender women (TW) in the United States experience high HIV incidence and suboptimal PrEP engagement. We sought to estimate PrEP initiation and discontinuation rates and to characterize PrEP discontinuation experiences among a longitudinal prospective cohort of TW.

Oral
abstracts

Poster
exhibition

Late-breaker
abstracts

Author
Index

Methods: Using a sequential, explanatory mixed methods design, 1,312 adult TW at risk for HIV acquisition were enrolled from March 2018 to August 2020 and followed for a median of 24 months (interquartile range 15-36). Cox regression models assessed predictors of initiation and discontinuation. A subset of 18 TW participated in qualitative in-depth interviews that included life history calendars to explore key events and experiences surrounding discontinuations and to establish temporality. Qualitative and quantitative data were integrated to inform meta-inferences and facilitate interpretation of findings.

Results: Among 1,312 TW, 21.8% (n=286) reported taking PrEP at one or more study visits while under observation. We observed 139 PrEP initiations over 2,127 person-years (6.5 initiations/100 person-years, 95% CI: 5.5-7.7) and 138 PrEP discontinuations over 368 person-years (37.5 discontinuations/100 person-years, 95% CI: 31.7-44.3). Predictors of initiation included identifying as Black and experiencing PrEP indication. Predictors of discontinuation included having a high school education or less and initiating PrEP for the first time while under observation. Four distinct archetypes of discontinuation emerged:

1. Seroconversion following discontinuation,
2. Ongoing HIV acquisition risk following discontinuation,
3. Reassessment of HIV/STI prevention strategy following discontinuation, and;
4. Dynamic PrEP use coinciding with changes in HIV acquisition risk.

Figure 1. PrEP initiations and discontinuations among transgender women in the United States enrolled in The LITE Cohort under observation from March 2018 to July 2022 (n=1,302).

Conclusions: PrEP initiation rates were low and discontinuation rates were high. Complex motivations to stop using PrEP, which did not consistently correspond with HIV acquisition risk reduction, point to the need for continued HIV prevention support for TW who discontinue PrEP. Evidence-based interventions to increase PrEP persistence among TW with ongoing acquisition risk are necessary to optimize PrEP effectiveness in this population.

TUPED09

A growth curve model to assess the effectiveness of a community-based intervention for the empowerment of Malian females in the decision to disclose (or not) their HIV status (ANRS-12373 Gundo-So)

L. Sagaon-Teyssier^{1,2}, B. Coulibaly², L. Riegel³, V. Villes³, D. Traoré², B. Spire¹, M. Mora¹, M. Perray⁴, G. Maradan¹, M. Fiorentino¹, B. Dembele Keita², M. Bourrelly^{1,3}, R. Delabre³, D. Rojas Castro³, A. Yattassaye², M. Préau⁴
¹Aix Marseille Univ, Inserm, Ird, Sessstim, Isspam, Marseille, France, ²Arcad Santé Plus, Bamako, Mali, ³Community-based Research Laboratory, Coalition PLUS, Pantin, France, ⁴Umr 1296, Université Lyon 2, Lyon, France

Background: In Mali, women living with HIV (WLHIV) who disclose their positive status are often confronted with stigma, violence, economic pressure, and social exclusion, including from family. We aimed to evaluate the effectiveness of an intervention for the empowerment of WLHIV on the decision to disclose or not their HIV-positive status, and associated factors.

Methods: ANRS-12373/Gundo-So (Chamber of Secrets in Bambara) was implemented in 6 community-based clinics in Mali in 2019/2020. The intervention consisted of 9 weekly sessions of peer-support for strengthening the capacity of WLHIV to manage the consequences concerning (non)disclosure of their HIV-positive status. Individual and psychosocial characteristics were collected at enrolment, pre-/post-intervention, then quarterly over 9 months.

Effectiveness was evaluated using a scale measuring the psychological burden related to the sero-status secret from 0 (none) to 5 (very high). A growth curve model using Poisson distribution was estimated to investigate changes before (=0) and after the intervention (=1).

Random-effects allowed controlling for unobserved/unobservable characteristics. This technique accounts for missing data and unequally spaced time points.

Results: Among 240 WLHIV enrolled, 222 (92.5%) and 146 (60.8%) responded to the pre-/post-intervention questionnaires respectively. Then, 139 (58.0%) continued follow-up at M3, and 136 (56.6%) at both M6 and M9. Analyses were carried out over the 1019 observations.

At baseline, median age[IQR] was 33[28-39] years, 76.7% of participants did not have any education level/low-level. The psychological burden of sero-status secret was self-evaluated ≤ 1 by 50% of participants, whereas it was ≥ 4 for 23%. Estimations without confounders showed that the psychological burden decreased on average by 42% after the intervention (IRR:0.58, 95%CI[0.46-0.61]).

Including covariates showed that the psychological burden decreases with age (IRR:0.98, 95%CI[0.97-0.99]), easy ARV uptake (IRR:0.81, 95%CI[0.68-0.97]), and absence of loneliness (IRR:0.83, 95%CI[0.71-0.96]).

The intervention effectiveness persisted after including covariates. The psychological burden decreased of 44% after the intervention (IRR:0.56, 95%CI[0.48-0.65]).

Conclusions: Our results have demonstrated that the Gundo-So intervention was effective for the empowerment of Malian WLHIV to reduce the psychological burden of HIV disclosure-related issues. Social and behavioral interventions adopting a community-based approach can effectively promote health outcomes among people confronted to sociocultural hostile environments such as Mali.

TUPED10

Introducing the DOME model as a community 'one-stop' shop focusing on key populations in Ho Chi Minh City, Vietnam

T.N Nguyen¹, R. Frescas¹, L.X Hang¹, L.T Nguyen¹, K.H Chung¹, H.H Mai¹, T.M Le², S.H. Pham³, T.M Nguyen⁴, L. Sa⁵, K.Q Do⁶, T.N Nguyen⁷, A.V Tran⁸, S.H. Pham⁹

¹Centre for Promotion of Quality of Life, Ho Chi Minh City, Vietnam, ²GLink DOME, Ho Chi Minh City, Vietnam, ³G3VN DOME, Ho Chi Minh City, Vietnam, ⁴Alo Boy DOME, Ho Chi Minh City, Vietnam, ⁵MforM DOME, Ho Chi Minh City, Vietnam, ⁶Galant DOME, Ho Chi Minh City, Vietnam, ⁷Gia Toc Rong DOME, Ho Chi Minh City, Vietnam, ⁸FGG DOME, Ho Chi Minh City, Vietnam, ⁹The Moon DOME, Ho Chi Minh City, Vietnam

Background: HIV services are just a part of the health care needs for vulnerable populations. In Vietnam, work has been done to expand services among community-based organizations (CBOs) and social enterprises (SEs) providing HIV serves to better address these broader health care needs. The DOME model attempts to provide community-based services to augment the clinical care provided by public or private clinics/hospitals.

Description: The DOME model was co-developed with input from CBOs and SEs in Ho Chi Minh City, who serve the key populations. The initiative launched officially September 2022 with 6 organizations enlisting.

In addition to HIV testing and linkage services, DOMEs also provide key populations with a standardized, yet tailored, set of services which may include screening, rapid testing, counseling and referral for STIs, Tuberculosis, hepatitis, mental health, substance abuse, and other primary care augmentation services. The model also incorporates support for business development for sustainability, branding and seed funding to support transition.

Lessons learned: Since the launch, the number of DOMEs has increased from 6 to 10. DOMEs have completed 5 finance and administration training, reviewed the business models and reassessing their revenue streams and connected with a mentor to coach them on finance and business management. Through January 30, 2023, DOMEs have received 10,098 clients, identified 706 new cases of HIV and enrolling 1,509 on PrEP. Additionally, DOMEs providing STI screening have tested 2,265 clients and referring 83 of those for treatment for either syphilis, chlamydia and Hepatitis B/C, others will be added in the coming months.

Conclusions/Next steps: Although this model is only in its first year, it has already garnered significant interest from other CBOs, and also gotten the support and attention of the Vietnam Administration for AIDS Control/Ministry of Health as a promising model to sustain the community's contribution to the public health response.

The model will continue to be evaluated for its acceptability, performance, quality, efficacy and efficiency as the approach matures to other services and builds the business capacity of community organizations.

TUPED11

How to reach left-behind Key Population Subcommunities to end the world's fastest growing HIV epidemic in Eastern Europe and Central Asia: lessons learned for funders and implementers

J. Rashbass¹

¹Elton John AIDS Foundation, London, United Kingdom

Background: Eastern Europe and Central Asia (EECA) has the world's fastest growing HIV epidemic. From 2010-2021, new HIV transmissions increased by 48% and AIDS-related deaths increased by 32%, whilst decreasing globally. Only 63% of PLHIV know their status, 51% are on ART, and 48% are virally suppressed.

The war in Ukraine has compounded this with a humanitarian crisis, with devastating impact on key populations (KPs) and PLHIV.

Description: Elton John AIDS Foundation is now the largest philanthropic HIV donor in EECA (FCAA). To turn the tide on HIV in the region, from 2020-2023 the Foundation has prioritised innovative community-led approaches to reach KP communities that have been historically left behind from the HIV response such as: KP migrants, KPs outside urban centres, KPs using new psychoactive substances (NPS), and PLHIV lost to follow-up (LTFU).

These groups' access to HIV services is impeded by neglect, criminalisation, lack of resources, and stigma and discrimination.

Lessons learned: Reaching left-behind communities is proving programmatically effective. For example: 13% of 2,500 KP migrants from Central Asia tested for HIV in our programmes have tested positive, indicating the vulnerability of this group and the importance of developing client-centred models that meet their needs; partners have also established new mechanisms that allow migrants to remotely initiate and receive ART from their home countries, which boosts initiation and retention rates. Person-centred approaches have (re-)initiated 9,773 LTFU PLHIV on ART. Approaches to decentralise state and community-led HIV services outside urban centres (where the majority of PLHIV and KPs reside in some EECA settings) has boosted HIV testing yields and ART uptake.

To engage NPS users, the Foundation is supporting online outreach, HIV prevention and incentive packages, remote self-testing and counseling, with encouraging early re-

sults. All Foundation-supported projects include activities to reduce stigma and discrimination towards KPs and PL-HIV in order to tackle systemic barriers. Including humanitarian services has been vital for maintaining HIV services in Ukraine.

Conclusions/Next steps: If the EECA HIV epidemic continues to grow, we will not achieve SDG3 of ending AIDS by 2030.

Further local government and international funding is needed to scale up evidence-informed approaches that successfully engage left-behind communities in EECA into HIV services.

Canada, ⁶St. Michael's Hospital, Unity Health Toronto,

Department of Medicine, Toronto, Canada

Background: Sexual orientation disclosure is an obstacle to accessing primary care among gay, bisexual and other men who have sex with men (gbMSM). We explored gbMSM preferences regarding hypothetical interventions for supporting disclosure to providers.

Methods: We recruited Ontario gbMSM (18+ years) from sexual networking applications and community-based organizations for a cross-sectional survey. A community advisory board assisted in conceiving ten potential interventions. Participants reported why they found each acceptable or unacceptable in open-ended textboxes.

Two authors coded responses independently and used content analysis to identify themes for positive opinions, negative opinions, suggestions for implementation and unrelated; discrepancies were resolved by discussion or a third author. We summarized themes from interventions with the most and least positive opinions.

Results: Of 404 gbMSM, most were White (59%) and gay (82%). Mean age was 39 (SD=12) years. We generated 378 unique codes from 1592 responses across all interventions. Seven interventions garnered mostly positive opinions (Figure 1).

The intervention with the most positive opinions (80%) was a directory of queer-friendly providers; themes suggested it could improve interpersonal experiences with providers and provide better overall healthcare (Figure 2).

The intervention with the most negative opinions (70%) was a performance-based incentive program; themes suggested it could cause clients to doubt their providers' intentions when seeking care and could result in negative consequences for clients.

Figure 1.

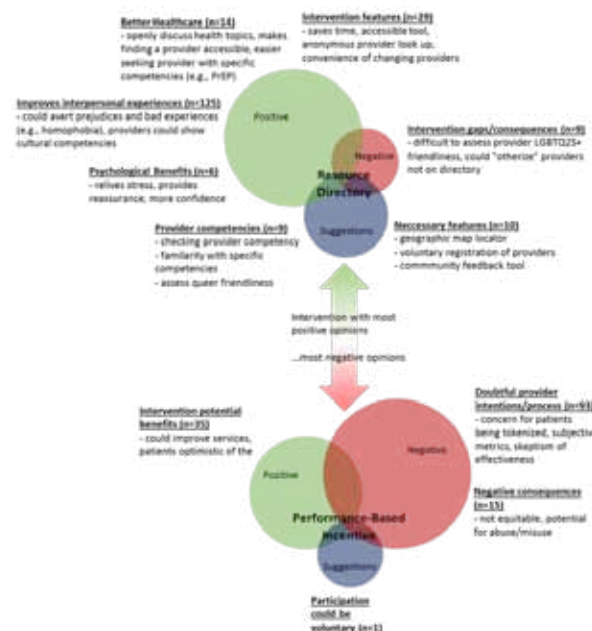

Figure 2.

Conclusions: Based on gbMSM's preferences, priority interventions are resource directories, promoting LGBTQ2S+ visibility, and further LGBTQ2S+ medical curriculum. Community-oriented implementation strategies should anticipate psychological and interpersonal benefits in supporting disclosure.

**TUPED13****"Door to door would be the best way": a qualitative analysis of peer delivered combination prevention for transgender women in Uganda**

J. Mugisha¹, A. Nakyanzi¹, M. Wyatt², N. Ware³, R. Nsubuga¹, T. Muwonge¹, J. Haberer⁴, A. Mujugira⁵

¹Infectious Diseases Institute, Makerere University, Research, Kampala, Uganda, ²Harvard Medical School, Harvard Global, Cambridge, Research, Boston, United States, ³Harvard Medical School, Research, Boston, United States, ⁴Massachusetts General Hospital, Research, Boston, United States, ⁵Infectious Diseases Institute, Makerere University, Kampala, Uganda, University of Washington, Seattle, Research, Kampala, Uganda

Background: Transgender women (TGW) have high HIV risk but low engagement in care. Peer delivery is an effective strategy for increasing HIV and sexually transmitted infection (STI) testing, but it has not been evaluated for TGW in Uganda.

Methods: We conducted formative research for a randomized trial of peer delivered HIV self-testing (HIVST), STI self-sampling and oral pre-exposure prophylaxis (PrEP) for TGW in Uganda (NCT04328025) between October 2019 and April 2020.

Twenty in-depth interviews with TGW peers explored:

- Barriers and facilitators of peer delivered combination HIV prevention, and;
- Preferences for HIV/STI testing approaches and PrEP refills.

Interviews were conducted in Luganda (local language) at a location convenient for the interviewee. They were audio recorded and transcribed verbatim to English by the interviewer.

We used an inductive content analytic approach centering on descriptive category development to analyze the data and identify themes representing TGW preferences for HIV prevention delivery.

Results: Four key themes that explain TGW preferences within a peer delivery system emerged from the qualitative data:

- Peer training.** TGW peers needed to be knowledgeable about the use and interpretation of HIV self-tests, PrEP adherence counseling and the correct way to self-collect samples for STI testing;
- Confidentiality.** Trust in peers to keep personal health information private was essential for successful delivery of HIV self-tests and PrEP refills, and for returning self-collected STI samples for laboratory testing;
- Trans-friendly care.** TGW peers and transgender-led drop-in-centers were perceived to be the most effective ways of distributing HIVST and PrEP refills and improving access to STI testing;
- Stigma reduction.** Peer delivered HIV services were seen as desirable because they would enable TGW to avoid stigma and discrimination experienced at health facilities from providers and other clients.

Overall, the desired peer attributes for facilitating HIV/STI testing and PrEP use were confidentiality, trustworthiness, and practical knowledge of biomedical HIV prevention tools.

Conclusions: Peer delivery and trans-friendly care may help to overcome barriers to HIV/STI testing and PrEP use among TGW. Community-based strategies such as peer delivery and drop-in-centers may improve testing and PrEP outcomes and decrease HIV burden in this population.

TUPED14**Interventions Targeted to Increase or Maintain Viral Suppression after Incarceration: A Systematic Review**

S. Prakot^{1,2}, S. Inwanna^{1,2}

¹University of Illinois Chicago, College of Nursing, Chicago, United States, ²Mahidol University, Ramathibodi School of Nursing, Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand

Background: Transition from incarceration to the community is a crucial phase, and an individual's transition experience can impact HIV treatment outcomes such as viral load, risk of HIV complications, and viral suppression. The purpose of this study was to systematically review publications describing interventions intended to improve or maintain HIV viral suppression among individuals released from prison or jail.

Methods: The systematic review followed PRISMA guidelines, and we searched for relevant publications in PubMed, CINAHL, PsycINFO, EMBASE, and Google Scholar.

We systematically screened intervention studies published through 2022 and then performed a narrative synthesis to organize and discuss the study findings. Eligible studies reported HIV viral suppression or viral load in formerly incarcerated individuals as an outcome.

Studies were excluded if they targeted only the incarceration phase or if the full article text was not available in English.

Results: A total of 753 articles were identified, and four eligible articles were included in the final review. Using Cochrane Collaboration's tool, three studies were rated as having a low risk of bias and one as having a high risk of bias; due to the small number of eligible studies, the latter was nonetheless included in the review.

All four studies were longitudinal randomized controlled trials and were conducted in the United States between 2017 and 2019.

Across the studies, viral suppression ranged from 30% to 61% at the end of follow-up. We categorized the interventions identified into two groups: behavioral and pharmacological interventions.

Only a peer-based behavioral intervention called the LINK LA peer navigation intervention showed statistically significant maintenance of viral suppression at 12-month follow-up ($p = 0.03$).

Moreover, half the reviewed studies reported a high attrition rate and a smaller sample size than originally planned.

Conclusions: This review revealed a limited number of existing studies in the area of interest and highlighted the need for more research in all parts of the world. Based on the data available in the reviewed studies, our preliminary conclusion is that peer-based behavioral interventions are the optimal choice for maintaining or improving viral suppression in the vulnerable population of individuals newly released from prison or jail.

TUPED15

Revolution of Transgender health programming: the role of transgender activists in Health programming for Malawi

P. Mikel Juao¹, L. Chipili¹

¹Lesbian Intersex Transgender and other Extensions, Programms, Lilongwe, Malawi

Background: Lesbian Intersex Transgender and other Extension (LITE) is a peer led organization that was formed in 2016 but officially got registered in 2018. The organization started as a support group to provide psychosocial support to one another.

In 2017, LITE conducted a series of community dialogues, consultative meetings and needs assessments with various stakeholders to give community members an opportunity to meaningfully contribute towards LGBTI Programming in Malawi, collect data and views to inform programming for community led organizations and ensure that individuals are considering self-security and also prevention of HIV/AIDS.

Description: Transgender persons have at least experience violence in the hospital when accessing health services. The highest ranking of perpetrators being the health personnel, transgender persons have been denied health services, chased away from the hospital only to be taught to come dressed in conforming clothes.

Those who have resisted the nurses are regarded as impersonators and they call police on them, who arrest them for impersonating. We used the health for all, human rights centered approach to advocate for Transgender health programming.

Lessons learned: Through resilient advocacy, LITE organization has successfully amplified the livelihood of Transgender persons in Malawi. The organization through its transition from a support group to an established organization has also transitioned with them the Transgender Health programming especially in ensuring that Transgender persons are able to access HIV services. We contributed towards the development of a minimum standard package for Transgender person which was developed in collaboration with National Aids Commission.

We facilitated the implementation of the transgender formative study conducted and successfully advocated for the inclusion Transgender persons in the Nation-

al Strategic Plan for HIV response for Malawi. In 2020, through the Key Population Investment Fund, LITE started to implement HIV programming for Malawi.

Conclusions/Next steps: Peer based approaches have been influential in informing transgender health programming in Malawi. Using lived realities, personal experience and shared stories we have managed to set a benchmark for transgender health programming in Malawi. However, no established epidemic patterns due to lack of population studies for transgender. As such, we are advocating for a national population size estimate study.

TUPED16

Vicarious trauma among health care workers serving GBV survivors. Case Busia County, Kenya

H. Mulebo¹, E. Apondi¹

¹MTRH, Eldoret, Kenya

Background: Vicarious trauma is the result of being exposed to and empathically listening to stories of trauma, suffering, and violence caused by humans to other humans (Pearlman and Saakvitne 1995). Described as the cumulative effect of working with traumatized individuals, such as survivors of violence, that can transform and interfere with a provider's feelings, memories, sense of safety, and self-esteem (McCann and Pearlman 1990; Pearlman and Saakvitne 1995; Hernandez, Gangsei et al. 2007). A provider's trauma response may become more severe with repeated exposure to traumatic material, such as a provider responding to survivors' experiences of violence and delivering first-line support.

The objective of the study is to determine the prevalence of vicarious trauma and the general state of mental health for healthcare workers.

Methods: The study population included healthcare workers within Busia County serving the survivors of GBV. A survey was administered through Kobo collect App to the healthcare workers serving survivors of GBV. These healthcare workers include clinical officers, nurses, counselors, and social workers. The survey was administered from 30th November 2022 to 13th January 2023.

Results: The respondents were 25 health care workers (N=25, Male, 8(32%) and Female 17(68%) with majority of the respondents aged between 31-35years (40%).

Clinical officers are the majority (48%) health care workers serving GBV survivors. Using the crisis & Trauma resource institute INC scale, 80% of the respondents are highly affected by vicarious trauma while with compassionate fatigue 48% are highly affected and 40% by moderate effect.

Conclusions: Vicarious trauma, compassion fatigue, and burnout can result in decreased morale among staff; lack of team cohesion; poor communication within an organization; decreased collaboration; and delivery of poor-quality services. There may be high levels of staff turnover within sites and organizations that do not provide mental health and psychosocial support for staff.

Labor Market Assessment: unpacking opportunities for Determined, Resilient, Empowered, AIDS free, Mentored and Safe program beneficiaries in ever-changing contexts in Zimbabwe, 2022

R. Makandwa¹, T. Galloway², F. Mudzengerere³, T.A Tapfuma⁴, E. Tachiwenyika³, D. Dhakwa⁴, F. Mudokwani⁴, B. Nyamwanza⁵, B. Madzima⁵, R. Yekeye⁵, A. Muchedzi⁴, H.W. Mafaune⁴, K.E. Ndwana⁶

¹FHI360, Program, Harare, Zimbabwe, ²FHI360, Working & Learnings, Washington DC, United States, ³Zimbabwe Health Interventions, Knowledge Management, Harare, Zimbabwe, ⁴Zimbabwe Health Interventions, Senior Management, Harare, Zimbabwe, ⁵National Aids Council (NAC), Programs, Harare, Zimbabwe, ⁶Zimbabwe Health Interventions, Programs, Harare, Zimbabwe

Background: Major factors which contribute to increased susceptibility of adolescent girls and young women (AGYW) to HIV infection include lack of education, economic dependence, gender-based violence (GBV), high rates of unemployment and underemployment, leading to high-risk sexual behaviours and early marriages. Economic strengthening and linkages to wage employment and income-generating activities for AGYW is key in disrupting HIV causal pathways.

There was paucity of data on sectors and entry points occupation with potential to grow and create opportunities for AGYW across districts implementing the Determined, Resilient, Empowered, AIDS free, Mentored and Safe (DREAMS) program in Zimbabwe.

Methods: We conducted a qualitative, descriptive cross-sectional labour market assessment (LMA) across 9 districts implementing DREAMS program to understand sectors and entry points occupation with potential to grow and create opportunities for AGYW.

Study participants were purposively selected and consisted of district economists, government stakeholders, non-governmental organizations (NGOs), training institutions and employers.

Data were collected using key informant interview guide in English, Shona, or Ndebele, audio recorded and transcribed in English. Line-by-line coding was conducted, and content analysis and constant comparison were used to identify key themes for each respondent type using NVivo.

Results: Retailing was a common sector selected as the growth sector for both rural and urban opportunities for AGYW; the sector was reportedly adaptable to prevailing operating conditions. Common sectors for urban areas were on the service side including catering, tailoring, construction, welding, and carpentry and for rural areas were

agro-based including poultry, crop production and agro-processing. Opportunities and entry points for AGYW per value chain differed within districts depending on whether they are formal or informal businesses.

There was limited engagement between the private sector and training institutions resulting in mismatch of expectations of the private sector and graduates released into the market.

Conclusions: Economic environment is constantly changing, hence the need to conduct regular LMA and value chain analysis to empower AGYW with relevant skills required in the growth sectors. This will increase AGYW's enterprises sustainability and access to employment which reduce chances of AGYW engaging in sexual behaviors which place them at risk of HIV infection.

TUPED18

Using comprehensive sexuality education to enhance uptake of HIV testing among adolescents and young people in secondary schools

G. Owuor¹, I. Wango¹, M. Ochillo¹, E. Bukusi², K. Agot¹

¹Impact Research and Development Organization, Kisumu, Kenya, ²Kenya Medical Research Institute, Nairobi, Kenya

Background: Adolescents and young people (AYP) aged 15-24 years in Kenya are disproportionately affected by HIV, yet in 2018, knowledge of HIV status was only 49.8% and in 2022, correct HIV knowledge on HIV prevention stood at 54.2%. Comprehensive sexuality education (CSE) can increase HIV testing. We piloted CSE among school-going AYP to promote uptake of HIV testing services (HTS) and STI screening.

Methods: We conducted a cluster randomized-control trial with HTS uptake as the main outcome. Six secondary schools were paired based on type (girls, boys and mixed) and one in each pair randomly assigned to intervention (CSE) or control. Data were collected on HIV risk perception, sexual behaviors and self-efficacy towards abstinence. Intervention students were taken through 12 peer-led CSE sessions implemented over a 6-month period. Control students continued with the life skills curriculum offered in schools.

All participants were asked to anonymously list the services they required. After the intervention, HTS counselors and clinicians were engaged to provide services in schools.

Results: We enrolled 293 students from 6 schools (148 in intervention and 145 in control); mean age was 17 years, 51.5% were female, 83.9% were single and 73.7% were Christian. Altogether, 66.9% requested for HTS services, 10.6% for STI services, and 27.7% for SRH information. Requests for HTS, STI and SRH information was higher in the intervention arm at 12.3%, 3.2% and 20.6%, respectively, than control.

Services have been offered for 47 students in one intervention school: 25 requested for HTS and 23 received the services, 3 requested for STI management and 4 received

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

(1 additional), and 19 requested for SRH information and 22 received (3 additional). The impact of the intervention on service uptake will be determined once service provision is complete in all schools in February/March 2023, and will be reported at the conference.

Conclusions: CSE led to high request for HTS services, and as demonstrated by one school where services have been offered, uptake is over 95% of the requests.

The life skills curriculum in Kenya should be expanded to include CSE to increase correct HIV knowledge and improve service uptake.

TUPED19

Prevalence and Determinants of GBV among adolescent girls and young women (AGYW) enrolled in a Determined, Resilient, Empowered, AIDS-free, Mentored and Safe (DREAMS) program at a military facility in Uganda

M. Ssemmanda¹, D. Bwayo¹, H. Tibihenda², G. Arinaitwe³, E. Asimwe³, J. Ngabirwe¹, A. Tumusiime¹, T. Rwegyema¹, A. Nyanzi¹, B. Turresson⁴

¹University Research CO., LLC, DOD Uganda URC Project, Kampala, Uganda, ²US Embassy, Department of Defense, Kampala, Uganda, ³Uganda Peoples' Defense Forces, Directorate of HIV, Bombo, Uganda, ⁴University Research CO., LLC, Center for Technical Excellency, Chevy Chase, United States

Background: The prevalence of HIV among young people in Uganda is three times higher among women compared to men. Harmful cultural practices such as child marriages subject women to unequal treatment and make them prone to sexual and gender-based violence (GBV) which increases their risk acquisition of HIV.

We describe the prevalence, type of GBV and support offered to GBV survivors among the AGYW from military barracks and surrounding communities enrolled in the DREAMS program at a military facility in Uganda.

Methods: We conducted a retrospective data analysis of the AGYW enrolled in the DREAMS program at a Ugandan military facility between October 2021 and Sept 2022 using a standard Ministry of Health tool for GBV. Survivors were linked to support services for GBV. Descriptive statistics were applied to determine the prevalence and types of GBV. Multivariable analysis with Odds Ratios (OR), a 95% CI using the Fisher's exact test was used to determine the factors associated with GBV.

Results: 1,832 AGYW were enrolled and screened for GBV. The prevalence of GBV was 29% (538/1832). The prevalence was highest among the AGYW aged 15-19 years at 43.7% (95% CI: 38.4-49.0) followed by those in the 20-24 years age band at 28% (95% CI: 24.7-31.6) and 25% (95% CI: 21.7-27.6) for the 10-14 years age band.

All survivors reported emotional or psychological abuse, while 15% reported physical GBV and 7% reported sexual GBV. The factors associated with GBV among the AGYW included being out of school (OR 1.48 [1.21, 1.83]), being

married increased odds of GBV by 35% (OR 1.35[1.047, 1.735]), being an orphan increased odds of GBV by 84% (OR 1.84 [1.116, 3.007]) and giving birth before the age of 15 years had a 41%, (OR 1.41 [1.252, 1.588]) higher likelihood of experiencing GBV.

Conclusions: GBV was highly prevalent among the AGYW who are out of school, orphaned and those in early marriages. Mitigation will require a targeted multi-sectoral approach that ensures AGYW enrolment and retention in school, prevention of childhood marriages as well as strengthening the policy environment addressing GBV to contribute to reduction of HIV acquisition and achieve HIV epidemic control.

TUPED20

Gay and bisexual men not on PrEP in Australia are increasingly choosing sexual partners based on their partner's PrEP use and viral load

C. Chan¹, M. Holt², J. MacGibbon², T.R Broady², L. Mao², J. Rule³, H. Paynter⁴, B.R Bavinton¹

¹Kirby Institute, UNSW Sydney, Sydney, Australia, ²Centre for Social Research in Health, UNSW Sydney, Sydney, Australia, ³National Association of People With HIV Australia, Sydney, Australia, ⁴Australian Federation of AIDS Organisations, Sydney, Australia

Background: HIV pre-exposure prophylaxis (PrEP) and viral suppression have changed the sexual practices of gay, bisexual, and other men who have sex with men (GBMSM). However, there is currently little evidence about whether GBMSM in Australia rely on their perceived partners' PrEP use ("PrEP sorting") or viral load status ("VL sorting") to prevent HIV acquisition. We therefore assessed trends in PrEP and VL sorting among GBMSM in Australia.

Methods: We analysed national data from repeated behavioural surveillance surveys of GBMSM at venues, events and online collected during 2017-2021. We used logistic regression to assess trends in PrEP sorting and VL sorting among participants who reported condomless anal intercourse with casual partners in the last 6 months and were not on PrEP.

Results: Among the 5435 surveys included of non-HIV-positive participants not on PrEP, 2682 (53.3%) reported PrEP sorting in the last 6 months, 1096 (22.3%) reported VL sorting, and 2568 (47.3%) reported neither PrEP nor VL sorting. PrEP sorting increased from 44.3% in 2017 to 63.0% in 2021 (OR=1.18, 95%CI=1.13-1.23), and VL sorting increased from 21.2% in 2017 to 27.7% in 2021 (OR=1.08, 95%CI=1.03-1.13). PrEP sorting was positively associated with having a university education (aOR=1.19, 95%CI=1.06-1.34), having 11 or more sexual partners in the last 6 months (aOR=1.44, 95%CI=1.26-1.65), having been tested for HIV in the last year (aOR=2.16, 95%CI=1.87-2.49) and having an STI in the last year (aOR=1.24, 95%CI=1.08-1.43).

VL sorting was positively associated with age (aOR=1.02, 95%CI=1.00-1.02), having 11 or more sexual partners in the last 6 months (aOR=1.62, 95%CI=1.40-1.89), having been

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

tested for HIV in the last year ($\alpha\text{OR}=1.41$, $95\%\text{CI}=1.18-1.70$) and having an STI in the last year ($\alpha\text{OR}=1.29$, $95\%\text{CI}=1.10-1.52$).

Conclusions: There has been an increasing reliance among non-HIV-positive GBMSM not on PrEP to depend on their partners' PrEP use or viral load status to prevent HIV. This group may benefit from adopting an individual prevention strategy, such as PrEP or condoms, rather than relying on their perception of their partners' PrEP use or viral load to prevent HIV. The changing sexual norms of GBMSM in Australia in the context of PrEP should continue to be monitored.

Mobilising a rapid and comprehensive community-led response to MPOX: lessons from the RESPND-MI study team

K. Makofane^{1,2}, J. Barnes-Balenciaga^{1,3}, P.B. Carneiro^{1,4}, N. Diamond¹, D. Kunichoff^{1,2}, E. Lett^{1,5,6}, K.M. Maloney^{1,7}, K.H. Mayer^{1,8,9}, C. McCombs^{1,10}, R. Pitts¹, G. Roth¹, M. Smith^{1,11}, N. Tran^{1,12}

¹RESPND-MI Study Team, New York City, United States,

²Harvard University, FXB Center for Health and Human Rights, Boston, United States, ³Crystal La'Beija Organizing Fellowship, KBCAN, New York City, United States, ⁴City University of New York, School of Public Health, New York City, United States, ⁵Boston Children's Hospital,

Computational Health Informatics, Boston, United States, ⁶University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States, ⁷Georgia State University,

Atlanta, United States, ⁸The Fenway Institute, Boston, United States, ⁹Harvard University, Harvard Medical School, Boston, United States, ¹⁰Boston University, School of Public Health, Boston, United States, ¹¹Rochester University,

School of Nursing, Rochester, United States, ¹²Stanford University, School of Medicine, Stanford, United States

Background: Early mpox responses by U.S. public health agencies (PHAs) failed to provide timely vaccination, testing, treatment, and educational materials to the public. Consequently, information about the outbreak, exclusively based on testing data, was unreliable. The RESPND-MI study team (RST) was established to gather actionable data on the social and spatial epidemiology of mpox in New York City (NYC).

Description: RST consists of 19 scholar-activists. Starting in May 2022, we prepared a study about sexual activity and mpox symptoms among those most vulnerable to mpox. To promote collective decision making, we organised an online community forum (CF). In the first CF, attendees expressed the need for a space to continually coordinate response efforts across organisations, and to address gaps not immediately met by local and federal public health agencies.

CFs thus became weekly calls where participants received epidemiologic updates, discussed problems, and provided input on study design and marketing decisions. From

June to September 2022, over 80 activists, community leaders, public health professionals participated in CFs. We produced policy briefs, op-eds, and educational materials; and conducted media outreach. The RST website became a clearing house for community-generated resources, as well as community-generated information on vaccination, testing, and treatment services.

Educational materials and policy recommendations from the CF were adopted by city, state, and federal PHAs. Reporters cited the RST in over 90 press clips. Survey data were used to inform NYC vaccination outreach services.

Lessons learned: Community-led research efforts can provide useful data in the context of public health emergencies. Consulting diverse stakeholders can improve data quality; whereas the RST initially planned to disseminate an English-only survey for gay and bisexual cis-gender men, CF participants successfully advocated to include trans individuals and to add a Spanish version.

Conclusions/Next steps: Structured community engagement can facilitate comprehensive responses to novel public health threats. Facilitating spaces for community members to discuss challenges can yield creative solutions that tackle multiple aspects of an emergency, identifying otherwise obscured problems and exploiting the collective strengths of all organisations and individuals in the coalition. To prepare for future outbreaks, PHAs should invest resources in platforms that enable such engagement.

TUPED22

Implementing a digital platform to fight against COVID-19 in primary care units in Brazil: lessons learned for future pandemics

T. Aranha Rossi¹, L. Magno¹, F. Soares², C.J.d.M. Santos², T. Torres³, D. Castanheira³, C.P.d.C. Garcia¹, I.C. Neves-Ramos⁴, T.S. Santos¹, I. Dourado², V. Veloso³, TQT study group

¹State University of Bahia, Salvador, Brazil, ²Federal University of Bahia, Salvador, Brazil, ³Oswaldo Cruz Foundation, National Institute of Infectious Diseases Evandro Chagas, Rio de Janeiro, Brazil, ⁴Federal University of Bahia, Collective Health Institute, Salvador, Brazil

Background: The COVID-19 (C19) pandemic affected the health, political, social, and economic sector around the world. Digital technologies with different functionalities have been widely used during the pandemic.

We aimed to describe the online digital platform based on surveillance and articulation with primary health care services (PHCS) in two Brazilian capitals.

Description: This is a case study of the digital platform implemented to expand testing, isolation, quarantine, and telemonitoring strategies for C19.

This qualitative and analytical approach design was carried out in nine PHCS in Salvador, Northeast Brazil. We conducted fifty-two interviews with health professionals,

Oral
abstracts

Poster
exhibition

E-posters

Late-breaker
abstracts

Author
Index

health managers, and community-based health agents. Interviews were analyzed according to thematic content analysis.

Lessons learned: The digital platform consists of a real-time health situation panel, participants registration modules, t-monitoring of people diagnosed with C19, contact tracking, testing and laboratory by type of test, reports with results, logistics, and database, plus a chatbot that interacted with the community sending messages of prevention, health education, testing, and tests results. The platform was developed based on formative research that sought to know the situation regarding coping with the pandemic by PHCS. It was observed that the platform enabled the fieldwork to articulate PHCS and surveillance in response to the pandemic. Managers reported that the system allowed more effective management and visibility of the actions in their services to plan the activities. Health professionals narrated that it was possible to perform and manage the surveillance steps of tracking and active search after implementing the platform. On the other hand, community-based agents highlighted the importance of real-time geospatial visualization of activities conducted in their territories, allowing the identification of C19 hotspots to articulate targeted individual and collective prevention and testing actions. The main difficulties were related to the internet's physical structure.

Conclusions/Next steps: We showed the successful implementation of a digital platform and its contributions to coping with C19 in PHCS. Furthermore, local health departments can expand the platform to monitor other diseases.

TUPED23

COVID-19 associated psychosocial outcomes among Black women with HIV affected by interpersonal violence participating in an mHealth HIV intervention in California, USA

D.M. Campbell^{1,2}, K. Tsuyuki¹, K. Anderson¹, K. Horvath³, J.K. Stockman¹

¹University of California, San Diego, La Jolla, United States,

²Charles R. Drew University of Medicine and Science, Los Angeles, United States, ³San Diego State University, San Diego, United States

Background: The COVID-19 pandemic has had immeasurable negative effects on the health and wellness of people living with HIV, including mental health disorders while disrupting sustained engagement in care. Black women living with HIV experience great socio-structural burden that was likely exacerbated by the pandemic. We provide a snapshot of how the COVID-19 pandemic affected the socio-structural, healthcare, and mental health of Black women living with HIV.

Methods: We analyzed baseline cross-sectional survey data of women (n=24) participating in the *LinkPositively* Study. *LinkPositively* is a trauma-informed mHealth inter-

vention to improve HIV care among Black women living with HIV affected by interpersonal violence residing in Alameda, Los Angeles, and San Diego counties in California – priority jurisdictions for the U.S. Ending the HIV Epidemic Initiative. Descriptive analyses were conducted using frequencies and percentages for categorical variables and medians and interquartile ranges for continuous variables.

Results: Descriptive statistics: Women were highly educated (67% had completed some college, vocational school or more); identified as heterosexual (75%), were not partnered (83%), and were unemployed (67%). Women had been diagnosed with HIV for an average of 17 years. Women reported the following impacts of the COVID-19 pandemic in the past 6 months:

Socioeconomic considerations: 42% of women reported experiencing food insecurity and 38% reported a loss of income or employment.

Care: 29% of women felt less connected with HIV care, and 21% felt less connected to support services (e.g., mental health, domestic violence, substance use).

Mental Health: Overall, 38% of women reported COVID-19 specific PTSD symptoms in the past six months. Specifically, half of participants felt numb or detached from people, activities, or their surroundings. 29% of women reported trying hard not to think about COVID-19 or going out of their way to avoid situations that reminded them of COVID-19 and 38% reported being constantly on guard, watchful, or easily startled because of COVID-19.

Conclusions: Culturally-tailored resources are needed to mitigate the effects of the COVID-19 pandemic on psychosocial outcomes among Black women living with HIV, who are already disproportionately affected by socio-structural burdens, trauma, lack of sustained engagement in HIV care, and adverse mental health outcomes.

TUPED24

Intimate partner violence among couples living with HIV during the COVID-19 pandemic in Nigeria

Z. Iliyasu¹, F. Tsiga-Ahmed¹, U. Gambo¹, A. Kwaku¹, N. Nass¹, T. Amole¹, A. Umar¹, H. Abdullahi¹, H. Salihu², M. Aliyu³

¹Bayero University/Aminu Kano Teaching Hospital, Community Medicine, Kano, Nigeria, ²Kano Independent Research Centre Trust, Kano, Nigeria, ³Vanderbilt University Medical Center, Vanderbilt Institute for Global Health, Nashville, United States

Background: There is substantial overlap between intimate partner violence (IPV) and HIV in Africa. The influence of COVID-19 measures on IPV among couples affected with HIV is not well documented. We assessed the magnitude, types, and IPV experiences of couples living with HIV at a tertiary center in Nigeria, during the period of COVID-19 restrictions/lockdown.

Methods: We used a cross-sectional, explanatory mixed-methods design with systematic sampling and a validated structured questionnaire (revised conflicts tactics

scales, CTS) to survey a clinic-based sample of married persons living with HIV ($n=305$). This was followed by in-depth interviews with a purposive sub-sample of respondents ($n=20$). Data were analyzed using logistic regression and a thematic framework approach. The study was conducted in March 2022.

Results: The prevalence of IPV was 34.4% in the 12-month period that encompassed COVID-19 restrictions (30th April 2020 to 1st March 2021). This number was higher than pre-COVID reported figures from the same area (22.1%). Nearly one-half (47.5%, $n=145$) of respondents had ever-experienced at least one form of IPV. Of those who ever-experienced IPV, 136 (44.6%), 43 (14.1%), and 19 (6.2%) reported verbal, physical, and sexual coercion, respectively. IPV was more prevalent among younger (<30 years) [adjusted Odds Ratio (aOR)=1.88; 95% Confidence Interval (CI) 1.15-3.35], formally educated [aOR=2.18; 95%CI=1.15-8.53], and ethnic Fulani respondents [aOR=3.27; 95%CI=1.39-7.68]. IPV risk was also higher among educated respondents [aOR=1.46; 95%CI=1.10-7.84], employed persons [aOR=2.12; 95%CI=1.17-14.93], and those whose spouses were business women [aOR=8.12; 95%CI=1.19-72.70], or traders/farmers [aOR=13.86; 95%CI=1.64-116.77]. IPV was also at least two-fold greater [aOR=2.14; 95%CI=1.16-10.76] among cigarette smokers, alcohol, and substance users. Finally, the odds of experiencing IPV was higher among sero-concordant couples [aOR=5.05; 95%CI=1.16-26.49] and inconsistent condom users [aOR=2.97; 95%CI=1.39-6.35]. Themes indicated that IPV either preceded COVID-19 or commenced during the lockdown and was related to the partner's personality, frustrations with accessing HIV care, and COVID-19 related socioeconomic stressors.

Conclusions: The prevalence of IPV in Nigeria was high during the period that encompassed COVID-19 restrictions, and influenced by the respondent's and partner's sociodemographics, sero-discordance, lifestyle, and safe sex practices. HIV programs should include context-specific IPV prevention, screening and support in contingency plans for future pandemic situations.

Methods: The PLWH cohort was identified through phenotyping based on relevant OMOP CDM concept sets. Psychiatric disorder status was derived from ICD-10 codes during 2018 to 2021. The COVID-19 impact on psychiatric disorders was examined via 6-month interval since pandemic (March 2020) via logistic regression models with mixed effects controlling key demographics, pre-existing chronic conditions (e.g., hypertension, diabetes), COVID-19 acquisition and socioeconomic status (e.g., income, education).

Results: We identified a cohort of 7,400 PLWH, of whom 3,365 had been diagnosed with at least one psychiatric disorder (45%). Regression model analysis suggests that the COVID-19 impact on psychiatric disorders varied by the pandemic period. Specifically, the psychiatric disorder increased within period 1 (March to August 2020) ($\beta=0.170$, $P<.001$), period 2 (March 2020-February 2021) ($\beta=1.084$, $P<.001$), period 3 (March 2020-August 2021) ($\beta=2.514$, $P<.001$), but decreased during period 4 (March 2020-December 2021).

These results implied that the negative impacts of COVID-19 pandemic increased each 6-month interval till March 2021, but significantly decreased afterward. The protective factors of psychiatric disorders include being male ($\beta=-.351$, $P<.001$), being married/living with partners ($\beta=-.361$, $P<.001$), and having yearly income over \$35,000 ($\beta=-1.024$, $P<.001$). COVID-19 acquisition ($\beta=.882$, $P<.001$) as well as pre-existing conditions including disability ($\beta=.397$, $P<.01$) and chronic conditions ($\beta=1.606$, $P<.001$) are risk factors of mental health.

Conclusions: Our study highlights heterogeneous experiences of PLWH during COVID-19 pandemic by time and across various disadvantaged subgroups of PLWH.

It is important to conduct assessments and intervention for mental health needs of PLWH at the early stage of the pandemic.

Among PLWH, women, people with low-income, people with disabilities and chronic conditions face higher risk of psychiatric disorders.

TUPED25

Utilizing *All of Us* data to examine the impact of COVID-19 pandemic on mental health among people living with HIV

S. Qiao¹, J. Zhang¹, R. Cai¹, B. He¹, C. Liang¹, S. Weissman¹, X. Li¹

¹University of South Carolina, Columbia, United States

Background: The COVID-19 pandemic has negatively affected people's mental health around the globe, especially vulnerable populations including people living with HIV (PLWH). However, large-scale data on mental health outcomes among PLWH are limited. Protective and risk factors for this group are still unclear. Leveraging electronic health records (EHR) and Basics survey data from *All of Us* program, we aim to comprehensively explore psychiatric disorders among PLWH during the pandemic.

TUPED26

COVID-19-related impacts on HIV treatment support strategy implementation and access in female sex workers living with HIV in Durban, South Africa

I.M. Shaw¹, C.A. Comins¹, M. Masinga², N. Mulumba³, L. Shipp¹, O. Caceres¹, S. Makama⁴, H. Hausler^{2,5}, S. Barai¹, S.R. Schwartz¹

¹Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States,

²TB HIV Care, Cape Town, South Africa, ³TB HIV Care, Priority Populations Prevention Programme, Pietermaritzburg, South Africa, ⁴TB HIV Care, Key Populations Programme, Durban, South Africa, ⁵University of Pretoria, Pretoria, South Africa

Background: COVID-19-associated restrictions in South Africa impacted local mobility and potential access to HIV prevention and treatment services, particularly among female sex workers (FSW) who rely on outreach services. We assessed both direct and indirect COVID-19-related impacts on implementation of HIV treatment support strategies among FSW.

Methods: Siyaphambili, a randomized trial of adaptive treatment support strategies among FSW living with HIV in Durban, South Africa, was implemented within an established FSW treatment program from June 2018 – January 2022. COVID-related implications were assessed through in-depth interviews (IDIs) with cohort participants (n=36) and implementors (n=12) between March 2021-January 2022. Maximum variation sampling was used to capture a diversity of FSW experiences. COVID-19-related themes emerged based on inductive coding.

Results: Key emergent themes constituted two major, interconnected components: COVID-19-related impacts on FSW and program and trial response (Figure 1).

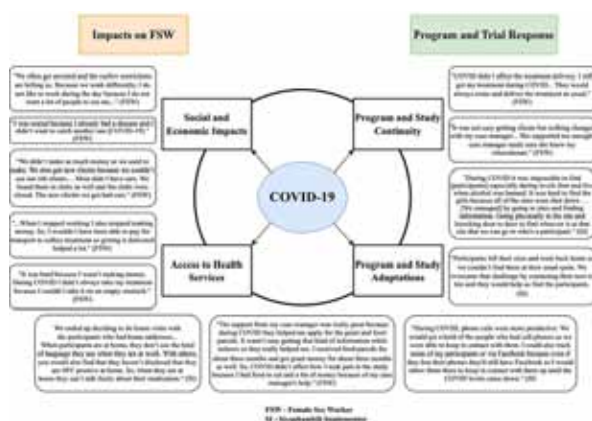

Figure 1. Framework of impacts of COVID-19 on female sex workers living with HIV, Siyaphambili study activities, and standard of care HIV services in Durban, South Africa.

Participants consistently reported adverse, complex economic and social consequences of COVID-19 lockdowns and venue shutdowns, influencing the ability to engage in sex work. These closures indirectly affected venue-based healthcare access and hindered participant en-

agement, necessitating implementor adaptations such as leveraging social networks to locate participants and bolstering social support services to alleviate pandemic-related difficulties. Nevertheless, participants and staff consistently highlighted the stable continuation of program and study activities.

Conclusions: The interplay of social, economic, and health access impacts of COVID-19 on participants caused disruptions to HIV-related care, despite the continued availability of HIV treatment services. Adaptations to address these factors mitigated the effects of these barriers to provide participants with clinical support.

However, the impacts of COVID-19 continued to highlight both new and pre-existing nuanced interactions of social well-being, economic status, and healthcare access among FSW. Increased focus from HIV care implementors is warranted to address the distinct needs and socio-economic well-being of marginalized populations, in addition to providing tailored healthcare services, particularly during periods of instability.

TUPED27

Lessons from take home dosage for Opioid Substitution Therapy (OST) during COVID-19 under National AIDS Control Programme in India

G. Ngaihte¹, S. Rajan¹, B. Singh¹, S. Purohit¹, S. Verma¹

¹National AIDS Control Organization, Ministry of Health and Family Welfare, Delhi, India

Background: National AIDS Control Organisation (NACO) under the Ministry of Health and Family Welfare, India has made significant achievements in reducing HIV transmission among People Who Inject Drugs (PWIDs) through the Harm reduction interventions particularly Opioid Substitution Therapy (OST). The OST programme currently has 42,503 active clients on treatment through 244 centres and 145 satellite centres and is primarily provided as a directly observed treatment (DOTS) under trained medical supervision.

Description: The COVID-19 outbreak and the nation-wide lockdowns directly impacted the OST clients and their access to daily medication. To address the problem of clients unable to present for daily medication and the safety of the service providers, NACO rolled out a low threshold policy for OST centres which included take home dosage for upto 15 days for stable clients, fast-track induction of new clients, flexible timings, virtual counselling and COVID-19 prevention.

This low threshold policy of take home dosage proved to be highly beneficial to both provider and beneficiary resulting in the take home dosage being incorporated into the Clinical Practice Guidelines for Opioid Substitution in India.

Lessons learned: NACO's take home policy immediately led to a reduction in direct physical interaction while fast track induction benefited many PWIDs who came forward to register for substitution therapy of which the majority

have decided to remain in the program (29 percent increase in enrolment). The use of virtual counselling, WhatsApp messaging groups for the Medical Doctors, Counsellors and PWIDs enabled constant support to PWIDs to cope with the psychological distress of COVID as well as treatment adherence which increased significantly (upto 82 percent). Flexible timings and travel passes issued to OST clients reduced barriers to access during lockdowns.

Conclusions/Next steps: NACO's take home policy helped to ensure uninterrupted service delivery and prevention of COVID among OST clients. This has resulted in better adherence and retention. Fast track induction provided PWIDs with an attractive option of substitution treatment with reduced waiting time.

In containment zones, take home dosage through outreach workers and virtual counselling was effective. Virtual clinical consultation was shown to be a successful option for follow up and counselling.

TUPED28

The impact of the COVID-19 pandemic on access, utilization, affordability and motivation to engage in HIV care services for African, Caribbean and Black women living with HIV in British Columbia, Canada

E. Ojukwu¹, S. Hirani¹, T. Sotindjo², E. McKay¹, I. Okedo-Alex³

¹University of British Columbia, School of Nursing, Vancouver, Canada, ²University of British Columbia, Faculty of Medicine, Vancouver, Canada, ³University of British Columbia, School of Population and Public Health, Vancouver, Canada

Background: The Covid-19 pandemic changed the method and delivery of HIV care services. Many care services switched to virtual or telephone format, and some support services disappeared altogether. African, Caribbean, and Black women living with HIV (ACB WLWH) face structural barriers to accessing, utilizing and affording HIV care services and the addition of virtual services further decreased the motivation to engage for many.

Methods: Purposive and snowballing techniques were used to recruit participants from women's health facilities, HIV and ACB organizations in British Columbia, who were 16 and older, identified as ACB WLWH, and diagnosed with HIV at least 3 months before the COVID-19 outbreak in January 2020.

We conducted a descriptive, qualitative study using in-depth interviews. Data was analyzed using a thematic content analysis and validated by participants at a member checking event.

Results: Barriers to accessing HIV care services primarily pertained to the alienated virtual delivery of care services. Barriers to utilization of HIV care services were reports of feeling dismissed, and/or symptom stigmatization by providers. Facilitators of HIV care utilization were improved medication delivery systems. The affordability of HIV care services was not impacted by the pandemic.

However, the impact of inflation and increased cost of living negatively influenced participants and their ability to engage with HIV services. Participants listed fear as the primary deterrent to their motivation to seek care.

Conclusions: Participants indicated that access to care can be improved through increased funding and availability of support groups. Hybrid models of care were cited as improving utilization for those who preferred in-person care services. Affordability of care services can be improved by providing extended coverage for supplements and related health expenses.

Thus, improving the barriers to accessing, utilizing, and affording HIV care services will reasonably improve motivation to engage with HIV care services.

TUPED29

The perceived vulnerability-protection continuum in people living with HIV and antiretroviral treatment regarding Covid-19 during the first wave of the pandemic in France. A mixed-method study (COVIDHIV)

G. Roucoux¹, Y. Amboise¹, I. Yaya¹, F. Thonon¹, J.W. Griffith², C. Psomas³, A. Chéret^{4,5}, M. Duracinsky¹

¹PROQOL Unit - URC ECO APHP - ECEVE INSERM, Paris, France, ²Feinberg School of Medicine, Chicago, United States, ³European Hospital of Marseille, Marseille, France, ⁴Pointe-à-Pitre University Hospital, Outpatient Medicine Service, Pointe-à-Pitre, Guadeloupe, France, ⁵Cochin Hospital, Internal Medicine Unit, Paris, France

Background: The vulnerability of people living with HIV (PLHIV) to severe acute respiratory syndrome coronavirus 2 (SARS-COV-2) has been vigorously debated by clinical researchers. This poster aims to describe how PLHIV perceived their vulnerability to SARS-COV-2 during the first wave of the pandemic in France.

Methods: COVIDHIV is a retrospective and prospective, mixed-methods, cohort study involving 42 medical centers. Quantitative data were collected from PLHIV diagnosed with Covid-19 by a questionnaire with five dimensions (HIV Symptom Index, PROQOL-HIV, HAD, an *ad hoc* Covid-19 module, PCL5), which were subsequently as covariates in a logistic regression. Qualitative data were collected using semi-structured interviews from a purposive maximum-variation sample of PLHIV without or with Covid-19. Interviews were conducted until data saturation. Thematic analysis of the interviews used a General Inductive Approach.

Results: Three hundred ninety-five participants completed the questionnaire, from which 53.3% (n=168) perceived themselves as vulnerable to Covid-19. In multivariate logistic regression with perceived vulnerability as the dependent variable, perceived vulnerability was positively associated with female (AOR = 2.58; 95%CI:1.45-4.67), time between Covid-19 confirmation and study inclusion >7 days (AOR = 1.90; 95%CI=1.02-3.59), number of Covid-19 symptoms (AOR = 1.10; 95%CI=1.04-1.17), over-

weight/obesity (AOR=2.55; 95%CI=1.45-4.55), and psychological support for Covid-19 (AOR = 1.85; 95%CI:1.05-3.30). It was negatively associated with respiratory diseases (AOR = 0.32; 95%CI:0.11-0.88), and CD4 count ≥ 500 (AOR = 0.47; 95%CI:0.26-0.81).

Thirty-four PLHIV were interviewed. Twenty were coinfect- ed with SARS-COV-2, 24 were men, with a median age of 55, 20 had a CD4 count ≥ 500 , and all were on antiretroviral therapy. Perceived vulnerability was expressed in a con- tinuum with perceived protection around 4 themes (and 14 subthemes): accepting or rejecting vulnerability, ques- tioning or affirming protection.

Affirming protection (dominant theme) indicated the general trend in our qualitative sample.

Conclusions: PLHIV reported feeling secure about their perceived vulnerability to SARS-COV-2, which appeared to result of many factors, such that perceived protection slightly outweighed perceived vulnerability.

Education may be needed for PLHIV who may be vulner- able to coinfection, but who are not motivated to seek screening, vaccination, or treatment due to a sense of se- curity, which may be overestimated.

TUPED30

Acceptability, feasibility, and preliminary effectiveness of a courier HIV-treatment delivery intervention for young people living with HIV in South Africa during the COVID-19 pandemic

D. Giovenco¹, A. Pettifor², Y. Qayiya³, L.-G. Bekker³

¹Emory University, Epidemiology, Atlanta, United States,

²University of North Carolina at Chapel Hill, Epidemiology, Chapel Hill, United States, ³Desmond Tutu HIV Centre, Cape Town, South Africa

Background: Young people living with HIV (YPLWH) have historically experienced worse virological suppression outcomes compared to adults. Differentiated service de- livery models directed specifically to YPLWH are urgently needed to address this disparity.

Methods: We conducted a longitudinal pilot study among YPLWH (13-24 years) to examine the acceptability, feasibil- ity, and preliminary effectiveness of courier ART delivery and SMS support interventions to retain YPLWH in HIV care during the COVID-19 pandemic. Participants were recruited from an HIV treatment clinic near Cape Town and enrolled into the study from February to October 2021. All YPLWH had the option to enroll in the courier ART delivery service and were randomized 1:1 to receive weekly SMS support. Modified Poisson regression was used to es- timate the preliminary effectiveness of each intervention on viral suppression (HIV-1 RNA < 200 copies/mL) at months 3 and 6.

Results: A total of 227 participants were screened for the study, of which 215 were eligible and enrolled. Participants were a median of 19 years and 58% female. There were 110 participants assigned to the SMS support intervention arm and 105 to the control arm.

Among all 215 YPLWH, 82% elected to enroll in the courier service at baseline, 41% reported receiving a delivery of their ART in the past three months at month 3, and 49% reported receiving a delivery at month 6.

Among those who reported receiving an ART delivery, most (91-100%) rated the intervention as highly accept- able across three questions. The SMS intervention was also rated as highly acceptable by 75-84% of participants. Participants who reported receiving a delivery in the past three months at month 3 were 1.26 times as likely to have a suppressed viral load at month 3 (95% CI 1.05, 1.54). Fur- ther, participants randomized to the SMS intervention were 1.34 times as likely to have a suppressed viral load a month 3 (95% CI 1.05, 1.70). No effects on viral suppression were observed at month 6.

Conclusions: Findings reveal high uptake and acceptabil- ity of a courier ART intervention among YPLWH, as well as promising evidence for intervention effectiveness in in- creasing viral suppression. A fully powered effectiveness- implementation hybrid trial is warranted.

Track E: Implementation science, economics, systems and synergies

MOPEE01

Index case contact testing to improve HIV case identification in the community settings of Ethiopia

A. Tefera Minda¹, E. Seid Ibrahim¹, L. Alemayehu Mekuria¹, D. Abrham Tsegaye¹, G. Andargie Biks¹, A. Negash², E. Liddell³

¹Project HOPE, Addis Ababa, Ethiopia, ²USAID, Addis Ababa, Ethiopia, ³Project HOPE, Washington DC, United States

Background: Community-based index case testing (ICT) is an innovative, person-centered and differentiated approach to increase HIV testing yield for epidemic control. This abstract summarizes the HIV testing yield in a Community HIV care and treatment (CHCT) activity in Ethiopia.

Description: Local partner organizations have been implementing the PEPFAR/USAID-funded CHCT activity since 2019. They deployed frontline community health workers, such as community engagement facilitators (CEFs), to receive index case line lists from health facilities or community platforms. CEFs located index cases, counseled, and elicited their sexual contacts or biological children, and offered them HIV testing. Index contacts who accepted the offer were tested at the community or referred to the health facility. The community ICT data from October 2020 to September 2022 were analyzed. The testing protocol was the same for community and facility testing. The yields between community- and health facility-based ICT services were compared using HIV program data from seven high burden regions. The CommCare application collected individual client level data. Excel and STATA software version-13 were used for data analysis.

Lessons learned: Between April 2019 to September 2022, 120,256 index case contacts were tested for HIV, of whom 53% were females. The majority (86,890, or 72%) were tested at the community and 33,360 (28%) were tested at the health facility.

Overall, 7,475 HIV cases were identified with 6.2% testing yield (95% CI: 6.09 to 6.3). The yield was higher among females (7.4%) than in males (5.3%) and was 19.7% in 50+ age groups. Majority of new cases 6,059 (81%) were identified at the community level, and the yield was 7% (95% CI: 6.9 to 7.1) at the community compared to 4.2% (95% CI: 4.01 to 4.50) at the facility level. The testing yield was 10.1% in Gambella region, 6.4% in Oromia and Amhara regions, 6.1% in SNNP, and 5.3% in Addis Ababa. Almost all (97.7%) of the newly identified positives were linked to care and treatment services.

Conclusions/Next steps: Community based ICT showed better testing yield, and increased access to care and treatment in older age groups. Therefore, we recommend wider implementation of the community ICT model to enhance the HIV epidemic control in Ethiopia.

MOPEE02

Measuring the performance of artificial intelligence to interpret images of HIV self-testing results

O. Ekwunife¹, S. Roche¹, R. Mendonca², B. Kwach³, P. Ongwen⁴, S. Zhang⁵, D. Hattery², S. Smedinghoff², S. Morris², V. Omollo³, D. Were⁶, D. Rech², E. Bukusi^{7,8,9}, K. Ortblad¹

¹Fred Hutchinson Cancer Center, Cancer Prevention Program, Seattle, United States, ²Audere, Seattle, United States, ³Kenya Medical Research Institute, Center for Microbiology Research, Kisumu, Kenya, ⁴Kenya Medical Research Institute, Centre for Microbiology Research, Kisumu, Kenya, ⁵University of Washington, Department of Epidemiology, Seattle, United States, ⁶Jhpiego, Nairobi, Kenya, ⁷University of Washington, Department of Global Health, Seattle, United States, ⁸University of Washington, Department of Obstetrics and Gynecology, Seattle, United States, ⁹Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya

Background: HIV self-testing (HIVST) is a promising intervention for supporting community-based HIV service delivery; however, it has yet to be fully embraced by policymakers, in part, due to concerns about result misinterpretation and subsequent incorrect treatment decisions. Identifying tools that can support correct HIVST interpretation will likely be an important prerequisite to any large-scale incorporation of HIVST into national HIV service delivery programs.

We sought to understand how well a cost-effective artificial intelligence (AI) algorithm could correctly interpret a common brand of blood-based HIVST kits.

Methods: At 20 private pharmacies in Kisumu, Kenya, we offered free blood-based HIVST to clients ≥18 years purchasing products indicative of sexual activity (e.g., condoms). Trained pharmacy providers assisted with testing, as needed. In real-time, each test was independently interpreted by:

1. The client,
 2. The pharmacy provider, and;
 3. A certified HIV testing service (HTS) counselor who then photographed the result.
- Each test image was subsequently interpreted by:
4. An AI algorithm and;
 5. A panel of three expert HIV rapid diagnostic test readers.

Using expert panel determination as the gold standard, we calculated the sensitivity and specificity of each group's interpretation.

Results: From March-June 2022, we screened 1691 pharmacy clients, enrolled 1500, and collected 855 test images. Among clients with test images, 63% (540/855) were female, the median age was 26 years (IQR 22–31), and 39% (335/855) reported casual sex partners. The AI algorithm correctly interpreted all positive tests as positive (100% sensitivity) and slightly outperformed HTS counselors and

Oral
abstracts

abstracts

Author
Index

pharmacy providers (each 98% sensitivity; 95% CI 97%-99%) as well as clients (93% sensitivity; 95% CI 91%-94%). The AI algorithm correctly interpreted nearly all negative tests as negative (99% specificity; 95% CI 98%-99%), similar to the aforementioned comparison groups, which all had 100% specificity.

Conclusions: AI algorithms are capable of correctly interpreting HIVSTs and may perform just as well, if not better, than HTS counselors, pharmacy providers, and clients.

As differentiated HIV service delivery continues to gain momentum, AI algorithms could provide additional quality control, validation, and disease surveillance to policy-makers and HIVST end-users, including new providers to whom HIV service delivery is being task-shifted.

MOPEE03

Perceptions of using a mobile health approach to support HIV self-test among men who have sex with men

T.H. Kwan^{1,2}, D.P.C. Chan², S.S. Lee²

¹The Chinese University of Hong Kong, Jockey Club School of Public Health and Primary Care, Shatin, Hong Kong, SAR of China, ²The Chinese University of Hong Kong, Stanley Ho Centre for Emerging Infectious Diseases, Shatin, Hong Kong, SAR of China

Background: With the extensive coverage of mobile devices, mobile health (mHealth) approach offers an innovative means to support HIV self-test and related services for men who have sex with men (MSM). Their perceptions and concerns towards such an approach were evaluated.

Methods: An augmented reality-enhanced HIV self-test web application was developed with the following functionalities: HIV information provision, HIV self-test request, augmented reality models for assisting the self-test performance, and result upload.

At the self-test request process, participating adult MSM were asked to complete a self-administered questionnaire on their perceptions and experiences of HIV self-test, and perceived benefits and concerns of using this mHealth approach for assisting HIV self-test.

Results: Between 1 December 2022 and 31 January 2023, totally 200 participants with a median age of 31 years (interquartile range 27-35 years) joined the study. The majority (89%) had tested for HIV before, among which 69% had self-tested. Some 92 preferred real-time support when performing the HIV self-test, of which 40% would like a friend/sex partner to accompany and 38% preferred digital means.

Participants who had never self-tested were less confident in reading the self-test result ($p=0.043$). They were also more likely to require support for HIV self-test ($p<0.0001$), preferably from a friend ($p=0.0004$).

Regarding channels of supporting service provision, 51% preferred instant messaging, 46% preferred an mHealth approach, and 31% preferred in-person. Participants accepting mHealth support were more likely to have a

higher perceived risk of HIV ($p=0.012$), and pay more attention to the test kit's window period when choosing one ($p=0.027$). They recognised mHealth could help access follow-up referral services if necessary ($p=0.012$), but concerned about metadata collection when using it ($p=0.017$). Participants requiring self-test support believed mHealth approach carried a benefit of verifying the self-test result ($p=0.012$).

Conclusions: mHealth approach was generally accepted by MSM for assisting HIV self-test, especially for those who had a higher risk of HIV acquisition that result verification and follow-up services would become necessary if screened positive. They, however, concerned about passive data collection when using such services. Minimum metadata collection with a transparent data collection policy would be reassuring.

MOPEE04

Social network strategy to reach people with living with HIV in two Vietnamese provinces

V. Nguyen¹, T.V. Nguyen¹, R. Coley¹, S. Vo², M. Hoang¹, T. Huynh², Q. Nguyen³, T. Ngo³, H. Phan⁴, D. Levitt¹

¹FHI 360, Hanoi, Vietnam, ²FHI 360, Ho Chi Minh City, Vietnam, ³USAID, Hanoi, Vietnam, ⁴Vietnam Administration of HIV/AIDS Control, Hanoi, Vietnam

Background: To meet the first HIV epidemic control target (95% of people living with HIV [PLHIV] know their status) in Vietnam, testing programs must differentiate effective approaches to reach individuals with HIV risk. Vietnam has implemented facility and community testing (traditional model) since 2006 and partner notification strategy (PNS) since 2018. Social network strategy (SNS), where relationships are used to motivate those with potential HIV risk to access testing, was introduced by the Meeting Targets and Maintaining Epidemic Control (EpiC) project in 2021.

EpiC analyzed the characteristics of PLHIV reached via SNS, PNS, and a traditional model in two provinces, Tay Ninh, and Tien Giang, to identify optimal testing strategies for different populations.

Methods: We reviewed de-identified data for newly diagnosed HIV cases in two provinces from October 2021 to September 2022. Data were extracted from the testing database. Appropriate statistical analyses, including univariate and multivariate logistic regression, were used to calculate odds ratios ([OR]) reflecting associations between characteristics for clients reached by different strategies.

Results: In total, 741 clients tested positive, among them 275 (37.1%), 150 (20.2%), and 316 (42.3%) came from SNS, PNS, and the traditional model, respectively. The mean age was 29.2 (± 9.0), and there was a statistical difference in mean age among the three approaches. Subgroup analysis showed that 15- to 19-year-old clients were more likely to be found by SNS ([OR]= 2.16, 95% CI: 1.34 to 3.48).

Females were 9.7% of PLHIV identified, and there was no statistical difference for gender among approaches. Almost all cases were men who have sex with men (MSM) (72.4%) or partners of high-risk populations and PLHIV (23.2%). SNS was more likely to help find MSM ([OR]= 1.76, 95% CI: 1.23 to 2.53) but was less likely to find the latter ([OR]= 0.61, 95% CI: 0.42 to 0.89) compared to other testing strategies.

Conclusions: Though recently introduced, SNS significantly supported HIV case finding. SNS was more effective at reaching adolescent PLHIV (age 15–19) and MSM, two populations of concern in Vietnam. This information will help HIV programs tailor testing strategies among adolescents.

MOPEE05

High prevalence of unconfirmed positive HIV PCR test results among African infants with perinatal HIV exposure in the International epidemiology Databases to Evaluate AIDS (leDEA) consortium

J. Carlucci¹, K. Technau², M. Yotebieng³, V. Leroy⁴, K. Anderson⁵, M. Amorissani-Folquet⁶, K. Wools-Kaloustian¹, A. Edmonds⁷

¹Indiana University School of Medicine, Indianapolis, United States, ²Rahima Moosa Mother and Child Hospital, Johannesburg, South Africa, ³Albert Einstein College of Medicine, New York, United States, ⁴CERPOP, Inserm, University of Toulouse, Toulouse, France, ⁵University of Cape Town, Cape Town, South Africa, ⁶University Houphouët-Boigny, Abidjan, Cote D'Ivoire, ⁷The University of North Carolina at Chapel Hill, Chapel Hill, United States

Background: Scale-up of vertical transmission prevention services has reduced incident infections among infants with perinatal HIV exposure (IPHE). However, as vertical transmission declines, the positive predictive value of HIV testing decreases and the probability of false-positive results increases, highlighting the importance of confirmatory testing.

This study aimed to determine the prevalence of unconfirmed positive HIV PCR test results among African IPHE in the International epidemiology Databases to Evaluate AIDS (leDEA) consortium.

Methods: This retrospective analysis utilized data from clinical sites in four leDEA regions: Central Africa (CA), East Africa (EA), Southern Africa (SA), and West Africa (WA). IPHE born 2004–2021 were included. IPHE with only one positive virologic test (qualitative or quantitative DNA and/or RNA PCRs) at <18 months and no additional positive virologic or antibody test at ≥18 months were considered “unconfirmed positives.” Among unconfirmed positives, virologic testing (or lack thereof) performed at any time after the initial positive result was described.

Results: This analysis included 72,618 IPHE. Overall, 3,652 (5%) had at least one positive virologic test at <18 months, and 1,610 (44%) of these lacked a confirmatory positive test. Among these unconfirmed positives, 1,393 (87%)

lacked additional virologic testing after the initial positive result, and 217 (13%) had ≥1 additional virologic test that was not positive (Figure and Table [stratified by region]).

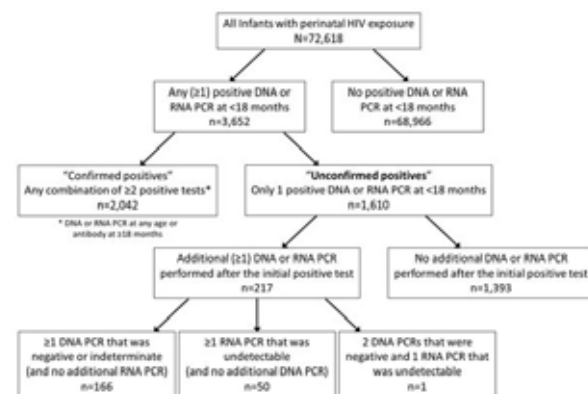

Figure: Cascade of HIV testing among African infants in the International epidemiology Databases to Evaluate AIDS (leDEA) consortium, 2004–2021.

	CA 2004–2020	EA 2004–2021	SA 2004–2019	WA 2004–2018	All Regions
1. Infants with perinatal HIV exposure [n]	10,520	47,015	8,600	6,483	72,618
2. Any positive virologic test at <18 months, among #1 [n (%)]	415 (4%)	2,980 (6%)	154 (2%)	103 (2%)	3,652 (5%)
3. Only one positive test (i.e., “unconfirmed positives”), among #2 [n (%)]	240 (58%)	1,256 (42%)	20 (13%)	94 (91%)	1,610 (44%)
4. No additional virologic test performed after the initial positive test, among #3 [n (%)]	192 (80%)	1,095 (87%)	19 (95%)	87 (93%)	1,393 (87%)
5. Additional (≥1) virologic test performed and not positive, among #3 [n (%)]	48 (20%)	161 (13%)	1 (5%)	7 (7%)	217 (13%)

Table: Infants with perinatal HIV exposure and their HIV testing data stratified by International epidemiology Databases to Evaluate AIDS region: Central Africa (CA), East Africa (EA), Southern Africa (SA), and West Africa (WA).

Conclusions: Unconfirmed positive HIV test results were highly prevalent among African IPHE in this cohort. Additional efforts are needed to ensure implementation of confirmatory testing to reduce the risk of potentially false-positive results.

MOPEE06

Empowering adolescent school girls with SKILLZ: process results from an integrated school- and community-based intervention for HIV and pregnancy prevention in Lusaka, Zambia

M. Musonda¹, C. Chiu², C. Manyele¹, D. Vumbi¹, C. Mulubwa³, C. Bolton³, J.X. Liu⁴, B. Mkandawire¹

¹Grassroot Soccer, Lusaka, Zambia, ²University of California, Berkeley, Berkeley, United States, ³Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, ⁴University of California, San Francisco, San Francisco, United States

Background: Adolescent girls face a confluence of unique barriers in accessing sexual and reproductive health (SRH) information and services. SKILLZ is a holistic sports-based intervention for empowering adolescent girls that

Oral
abstracts

abstracts

Author
Index

provides comprehensive sexuality and SRH education in 12 sessions delivered by trained young adult "Coaches," who also offer community-based distribution of HIV self-testing and contraceptives and referrals to youth-friendly clinic services as needed.

As part of the 12-month cluster-randomized effectiveness trial (cRCT; NCT04429061) in Lusaka, Zambia, we assess process outcomes for characterizing intervention engagement.

Methods: We descriptively analyze routine monitoring and evaluation data from 23 schools participating in the SKILLZ evaluation. Focusing on 1,135 Grade 11 female students randomly sampled from school rosters and enrolled in the cRCT, we quantify SKILLZ attendance, changes in HIV and SRH knowledge from tests administered pre- and post-intervention, and uptake of HIV testing and contraceptives.

We examine whether each outcome is correlated by school and Coach, respectively, using F-tests for their joint significance.

Results: About 79% of sampled students attended at least one SKILLZ session, of which 90% attended at least 8 of 12 sessions, meeting the requirements to "graduate" from the program; mean attendance was 9.9 of 12 sessions. Attendance remained stable across the 12 sessions with minimal drop-off.

Mean attendance varied substantially by school (50-100%; $F=4.96$, $p<0.001$) and by coach ($F=2.85$, $p<0.001$) but was not correlated with prior HIV testing. HIV and SRH knowledge mean test scores increased by 15 percentage points, a 1.4 standard deviation from the pre-intervention quiz score. Changes in test scores also varied substantially by school (8-26 percentage points; $F=7.05$, $p<0.001$) and by coach (4-30 percentage points; $F=5.48$, $p<0.001$), but were not correlated with mean SKILLZ attendance by school. About 59% of girls received HIV testing and 10% of girls received contraceptives during the intervention period.

Conclusions: SKILLZ was well-attended and lead to large knowledge gains in HIV and SRH and substantial uptake of HIV testing during the intervention period.

Further research is needed to understand variations in attendance and knowledge gains across schools, and linking to cRCT primary outcomes for assessing pathways to impact.

The effect of receiving an oral PrEP delivery model supported with a preferred HIV testing modality on PrEP continuation outcomes: findings from a randomized implementation trial in Kenya

A. Bardon^{1,2}, K. Ngure^{3,4}, P. Mogere⁵, K. Thomas², S. Gakuo⁴, C. Kiptinness⁴, S. Mbaire⁴, D. Mangale², J. Nyokabi⁴, N. Mugo^{2,6}, J. Baeten^{2,6}, K. Ortblad⁷

¹University of Washington, Department of Epidemiology, Seattle, United States, ²University of Washington, Department of Global Health, Seattle, United States, ³Jomo Kenyatta University of Agriculture and Technology, School of Public Health, Juja, Kenya, ⁴Kenya Medical Research Institute, Center for Clinical Research, Nairobi, Kenya, ⁵Novartis Pharmaceuticals, Basel, Switzerland, ⁶Gilead Sciences, Foster City, United States, ⁷Fred Hutchinson Cancer Center, Public Health Sciences Division, Seattle, United States

Background: In a randomized implementation trial in Kenya, biannual clinic visits supported with six-monthly PrEP dispensing and interim HIV self-testing (HIVST) resulted in non-inferior PrEP continuation outcomes compared to quarterly clinic visits. However, participants did not always receive their preferred model of care. We explored the effects of receiving a preferred HIV testing modality on PrEP continuation outcomes.

Methods: The JiPime-JiPrEP trial (NCT03593629) enrolled PrEP clients (≥ 18 years) in Kiambu County. At enrollment, participants stated their preferred HIV testing modality (clinic-based or HIVST) then were randomized 2:1 to six-monthly PrEP dispensing supported with interim HIVST or three-monthly dispensing with clinic-based HIV testing (standard-of-care).

We categorized participants as 'exposed' if the HIV testing modality supporting their assigned PrEP delivery model matched their preference and 'unexposed' if it did not. Participants completed follow-up visits at six and 12 months.

We used binomial regression models, adjusting for sex, serodifferent partnership status, and study arm, to estimate risk differences (RDs) for continuity in HIV testing (≥ 3 tests), PrEP refilling (at six and 12 months), and PrEP adherence (detectable tenofovir-diphosphate in dried blood spots at six and 12 months).

Results: From May 2018 to February 2020, we screened 527 and enrolled/randomized 495. The median age was 33 years (IQR 27-40), and 66.6% (329/494) were female. At enrollment, 77.3% (382/494) reported a preference for HIVST, and 22.7% (112/494) reported a preference for clinic-based HIV testing; 59.7% (295/494) were randomized to a PrEP delivery model supported with their preferred HIV testing modality.

There were no significant differences between the exposed and unexposed groups in HIV testing (exposed: 67.1%, unexposed: 62.3%; RD 7.0%; 95%CI -3.0%, 17.0%), PrEP refilling (exposed: 55.9%, unexposed: 57.8%; RD -1.6%; 95%CI -12.1%, 8.8%), or PrEP adherence (exposed: 42.7%, un-

exposed: 36.7%; RD 7.9%; 95%CI -1.9%, 17.8%). Additionally, 50.0% (70/140) of exposed and 45.2% (42/93) of unexposed participants changed their preference at 12 months.

Conclusions: PrEP continuation outcomes were similar between participants who received a PrEP delivery model supported with their preferred HIV testing modality and those who did not. Preference-based models of PrEP delivery and HIV testing can provide clients with tailored, person-centered care with comparable outcomes.

MOPEE08

Familiarity with, perceived accuracy of, and willingness to rely on U=U among Australian gay and bisexual men: results from the PrEPARE Project 2021

J. MacGibbon¹, B.R Bavinton², T.R Broady¹, J. de Wit^{1,3}, J. Kolstee², A. Molyneux⁴, D. Murphy², C. Power⁵, H. Paynter⁶, M. Holt¹

¹UNSW Sydney, Centre for Social Research in Health, Kensington, Australia, ²UNSW Sydney, Kirby Institute, Kensington, Australia, ³Utrecht University, Department of Interdisciplinary Social Sciences, Utrecht, Netherlands, ⁴ACON, Sydney, Australia, ⁵New South Wales Health, Sydney, Australia, ⁶Australian Federation of AIDS Organisations, Sydney, Australia

Background: The Undetectable=Untransmittable (U=U) message has been promoted since it was demonstrated that viral suppression through HIV treatment prevents sexual transmission between serodiscordant partners. Awareness of U=U has not been previously assessed nationally among Australian gay and bisexual men (GBM).

Methods: A national online survey of GBM was conducted April–June 2021. We assessed familiarity with U=U, its perceived accuracy, and willingness to rely on U=U, i.e. have sex without condoms with an HIV-positive person who has an undetectable viral load (UVL).

Levels of familiarity and willingness to rely on U=U were assessed by HIV status using chi-squared tests. Factors associated with perceived accuracy of U=U were assessed using ordered regression.

Results: The mean age of 1,280 participants was 41 years, 80.8% identified as gay, 15.1% as bisexual. 82.7% were HIV-negative, 9.8% untested and 7.4% HIV-positive. 36.9% of the sample was using PrEP, and 78.6% were familiar with U=U. HIV-positive GBM were more familiar than other participants (95.8% vs. 77.2%, $\chi^2(1, 1,280)=18.04$, $p<.001$).

Among those who were familiar with U=U ($n=1,006$), 67.3% thought it was accurate. Greater familiarity with U=U was associated with greater odds of believing U=U was accurate. PrEP users, HIV-positive and university-educated participants were also more likely to perceive U=U as accurate, whereas participants aged ≥ 40 years old (compared to under 30s) and Latin-American and Asian-born participants (compared to Australian-born participants) were less likely to perceive U=U as accurate. Among those familiar with U=U ($n=1,006$), 47.0% were willing to have

condomless sex with a partner with UVL. Among those familiar with U=U who believed it was accurate ($n=677$), 90% of HIV-positive participants, 72% of PrEP users, 44% of HIV-negative and 25% of untested/unknown status participants were willing to rely on U=U ($\chi^2(1, 677)=90.82$, $p<.001$).

Conclusions: Most Australian GBM were familiar with U=U, but fewer believed it was accurate or were willing to rely upon it. HIV-positive GBM and PrEP users were more familiar with U=U, believed in its accuracy and were willing to rely upon it. As well as continuing to educate GBM (particularly HIV-negative men) about U=U, finding ways to encourage reliance upon it could be useful for combination prevention efforts.

Preference heterogeneity among potential users of online pre-exposure prophylaxis provision in Kenya: a discrete choice experiment

Y. Chen¹, E. Saldarriaga¹, M. Montaña², N. Thuo³, C. Kiptinness³, F. Terris-Prestholt⁴, A. Stergachis^{5,1}, M.L. Mugambi⁵, K.F. Ortblad⁶, K. Ngure⁷, M. Sharma⁵
¹The Comparative Health Outcomes, Policy, and Economics (CHOICE) Institute, University of Washington, Seattle, United States, ²Vaccine and Infectious Diseases Division (VIDD), Fred Hutchinson Cancer Center, Seattle, United States, ³Partners in Health and Research Development, Thika, Kenya, ⁴London School of Hygiene and Tropical Medicine, Department of Global Health and Development, Faculty of Public Health and Policy, London, United Kingdom, ⁵University of Washington, Department of Global Health, Seattle, United States, ⁶Public Health Science Division, Fred Hutchinson Cancer Center, Seattle, United States, ⁷School of Public Health, Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Background: In east and southern Africa, pre-exposure prophylaxis (PrEP) is mainly delivered through clinics, achieving limited coverage due to barriers including long wait times and privacy concerns. Obtaining PrEP via an online pharmacy is a novel approach to expanding PrEP access, but user preferences for this service delivery model are unknown.

Methods: We recruited participants for a discrete choice experiment (DCE) through an online-pharmacy retailer, MYDAWA, in Nairobi, Kenya. Eligible participants were ≥ 18 years, not known to be living with HIV, and interested in PrEP. DCE attributes included: PrEP eligibility assessment (self-administered or guided); HIV test type (oral-fluid self-test (HIVST), blood-based self-test HIVST or provider-performed test); clinical consultation (remote or in-person); and user support options (test messages, phone call, or emails).

Participants were presented with eight scenarios of two hypothetical PrEP services with varied combinations of four attributes. We also assessed willingness-to-pay for

Oral
abstracts

Poster
exhibition

E-posters

Late-breaker
abstracts

Author
Index

online PrEP services. We used conditional logit models to obtain preference weights and relative importance of attributes, and included participants' characteristics as interactions to test whether preferences differ.

Results: From May–Nov 2022, we enrolled 772 participants; with a median age of 25 years (IQR 22–29), 54% were female, and 58% were PrEP naïve users.

Overall, participants preferred remote consultation, support via phone call, and HIVST. HIV test type was the most influential attribute (relative importance: 32.1%), followed by user support (31.5%), clinical consultation (27.8%) and eligibility assessment (8.6%).

Preferences were similar across participant characteristics aside from history of PrEP use; among prior PrEP users, user support options (44%) had the highest relative importance; compared to clinical consultation (34.3%) for PrEP naïve individuals.

Most participants showed strong interest in acquiring their chosen online PrEP service if available (82% of scenarios), which was high in PrEP naïve individuals compared to prior PrEP users (85% vs 33%). The median maximum willingness-to-pay for online PrEP services was \$8.10 USD (IQR \$6.50–\$15.80).

Conclusions: Online PrEP delivery is highly acceptable and likely to attract new PrEP users. PrEP naïve users most valued clinical consultation, while experienced PrEP-users most valued user support. Findings can inform the design of an online PrEP service.

What men want: preferences for pre-exposure prophylaxis for HIV among men who have sex with men in 16 countries in the Asia-Pacific: a discrete choice experiment

W. Tiesapjaroen^{1,2}, B.R. Bavinton³, H.-M. Schmidt^{4,5}, K.E. Green⁶, N. Phanuphak⁷, M. Poonkasetwattana⁸, N.S. Suwandi⁹, D. Fraser³, C. Chan³, M. Cassell⁹, L. Zhang^{1,2}, W. Tang¹⁰, J.J. Ong^{1,2,11}

¹Alfred Health, Melbourne Sexual Health Centre, Carlton, Australia, ²Monash University, Central Clinical School, Melbourne, Australia, ³University of New South Wales, Kirby Institute, Sydney, Australia, ⁴UNAIDS Regional Office for Asia and the Pacific, Bangkok, Thailand, ⁵Global HIV, Hepatitis and STIs Programme, World Health Organization, Geneva, Switzerland, ⁶The Program for Appropriate Technology in Health, Hanoi, Vietnam, ⁷Institute of HIV Research and Innovation, Bangkok, Thailand, ⁸Asia Pacific Coalition on Male Sexual Health, Bangkok, Thailand, ⁹Family Health International 360, Hanoi, Vietnam, ¹⁰The University of North Carolina at Chapel Hill Project-China, Guangzhou, China, ¹¹London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom

Background: Scale-up of pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) in Asia-Pacific has been slow. Tailored PrEP services informed by prefer-

ences of potential users could maximise PrEP uptake. We evaluated the drivers of choice for PrEP among MSM in 16 Asia-Pacific countries and forecasted PrEP uptake given different PrEP program configurations.

Methods: We included MSM aged ≥ 18 years with no prior HIV diagnosis. An online discrete choice experiment (DCE) survey was delivered to participants between May–November 2022 through gay dating apps and local MSM networks. We used random parameters logit (RPL) models to estimate the relative importance of attributes in each country and by country-income level, and predict PrEP uptake for different program configurations.

Results: Overall, 21,722 individuals were included, with a mean age of 31.7 (± 9.6), 8% (1,709/21,722) were diagnosed with a sexually transmitted infection (STI) and 60% (12,955/21,722) reported multiple partners in the last six months. Despite variations in the relative importance of attributes across countries, cost was the biggest driver for using PrEP (Figure 1).

The least preferred PrEP program resulted in 42% uptake of PrEP in high-income Asian countries (HIC) and 47% in middle-income Asian countries (MIC). This improved to 95% with an optimal PrEP service configuration in HIC and 89% for MIC. The optimal PrEP service configurations in HIC and MIC were similar; cost (free), location (a peer-led community clinic), side effect (none), extra service (STI testing), and visit frequency (annually). But MSM in HIC preferred long-acting oral PrEP, while those in MIC preferred daily oral PrEP.

Figure 1. Drivers of choice (relative importance) of PrEP for men who have sex with men in each country (N = 21,722)

Conclusions: This is the largest DCE globally, providing rich country-level preference data from MSM in the Asia-Pacific region. The DCE demonstrated the need to tailor services to country context, including ensuring affordability, preferred type of PrEP and the need for differentiated services to accelerate uptake.

MOPEE11

Qualitative segmentation of adolescent girls and young women (AGYW) PrEP users: the role of differentiated PrEP delivery platforms

E. Rousseau¹, K. Sikkema², R. Julies³, K. Mazer⁴, G. O'Malley⁵, R. Heffron⁶, J. Morton⁵, R. Johnson⁵, C. Celum⁵, J. Baeten^{5,7}, L.-G. Bekker¹

¹University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa, ²Columbia University, Department of Sociomedical Sciences, Mailman School of Public Health, New York, United States, ³University of the Western Cape, Department of Psychology, Cape Town, South Africa, ⁴University of California, Infectious Diseases, School of Medicine, Los Angeles, United States, ⁵University of Washington, Departments of Global Health, Medicine and Epidemiology, Seattle, United States, ⁶University of Alabama, Department of Medicine, Heersink School of Medicine, Birmingham, United States, ⁷Gilead Sciences, Seattle, United States

Background: Adolescent girls and young women (AGYW), a target population for HIV prevention in Africa, show high PrEP interest but difficulty in sustained effective use. With ongoing PrEP scale-up focused on increasing PrEP access, it is important to understand what influences AGYW's choice of PrEP delivery platforms.

Methods: The POWER (Prevention Options for Women Evaluation Research) PrEP implementation study in Cape Town utilised a differentiated delivery model from July 2017 to November 2020. AGYW 16-25 years could access PrEP from any of four delivery platforms: mobile clinic, government facility, courier delivery service, or community-based youth club. At government and mobile clinics, healthcare providers delivered comprehensive integrated sexual and reproductive health services.

The courier and youth club platforms provided light-touch PrEP follow-up services incorporating rapid HIV self-testing. We conducted in-depth interviews with a purposive sample of AGYW who had ≥3 months of PrEP use based on pharmacy records and who accessed more than one PrEP delivery platform.

Thematic analysis explored the preferences, decision-making, influences, and habits related to PrEP access to inform market segmentation.

Results: We interviewed 26 AGYW (median age 20) persistent PrEP users between November 2020 – March 2021. Of these, 24 used mobile clinics, 17 courier delivery, 9 the government facility, and 4 the youth club. Qualitative findings highlighted three potential behavioural profiles.

The "Social PrEP-user" seeks PrEP delivery in shared peer spaces such as youth clubs or adolescent-friendly mobile clinics, that provide affirmation and social support for continued PrEP use.

The "Convenience PrEP-user" seeks PrEP delivery at easily accessible locations, providing quick (courier) and/or integrated service with contraception and PrEP refills in a single visit (mobile and government clinic).

The "Independent PrEP-user" seeks PrEP delivery that is discreet, outside of traditional medical environments, and offers control over delivery times that fit into their schedule as offered by the courier service.

Comfort with HIV self-testing had minimal influence on PrEP delivery choice.

Conclusions: PrEP delivery platforms and demand creation for these services must be tailored to thematic groups of AGYW and more closely aligned to individual characteristics and needs for convenience, independence, or social engagement to improve AGYW's PrEP persistence.

MOPEE12

Where are the Men? Finding high-risk men through their AGYW sexual partners who are on PrEP in Zambia using HIV prevention indexing

B.C. Simpasa¹, L. Kawanga¹, A. Ndhlovu¹, M. Nyumbu¹

¹JSI Research & Training Institute (JSI), Prevention Behavioural Intervention, Lusaka, Zambia

Background: HIV program data in Zambia shows that men are missing from HIV prevention and treatment services despite men having a low HIV prevalence of 8% compared to females (14%), according to ZAMPHIA 2021. The lack of access to services has not only affected men but also contributed to a higher HIV incidence of 5.6 percent among adolescent girls and young women (AGYW) who have been linked to a sexual triangle with men. To reach epidemic control, men must be reached to interrupt the HIV transmission cycle.

Description: The USAID DISCOVER-Health Project implemented by JSI developed an innovative approach known as HIV prevention indexing (HPI) to reach men through AGYW at high HIV risk on PrEP in supported sites in Zambia 2021. 5687 AGYW were offered HPI, from which 4296 were elicited with 2,677 men tested for HIV. The assumption was that contacts elicited could also be at high risk of contracting HIV and may benefit from PrEP, or maybe living with HIV and would benefit from antiretroviral therapy.

Lessons learned: HPI provided an opportunity to reach unreached men and contributed to 19% of men newly initiated on PrEP. The acceptance of PrEP was high among contacts who tested negative that were at substantial HIV risk 83% of men. The HPI positivity rate of 4.4% was confirmed. high HIV risk remains within these sexual networks and the need for HPI to find men living with HIV and put them on ART is needed to further reduce the risk for AGYWs.

Figure. Results: Cascade for male contacts (20-40 years).

Conclusions/Next steps: HPI is useful in settings like Zambia where there are men at high HIV risk who feel “shut out” of the health system and do not access HIV services. Through the HPI approach, men can be reached and provided with HIV services, ultimately helping Zambia attain and sustain epidemic control.

MOPEE13

Healthcare worker perspectives on anticipated barriers and facilitators to implementing long-acting injectable PrEP for HIV prevention in Vietnam

T.M. Dang^{1,2}, N.Y. Le³, S. Naz-McLean^{2,4}, T.T.N. Vo^{1,2}, T.P. Do³, T.P. Tran^{1,2}, T.T.L. Doan⁵, T.N. Do⁵, T.M. Nguyen⁵, R. Bhatia⁶, L. Cosimi^{1,2,4}, T.T.H. Phan⁵, T. Pollack^{1,2}

¹Beth Israel Deaconess Medical Center, Boston, United States, ²The Partnership for Health Advancement in Vietnam, Hanoi, Vietnam, ³Division of Global HIV and TB, Center for Global Health, US Centers for Disease Control and Prevention, Hanoi, Vietnam, ⁴Brigham and Women's Hospital, Boston, United States, ⁵Vietnam Administration of HIV/AIDS Control, Hanoi, Vietnam, ⁶Division of Global HIV and TB, Center for Global Health, US Centers for Disease Control and Prevention, Atlanta, United States

Background: Long-acting injectable cabotegravir (CAB-LA) is recommended by the World Health Organization as an additional HIV prevention option for people at substantial risk of HIV transmission. However, there are limited data on the feasibility of implementing CAB-LA in low-middle-income settings, particularly in Asia.

The study describes anticipated barriers and facilitators of implementing CAB-LA in Vietnam among healthcare workers and public health managers.

Methods: From July-August 2022, in-depth interviews following a semi-structured questionnaire were conducted with key stakeholders in HIV program implementation at the national, provincial, and clinic levels across four provinces of Vietnam. Interviews were audio recorded and data were analyzed using a rapid thematic analysis approach.

Results: Participants included healthcare providers (n=15) and provincial (n=6) and national-level (n=6) public health managers, with an average of 11.4 years working in HIV programming. Participants identified key facilitators to successful implementation of CAB-LA, including the perception that CAB-LA would be highly acceptable to clients and that nurses were already trained to administer injections.

While some participants felt existing facilities were adequate, most agreed that clinical sites lack the necessary infrastructure and equipment for CAB-LA, including physical space and beds for injection procedures and anaphylaxis response kits.

Participants expressed concern that more frequent appointments due to CAB-LA injection schedules would increase workload and necessitate additional nursing staff.

At the provincial and national health systems level, perceived barriers included the need for separate reporting systems for injectable medication management and the lengthy regulatory procedures to obtain approval for new medications.

Overall, participants agreed that the lack of clear guidelines on handling adverse reactions and client eligibility was also a barrier. Despite potential barriers, participants felt that CAB-LA could help Vietnam reach 95-95-95 targets.

Conclusions: Participants were optimistic about the benefit of CAB-LA on HIV prevention, though they acknowledged infrastructure, human resources, and systems barriers to implementation. Demonstration projects may be an important next step in order to develop real-world strategies that can be scaled to overcome these barriers and enable successful CAB-LA implementation in Vietnam.

MOPEE14

Who chooses event-driven PrEP (PrEP 2-1-1) in a US national cohort? Exploring the role of demographics, wealth, access to health care, sexual behavior and practices on PrEP choice

P.B. Carneiro¹, V.V. Patel², C. Grov¹

¹CUNY School of Public Health, New York, United States,

²Albert Einstein College of Medicine, New York, United States

Background: Event-driven PrEP (ED-PrEP) is an effective option for PrEP and is included in the US CDC PrEP clinical guidelines for off-label use. Successful implementation of ED-PrEP elsewhere has expanded PrEP access and uptake. In the US, little is known about characteristics of individuals using ED PrEP, which is detrimental to future implementation.

Methods: Our sample includes PrEP users (n =1367) from the *Together 5,000* US cohort of cis men and Trans people who have sex with men – who started PrEP in the past 36-months. We conducted an adjusted logistic regression analysis predicting ED regimen choice, including baseline demographic characteristics, income, healthcare access, sexual behaviors and practices. All variables were included together.

Results: Overall, 153 (11.2%) participants used ED-PrEP. Higher educational attainment was a significant predictor of ED PrEP with individuals who reported some college, bachelor's degree, and those with graduate school all having much greater odds of choosing ED-PrEP when compared to individuals who had high school or less (Full results on Table 1).

Individuals who reported having 2 or more hours of lead time during their last sexual encounter had 3.45 times the odds of using ED-PrEP when compared to those with no lead time or less than 2 hours. Participants who reported having an STI within the last year had 61% lower odds of using ED-PrEP when compared to those who did not have

an STI. Participants who reported not finding the science for U=U trustworthy had 3.44 times the odds of using ED-PrEP than those who said they trusted U=U.

Table 1. Demographic, wealth, access to health care, sexual behavior and practices, and PrEP-related predictors of ED PrEP use: Logistic regression analysis output (Sample ED PrEP use = 11.2%).

Conclusions: Our findings show an educational divide in access to ED-PrEP suggesting that those with lower educational attainment may not be aware of or have access to information about ED-PrEP. Instead, interventions focusing on behavior compatibility and sexual practices are likely to be more successful.

MOPEE15

Machine learning models to predict lost to follow-up of people receiving antiretroviral therapy in Brazil, 2014-2022

T. Benoliel¹

¹Ministry of Health of Brazil, Brasília, Brazil

Background: Antiretroviral therapy (ART) is only effective when people living with HIV (PLHIV) maintain their treatment retention. Lost to follow-up (LTFU) is the major challenge to Brazilian national public health system and traditional strategies to reach out to these people are often ineffective due to registration problems and outdated information. This study aims to apply machine learning models to predict LTFU of people receiving ART in Brazil.

Methods: Programmatic data from Brazilian MoH ART dispensing national system from 2014 to 2022 were used to build a behaviour and sociodemographic profile database of PLHIV.

Five machine learning models were initially trained and tested in the 2014-2018 database, and then accuracy and area under the receiver operating characteristic curve (AUROC) were evaluated.

False-positive individuals (classified as LTFU by the model, but were in regular ART by the end of 2018) were flagged and reassessed by the end of 2019. The same logic was annually applied until the end of 2022. Each model was performed five independent times.

Results: The best results were obtained by random forest classifier model, which had average accuracy of $0,734 \pm 0,011$ and average AUROC of $0,824 \pm 0,014$ for the studied period.

False-positive individuals flagged by this model represented an average of $25,8\% \pm 0,8\%$ of all ART patients, of which $16,9\% \pm 1,6\%$ converted to LTFU by the end of the next year, representing an average of $53,6\% \pm 1,9\%$ of all new LTFU cases in the period.

The incidence of LTFU in flagged individuals was in average $333,3\% \pm 24,4\%$ higher than in unflagged ones.

Train-test database	Predicted year	Accuracy in test database	AUROC	Flagged / Total ART (%)	LTFU conversion / Flagged (%)	LTFU conversion / All new LTFU (%)	LTFU incidence: Flagged / Unflagged (%)
2014-2018	2019	$0,746 \pm 0,005$	$0,840 \pm 0,001$	24,9	15,4	51,3	317,7
2014-2019	2020	$0,738 \pm 0,004$	$0,828 \pm 0,004$	25,4	16,4	54,2	347,6
2014-2020	2021	$0,734 \pm 0,005$	$0,820 \pm 0,001$	25,9	16,5	55,7	359,7
2014-2021	2022	$0,720 \pm 0,001$	$0,806 \pm 0,005$	26,8	19,2	53,0	308,0

Conclusions: Machine learning models are valuable tools to identify most likely lost to follow-up PLHIV. Signalling these individuals to health care professionals might allow an early and customized intervention to prevent a future LTFU case, reducing incidence of this outcome.

MOPEE16

Preparing for next-generation PrEP: awareness and willingness to use long acting injectable cabotegravir (CAB-LA) among men who have sex with men and trans women across Asia and Australia

H.-M.A. Schmidt^{1,2}, C. Chan³, K.E. Green⁴, M.M. Cassell⁵, J.J. Ong^{6,7}, N. Phanuphak⁸, H. Boonyapisompan⁹, D. Fraser³, N. Suwandj¹⁰, L. Zhang^{11,12,13},

M. Poonkasetwattana¹⁰, B.R. Bavinton³

¹UNAIDS Asia Pacific, Bangkok, Thailand, ²World Health Organization, Geneva, Switzerland, ³The Kirby Institute, UNSW Sydney, Sydney, Australia, ⁴PATH, Hanoi, Vietnam, ⁵FHI 360, Hanoi, Vietnam, ⁶Monash University, Melbourne, Australia, ⁷London School of Hygiene and Tropical Medicine, London, United Kingdom, ⁸Institute of HIV Research and Innovation, Bangkok, Thailand, ⁹Asia-Pacific Transgender Network, Bangkok, Thailand, ¹⁰APCOM, Bangkok, Thailand, ¹¹Melbourne Sexual Health Centre, Alfred Health, Melbourne, Australia, ¹²University of Melbourne, Central Clinical School, Faculty of Medicine, Melbourne, Australia, ¹³Xi'an Jiaotong University Health Science Center, China-Australia Joint Research Centre for Infectious Diseases, Xi'an, China

Background: Offering choice in pre-exposure prophylaxis (PrEP) products, including the new WHO-recommended long acting injectable cabotegravir (CAB-LA), is expected to help accelerate PrEP uptake globally. This study aimed to assess awareness, values, and preferences related to CAB-LA among gay men and other men who have sex with men (MSM) and trans women (TGW) across Asia and Australia to inform successful introduction.

Methods: We conducted an online cross-sectional survey among self-identified MSM and TGW aged ≥ 18 years in 16 and 11, respectively, countries/territories in Asia and Australia between May-November 2022. Participants were asked about CAB-LA awareness, willingness to use and reasons for preferring / not preferring CAB-LA. Descriptive statistics and bivariate logistic regression models were calculated for associations between awareness and willingness to use PrEP.

Results: Among 17032 MSM and 1260 TGW, 18.2% (n=3103) and 26.6% (n=335), were aware of CAB-LA, respectively. Willingness to use CAB-LA among all MSM and TGW respondents was 16.1% (n=2742) and 15.6% (n=196), respectively. Both awareness and willingness varied substantially across countries (Figure). Prior awareness of CAB-LA was positively associated with willingness to use CAB-LA among MSM (OR=1.74, 95% CI=1.58-1.91) but not TGW (OR=1.17, 95% CI=0.83-1.65). Perceived benefits of CAB-LA were similar between MSM and TGW: HIV protection (55.2% and 45.7%); not having to remember to take pills (37.2% and 27.8%); and longer-term protection (35.1% and 21.1%). Perceived concerns varied across populations: unaffordable cost (36.3% and 19.9%); side effects (34.0% and 20.6%); insufficient knowledge (32.5% and 21%); and pain (20.0% and 24.0%).

Figure. Awareness and willingness to use CAB-LA

Conclusions: Awareness of CAB-LA is low among MSM and TGW across Asia and Australia, with substantial variability between countries.

Urgent efforts are needed to increase awareness which will support higher willingness to use CAB-LA. With CAB-LA imminent registration and/or availability in some Asian countries and Australia, tailored demand generation activities are needed to address perceived benefits and concerns.

MOPEE17

High rate of missed HIV testing among oral PrEP users from 2018-2020 in the United States: a national assessment on compliance with HIV testing recommendations of the CDC PrEP Guidelines

J. Baron¹, T. Tchelidze¹, B. LaBrot², J. Yao³, K. Mayer⁴, D. Kuritzkes⁴, N. Robinson¹, R. Patel⁵

¹Roche Diagnostics, Indianapolis, United States, ²Roche Molecular Systems, Los Angeles, United States, ³Mayo Clinic, Rochester, United States, ⁴Harvard Medical School, Boston, United States, ⁵Washington University in St Louis, St. Louis, United States

Background: CDC has highly recommended combined HIV Ag/Ab testing for PrEP initiation and quarterly monitoring. We examined compliance with HIV testing guidance among oral PrEP users nationally.

Methods: We conducted an analysis of 396,385 PrEP prescriptions issued to 42,890 PrEP users using MarketScan®, a national insurance claims database for private and public companies.

The primary outcome was the number of calendar months between each PrEP medication fill and the PrEP user's most recent prior HIV Ag/Ab test (identified by CPT codes).

Secondary outcomes included HIV testing patterns (with antibody only and NAAT testing) and sociodemographic and geographic differences. The inclusion criteria were PrEP prescriptions filled from 2018-2020. PrEP use was defined as two or more prescription fills in different calendar months for ARVs approved for oral PrEP in HIV-negative persons (ICD codes) who had no additional ARV prescriptions (NDC numbers).

Analyses included survival methods and proportional hazard models with persons censored to the time of enrollment in the database.

Author Index

Results: Of 42,890 PrEP users, 39,860 had private and 3,030 had public insurance, 96% identified as male, and the median age was 35 years (IQR 29-44). Individuals were 48% White, 24% Black/African American, and 10% Hispanic/Latinx. 30.9% (95% CI: 30.7-31.0%), 21.2% (21.0-21.3%), and 14.5% (14.4-14.6%) of PrEP prescriptions were filled in persons who had not received an HIV Ag/Ab test within the prior 3, 6, and 12 months, respectively. HIV testing patterns revealed 22.8% (95% CI: 22.7-23.0%), 12.7% (12.6-12.8%), and 6.5% (6.4-6.6%) of PrEP prescriptions were filled in individuals who had not received any type of HIV test in the prior 3, 6, and 12 months.

PrEP users with public insurance (HR 0.60; $p < 0.001$), rural residence (HR 0.79; $p < 0.001$), Northcentral U.S. residence (HR 0.72; $p < 0.001$), younger age (16-24 years) (HR 0.89; $p < 0.001$) and who identified as female (HR 0.84; $p < 0.001$) received less testing ($p < 0.001$).

Conclusions: Nearly one in three oral PrEP prescriptions were filled in persons who had not received a combined HIV Ag/Ab test within the prior three months, with evidence of health disparities in several key population groups. Study findings can inform efforts to optimize HIV testing compliance with national PrEP guidance.

MOPEE18

Evidence of peer-led demedicalized delivery of same-day PrEP in various community centers in the Philippines

J.D.M. Dela Cruz¹, G. Aspiras¹, J.D. Rosadiño^{1,2}, R. Pagtakhan¹
¹LoveYourself, Inc, Mandaluyong, Philippines, ²University of the Philippines - Open University, Faculty of Management and Development Studies, Los Baños, Philippines

Background: LoveYourself serves a large number of clients for HIV screening and PrEP through a peer-led approach in its network of community centers in the Philippines. Observed challenges were delay of PrEP initiation due to long queues for medical consultation, long turnaround time of test results for serum creatinine, hepatitis B screening, and hesitancy of clients who use gender-affirming hormone therapy or body-building supplements. We explored the program that shifted PrEP delivery to trained peer counselors known as PrEPY Peers.

Description: An algorithm (Figure-1) was developed to guide PrEPY Peers to provide same-day PrEP, and when to refer to a physician. Counselors were trained to assess HIV non-reactive clients without symptoms of acute retroviral syndrome within 30 days, age 18-50, body weight of 35-90 kg, kidney-related comorbidity, and supplementation. They were also trained to compute creatinine clearance, and health teaching regarding follow-up care. A physician is on-call for any urgent referral. All charts were submitted to the physician for quality check. All PrEP-naïve were advised daily-PrEP for at least 3 months before considering event-driven PrEP to monitor recent exposure and possible seroconversion.

Figure 1. Updated PrEPY process flow as of April 2022.

Lessons learned: Upon demedicalizing PrEP, enrolled clients increased from a moving average of 568 since Q3 2021 to 1256 from Q2 2022 (Figure-2). The facility had a total of 7,134 enrolled at the end of Dec. 2022.

Note: Broken lines show moving average.

Figure 2. Graph showing quarterly PrEP enrolment for 2021 to 2022.

Conclusions/Next steps: This study presents evidence that peer-led demedicalized delivery is possible. This mechanism promotes task-shifting, showing that peers can provide PrEP at scale to high-priority populations. This evidence also empowers nonmedical providers through a guided approach.

MOPEE19

Fast-tracking treatment optimization to address treatment continuity among PLHIV through comprehensive approach and use of digital and telehealth platforms during the COVID -19 pandemic in Andhra Pradesh, India

R. Agarwal¹, P. Turaka², A. Rajendran², U. Krantha², N. Chava², G Ramesam², A. Rao², P. Kumar², R. Allam¹, R. Prasad², V. Yeldandi², A.E. Florence³, M. Nyendak¹, K. Prasad³

¹U S Centers for Disease Control and Prevention, Division of Global HIV and TB, Delhi, India, ²Society for Health Allied Research & Education India, Hyderabad, India, ³Andhra Pradesh State AIDS Control Society, Vijayawada, India

Background: Transition to DTG based regimens (DTG) in India coincided with the devastating second wave (April to June 2021) of COVID-19 pandemic. With urgency for transition to DTG due to depleting stock of the previously used ART regimens and lockdown that hit the mobility, it was critical to devise comprehensive approach to address treatment continuity and fast-track ART optimization.

Description: Between April to June 2021, we adopted multi-pronged strategy to fast track DTG transition in 13 districts of Andhra Pradesh (Figure) including-- mapping of all PLHIV eligible for transition to DTG by sub-district unit using epidemiological tools; engagement with all stakeholders for preparation of transition plan; proactive outreach of PLHIV for transition to DTG through digital modalities such as phone follow-ups, text messages and interactive voice response systems; teleconsultation sessions; and physical camps for PLHIV at decentralized and remote locations who couldn't reach the ART sites due to restricted mobility.

In addition, we prepared job-aids and education material on DTG for ART staff and PLHIV, ensured drug supply chain and monitored the progress of transition daily.

Lessons learned: During the surge period (April-June 2021), 80,553 of 186,170 PLHIV receiving ART (43%) were transitioned to DTG-based regimens, of which 49,405 (61.3%) PLHIV reached ART clinics for transition subsequent to the

digital outreach; 19,718 (24.5%) were transitioned through teleconsultation modalities; and 11,430 (14.2%) through decentralized camps.

Conclusions/Next steps: Transition to DTG-based regimen was feasible amidst the peak of COVID-19 through the sequential and coordinated approach, including use of digital and telehealth platforms, for a sustained treatment continuity. Further, telehealth models have potential to reach the PLHIV residing in remote locations and provide them appropriate management, thereby enhancing health equity. Sustaining and scaling up telehealth care models for HIV service delivery could ensure enhanced access to services while maintaining continuity to care and treatment for PLHIV.

MOPEE20

A Quality Improvement Collaborative improves viral load testing coverage in Western Province, Zambia

G. Dougherty¹, S. Kasonka², A. Mwila³, P. Kasonde², P. Koni², J. Mhone⁴, J. Mwanza², M. Mwamba², P. Milimo², S. Michaels-Strasser⁵

¹Columbia University Mailman School of Public Health, ICAP, New York, United States, ²ICAP Zambia, Lusaka, Zambia, ³U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, ⁴Ministry of Health, Western Provincial Health Office, Lusaka, Zambia, ⁵Columbia University Mailman School of Public Health, Department of Epidemiology, New York, United States

Background: Zambia has made great strides towards attaining 95-95-95. Population-based HIV/AIDS Impact Assessment (ZAMPHIA, 2021) data demonstrates that 88.7% of adults living with HIV were aware of their status, among adults who knew their status, 98% were on ART and among these individuals, 96.3% were virally suppressed (VLS). Important geographic variations in VLS were noted with Western Province (WP) having 87.9% VLS. Improving viral load coverage (VLC) with early identification of unsuppressed VL is critical for preventing HIV transmission and achieving epidemic control.

Methods: In collaboration with ICAP Columbia University and CDC Zambia, the Zambia MoH led the design and implementation of a quality improvement collaborative (QIC) to improve VLC at 18 high priority health facilities in 10 districts across WP from January- August 2022. Indicators were collected at baseline and throughout implementation. The MoH and ICAP provided training on QI methods and ART adherence counseling skills for 35 health care workers followed by monthly supervision and two quarterly learning sessions. Each QIC team used QI methods to conduct rapid tests of change; and analyzed monthly progress using run charts. QI teams tested interventions including assigning a VL focal person at each clinic, VL media campaigns, community based VL sampling, VL data reviews, and reduction in lab to clinic turn-around time. This quasi-experimental, descriptive study

IAS 2023

provides analysis of outcomes using summary statistics and demonstrates progress on a run chart before, during and after the QIC implementation.

Results: Preliminary data demonstrates VLC improved from **76.1%** at baseline (November 2021) to **85.4%** in August 2022, and **89.6%** in October 2022 (post intervention). There was substantial shift above the baseline median after May 2022 (4 months of implementation) and progress is sustained.

Conclusions: The QIC approach led to important improvements in VL coverage at 18 sites in WP. Continued monitoring will assess sustainability following the QIC.

MOPEE21

Lessons Learned from the introduction of advanced HIV disease package of care in Nigeria

B. Levy-Braide¹, N. Otubu¹, O. Abudior¹, W. Eigege¹, O. Sowale¹, I. Inyang¹, I. Amamilo², D. Rathakrishnan², A. Moore², J. Conroy², C. Amole², F. Lufadeju¹, O. Wiwa¹, C. Adesigbin³, P. Nwaokenneya³, U. Atu³, M.-I. Patiko³, A. Ikpeazu³, R. Oladele⁴, O. Agbaji⁵, S. Akanmu⁶

¹Clinton Health Access Initiative, HIV Access Program, Abuja, Nigeria, ²Clinton Health Access Initiative, HIV Access Program, Boston, United States, ³National AIDS and STI Control Program, Federal Ministry of Health, Abuja, Nigeria, ⁴Medical Mycology Association of Nigeria, Lagos, Nigeria, ⁵Jos University Teaching Hospital, Jos, Nigeria, ⁶Lagos University Teaching Hospital, Lagos, Nigeria, Lagos, Nigeria

Background: In Nigeria, 32% of PLHIV who received CD4 tests in 2018 had Advanced HIV Disease (AHD), this population had the highest mortality. Despite this, a package of care for AHD (AHD PoC) was not clearly defined in-country. This abstract outlines the process and lessons learned from introducing the AHD PoC in Nigeria.

Description: The Nigeria MOH constituted a working group in 2019 to develop and oversee implementation of the AHD PoC in-country. The first phase of implementation involved 28 facilities across 4 high-burden states that account for 31% of national HIV burden (Lagos, Akwa-Ibom, Rivers, Anambra). In 2020, National guidelines, training materials, and reporting tools were reviewed to include the AHD PoC. Healthcare-worker (HCW) capacity was built to implement AHD PoC. Commodities were

distributed and facility implementation commenced in February 2021. Newly identified PLHIV were screened for AHD. Those with AHD were screened for Tuberculosis and Cryptococcal-Meningitis (CM), followed by rapid ART initiation and intensive adherence support.

Lessons learned: By September 2022, 13,795 new PLHIV were identified; 85.4% (11,781) received CD4 tests, of which 46.6% (5,487) had CD4 <200cell/mm³. Of the 5,487 AHD clients, 77.9% (4,277) were screened for TB using TB LF-LAM, 34.1% (1,458) were positive, of which 67.8% (989) started TB treatment. The screening coverage for blood cryptococcal antigen (CrAg) using CrAg LFA was 83.4% (4,576), 2.3% (106) were positive. Only 35.8% (38) of blood CrAg-positive clients received a CSF CrAg test, 23.7% (9) were CSF positive, of which 66.7% (6) started CM treatment. Poor access to adjunct commodities contributed to observed gaps in TB LF-LAM and CSF CrAg testing.

Programming for CrAg and TB LF-LAM tests should consider adjunct commodities vital to close gaps observed across the cascade, particularly lumbar-puncture packs for CSF CrAg and urine cups for TB LF-LAM. Considering HCW capacity gaps for lumbar puncture (LP) at some facilities, a hub-and-spoke model will be ideal for scale-up, and LP referral mechanisms should be strengthened.

Conclusions/Next steps: Implementing the AHD PoC increased TB and CM case-finding among PLHIV, and could potentially reduce mortality associated with AHD.

MOPEE22

Community Retail Pharmacy Drug Distribution Points (CRPDDPs) to provide a convenient, cost-saving, client-preferred model for pick-up of antiretrovirals in Uganda

P. Bitarabeho¹, I. Arinaitwe², C. Katureebe², L.B. Taljaard¹, K. Gibbons¹, I. Ddumba³, H. Balidawa²

¹Africa Resource Centre, Kampala, Uganda, ²Ministry of Health, AIDS Control Program, Kampala, Uganda, ³United States Agency for International Development (USAID), Kampala, Uganda

Background: In Uganda median waiting time to access ART services is 170 minutes, and 39.4% of surveyed ROCs were unsatisfied with service efficiency. In order to make ART services more efficient and person-centered, Ministry of Health (MOH) set a target that 80% of ROCs be enrolled in less intensive models (LIMs) of Differentiated Service Delivery (DSD), but by September 2021, only 56.0% (735,864) were in LIMs.

MOH collaborated with Africa Resource Centre (ARC) to establish the Community Retail Pharmacy Drug Distribution Point (CRPDDP) to improve convenience to ROCs and reduce health facility (HF) congestion.

Description: Stable ROCs are enrolled and attached to a convenient pharmacy through the national electronic medical records platform (UgandaEMR/OpenMRS). At the time of dispensing, trained pharmacy staff provide ROCs with 3-or-6-month ARV packs for free, and the phar-

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

macy receives \$0.54 (UGX 2,000) per ROC dispensing, paid by implementing partners. This public-private partnership builds on an initial pilot to provide person-centered services to ROCs by leveraging existing resources in the health system.

As of January 2023, 104 pharmacies across Uganda are providing refills to over 40,000 ROCs from 61 high-traffic health facilities, with a 2023 target of over 150 health facilities, 200 pharmacies, and 150,000 ROCs.

Lessons learned: Preliminary results of a nationwide survey of 403 ROCs (55.8% female) show that 99.8% would recommend the program to a friend. Waiting time was under 20 minutes for 97% (compared to 3 hours at the HF), and 92.4% reported being treated "respectfully".

National implementation requires a focus on defining critical service processes and focusing on ROC awareness. Electronic records systems for enrolment, stock movement, dispensing, and monitoring must be interoperable. "High touch" interaction with all stakeholders is required to ensure that delays in implementation are addressed in a timely manner.

Conclusions/Next steps: The pharmacy pick-up model can be implemented at scale if it is designed to fit the health system and coordinated effectively with service providers and ROCs. The low-cost, person-centered, and scalable CRPDDP model make it ideally suited for adoption. MOH is scaling up the model nationwide and integration of more services (like PrEP, family planning, NCDs) is being explored.

MOPEE23

Smartphone- enabled video directly observed therapy to improve viral suppression among unsuppressed children and adolescents in Kenya

P. Wekesa¹, M. Ndisha², B. Makone², K. Kamenwa¹, K. Owuor¹, I. Mutisya²

¹Centre for Health Solutions - Kenya, Nairobi, Kenya,

²Division of Global HIV&TB (DGHT), Center for Global Health, U.S. Centers for Disease Control and Prevention, Nairobi, Kenya

Background: Video directly observed therapy (vDOT) has been used as an acceptable, cost-effective, client-centered intervention for tuberculosis management. vDOT targeting children and adolescents not achieving viral suppression (VS) [<1000 copies/ml] was piloted in 128 sites in Kenya. We evaluated utilization and re-suppression rates of clients enrolled in vDOT.

Methods: A retrospective review of data from 223 (out of 470) virally unsuppressed clients aged between 0-19 years on antiretroviral therapy (ART) using the NimeCONFIRM vDOT application for at least 12 weeks between February 2021 and October 2022 at 73 facilities were conducted. Clients stopped using the application upon achieving VS. VS was assessed after at least 12 weeks of follow-up through self-care (user) or Healthcare worker (HCW)-assisted recording and upload of vDOT. Using a multi-

variable Fine-Gray sub distribution hazard (SH) model we assessed demographic and clinical determinants of VS presenting adjusted sub distribution hazard ratios (aSHR) and 95% confidence interval (CI). Participants were censored on loss to follow-up, death, and transfers.

Results: Most users were aged 10-14 years (84 [37.7%]) and 15-19 years (79 [35.4%]). Only 19 (8.5%) were on self-care vDOT. Median time on follow up was 19.36 weeks (interquartile range [IQR]: 16.50 – 23.07), median number of videos uploaded were 126 (IQR: 96 – 197), and with 75% (IQR: 60% – 85%) vDOT adherence.

About half, 108 (48.4%), were active, 39 (17.5%) had achieved VS, and 76 (34.1%) discontinued. Cumulative incidence of VS was 22.1%. Results show higher incidence of VS among children aged 5-9 years compared to 0-4 years, aSHR = 3.12 (95% CI: 1.03 – 9.39) and those on selfcare compared to healthcare worker led option, aSHR = 2.51 (95% CI: 1.95 – 3.24). Similarly, there was higher incidence of VS for those with guardians and siblings as caregivers compared to grandparents; aSHR = 1.28 (95% CI: 1.11- 1.48), and aSHR = 2. 83 (95% CI: 1.83 - 4.37), respectively.

Conclusions: Achieving VS using vDOT was significantly associated with age, selfcare option, and type of caregiver. Findings suggest vDOT as an additional tool to support unsuppressed children and adolescents to achieve more equitable health outcomes.

MOPEE24

Tracking the effect of paediatric dolutegravir (pDTG) on viral load suppression in a large population cohort of children on ART in Malawi

J. Nkhonjera¹, B. Chiwandira¹, M. Maulidi¹, R. Nyirenda¹

¹Ministry of Health, Malawi Government, HIV, STIs and Hepatitis, Lilongwe, Malawi

Background: Sub-Saharan Africa is home to nearly 90% of all children living with HIV (CLHIV). Overall paediatric HIV incidence declined by 54% from 2010 to 2020 globally, mainly due to the increased provision of antiretroviral therapy to pregnant and breastfeeding women living with HIV [1].

Despite progress in reducing HIV incidence in children, the region remains behind in reaching the 95-95-95 UNAIDS fast-track targets. Viral load suppression (VLS) is critical to treatment success and reducing child morbidity and mortality to accelerate progress towards ending AIDS. According to UNAIDS, only 40% of CLHIV had attained VLS, compared to 67% of adults in 2021 [2].

The 2015/16 MPHIA survey [3] reported that one in three children who had a viral load test had not achieved VLS. Malawi has slightly above 1 million people living with HIV with 15% being children under the age of 14. The country has made strides to achieve UNAIDS fast-track targets with a performance of 88%:98%:97% among the 15+ cohort (MPHIA 2020/21). In 2021, ART Coverage in children was at 78% with all of them taking either LPV/r or NVP based regimens.

Description: We conducted a review of client-level data over a 12-month period to track the rates of VLS for children who had been taking pDTG-based ART.

We reviewed national program data that was collected from client records in over 800 health facilities to compare the rates of VLS prior to introduction of pDTG in 2021 to 12-month post transition of all children to pDTG-based ART.

Lessons learned: pDTG rollout was initiated in July 2021 when national paediatric VLS was at 55%. By the end of a 12-month period, suppression rose to 73.5% which translates to 18.5% jump in 12 months.

Similarly, the proportion of children with viraemia of >1,000 copies/mL had also decreased from about 27% to 16% in these 12 months.

Conclusions/Next steps: The effect of pDTG on VLS is evident regardless of other associated factors such as adherence. National HIV programs need to finalize transitioning of all paediatric ART cohorts to pDTG while monitoring outcomes and other associated factors to achieve optimal VLS in children.

Barriers and facilitators to the implementation of Cabotegravir + Rilpivirine long-acting injectable HIV treatment among healthcare providers: baseline qualitative findings from the ILANA study

R. Hayes^{1,2}, C. Mwendera^{1,3}, V. Apea^{1,4,5}, S. Paparini^{1,2}, C. Orkin^{1,4,5}, for the ILANA Writing Group (Bakita Kasadha, Julie Fox, Emily Clarke, Ruth Byrne, Amanda Clarke, Tristan J Barber, Sadna Ullah, Nishat Halim, James Hand, Hamzah Farooq, Rachel Parker, John Thornhill)
¹SHARE Collaborative, Queen Mary University of London, London, United Kingdom, ²Wolfson Institute of Population Health, Queen Mary University of London, London, United Kingdom, ³University of Liverpool, Liverpool, United Kingdom, ⁴Blizard Institute, Queen Mary University of London, London, United Kingdom, ⁵Barts Health NHS Trust, Department of Infection and Immunity, London, United Kingdom

Background: This study explores the early experiences of barriers and facilitators to the implementation of Cabotegravir + Rilpivirine long-acting injectable HIV treatment (CAB+RPV LA) among healthcare providers (HCPs) participating in the ILANA implementation study.

Methods: ILANA is examining the acceptability and feasibility of implementation of CAB+RPV LA in clinics and community settings. From August to November 2022, semi-structured baseline interviews were conducted with HCPs from six HIV clinics in the UK across Brighton, Liverpool, and London participating in ILANA. The interviews were analysed using reflexive thematic analysis.

Results: Thirteen HCPs were interviewed, including doctors, nurses, and pharmacists. All participants felt that CAB+RPV LA would offer substantial benefits for their service users, including: removal of daily reminder of their HIV status; reduced pill fatigue; and increased privacy about treatment use.

Initial barriers to implementation included: HCP anxieties about switching service user participants to a new regimen; the additional burden created by CAB+RPV LA delivery on clinical resources and time; and lack of clarity about novel delivery in community settings.

Facilitators included: ongoing, open, and accessible communication with service user participants; high acceptability of CAB+RPV LA to service user participants once initiated; and the adoption of tools and strategies to aid implementation. The latter included: establishing working groups; virtual screening and results management apps; a range of staff information resources; dedicated staff time for CAB+RPV LA provision; and flexibility in appointment scheduling.

Conclusions: HCPs had initial anxieties about CAB+RPV LA but these were mostly assuaged when treatment commenced and service user participants found it highly acceptable. Enabling ongoing, open, and accessible communication with trusted staff members was a key facilitator in reassuring service user participants and managing expectations around treatment. While the implementation of CAB+RPV LA has increased the demand on clinical resources and time, HCPs have found tools and strategies to manage this, and feel positive about the benefits of CAB+RPV LA for service users. HCPs felt more hesitant about delivery of CAB+RPV LA in community settings, and increased information and planning is required to facilitate community roll-out.

Methods: Quantitative and qualitative data regarding clinic processes were collected from 62 staff study participants (SSPs) from 18 sites across Belgium, France, Germany, the Netherlands, and Spain at Months 1, 5, and 12. Clinic processes used in CARISEL to implement CAB+RPV LA were summarized in three distinct phases: pre-appointment, during appointment, and after clinic visit.

Results: Pre-appointment processes included sending appointment reminders, preparation of paperwork, and arranging medication pick-up process with the pharmacy (Figure).

Medication collection processes differed; some SSPs (24%) reported patient participants collected CAB+RPV LA during clinic visits, while others (19%) had staff collect it from the pharmacy prior to visits. Some sites in Germany and France were unique as prescriptions were given to the patient during the previous clinic visit to allow for pick-up prior to their next appointment (discussed by 19% of SSPs). Clinic appointment process flows were similar across countries (example flows shown in Figure): patients consulted with a nurse or doctor, medication was brought to room temperature, injection was administered, and patient was monitored for 10 min.

Some clinics scheduled future appointments at the start of the clinic visit, while some scheduled them after injection administration. Post-visit tasks included laboratory work and cleaning up workspace. Over 50% reported spending 20 min or less with patients at visits. Most (76%) spent 20 min or less per week ensuring appointment attendance. The majority (68%) found time spent in clinic for patient appointments very to extremely acceptable.

Figure.

Conclusions: Process flows varied slightly, yet there were many common components across clinics and countries. CARISEL data suggest implementation processes were incorporated into routine care and were acceptable compared with other HIV routine appointments in European clinics.

Robot-based assessment: a novel tool to objectively quantify the impact of HIV on aging

P. Yeboah¹, S. Damaraju², N. Stroutinsky³, N. Johnson³, M. Johnson⁴

¹University of Pennsylvania, Bioengineering, Philadelphia, United States, ²University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States,

³University of Pennsylvania, Department of Physical Medicine and Rehabilitation, Philadelphia, United States,

⁴University of Pennsylvania, Bioengineering/Department of Physical Medicine and Rehabilitation, Philadelphia, United States

Background: About 37 million people worldwide live with HIV. As they age, there is a growing concern over the decline in cognitive and physical function, which impacts everyday functioning; this prevalence ranges from 50% to 80% of population.

These impairments tend to be prominent in people with chronic HIV than those without and may be due to a combination of aging and the effect of the virus on the brain. There is a lack of objective assessment tools that can predict early motor, cognitive, and activity functional decline. We propose using a rehabilitation robotics approach to understand the impact of HIV on functional decline in older adults.

Objective: To assess how a robot tool can objectively predict clinical assessment scores for motor and cognitive domains in people aging with HIV.

Methods: This study was conducted at the University of Pennsylvania and involved 10 male participants (5 HIV+, 5 HIV-: matched on age, gender, and education level).

Participants underwent an evaluation of motor and cognitive performance using standard neuropsychology tools and performed a 30-minute robot-based task with the upper limb based on the traditional Corsi block spatial span task.

Results: HIV+ participants were more cognitively impaired overall, in executive function and more physically impaired in gross and fine hand function (Table 1).

Participants/ Test	Mean Age	MOCA Score	Color Trails 2	Dominant Grooved Pegboard	Box and blocks	Spatial Span Dominant
Controls	57.80 ± 6.61	28.60 ± 2.07	53.07 ± 11.06	63.97 ± 12.81	67.00 ± 10.46	4.59 ± 0.87
HIV	60.60 ± 5.55	24.00 ± 3.00	101.33 ± 42.85	78.79 ± 18.67	57.07 ± 11.57	3.68 ± 0.62

Table 1.

Robot assessment indicates that persons with HIV+ were less likely to remember and move accurately as the number of block sequences increased from 3 to 7 (Figure 1).

Figure 1. All paired subjects, dominant hand.

Conclusions: Robot-based assessment approaches show promise in quantifying cognitive and motor impairment in Chronic HIV and have the potential to provide a better understanding of how HIV specifically impacts the progression of functional decline.

MOPEE28

Improving viral load suppression among children aged 0-14 years through community ART distribution in rural Uganda: lessons from Anyeke HCIV

A. Nanteza¹, P. Nekesa¹, M. Nassim², T. Malinga², J. Basiima¹, H. Kisamba¹, M. Namubiru³, C. Kityo³

¹Joint Clinical Research Centre, Programs, Lira, Uganda,

²Oyam District Local Government, Health, Lira, Uganda,

³Joint Clinical Research Center, Health, Kampala, Uganda

Background: Ministry of Health Uganda has a goal of achieving HIV viral load suppression of 95% by 2030. Children's dependence on others for HIV care often leads to ART non-adherence and viral non-suppression and thus an impediment to achieving the goal. Viral load suppression for the 0-14-year children was as low as 79% by June 2022 at Anyeke HCIV. The children often missed their facility appointments thus missed opportunities for ART, viral load monitoring and other services. Long distances to the facility, expensive transport costs, multiple care takers and absence of community ART delivery were major barriers to care.

Description: Children were profiled based on age and address. Groups of 3-6 children based on age and proximity by address formed. These were meaningfully attached to a counsellor and community health worker (CHW) positively living with HIV for follow up. Clinic preparations a day before to the scheduled community visits at preferred venues.

This preparation consisted pre-clinic file retrieval, service gap identification tags of masking tape on the retrieved files using the service layering package and pre-filing of viral load forms. Clear role assignment for attending staff team who used a checklist to assemble required commodities. Weighing scales carried for weight-based ART dosing. Intensified Adherence Counselling was done

at the community. When community visit was missed, a counsellor and CHW proceeded for a home visit. Weekly update and review of the children's audit tool supported performance monitoring.

Lessons learned: Viral load suppression improved from 79% in June 2022, 81% in September to 94% in December 2022 for children 0-14 years at Anyeke HCIV due to community service delivery model of care.

Proper service layering at the community is possible with proper preparation and clear role assignment. The aim of improving access to services is easily achieved with frequent contacts, supported disclosure as well as home visits to handle adherence barriers.

Conclusions/Next steps: Viral load suppression can be achieved using community service delivery models of care in low income settings. Community ART service delivery once adopted and scaled can be a game changer to Pediatric HIV management.

Sustainable financing of key population HIV programs in Asia: findings from a 4 country baseline assessment by the SKPA-2 program

M. Merrigan¹, F. Young², B. Morris³, H.-M. Schmidt^{4,5,6}, P. Shah⁶, J. Rock⁷, M. Kusen⁸, K. Burns⁹, Y.Y. Shwe⁴, G. Sithey¹⁰, Y. Dorji¹⁰, T. Dorji¹⁰, B. Dangaa¹¹, C. Batbayar¹¹, G. Altankhuyag¹¹, A. Satkunanathan¹², K. Navaratne¹², I. Kumar¹², M. Rillera¹³, A.K.A. Quilinguing¹³

¹Australian Federation of AIDS Organisations (AFAO), Sunshine Coast, Australia, ²Australian Federation of AIDS Organisations (AFAO), Brisbane, Australia, ³Global Fund, Geneva, Switzerland, ⁴UNAIDS Regional Support Team, Bangkok, Thailand, ⁵UNAIDS, Bangkok, Thailand, ⁶UNAIDS/WHO, New Delhi, India, ⁷Independent Consultant, Canberra, Australia, ⁸Australian Federation of AIDS Organisations, Bangkok, Thailand, ⁹Independent Consultant, New York, United States, ¹⁰Independent Consultant, Thimphu, Bhutan, ¹¹Independent Consultant, Ulaanbaatar, Mongolia, ¹²Independent Consultant, Colombo, Sri Lanka, ¹³Independent Consultant, Manila, Philippines

Background: The Sustainability of HIV Services for Key Populations in South-East Asia (SKPA)-2 program is a three-year (July 2022 to June 2025) program funded by the Global Fund in Bhutan, Mongolia, the Philippines and Sri Lanka. Between July to December 2022, a team of independent regional and national consultants conducted a rapid baseline assessment to understand the extent to which the four countries are prepared to provide domestic financial and programmatic support for HIV service delivery for key populations.

Description: Data collection tools including structured key informant interview guides and an online "sustainability pulse check" survey, were developed covering SKPA-2 objectives (financial sustainability, strategic information, programmatic sustainability and human rights

and gender). Key informant interviews were conducted during October–November 2022 with over 136 individuals, while 60 stakeholders completed the online survey. These stakeholders were broadly categorized into four groups: key populations, government, non-governmental organizations, and multi-lateral (UN) agencies.

Lessons learned: Only 5% of survey respondents saw their government as being able to afford to expand key population HIV services without reliance on external donors in the next three years. At the same time 35% of respondents saw key populations as 'readily' able to access PrEP in their country, compared to 40% for HIV self-testing. Slightly over a quarter (28%) of respondents thought their country has a functioning referral system to legal services for human rights violations linked to HIV service access.

The bottlenecks identified in survey data and by key informants are similar across countries, indicating the twin challenges for sustainable HIV responses of increasing domestic resource commitments alongside expanding access to targeted key population services. A partnership approach that recognizes key population-led service provision and values the voice of key populations is needed to efficiently address these gaps.

Conclusions/Next steps: The assessment will help governments and community advocates generate concrete actions that can be used for evidence-based planning and advocacy. Increasing efficiencies while investing in the right mix of high impact services, including those led by key population service providers, will be needed to reach the 95–95–95 targets in the face of declining external donor support.

Out-of-pocket payments in accessing antiretroviral treatment among People Living with HIV (PLHIV) in Indonesia

D. Kurniawati¹, D.E. Husnul Khotimah¹, I. Safika¹, Y. Farianti², N.T. Indriasari², N. Afriana³, L. Luhukay³, H. Thabrany¹

¹ThinkWell, LLC/USAID Health Financing Activity, Jakarta, Indonesia, ²Ministry of Health of Republic of Indonesia, Center for Health Financing and Decentralization Policy, Jakarta, Indonesia, ³Ministry of Health of Republic of Indonesia, HIV, Sexually Transmitted Infections, Hepatitis, and Infections of the Digestive Tract Working Group, Jakarta, Indonesia

Background: Indonesia's National Health Insurance program introduced in 2014 and the National HIV Program of the Ministry of Health (MoH), provides comprehensive coverage for HIV services. However, due to a lack of coordination, there were still out-of-pocket (OOP) payments by people living with HIV (PLHIV) who accessed ARV treatments. The reported OOP includes payments for diagnostic tests, drugs, and administrative fees.

To understand better and to develop policy options for

achieving Triple 95 by 2020, we conducted an analysis of factors associated with OOP payments among JKN members based on our survey in 2022.

Methods: We conducted a survey of JKN members who had utilized HIV services in 16 municipalities in Indonesia. A total of 561 PLHIV participated in the survey from April–August 2022. We applied multivariate logistic regression to determine the factors associated with OOP payments in accessing ARV treatment.

Results: Descriptive statistics indicated that 45% of respondents reported paying OOP when they accessed healthcare providers to get ARV treatment. PLHIV who accessed ARV outside of their residence were almost three times more likely to pay OOP than their counterparts who accessed ARV in the same location of their residence (OR=2.8; 95% CI= 1.8–4.6).

Furthermore, those who reported travelling more than 30 minutes to the healthcare providers were more likely to pay OOP compared to those who said otherwise (OR=1.6; 95% CI = 1.2–2.3). Meanwhile, those who experienced internalized stigma were twice more likely to pay OOP than those who reported otherwise (OR=1.9; 95% CI = 1.3–2.8). Finally, those who visited hospitals were 1.4 more likely to pay OOP than those who visited primary health care (PHC) providers (OR=1.4; 95% CI = 1.0–2.1).

Conclusions: We found that almost half of the PLHIV surveyed had OOP payments when visiting healthcare providers. Several factors associated with OOP payments are the location of healthcare providers, internalized stigma (self-stigma), and the type of health healthcare providers (p-value < 0.05).

These findings should be communicated effectively to policymakers in ensuring the triple 95 targets of HIV intervention in Indonesia.

TUPEE03

Achieving sustainability of Unitaid investment in HIV self-testing through demand-side subsidy financing: successes and lessons learnt from STAR-Nigeria partnerships with private pharmacies

V.A. Adepoju¹, A. Solanki², C. Umehido¹, Z. Hassan¹, A. Ajijele¹, W. Oladigbolu³, I.-J. Dada⁴, C. Nwakaego⁴, Y. Olaifa⁵, G. Ujam⁵, D. Ndukwe⁵, A. Oniyire⁶, C. Laube⁷, M. Strachan⁸, K. Grabbe⁷

¹Jhpiego Nigeria, an affiliate of John Hopkins University, HIV and Infectious Diseases, Abuja, Nigeria, ²Population Services International, HIV and TB International, Cape Town, South Africa, ³Association of Community Pharmacists of Nigeria, Abuja, Nigeria, ⁴National AIDS/STI Control Program, Abuja, Nigeria, ⁵National AIDS Control Agency, Abuja, Nigeria, ⁶Jhpiego Nigeria, an affiliate of John Hopkins University, Abuja, Nigeria, ⁷Jhpiego USA, HIV and Infectious Diseases, Baltimore, United States, ⁸Jhpiego USA, Baltimore, United States

Background: The Unitaid HIV self-testing in Africa (STAR) project, implemented by Jhpiego in Nigeria in collaboration with the Ministry of Health and key stakeholders distributed 318,750 oral and blood-based HIV Self-testing (HIVST) kits through 5 distribution models between 2020-2022. A demand side financing pilot, addressing barriers of high commodity cost and poor demand, to increase access and uptake of HIVST through private sector pharmacies as a sustainable model of HIVST was implemented between November 2021 and October 2022.

We aimed to demonstrate that implementation of demand side subsidy financing would lead to sustainable HIVST market through private pharmacies in Nigeria.

Description: Demand side financing (DSF) was implemented between November 2021-October 2022 as a strategy to scale and sustain HIVST through the private sector in Nigeria. We mapped 166 private retail pharmacies across four Nigerian states, trained pharmacists on HIVST detailing, and provided simplified digital reporting tools and promotional materials. We used the "buy 1 get 3 free" model to stimulate demand and gradually transferred costs to end users through 3 cost transfer phases at agreed end-user profit margins. Consumers (walk-in, online referrals, referrals by community-based organizations) redeemed paper- or digital vouchers to receive HIVST kits. The cascade of voucher redemption, demand for HIVST and investment made by private pharmacies were tracked.

Lessons learned: A total of 2,920 HIVST kits (USD\$10,000 value) were purchased by 166 pharmacies within 3 months of first and second cost transfers. Voucher redemption dropped initially from 91% in the free phase to 60% in the first and then increased to 72% in the second cost transfer phases. 85% of pharmacies invested at least USD\$10-50. Of the 12,718 kits distributed across the three phases, community referrals, walk-in and online referrals accounted for 75%, 21.3% and 3.4% of HIVST uptake respectively.

Additional investment of USD\$32,000 have been made by pharmacies in scale-up states, via pooled procurement by the Association of Community Pharmacists of Nigeria, after DSF pilot.

Conclusions/Next steps: The DSF initiative was effective in sustaining market for fee-based HIVST in Nigeria. The successful pilot has been expanded country-wide through the governance structure of the "Local Pharmacy Distribution Network".

The cost and intermediate cost-effectiveness of delivering U=U messaging to increase HIV testing among South African men

P. Smith¹, D. Joseph Davey^{1,2,3}, L. Schmucker^{4,5}, L.-G. Bekker¹, A. Medina-Marino^{6,7}, H. Thirumurthy^{4,5}, A.M. Buttenheim^{4,5,8}, G. Meyer-Rath^{9,10}

¹University of Cape Town, Desmond Tutu HIV Centre, Department of Medicine, Cape Town, South Africa, ²University of California Los Angeles, Division of Infectious Diseases, Geffen School of Medicine, Los Angeles, United States, ³University of Cape Town, Division of Epidemiology and Biostatistics, School of Public Health and Family Medicine, Cape Town, South Africa, ⁴University of Pennsylvania, Medical Ethics and Health Policy, Perelman School of Medicine, Philadelphia, United States, ⁵University of Pennsylvania, Center for Health Incentives and Behavioral Economics, Medical Ethics and Health Policy, Perelman School of Medicine, Philadelphia, United States, ⁶University of Cape Town, Division of Men's Health, Desmond Tutu HIV Centre, Cape Town, South Africa, ⁷University of Pennsylvania, Department of Psychiatry, Perelman School of Medicine, Philadelphia, United States, ⁸University of Pennsylvania, Department of Family and Community Health, School of Nursing, Philadelphia, United States, ⁹University of the Witwatersrand, Health Economics and Epidemiology Research Office (HE2RO), Faculty of Health Sciences, School of Clinical Medicine, Johannesburg, South Africa, ¹⁰Boston University, Department of Global Health, School of Public Health, Boston, United States

Background: South African men have lower HIV testing uptake than their female counterparts, leading to lower antiretroviral treatment (ART) uptake and higher HIV related mortality. A recent cluster randomised trial in a high HIV prevalence area in Cape Town showed that relaying the "undetectable equals untransmittable" (U=U) message to South African men was effective in increasing their HIV testing uptake compared to standard testing invitations.

We conducted an economic analysis based on this trial to inform decision-making for implementing U=U messaging in routine HIV care.

Methods: We analysed the mean cost of the U=U intervention as well as its incremental cost-effectiveness over the control arm. Costs were estimated based on trial expenditure data, analysed from the provider perspective

in 2020 ZAR and converted to US\$ using March 2020 exchange rates. Joint trial costs were allocated to each trial arm based on participant volume or days of operation; capital costs, including the creation of the U=U message via human-centred design workshops, were annualised over 8 years. In a second scenario, trial resource use was adjusted for potential implementation in routine care.

Results: Peer promoters delivered 504 U=U invitations over seven intervention days and 544 standard invitations over five control days in March 2020. The average trial cost was \$5.40 per U=U message delivered (\$2.35 after adjustment for routine implementation), \$388.47 (\$168.99)/ person testing HIV-positive, and \$906.44 (\$394.31)/ person initiating ART. Within trial costs, staff, overhead and research costs were the largest cost items, accounting for 20-30% of total costs each.

After routine implementation adjustment, message creation via human-centred design workshops, personnel (peer promoters, research staff) and supplies costs were the largest cost items. Cost of U=U messaging per person confirmed HIV-positive and initiating ART was lower than conventional HIV testing messaging and at the lower end of cost ranges of HIV self-test distribution models targeted at men (\$62-\$7,936/ person confirmed positive and \$117-\$8,198/ person initiating ART) established in previous work.

Conclusions: Delivering tailored U=U messaging can increase HIV testing and ART uptake among men, while saving costs over standard untargeted HIV testing messaging and a number of HIV self-test distribution models.

TUPEE05

Supervising rural community health workers (CHW) increases children's perinatal survival, with outcomes related to timing and quality of CHW's perinatal home visits

M.J. Rotheram-Borus¹, K. Le Roux², I. Le Roux³, L. Stansert⁴, M. Tomlinson⁵

¹University of California, Los Angeles, Psychiatry, Los Angeles, United States, ²Groote Schuur Hospital, Primary Health Care, Cape Town, South Africa, ³Philani Nutrition Program, Nutrition, Cape Town, South Africa, ⁴Stellenbosch University, Medicine, Tygerberg, South Africa, ⁵Institute for Life Health Course Research, Medicine, Tygerberg, South Africa

Background: Lacking sufficient professional health providers, CHW are increasingly deployed globally to provide perinatal home visits to mothers/infants. While efficacy of CHWs is repeatedly found in randomized trials, health systems often fail to provide sufficient training, supervision and monitoring of CHW and CHW are often found ineffective in large system implementation.

Methods: All government CHW (N=43) in 8 rural South African clinics were randomized by clinic to receive: 1) Standard Supervision (SS; n=392 mothers/infants); or 2) Accountable Supervision (AS; n=423). Perinatal outcomes were

repeatedly monitored at six points from pregnancy to 2 years post birth. CHW were Black, xhosa-speaking mothers with a high school or less than high school education, typically employed by the government for 12 years. Random regressions examined child outcomes over 2 years, associated with the timing and frequency of home visits, and supervisors' ratings of CHW qualities.

Results: Mothers reported only 7-9% of CHW in SS made any home visits during any follow-up period; 62%-77% of AC CHW visited an average of 14 times.

Among the AS condition, almost all pregnant women were visited, 140 home visits were made within 2 days post-birth, more than 475 visits within the first week post-birth, and 483 in the first three months, with similar rates at 6, 15, and 24 months post-birth.

Perinatal mortality in the first six months of life was reduced by 50% in the AS compared to the SS (5% vs 2.3%, $p < 0.013$), however, 13 other outcomes did not demonstrate a benefit over two years.

Random regressions controlling for timing of home visits and the quality of the CHW's visits were related to child outcomes over time.

Conclusions: Introducing supervision results in short-term survival benefits, but long-term outcomes appear associated with the timing and quality of CHW's visits. Staff recruitment strategies (e.g., choosing local role models as CHW) are likely as critical as supervision strategies to improve child and maternal outcomes.

TUPEE06

Adapting and reorienting a patient reported outcome measure (PROM) consensus study to achieve more culturally diverse perspectives from HIV peer and clinical settings: a reflective case study in HIV research

A. Olekalns¹, C. Mai¹, D. Cifali², G. Brown¹

¹University of New South Wales, Centre for Social Impact, Sydney, Australia, ²New South Wales Department of Health, Multicultural HIV and Hepatitis Service, Sydney, Australia

Background: Patient Reported Outcome Measures (PROMs) are tools that can measure quality of life for people with HIV, and support person-led care. An online Delphi consensus study was undertaken with PLHIV peer, community, clinical and research settings to achieve consensus on a recommended set of PROMs in Australia.

This paper describes the adaptation and reorientation of the study part way through to better incorporate diverse perspectives of people with HIV from culturally and linguistically diverse backgrounds and women.

Methods: Following feedback that the methodology had created a barriers for culturally and linguistically diverse groups to participate in the development of a PROM outcome set, nine participants were purposively sampled from within a first round Delphi consensus survey and invited for interview.

Participants were those who had raised feedback, or who were PLHIV peer support workers, clinicians working with people from culturally and linguistically diverse backgrounds, or women with HIV.

Participants were asked to discuss the aspects of care most important to include in the PROMs, and aspects of survey and outcome set accessibility to increase diversity of participants in the study.

Two researchers analysed and reviewed the data, identifying themes and discussing conflicting statements.

Results: Three themes were defined:

1. The need to recognise diversity within the HIV community (i.e., challenging assumptions about the HIV community, language and culture),
2. Exploring specific aspects and understandings of quality of life and social outcomes that matter (i.e., particularly psychological wellbeing and stigma), and;
3. Measuring patient outcomes appropriately (i.e., practitioner training to support measurement and patient understanding, and environmental factors important to the implementation process).

A limitation identified through the research was that the availability of PROMs that have been developed and validated for PLHIV from diverse backgrounds.

Conclusions: This research provides a case study for how to balance the need for consensus and diversity for PLHIV using adaptive methods in a Delphi consensus process, such as qualitative interviews.

Studies can be reoriented to ensure that the process actively seeks out views from culturally and linguistically diverse contexts to create a minimum set of recommended PROMs that are suitable across the diverse range of PLHIV.

TUPEE07

Agreement of and discussion with clients about Undetectable equals Untransmissible (U=U) among General Practitioners in Australia

J. Wu¹, E.P. Chow², C.K. Fairley², D. Grace³, J.J. Ong²

¹Kings Park Medical Centre / Monash University, General Practice, Melbourne, Australia, ²Melbourne Sexual Health Centre, Melbourne, Australia, ³University of Toronto, Dalla Lana School of Public Health, Toronto, Canada

Background: The message of Undetectable equals Untransmissible (U=U) is important to reduce HIV stigma. However, it is unclear whether this message is being disseminated by health professionals to clients living with HIV and to other patients during a sexual health consult. We examined Australian general practitioner (GP)'s agreement of and discussion with clients about U=U.

Methods: We distributed an online survey through GP networks from April to October 2022: eligibility was a GP working within Australia. Logistic regression analyses were used to identify variables associated with: 1) agreement of U=U; and 2) discussing U=U.

Results: Of 703 surveys, 407 were included in the final analysis. Mean age was 39.7 years (standard deviation: 8.4), most were female (70.5%, n=287), and 40% (n=161) had extra training with sexual health. Most GPs (74.2%, n=302) agreed with U=U but only 33.9% (n=138) had ever discussed U=U with their clients (Figure 1).

Key barriers to discussing U=U were lack of relevant client presentations (48.7%), lack of understanding about U=U (39.9%), and difficulty identifying those who would benefit from the U=U message (6.6%). Agreement with U=U was associated with greater odds of discussing U=U (Adjusted odds ratio (AOR) 4.75, 95% confidence interval(CI): 2.33-9.68), younger age (AOR 0.96 per additional year of age, 95%CI: 0.94-0.99), and extra training in sexual health (AOR 1.96, 95%CI:1.11-3.45). Discussing U=U was associated with younger age (AOR 0.97, 95%CI: 0.94-1), extra training with sexual health (AOR 1.93, 95%CI 1.17-3.17), and negatively associated with working in Metropolitan or Suburban area (AOR 0.45, 95%CI: 0.24-0.86).

Key barriers to discussing U=U were lack of relevant client presentations (48.7%), lack of understanding about U=U (39.9%), and difficulty identifying those who would benefit from the U=U message (6.6%). Agreement with U=U was associated with greater odds of discussing U=U (Adjusted odds ratio (AOR) 4.75, 95% confidence interval(CI): 2.33-9.68), younger age (AOR 0.96 per additional year of age, 95%CI: 0.94-0.99), and extra training in sexual health (AOR 1.96, 95%CI:1.11-3.45). Discussing U=U was associated with younger age (AOR 0.97, 95%CI: 0.94-1), extra training with sexual health (AOR 1.93, 95%CI 1.17-3.17), and negatively associated with working in Metropolitan or Suburban area (AOR 0.45, 95%CI: 0.24-0.86).

Figure 1. Proportion of general practitioners who ever discussed about U=U according to their agreement with U=U*

*People living with HIV who have been taking ART (antiretroviral therapy) regularly enough to achieve an undetectable viral load, cannot sexually transmit the virus to others?

Conclusions: Most GPs agreed with U=U, but most had not discussed U=U with their clients. Concerningly, 1 in 4 GPs disagreed with U=U, suggesting that further qualitative research to understand this finding and implementation research to promote U=U among Australian GPs is urgently needed.

Efficacy of a multi-level pilot intervention to reduce discrimination faced by MSM and transgender women in public hospitals in India: findings from a pre-/post-test quasi-experimental trial among healthcare workers

V. Chakrapani¹, S. Nair², S. Subramaniam³, K. Ranade², B. Mohan³, R. Nelson¹, S.T Sivaraman¹, M. Shunmugam¹, J. Kaur⁴, S. Rawat⁵, T. E³, C. Das⁶, S. Rajan⁶, A.K. Puri⁶, B.S. Kushwaha⁶, B. Rao⁶, U. Das⁶, V. Verma⁶, N. Kapoor⁶

¹Centre for Sexuality and Health Research and Policy (C-SHaRP), Research, Chennai, India, ²Tata Institute of Social Sciences (TISS), Research, Mumbai, India, ³Madras Medical College and Rajiv Gandhi Government General Hospital (RGGGH), Institute of Community Medicine, Chennai, India, ⁴Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India, ⁵The Humsafar Trust, Mumbai, India, ⁶National AIDS Control Organisation (NACO), New Delhi, India

Background: Reducing stigma and discrimination faced by men who have sex with men (MSM) and transgender women (TGW) in healthcare settings is key to improving health outcomes. We tested the efficacy of a theory-informed, multi-level pilot intervention ('Harmony') among 98 healthcare workers (HCWs) to reduce sexual orientation and gender identity (SOGI)-related stigma and discrimination faced by MSM and TGW in two public hospitals.

Methods: We used a one-group pre- and post-test quasi-experimental design. The intervention contained group-level (a half-day workshop) and individual-level (4 videos) components. Using multi-level modelling, we compared knowledge, attitudes, and comfort level among HCWs across three timepoints: pre-intervention, post-intervention and follow-up.

Client surveys were conducted among 400 MSM/TGW attending the intervention hospitals, before and after the intervention among HCWs. Generalised estimating equations (GEE) assessed service users' satisfaction with hospital services, discrimination experiences and positive interactions with HCWs.

Results: Significant changes were observed in primary outcomes: 30% increase in positive attitude scores (incidence rate ratio [IRR]=1.30, 95% CI 1.13-1.49); and 23% increase in the proportion of HCWs reporting being comfortable in providing care to MSM/TGW (IRR=1.23, 95% CI 0.03-1.68). Similarly, there was a significant improvement in secondary outcomes (scores): support for non-discriminatory hospital policies (IRR=1.08, 95% CI 1.004-1.15), the importance of asking SOGI questions in clinical history (IRR=1.17, 95% CI 1.06-1.29), and perceived self-efficacy in providing clinical care (IRR=1.13, 95% CI 1.01-1.27).

Service users' data provided corroborative evidence for intervention efficacy: e.g., 14% increase in the proportion of MSM reporting overall satisfaction with hospital services, and 6% and 15% increase in the scores of positive interactions with HCWs in the combined sample of MSM/TGW and TGW, respectively.

Conclusions: The Harmony intervention showed evidence for improving positive attitudes, comfort level and understanding of the healthcare issues of MSM/TGW among HCWs, and warrants large-scale implementation research.

TUPEE09

Managing pediatric and adolescent treatment failure among children and adolescents living with HIV in seven sub-Saharan African countries

M. Spencer¹, H. Bouba², N. Mthethwa³, B. Mambo⁴, M. Mohoanyane⁵, A. Ikpeazu⁶, E. Nameusoke⁷, S. Sivile⁸, N. Rakhmanina¹

¹Elizabeth Glaser Pediatric AIDS Foundation, Technical Strategies and Innovation, Washington DC, United States, ²Cameroon Ministry of Health, Yaounde, Cameroon, ³Swaziland National AIDS Program, Mbabane, Eswatini, ⁴Kenya National AIDS and STI's Control Programme, Nairobi, Kenya, ⁵Lesotho Ministry of Health, Maseru, Lesotho, ⁶National AIDS and STIs Control Programme FMOH Nigeria, Abuja, Nigeria, ⁷Uganda Ministry of Health, Pediatric and Adolescent Care and Treatment, Kampala, Uganda, ⁸Zambia Ministry of Health, Lusaka, Zambia

Background: Children and adolescents living with HIV (CALHIV) with treatment failure (TF) experience prolonged viremia and delayed transition to optimal regimens. The New Horizons Collaborative (NH) is a multisectoral partnership to donate Darunavir/ritonavir (DRV/r) and Etravirine (ETR) for treatment of children with TF and to improve outcomes in CALHIV.

The objective of this analysis is to describe the TF management cascade among CALHIV in NH-supported countries.

Methods: Data from Cameroon, Eswatini, Kenya, Lesotho, Nigeria, Uganda and Zambia were obtained from national reports during the annual NH workshop in October 2022. Descriptive data were extracted from Ministry of Health guided presentations on the TF management cascade for CALHIV.

Results: Most CALHIV with TF received enhanced adherence counseling and had viral resuppression rates ranging from 42.1% (Cameroon) to 87.6% (Eswatini) (Figure 1).

	# of CALHIV failing PI or DTG based ART	# of CALHIV re-suppressed after EAC	# of CALHIV who remain suppressed after EAC	# of CALHIV approved for CRT	# of CRT samples obtained	# of CRT results received	# of CALHIV selected to switch to DRV/r-based ART	# of CALHIV switched to DRV/r-based ART	# of CALHIV re-suppressed at national/regional TMO

¹Seven clients in Eswatini were transferred or had treatment interruption in this time period. ART = antiretroviral treatment; CALHIV = children and adolescents living with HIV; CRT = drug resistance testing; DTG = dolutegravir; EAC = enhanced adherence counseling; PI = protease-inhibitor; TMO = treatment monitoring group; N/A = Not Available.

Figure 1. Pediatric treatment failure cascade for children and adolescents aged 0-24 in seven countries, January - October 2022.

A significant proportion of CALHIV with continued viremia was referred to technical working groups (TWGs) for review and drug resistance testing (DRT) approval. Uganda (95.2%) and Cameroon (67.0%) had the highest rates of DRT approved, although in both countries, less than 60% of approved DRT samples were collected.

DRT challenges included high client fees, low laboratories DRT capacity, and long turnaround time for results.

TF cases discussed at the national/regional TWGs varied widely by country. The highest numbers of CALHIV transitioned to DRV/r antiretroviral treatment were reported from Uganda, where national tracking system and decentralized TF management is implemented among CL-HIV.

Conclusions: We observed high variability in the TF management among CALHIV by country and ongoing challenges with accessing DRT. NH continues supporting countries with decentralizing TF management and improving DRT access.

TUPEE10

Maximising voluntary medical male circumcision (VMMC) outputs through the utilisation of the the 'Roving team concept'

W. Chikanya¹, P. Nyoni¹, S. Tshimanga¹, T. Madoda¹, M. Tshimanga¹

¹ZiCHIRE, Health, Harare, Zimbabwe

Background: The VMMC program was adopted by the Zimbabwean government because there is overwhelming evidence that male circumcision reduces heterosexual transmission of HIV by 60% among other benefits. ZiCHIRE as one of the PEPFAR implementing partners is responsible for 7 districts.

Shortage of VMMC staff due to competing priorities and high staff attrition rate among Ministry of Health workers continues to be a huge challenge which requires urgent attention in order to achieve one of the set objectives, to strengthen VMMC services to ensure they are accessible, affordable and effective enough to meet both scale-up and maintenance phase targets.

As ZiCHIRE we had to come up with an innovation, the Roving team concept to address this problem.

Description: ZiCHIRE employed nurse circumcisers who were then deployed to the various VMMC sites in the districts to augment the existing work force. Each team of nurse circumcisers known as the Roving team moves from one site to the other depending on the staff requirements and workload. The aim of the Roving team concept is to always ensure availability of VMMC staff so that clients get high quality services timeously and minimize adverse events related to work overload. The role of roving teams includes service delivery, demand creation, program quality, strategic information and financing.

Lessons learned: The Roving team concept increased VMMC outputs from a 60% to 85%, boosted the confidence and morale of MOH teams, improved data quality,

and clients' satisfaction due to availability of clinicians in the various sites supported by ZiCHIRE.

In addition, roving team members who participated in demand creation activities reduced the workload for the district health communications unit and helped in the dissemination of key VMMC messages to prospective clients.

However, a multiple of challenges were encountered in the operationalisation of this intervention such as rejection by existing MOH teams who thought this would reduce their allowances.

Conclusions/Next steps: The roving team concept is an important innovation that has helped the ZAZIC consortium and the Ministry of health to achieve set targets in the previous country operational plans.

TUPEE11

Reproductive coercion, viral suppression, and integrated sexual and reproductive health services among women living with HIV in 11 countries

K. Rucinski¹, G. Turpin², O. Syarif³, P. Looze³, K. Lalak³, J.d.D. Anoubissi³, S. Brion⁴, K. Dunaway⁴, L. Sprague⁵, C. Garcia de Leon Moreno⁵, D. Matyushina⁵, N. Kakpo⁶, A. Ouedraogo⁷, N.A.J.C. Vako⁸, E. Ayeh⁹, S. Bessonov¹⁰, I. Abdulkadir¹¹, N. Otswana¹², S. Baral³, C. Lyons²

¹Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, ²Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, ³Global Network of People Living with HIV (GNP+), Amsterdam, Netherlands, ⁴The International Community of Women Living with HIV (ICW), London, United Kingdom, ⁵Joint United Nations Programme on HIV/AIDS (UNAIDS), Geneva, Switzerland, ⁶REBAP+, Cotonou, Benin, ⁷REGIPIV-BF, Ouagadougou, Burkina Faso, ⁸Ivorian Network of People Living with HIV/AIDS, Abidjan, Cote D'Ivoire, ⁹Ghana Network of Persons Living with HIV, Accra, Ghana, ¹⁰Harm Reduction Network Association, Bishkek, Kyrgyzstan, ¹¹Network of People Living with HIV/AIDS in Nigeria, Abuja, Nigeria, ¹²NEPHAK, Nairobi, Kenya

Background: Women living with HIV (WLHIV) experience coercive practices in healthcare settings threatening independent reproductive decision-making. Integration of high-quality, rights-based HIV and sexual and reproductive health (SRH) programs may prevent coercive practices and improve treatment delivery for WLHIV, although data remain limited.

We examined the relationship between reproductive coercion and viral load suppression (VLS) among WLHIV in the context of 11 country-level integrated HIV/SRH programs.

Methods: Data from the People Living with HIV (PLHIV) Stigma Index 2.0 study were pooled from 11 countries across Eastern Europe, Central Asia and Sub-Saharan Africa. Study implementation was led by networks of PLHIV in partnership with GNP+, the ICW, and UNAIDS (2020-2022).

Interviewer-administered questionnaires captured socio-behavioral measures for 10449 cisgender 18+ year-old WLHIV. Reproductive coercion was categorized based on coercive experiences relating to sterilization; contraception/family planning; and pregnancy/feeding practices. Antiretroviral use and past-year VLS were self-reported. Country-level scores of HIV/SRH integration were compiled from the SRHR and HIV Linkages Index. Stratified hierarchical log-binomial regression models were used to assess associations between coercive reproductive practices and VLS.

Results: A total of 1111 (10.6%) WLHIV reported reproductive coercion, including coercive practices related to sterilization (n=44;0.42%), contraception/family planning (n=548;5.2%), and pregnancy/feeding practices (n=830;7.9%). Experiences of reproductive coercion were similar by HIV/SRH integration score. Nearly all women (n=9626;94.2%) had ever initiated antiretrovirals, of whom 5421(55.4%) reported VLS in the last year. Past experience of reproductive coercion was associated with a significant overall decrease in VLS (aPR 0.47, 95%CI 0.35-0.64) with limited differences across country-level HIV/SRH integration scores.

	Unadjusted PR (95% CI)	Adjusted PR (95% CI) ^c
Overall		
Ever experienced reproductive coercion	0.56 (0.48, 0.69)	0.47 (0.35, 0.64)
No experience of reproductive coercion	Ref.	Ref.
Stratified by HIV and SRHR linkage score ^b		
Moderate HIV and SRHR linkage		
Ever experienced reproductive coercion	0.63 (0.53, 0.75)	0.50 (0.36, 0.70)
No experience of reproductive coercion	Ref.	Ref.
Limited HIV and SRHR linkage		
Ever experienced reproductive coercion	0.49 (0.34, 0.70)	0.46 (0.27, 0.77)
No experience of reproductive coercion	Ref.	Ref.

a Defined as having ever experienced coercive practices related to sterilization, contraception/family planning, and pregnancy/feeding practices.
b Defined by whether a country has an HIV strategy with integrated SRHR components as reported by the SRHR and HIV Linkages Index. Scores were compiled using UNFPA and IPPF coding and dichotomized at the mean.
c Models adjusted for a minimally sufficient set of covariates: age, education level, unable to meet basic needs in the last year, number of children living in household, in an intimate or sexual relationship.

Table. Prevalence ratios (PR) and 95% confidence intervals (CI) for the association of reproductive coercion and viral suppression among 10449 women living with HIV in Angola, Benin, Burkina Faso, Cote D'Ivoire, Ghana, Kenya, Kyrgyzstan, Nigeria, Lesotho, Russia and Togo.^a

Conclusions: Reproductive coercion was common in this multi-country analysis, reflecting ongoing challenges to the delivery of effective and rights-affirming SRH services for WLHIV and ultimately worsening individual HIV treatment outcomes and threatening HIV epidemic control. Decreasing implementation gaps between broad country-level integration policies and real-world SRH programs are needed to reduce HIV-related stigmas, strengthen quality SRH services, and improve accountability for human rights violations of WLHIV.

TUPEE12

Scaling-up cervical cancer prevention: Catholic Relief Services (CRS) Epidemic Control 90-90-90 (EpiC 3-90) project in Zambia

M.J. Chaila¹, L.M. Chibesa¹, M. Kachimbe¹, N. Muhongo¹, P. Saili¹, D. Moyo¹, T. Nachula¹, M. Nkashi¹, K. Hanyinda¹, B. Mukanyimi¹, F.C. Ng'uni², P. Kamfwa³, C. Chungu⁴

¹Catholic Relief Services, EpiC 3-90 Project, Lusaka, Zambia,

²Ministry of Health, Lusaka Provincial Health Office, Lusaka,

Zambia, ³Ministry of Health, Headquarters, Ndeke House,

Lusaka, Zambia, ⁴Catholic Relief Services, EpiC 3-90 Project, Lusaka, Zambia

Background: Zambia recorded an estimated 13,831 new cancer cases in 2020 with cervical cancer accounting for 22.9% (3,161). Women Living with HIV (WLHIV) are at six times more risk than HIV-negative women. This increased risk has necessitated integrating cervical cancer prevention into routine HIV services.

To improve the uptake of cervical cancer screening services during the peak of the COVID-19 pandemic, we embarked on scaling-up both static, and mobile screening points from 2020 to 2021.

Methods: We started scaling-up cervical cancer prevention services in June 2020. Health facilities with the highest number of WLHIV were considered for the establishment of new static sites. Outreach services were provided in all supported districts targeting health facilities that did not have static clinics.

Working with the Ministry of Health, we established 20 static screening sites and trained 70 providers to support the implementation of cervical cancer prevention services.

We present our findings from October 2019 to September 2021.

Results: The average number of WLHIV screened for cervical cancer increased from 245 per month (October 2019 – May 2020) to 477 (June – September 2020), indicating 94.2% improvement (Pr(|T| > |t|) = 0.0135). By September 2020, we screened 68% (n=4,101) of the 2020 target of WLHIV. In 2021, following the expansion of cervical cancer screening services, we recorded a four-fold increase in the number of WLHIV from 4,101 to 16,352 which represented 84% achievement against the 19,549 target of 2020. Overall, we reached 20,453 WLHIV with cervical cancer prevention services during the two-year reporting period.

Figure 1. Cervical cancer screening performance against targets (2020 and 2021).

Conclusions: Safe cervical cancer prevention services during the COVID-19 pandemic in WLHIV may be provided through a coordinated approach. This is an essential service in high cervical cancer burden settings like Zambia.

TUPEE13

Effect of economic strengthening on treatment outcome among people living with HIV

A. Hajji¹, W. Endale², A. Alemayehu³, T. Deksis⁴, D. Halefom⁵
¹Mekdim Ethiopia National Association- USAID FFHPCT, Quality Improvement, Addis Ababa, Ethiopia, ²Mekdim Ethiopia National Association- USAID FFHPCT, Knowledge Management, Addis Ababa, Ethiopia, ³Mekdim Ethiopia National Association- USAID FFHPCT, Chief of Party, Addis Ababa, Ethiopia, ⁴Mekdim Ethiopia National Association- USAID FFHPCT, OVC Service, Addis Ababa, Ethiopia, ⁵Mekdim Ethiopia National Association- USAID FFHPCT, Monitoring and Evaluation, Addis Ababa, Ethiopia

Background: In resource-constrained settings, poor economic circumstances may pose a significant challenge to the success of antiretroviral treatment (ART) outcomes. Economic strengthening is when a group of 10-25 people save together and take loans from savings either to support household needs or to generate income.

We aimed to assess the effect of economic strengthening on HIV care and treatment outcomes among people living with HIV in Addis Ababa, Ethiopia.

Methods: An institutional-based retrospective cohort study design was conducted on 273 people living with HIV/AIDS in public health facilities of Addis Ababa, followed from June 2021 to November 2022. Study participants who were active and on follow-up during this study period were selected using a systematic random sampling technique. Sociodemographic, treatment, clinical, adherence, economic strengthening status and viral load data were extracted from electronic medical records, entered and analyzed with SPSS 26. Multivariate logistic regression analysis was conducted to test the main hypothesis at a 95% CI with $P < 0.05$.

Results: The mean age of the respondents was 40 years with a standard deviation of 8 years. Eighty-seven percent of the study participants were successful in achieving viral suppression (80.30% vs 94.80%) Economic strengthening was also associated with higher odds of viral load suppression (less than 50 copies/ml) with (AOR 4.52, 95% CI 1.90-10.80 $p < 0.001$). Moreover, economic strengthening was also associated with higher odds of ART adherence with (AOR 4.89, 95% CI 1.64-14.29, $p < 0.001$).

Conclusions: Economic strengthening is associated with good adherence to HIV treatment and viral load suppression. Intervention research is needed to determine the extent to which economic strengthening is causally associated with improved HIV treatment outcomes and to identify the most effective policies and programs to improve economic status and health.

TUPEE14

Going beyond the soundbites: establishing a mental health integration guidance for key populations programme in Kenya as a best practice for Africa

G.V. Owino¹, P. Battacharjee², S. Tabbu³, H. Oneya⁴, E.N. Simiyu⁵, M. Migot⁶, M. Mugambi⁷

¹IAVI, Global Affairs, Nairobi, Kenya, ²University of Manitoba, Institute of Global Public Health, Nairobi, Kenya, ³KYDESA, Programs, Nakuru, Kenya, ⁴Pictures Youth Group, Management, Kisumu, Kenya, ⁵HAPA Kenya, Advocacy, Mombasa, Kenya, ⁶MAAYGO, Programs, Kisumu, Kenya, ⁷Ministry of Health Kenya, Division of Mental Health, Nairobi, Kenya

Background: In Kenya, Key populations (KPs) who include transgender people, men who have sex with men, people who inject drugs, and female sex workers continue to face stigma and discrimination which affects their mental and physical health outcomes. More than 30% of counties in Kenya have no programmes for mental health and 40% have no mental health policy. The COVID-19 pandemic worsened the situation, with cases of maladaptive coping mechanisms reported among KPs with no response, heightening the urgency to provide national guidance to address mental health for KPs in Kenya.

Description: In 2021, the National AIDS and STI Control Programme (NASCOP) in partnership with IAVI supported 1 virtual consultative meeting with 50 stakeholders from the Key and Vulnerable Populations Technical Working Group (KVP TWG) including researchers, implementers, and donors to prioritize the integration of mental health services into the Key and vulnerable Populations (KVP) program. A writing meeting was organized, and 20 technical experts and community representatives developed the draft guidance.

To ensure the integration of mental health services a trainer of trainers was then conducted with 26 participants from 10 NASCOP priority counties in Kenya. Learnings from the training provided feedback for the finalization and validation of the national guidance by the KVP TWG.

Lessons learned: Through the consultative meetings, writing, and validation process the KP community was actively involved in informing the process and providing relevant data, case studies, and information. It emerged that the participatory processes for the development and the joint training gave greater insights, credibility, and acceptability of the national guidance and enriched the learning outcomes respectively. Kenya was the first country to develop a guidance document on mental health for KVP spearheaded by the government.

Developing this guidance was enhanced by the multisectoral approach adopted during its development.

Conclusions/Next steps: There is a need to ensure the use and continued participatory approaches in the implementation of the National guidance on integrating mental health into KVP programming in Kenya and the

roll-out of mental health training across the country, to reduce maladaptive coping mechanisms among KPs, and expand this best practice to other populations and countries.

TUPEE15

Family planning experiences of young women with and without HIV in Zimbabwe: a case for integrated HIV and sexual and reproductive health services

C. Mavodza¹, J. Busza², C. Mackworth-Young², R. Nyamwanza¹, P. Nzombe¹, E. Dauya¹, C. Dziva Chikwari², M. Tembo², V. Simms², O. Mugurungi³, T. Apollo³, R. Ferrand², S. Bernays⁴

¹Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, ²London School of Hygiene and Tropical Medicine, London, United Kingdom, ³Ministry of Health and Child Care, HIV and TB Unit, Harare, Zimbabwe, ⁴University of Sydney, Sydney, Australia

Background: Young people have high unmet sexual and reproductive health needs. Evidence shows this need is higher for those living with HIV. We explored the family planning experiences and preferences of young women with and without HIV accessing a community-based integrated HIV and SRH intervention for young people aged 16–24 years, evaluated through a cluster randomised trial in Zimbabwe (CHIEDZA).

Methods: Weekly services (HIV testing and care combined with family planning, STI and menstrual health management, condoms, and health counselling) were delivered in intervention communities over 30 months from 2019–2022. A mixed methods study investigated uptake, including type, of family planning within CHIEDZA by HIV status. In-depth interviews with young women who had ever used contraceptives and were living with HIV (n=12), and without HIV (n=15) were thematically analysed to understand experiences and preferences.

Results: Of 27,462 women who accessed CHIEDZA, 1355 (4.9%) were living with HIV. Young women with HIV aged 16–19 were more likely to access family planning services than those without [OR 1.91 95%CI 1.52–2.39], while there was no difference by HIV status among those aged ≥20. Those with HIV were more likely to take up the injectable as their contraceptive choice (24.0% vs 17.9%).

Regardless of HIV status, young women valued the opportunity to access non-judgemental support which encouraged their confidence, literacy, and engagement with family planning.

Those who had been accessing HIV care at health facilities struggled to access family planning. Part of this struggle was inadequate information and counselling about the interactions between some ART regimens and hormonal contraceptives. Some of those who did not receive HIV care within CHIEDZA chose to access family planning care, alongside ART adherence support while continuing

to access ART at their local clinic. Those living with HIV reported a contraceptive preference for injectables to reduce pill burden.

Conclusions: Offering family planning within HIV programmes is more likely to address the unmet SRH needs that young women living with HIV face. It may improve efficiency, make care more person-centred and provide a further opportunity to address concerns about drug interactions and support for addressing wider challenges with adherence to oral HIV treatment.

TUPEE16

Psychiatrists' role in ending the HIV epidemic: a mixed-methods investigation of knowledge, perceived barriers to implementation, and training needs to support pre-exposure prophylaxis (PrEP) prescription by psychiatrists

S. Bunting¹, B. Feinstein², A. Hazra³

¹University of Chicago, Psychiatry & Behavioral Neuroscience, Chicago, United States, ²Rosalind Franklin University of Medicine and Science, Department of Psychology, North Chicago, United States, ³University of Chicago, Section of Infectious Diseases, Department of Medicine, Chicago, United States

Background: Patients living with mental illnesses experience disproportionately high HIV incidence and prevalence, while simultaneously experiencing numerous barriers to care. Psychiatrists are mental health providers and gateways for additional healthcare for many patients with mental illness but investigations of knowledge and practice barriers regarding biomedical HIV prevention methods, like pre-exposure prophylaxis (PrEP), are absent from the literature.

Methods: We conducted a mixed-methods, pilot study of psychiatrists practicing in the 50 U.S. counties accounting for 50% of new HIV diagnoses about knowledge, practice barriers, and training needs regarding PrEP prescription for patients with mental illness and HIV risk-factors.

Results: Overall, 77 psychiatrists participated. A majority (96.3%) were aware of PrEP and 24.7% had prescribed PrEP to a patient. We found that 68.4% believed psychiatrists should be PrEP prescribers, and 47.3% were interested in prescribing PrEP. The most common barriers to prescribing PrEP were limited knowledge (77.9%), the belief that PrEP prescription was outside the scope of psychiatric practice (51.9%), and concerns about managing follow-up care (57.1%). Only 31.5% reported receiving training about PrEP but 66.2% were interested in receiving training about PrEP prescription and management. From qualitative data, several themes were identified, which complimented quantitative findings:

1. The need to minimize logistical barriers to PrEP prescription for patients with mental illness and HIV risk-factors;
2. Collaborative practice between psychiatrists and primary care clinicians to facilitate PrEP prescription for patients seeking psychiatric care;

Oral
abstracts

Poster
exhibition

E-posters

Late-breaker
abstracts

Author
Index

3. Limited PrEP knowledge and a need for training to facilitate PrEP prescription by psychiatrists;
4. Importance of integration of PrEP prescription into existing psychiatric practice workflows to facilitate uptake; and
5. Differing opinions on whether PrEP prescription falls within the scope of psychiatric practice.

Conclusions: Reducing HIV among patients with mental illness through PrEP requires interdisciplinary, coordinated approaches to minimize barriers to care for this hard-to-reach patient population. Psychiatrists practicing in high-HIV incidence areas were largely interested in prescribing PrEP, but need additional training with a specific focus on practical management and integration with existing clinical workflows.

These findings suggest psychiatrists may be an untapped resource for improving PrEP prescription and reducing HIV among patients with mental illness.

TUPEE17

FADE OUT HIV: results of an educational intervention allying Black community barbers, their clients and community clinicians

O. Blackstock¹, W. King², T. Jackson³, D. Beals⁴, S. Pogroszewski⁴, T. Washington⁴, L. Simon⁴, R. Deerr⁴, A. Muehlenhaupt⁴
¹MHS Health Justice, New York, United States, ²W King Health Care, Los Angeles, United States, ³Premier Barber Institute, Norstown, United States, ⁴DKBmed, New York, United States

Background: Black and Brown individuals in the US are disproportionately affected by HIV. In 2018, they accounted for 13% of the population but 42% of new HIV diagnoses with Black men accounting for 31% of new diagnoses. Fade Out HIV addressed these gaps by establishing alliances between healthcare providers and barbershops serving the Black and Brown community in Los Angeles. Barbershops have been recognized as effective venues for delivering health care interventions. In fact, several programs are ongoing.

Barbers see themselves as "counselors," developing long and trusted relationships with their clients. Based on this, an educational grant was secured to develop this program.

Description: Fade Out HIV delivered education to barbers in the Black and Brown communities, their clients, and community clinicians. The initiative started at a barber convention (BarberCon LA). Staff, faculty, and barber influencers introduced the initiative, encouraged enrollment, and educated on HIV prevention and care. Connections from BarberCon facilitated follow-up at local barbershops.

Following BarberCon, staff and barber influencers visited 15 barbershops to kick-off the Fade Out HIV initiative, providing information about the risk of HIV and the role barbers can play in prevention.

Staff delivered client education materials and coupons for free haircuts to encourage clients to get tested by community clinicians. Clinician education was targeted to providers serving the community and included a review of HIV and PrEP treatments, monitoring, and tips on overcoming barriers to screening and prevention.

The initiative included social media campaigns for barbers, their clients, and clinicians that achieved 57,000 views/plays.

Lessons learned: Initially, this program was developed for NYC, but was moved due to COVID. Despite training and tools, barbers were inconsistent/sometimes reluctant to discuss HIV with clients. The partners pivoted and found a local healthcare center to offer onsite HIV rapid testing along with free haircuts.

Overall, the initiative was very successful educating 385 barbers and 297 clinicians leading to 308 HIV tests and improved clinician, barber and client knowledge.

Conclusions/Next steps: Based on the success of this pilot program, faculty, supporters, and participants were encouraged about the reach and impact. Our next steps are to expand the initiative to other US cities.

Mental health and pre-exposure prophylaxis (PrEP) service integration in Vietnam: an important opportunity to boost PrEP adherence, continuation and service quality

K. Green¹, N. Ngo¹, H.T.T. Phan², T.M. Le³, K.Q. Do⁴, P.A. Nguyen⁵, B.H. Nguyen⁶, L. Doan², L. Basu⁷, B.N. Vu¹, A.H. Doan⁷, D. Nguyen⁷, T.T. Tran¹, L.K. Tran¹, V.M. Nguyen¹, Z. Humeau¹

¹PATH, Hanoi, Vietnam, ²Vietnam Administration for HIV/AIDS Control, Vietnam Ministry of Health, Hanoi, Vietnam, ³Glink Social Enterprise, Ho Chi Minh City, Vietnam, ⁴Galant Social Enterprise, Ho Chi Minh City, Vietnam, ⁵My Home Clinic, Ho Chi Minh City, Vietnam, ⁶Bien Viet Clinic, Hanoi, Vietnam, ⁷USAID/Vietnam, Hanoi, Vietnam

Background: Mental health (MH) issues may limit key populations' (KP) uptake of and continuation on pre-exposure prophylaxis (PrEP) and reduce overall quality of life. The USAID/PATH STEPS Project integrated MH screening, assessment, and treatment at five KP-led one-stop shop clinics as part of an effort to advance comprehensive and person-centered PrEP services.

Description: PrEP users at five OSS clinics are screened for MH using an online form or provider-led tools including the DASS21, AUDIT-C and Functioning Suicide Risk screening, and ASSIST. Clients are triaged based on their screening results and offered counseling for any MH conditions identified.

Clients with mild- and moderate-level MH conditions are counselled in-clinic and receive psychoeducation support. Clients with severe-level MH conditions are counselled and referred to expert psychiatric care, while continuing to receive counseling, PrEP, and other services at the clin-

ics. During follow-up visits, PrEP clients are re-screened and supported with ongoing management of their MH conditions. PrEP behavior change campaigns incorporate information on MH to enhance awareness and service uptake among new and current PrEP users.

Lessons learned: From January–December 2022, 6,298 PrEP clients received MH screening, of whom 10.6% presented with a MH condition (7.3%, 7.0%, and 4.6% presenting clinical symptoms of stress, anxiety, and depression, respectively). MH morbidity was higher among partners of people living with HIV (18.9%) and transgender people (16.7%) compared to female sex workers (10.8%) and men who have sex with men (9.7%).

PrEP clients with MH conditions were 50% more likely to drop out of PrEP after three months compared to those without MH conditions (OR = 1.5, $p < 0.001$, 95%CI 1.2–1.8). Of 667 PrEP clients with MH conditions, 235 (48.7%) received follow-up care at least once; of these, 78.7% exhibited a significant reduction in the severity of their MH symptoms when re-screened during follow-up.

Conclusions/Next steps: We found significant association between MH morbidity and reduced PrEP continuation, indicating that integrative MH and HIV services may play an essential role in improving PrEP outcomes. Further scale-up of MH services within public and private PrEP sites will be undertaken to support greater quality of PrEP services and AIDS elimination by 2030.

TUPEE19

First electronic viral load assisted ordering and reporting application: increased data interoperability to improve viral load testing and monitoring in Lao PDR

P. Phoumsavanh¹, S. Nookhai², K. Thongkham¹, L. Sadettan¹, A. Kanphukiew², B. Simanovong¹, K. Koummarasy¹, D. Xaymounvong², S. Aungkulanon², T. Naiwatanakul², S. Northbrook²

¹Center for HIV/STI, Ministry of Health, Vientiane Capital, Lao People's Democratic Republic, ²Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Thailand/Lao, Nonthaburi, Thailand

Background: Lack of interoperability between GeneXpert and the DHIS2-based national health information system may delay clinical decisions and compromise quality of HIV care. The first electronic Viral Load Assisted Ordering-Reporting (VLAO) application was developed across central, provincial, district, and hospital levels to efficiently integrate viral load (VL) orders and testing results from GeneXpert machines into DHIS2 in 2021.

Methods: VLAO, a web-based application that allows data exchange with DHIS2 in real-time, was implemented in 18 facilities nationwide in Lao PDR from January to December 2022. The application allowed clinics to submit lab orders, link samples using barcodes in DHIS2, provide VL real-time results, send automatic unsuppressed VL result notifications, and track clients in need of a VL test. A

mixed methods approach analyzing stakeholder surveys and quantitative analysis of laboratory results and turnaround times from sample collection to electronic reporting was conducted. The Wilcoxon-Mann-Whitney test was used to assess differences in turnaround times.

Figure. VLAO Application workflow.

Results: Median turnaround time from VL sample processing to reporting decreased from 19 (interquartile range (IQR): 8–29) days before VLAO implementation to 3 (IQR: 1–5) days in December 2022 ($p = 0.05$). VL testing coverage increased from 68% in January to 86% in December. A survey of providers revealed reduced workload and manual matching of test results from labs and clients in DHIS2. Data quality monitoring increased reliability and accuracy of data for analysis and upload to cloud-based servers. Limitations included insufficient computer and internet access at rural facilities.

Conclusions: VLAO reduced and simplified processes for ordering and reporting VL results in DHIS2. By ensuring data accuracy and completeness within DHIS2, providers and public health officials can make timely clinical decisions, allocate resources to sub-populations and geographical areas with low levels of VL coverage and suppression, and improve clinical management of HIV in Lao PDR.

Mapping the digital health ecosystem in Africa in the context of endemic infectious and non-communicable diseases: a cross-national analysis of 54 countries

T. Manyazewal¹, M. Ali^{2,3}, T. Kebede⁴, M. Magee², T. Getinet⁵, S. Patel², D. Hailemariam⁶, C. Escoffery⁷, Y. Woldeamanuel¹, N. Makonnen⁸, S. Solomon⁵, W. Amogne⁹, V. Marconi¹⁰, A. Fekadu¹

¹Addis Ababa University, College of Health Sciences, Center for Innovative Drug Development and Therapeutic Trials for Africa (CDT-Africa), Addis Ababa, Ethiopia,

²Emory University, Rollins School of Public Health, Hubert Department of Global Health, Atlanta, United States,

³Hubert Department of Global Health; Emory University, School of Medicine, Department of Family and Preventive Medicine, Atlanta, United States, ⁴Addis Ababa University, College of Health Sciences, School of Medicine, Addis Ababa, Ethiopia, ⁵St. Paul's Hospital Millennium Medical College, School of Public Health, Addis Ababa, Ethiopia,

⁶Addis Ababa University, College of Health Sciences, School of Public Health, Addis Ababa, Ethiopia, ⁷Emory University, Rollins School of Public Health, Department of Behavioral, Social, and Health Education Sciences, Atlanta, United States, ⁸University of Virginia, School of Medicine, Department of Emergency Medicine, Charlottesville, United States, ⁹Addis Ababa University, College of Health Sciences, Addis Ababa, Ethiopia, ¹⁰Emory University School of Medicine and Rollins School of Public Health, Atlanta, United States

Background: Investments in digital health technologies may support Africa achieve United Nations (UN) Sustainable Development Goal for Health by 2030. We aimed to characterize and map digital health ecosystems of all 54 countries in Africa in the context of endemic infectious and non-communicable diseases (ID and NCD).

We performed a cross-national ecological analysis of the digital health ecosystem across Africa using 20-year data from the World Bank, UN Economic Commission for Africa, World Health Organization, and Joint UN Programme on HIV/AIDS.

Methods: Spearman's rank correlation coefficient was used to evaluate ecological correlations between exposure (technology characteristics) and outcome (IDs and NCDs incidence/mortality) variables. Weighted linear combination model was used as the decision rule, combining disease burden, technology access, and economy, to explain, rank, and map digital health ecosystem of a given country.

Results: The 20-year trend showed that technology characteristics have been steadily growing in Africa, including internet access, mobile cellular and fixed broadband subscriptions, high-technology manufacturing, GDP per capita, and adult literacy.

While many were overwhelmed by a double burden of IDs and NCDs. Negative correlations exist between technology characteristics and IDs, such as fixed broadband

subscription and incidence of tuberculosis and malaria, or GDP per capita and incidence of tuberculosis and malaria.

Highest-priority countries for implementation of digital health were South Africa, Nigeria, and Tanzania for HIV; Nigeria, South Africa, and Democratic Republic of the Congo (DROC) for tuberculosis; DROC, Nigeria, and Uganda for malaria; and Egypt, Nigeria, and Ethiopia for endemic NCDs including diabetes, cardiovascular disease, respiratory diseases, and malignancies.

Conclusions: Digital health investments in Africa, including clinical utility trials, require preliminary analysis of the enabling environments to bring about sustainable health and economic returns. Equally, African countries with a high burden of endemic diseases but lacking digital infrastructure should be prioritized for economic development not to worsen existing inequities.

Though infrastructure developments alongside digital health remain on the shoulders of African governments, global health initiatives can cultivate digital health substantially by bridging knowledge and investment gaps, both through technology transfer for local production and negotiation of prices for large-scale deployment of the most impactful digital health solutions.

No data no more: a tool to end the exclusion of trans and gender-diverse people in HIV research

B. Minalga¹, C. Feuer², L.-A. van der Merwe³

¹Fred Hutchinson Cancer Center, Office of HIV/AIDS Network Coordination, Seattle, United States, ²AVAC, New York, United States, ³Social, Health and Empowerment Feminist Collective, Cape Town, South Africa

Background: Finally, the world has begun to recognize transgender and gender-diverse (TGD) people as a key population in the global HIV response. The limited estimates we have suggest that global HIV incidence is 66 times higher for transgender women, 7 times higher for transgender men, and unknown for gender nonbinary people relative to cisgender people. Most agree that TGD people face a disproportionate burden of HIV, yet still, the refrain of "no data" echoes when it comes to TGD representation in HIV research and public health interventions. At IAS 2021, AVAC released the "No Data No More Manifesto to Align HIV Prevention Research with Trans and Gender Diverse Realities."

This manifesto lays out concrete visions for a future of HIV research that is TGD-responsive. In 2023, we are releasing an expansion of the Manifesto known as the TGD-Inclusion Scorecard—an evaluation tool to ensure TGD inclusion in all HIV clinical trials—and to manifest the vision of the No Data No More Manifesto.

Description: We undertook a project to synthesize the Manifesto's visions into a series of scoreable indicators (Scorecard) of TGD representation in HIV clinical trials. We then pilot-tested the Scorecard, assessing 41 milestone

HIV studies that took place from 1991-2023. Source documents for this assessment included study protocols, study publications, and study records on clinicaltrials.gov.

Lessons learned: Only 12 out of the 41 studies in our analysis included TGD people. From 1991-2006, there was no TGD representation in milestone HIV trials. Out of the 171,062 participants in the 38 completed studies, less than 1% were TGD (n=1,340). Among the TGD participants that were included, 94% were transgender women; transgender men and gender nonbinary participants represented only 3% of TGD participants, respectively. Only 6 studies reported the gender of participants in primary publications, and research systems to support TGD enrollment are underutilized.

Conclusions/Next steps: Findings from our analysis confirm that TGD people remain grossly underrepresented in HIV research. Next steps include availing our Scorecard tool to HIV researchers around the world.

We implore researchers to utilize our Scorecard evaluation tool proactively as study design guide to urgently end the inexcusable exclusion of TGD people.

TUPEE22

The progress and utility of HIV case-based surveillance in Kenya for public health response, 2014-2022

A. Waruru¹, W. Waruiru², K. King'utu², M. Ndisha¹, O. Osborn Otieno³, L. Kingwara³, F. Weissglas², P. Mwele⁴, L. Odera⁵, G. Omoro⁶, N. Springstubb⁷, M. Patel⁷, S. Jonnalagadda⁷

¹US Centers for Disease Control and Prevention (CDC), Division of Global HIV and TB, Nairobi, Kenya, ²University of California San Francisco, Global Programs for Research and Training (GPRT), Nairobi, Kenya, ³National AIDS and STI Control Program (NASCOP), Nairobi, Kenya, ⁴Palladium, Nairobi, Kenya, ⁵The United States Agency for International Development (USAID), Nairobi, Kenya, ⁶Walter Reed Army Institute of Research, Nairobi, Kenya, ⁷US Centers for Disease Control and Prevention (CDC), Atlanta, United States

Background: HIV case-based surveillance (CBS) is a person-centric system that provides timely data across the HIV cascade – from prevention, testing, and treatment to longer-term health care and outcomes. The CBS system has individual-level robust data for sentinel events-driven public health response (PHR), thereby achieving the complete data collection cycle and use for improving treatment outcomes. We present the Kenyan experiences, 2014 to date, and the system's utility for PHR.

Description: In Kenya, CBS pilot activities were started in 2014-15 in two counties, followed by a proof of concept in 2016-17. Since 2018, the national data warehouse (NDW) data have been used for CBS after an extraction, loading, and transformation (ETL) process. By 2021, data from 40/47 counties accounting for ~95% (1,107,173) of PLHIV currently on treatment were part of the CBS system.

Reporting rates to NDW are estimated to be 89% (figure). To support CBS, county and health facility staff are routinely trained through an interactive eLearning platform, and CBS implementation is monitored through quarterly progress review meetings.

Lessons learned: Case-level data are used to generate individual-level PHR reports identifying every client needing attention, e.g., diagnosed but not linked to care, not virally suppressed, and shared with the facilities for timely decision-making. CBS data are extracted from NDW and analyzed for scientific dissemination, addressing key epidemiologic questions and identifying areas for programmatic strengthening and focus.

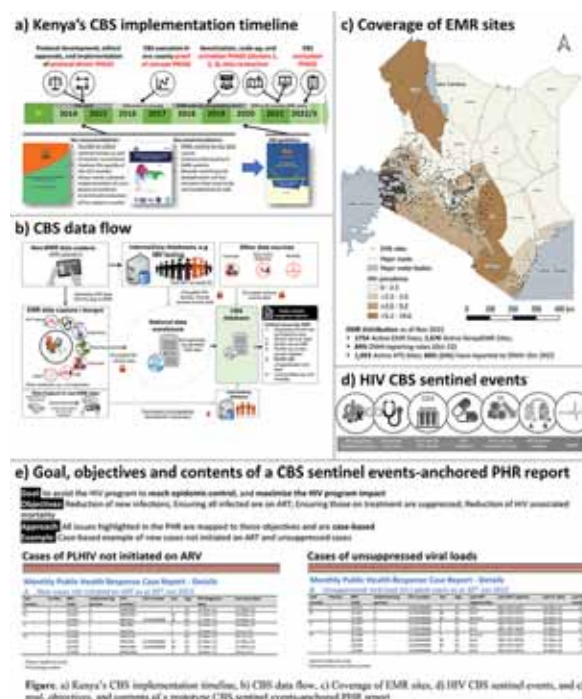

Figure. a) Kenya's CBS implementation timeline. b) CBS data flow. c) Coverage of EMR sites. d) HIV CBS sentinel events. e) goal, objectives and contents of a prototype CBS sentinel events-anchored PHR report.

Conclusions/Next steps: The high coverage of PLHIV in EMRs provides rich data for informing CBS sentinel events-anchored PHR in Kenya. The PHR reports have revolutionized the utility of CBS and accelerated its buy-in in Kenya. To the best of our knowledge, Kenya is the first sub-Saharan African country to implement the complete cycle of CBS, including PHR as a feedback loop to the facilities and improving services to PLHIV. To strengthen the CBS system, an evaluation is currently underway.

A pilot study of Paediatric Dolutegravir (pDTG) automation using technology to improve adherence among children living with HIV in Akwa-Ibom State

O. Adeyemi¹, C. Aruku¹, F. Lannap¹, A. Ajonye¹, P. Adekoya¹, A. Olutola¹, D. Magaji²

¹Center for Clinical Care and Clinical Research, Uyo, Nigeria, ²United States Agency for International Development, Abuja, Nigeria

Background: Weight based antiretroviral therapy (ART) administration is the gold standard for optimizing treatment in children living with HIV (CLHIV). It ensures that children are not under or over dosed while administering ARVs. In community-based differentiated service delivery models, checking children's weight before placing them on ARVs can be challenging as functional weighing scales are not readily available.

This study measured consistency of estimated weight-based ART optimization through digital automation using the mobile technology in comparison to the actual weight obtained through a weighing scale.

Methods: The Center for Clinical Care and Clinical Research (CCCRN) implementing USAID- funded Integrated Child Health and Social Service Award (ICHSSA) devised an innovative digital automation called "pDTG Optimizer" hosted on the CHILD Monitor app that operates both off and online. The pDTG Optimizer uses date of birth of CLHIV to auto calculate estimated weight and display appropriate ARV regimen based on weight. The app is downloaded and installed on Community Case Workers(CCWs) phone and use to monitor children's adherence on ARVs. Before roll out, CCWs were trained on its use, conducted a pilot study in 7 high volume facilities selected from different context to compare actual weight and estimated weight ARV dosing for a total of 95 CLHIV (0 – 7 years) who were expected to pick up drugs within three months of the study period. Analysis was conducted by Excel and SPSS.

Results: A total of 87 CLHIV participated in the study of 93 Children who were expected for ARV pick up. Mean age was 3.5 years (1 – 7 years), mean for actual weight for participants – 14.8kg (7.2-49Kg) standard deviation- 5.18, mean for estimated weight – 20.9kg (7.2 – 49kg) standard deviation -7.38.

Generally, compared to the standard (actual weight) we recorded a 72.4% concordance for the estimated weight. Highest concordance was recorded in the under 2 years (78.9%) while the least were seen in the 5-7 years (50%).

Conclusions: Data from Child Monitor is scalable compared to conventional weighing scales, this point to the fact that programs can explore leveraging on the technology for ART adherence tracking in resource limited setting.

TUPEE24

Favorable outcomes of Option B+ strategy despite COVID-19 restrictions: retrospective cohort study in Zambézia Province, Mozambique (2019-2021)

C. De Schacht¹, Z. Yu², M. Bravo¹, E. Graves³, K. Tibana⁴, C. Cugara⁵, C. Veríssimo⁵, C. Belo¹, G. Amorim², J. Tique¹, A. Couto⁴, C.W. Wester⁶

¹Friends in Global Health, Maputo, Mozambique,

²Vanderbilt University Medical Center (VUMC), Department of Biostatistics, Nashville, United States, ³Vanderbilt University Medical Center (VUMC), Vanderbilt Institute of Global Health (VIGH), Nashville, United States, ⁴Ministry of Health, National Directorate of Public Health, Maputo, Mozambique, ⁵Provincial Health Directorate Zambézia, Quelimane, Mozambique, ⁶Vanderbilt University Medical Center (VUMC), Department of Medicine, Division of Infectious Diseases, Nashville, United States

Background: In response to the COVID-19 pandemic, the Ministry of Health of Mozambique installed mitigation measures in April 2020, including expansion of differentiated models of care (DMC). Quarterly dispensation (QD) for pregnant women (PW) was implemented April-August 2020.

We herein describe trends of pre-pandemic (April2019-March2020) and within-pandemic (April2020-March2021) maternal and infant HIV outcomes.

Methods: Aggregated routine data from 173 health facilities in Zambézia Province for PW initiating ART and their HIV-exposed infants (HEI) were used.

Outcomes included: proportion of PW retained in care 3- and 6-months post-ART initiation, early infant diagnosis (EID) coverage, and proportion of positive tests among HEI by 9 months of age.

Generalized linear mixed-effect models were used to compare trends pre- and within-COVID-19.

Results: The odds of PW being retained at 3-months decreased significantly to 56.6% in April 2020 (OR 0.57 [95%CI:0.44-0.74], p<0.001). During COVID-19 period, the odds of being retained at 3-months increased ~3.9% per month (OR 0.57 [95%CI:1.06-1.10], p<0.001). The odds of PW being retained at 6-months increased (OR 2.16 [95%CI:1.50-3.10], p<0.001) within-pandemic.

Although the odds decreased within-pandemic (OR 0.91 [95%CI:0.88-0.93], p<0.001), 6-month retention proportion remained higher than the pre-pandemic period. EID coverage experienced an increase immediately after April 2020 (OR 1.94 [95%CI:1.26-2.98], p=0.003) and had a sustained effect, with odds of HEI undergoing EID increasing ~4.7% per month.

There were no significant differences in proportion of HEI testing positive, decreasing 2.7% per month, over time regardless of period (Figure).

Conclusions: In Zambézia Province, the pandemic and associated restrictions did not adversely impact maternal retention in care, EID coverage or EID positivity rates among PW and their HEI. Despite transient reductions in

early retention, rapid expansion of DMC including QD for PW, introduced in response to COVID-19 pandemic, appeared to have a favorable impact on mother and child outcomes.

Using HIV platform to improve COVID-19 vaccination uptake through a combination intervention approaches in Eastern Province, Zambia

T. Malebe¹, G. Kibombwe², C. Nkama³, J. Mukundu⁴, M. Goma⁴, P. Makelele², N. Persaud⁵, H. Satti⁶, K. Kane⁷, E. Oladele¹, O. Chabikuli⁸

¹FHI360, Global Health, Lusaka, Zambia, ²FHI360, Technical, Lusaka, Zambia, ³FHI360, Global Health, Abidjan, Cote D'Ivoire, ⁴FHI360, Strategic Information, Lusaka, Zambia, ⁵FHI360, Strategic Information, Washington, United States, ⁶FHI360, Global Health, Washington, United States, ⁷FHI360, Programs, Pretoria, South Africa, ⁸FHI360, Global Health, Pretoria, South Africa

Background: The COVID-19 pandemic is a public health issue affecting all sectors globally. The first cases were reported on March 18, 2020, in Zambia, and the country had recorded four outbreaks as of December 2021. These outbreaks were partly attributed to low vaccination coverage among eligible people. As of November 19, 2021, only 7.4 % of the eligible population was fully vaccinated in Zambia, and another 4.6% received the first dose. In the same period, Eastern Province vaccinated 176,537 (18%) of its 973,790 target. Though the vaccine has proven effective in averting severe forms of COVID-19 and mortality, many people remain reluctant to receive it. Thus, in December 2021, the FHI 360-led, PEPFAR-funded technical assistance project through the CDC supported the Eastern Province Health Office (EPHO) to implement a combination intervention approach to surge COVID-19 vaccination with 100,000 persons aged 18 years and older as the provincial target by the end of 2021.

Description: A total of 600 facility and community-based teams were oriented on COVID-19 sensitization messaging, 250 health care workers and 70 data entry clerks were trained in data management. Conducted 14 stakeholder

engagement meetings in chiefdoms with traditional leaders (chiefs and village headmen) on the importance of vaccination. Conducted live interactive community radio programs to address COVID-19 vaccination-associated myths and misconceptions.

Lessons learned: From April to November 2021, 176,537 (58%) people were vaccinated against a target of 300,000. In December 2021 alone (surge period), 117,630 (117%) persons were vaccinated against a target of 100,000 people. The surge achievements were fivefold the 21,935 monthly average vaccinations before the surge.

Results also showed significant differences in vaccine uptake by sex (p value=0.001, CI=95%). Distribution by sex showed more females (62%) vaccinated than males (38%), while preference by vaccine type showed that most people received Johnson & Johnson (160,314; 90.8%), followed by AstraZeneca (16,192; 9.2%) and Sinopharm (31; 0.02%).

Conclusions/Next steps: The intervention improved stakeholders' involvement, facility and community teams' coordination, supply chain, logistics, and data management. If scaled up and coupled with accountability and leveraging of HIV program resources, this approach has the potential to increase COVID-19 vaccination coverage.

TUPEE26

Exploring the impact of the COVID pandemic on sexual health services in community health centers across the US

P.B. Carneiro^{1,2}, J. Du Mond², J. Osika², C. Nwachuku², R. Uy², J. Gresh², A. Price², J. Skapik²

¹CUNY School of Public Health, New York, United States, ²National Association of Community Health Centers, Informatics, Bethesda, United States

Background: The COVID-19 pandemic of 2020 had a significant impact on the sexual health infrastructure of the US. Community health centers (CHCs), which serve those in highest need, faced challenges providing routine primary care services like sexual health screening, routine PrEP care and treatment for sexually transmitted infections (STIs).

Description: Using a database collective of electronic health records (EHR) data, we explored the impact of the pandemic on sexual health services for a population of individuals attending CHCs across the U.S. by developing surveillance tools to track resilience of services. A collective of partners extracted data from 4 different EHR systems using a common data dictionary and a set of business requirement parameters.

There were over 400,000 unique people in the database. The extraction timeframe spanned January 2019 – February 2021. We built several dashboard surveillance tools using monthly counts to track the volume of services and outcomes.

We built a graphic with the number of unique monthly people being screened for bacterial STIs, as well the number of positive test results, including HIV test results.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Lessons learned: The pandemic had a clear impact on services in CHCs. The average count of bacterial STI and HIV-positive tests and results reduced by more than 80% from its monthly average pre-pandemic (Figure 1). The PrEP cohort pre-pandemic was reduced by about 10% in the year following the onset of the COVID-19 pandemic (data not shown). Significant informatics and data extraction challenges limited our ability to explore data in more detail and greater accuracy.

Conclusions/Next steps: Surveillance tools were beneficial to assess CHCs resilience of services following the pandemic. Overall, it took health centers more than 12-months to resume sexual health services to about 95% of the pre-pandemic volume. Overcoming data infrastructure and governance challenges will be essential to ensure the viability and relevance of this type of tool.

itized, and teams assigned to optimize outcomes. Teams were provided with IIT listings and logistics support to follow-up clients and return them B2C. Monitoring of individual performance was used to assess outcomes and implement improvements.

Lessons learned: Follow-up was attempted over one month for 56% (n=636) of the 1,126 clients confirmed to have IIT. Attempts were successful for 74% (n=473). Of those, 35% (n=164) were reconnected to treatment, 31% (n=146) were identified as silent transfers, 10% (n=47) died, 19% (n=90) were tracked but did not return to care, and 5% (n=26) opted-out of ART. A total of 26% (n=163) lacked clear physical addresses in clinic records, changed their phone numbers, or used false names, which made them impossible to follow-up.

Given the success of this initial intervention and the number of clients still requiring follow-up, enhancing B2C by extending the implementation period and/or increasing the number of follow-up teams was needed.

Conclusions/Next steps: Though only 1-month, this health-facility-owned, peer-driven B2C surge activity was effective in returning disengaged PLHIV to treatment. Regular B2C surges can be used by programs to complement routine follow-up and active case management. Qualitative analysis exploring reasons for treatment cessation can be used to complement surges and improve understanding of barriers.

Lessons learnt from an HIV continuity-of-treatment surge initiative to alleviate the effect Of COVID-19 pandemic on HIV care in National Capital District, Papua New Guinea

V. Kapus¹, W. Yeka¹, J. Nankinga¹, P. Temu¹, R. Nopa¹, D. Kunjil¹, P. Nwaokoro¹, H. Kiromat-Geno¹, R. Luluai¹

¹Family Health International 360, Port Moresby, National Capital District, Papua New Guinea

Background: By 2020, 89% of the estimated 55,000 people living with HIV (PLHIV) in Papua New Guinea (PNG) were on antiretroviral therapy (ART), although the effectiveness of therapy was reduced by interruptions in treatment (IIT) and recycling in care. Attrition was aggravated by COVID-19 related restrictions on travel and HIV service delivery. In September 2021, the USAID HIV Support in PNG project implemented a back-to-care (B2C) surge activity to trace and return clients who had IIT after starting ART in 11 clinics of the National Capital District.

Description: A list of PLHIV who had started ART but discontinued as of September 30, 2020, was generated from facility electronic medical records. In collaboration with ART clinic staff, the project team reviewed client files to verify attendance status. FHI 360, in collaboration with the PNG network for PLHIV (IGAT HOPE), developed clinic-specific follow-up plans. Using geospatial information extracted from electronic records, specific areas were prior-

Understanding the viral and host transmission fitness factors associated with different modes of HIV-1 subtype B transmission

Y. Zhang¹, A. Ratcliff², C. Venner¹, E. Arts^{1,2}

¹University of Western Ontario, Department of Microbiology and Immunology, London, Canada, ²Case Western Reserve University, Department of Molecular Biology and Microbiology and Division of Infectious Diseases, Cleveland, United States

Background: HIV-risk groups include heterosexual individuals (HET), men-who-have-sex-with-men (MSM), people who inject drugs (PWID) and people who received contaminated blood transfusions (CBT). When HIV-1 is transmitted, typically only a single clone, or in rare cases, a small number of HIV-1 clones establish the new infection, creating a transmission bottleneck for the virus. The viral clone that establishes infection is called the transmitted/founder (T/F) virus. Specific traits that permit successful transmission have not been well characterized.

Methods: *In vitro* competitions on human genital tissues followed by deep sequencing were performed to determine transmission fitness between T/F viruses from different transmission routes. Subsequently, phenotypic assays were used to analyze the contribution of select factors (for example, entry speed and receptor binding efficiency) to transmission fitness.

Results: Competitions on human cervical tissues suggested that tissues favored T/F viruses and glycosylation might play a role in the process. In control competitions directly on susceptible cell lines, T/F viruses from HET and MSM group often outcompeted T/F viruses from PWID group in T helper type 1 (Th1) cells, while viruses from HET and PWID groups dominated infection in Th17 cells.

T/F viruses showed different phenotypic characteristics between different transmission routes and from chronic viruses. T/F viruses from HET group required more stringent cellular co-receptor conformations to enter susceptible cells compared to others.

Furthermore, T/F viruses also exhibited more rapid cell entry than chronic viruses.

However, there is no significant difference of envelope expression level across all T/F virus groups and chronic viruses, which indicates that differences between T/F and chronic viruses in this study are more likely to be based on envelope structure or glycosylation patterns/levels.

Conclusions: This project will establish the key viral phenotypes contributing to successful virus transmission to inform the design of a robust anti-HIV vaccine. Mean-

while, the drug sensitivity against T/F viruses from different transmission routes provided by this project will help the improvement of personalized antiretroviral treatment regimens.

EPA0002

Preexisting and postbaseline resistance analyses in pooled pediatric studies of emtricitabine/tenofovir alafenamide (F/TAF)-based antiretroviral therapy (ART)

K. Andreatta¹, S. Cox¹, K. Chokephaibulkit², C.A. Rodriguez³, A. Liberty⁴, E. Natukunda⁵, V.A. Vieira¹, K. Kersey¹, C. Callebaut¹

¹Gilead Sciences, Inc., Foster City, United States, ²Mahidol University, Bangkok, Thailand, ³Morsani College of Medicine, University of South Florida, Tampa, United States, ⁴Chris Hani Baragwanath Hospital, Johannesburg, South Africa, ⁵Joint Clinical Research Centre, Kampala, Uganda

Background: Emtricitabine/tenofovir alafenamide (F/TAF) is a guideline-recommended NRTI backbone for HIV treatment in children. F/TAF is coformulated with cobicistat-boosted elvitegravir (E/C/F/TAF) or bictegravir (B/F/TAF) as complete regimens. Here we present pooled analyses of baseline resistance and long-term follow-up data from four studies evaluating safety and efficacy of F/TAF-based ART in pediatric populations.

Methods: Participants were treatment-naïve (TN) or virologically suppressed (VS), aged 2 to <18 years, and received B/F/TAF, E/C/F/TAF or F/TAF+third agent. Baseline resistance was assessed by RNA or DNA HIV-1 genotyping and/or historical genotype. Postbaseline HIV-1 genotyping/phenotyping was performed for participants with HIV-1 RNA >200 (B/F/TAF) or >400 copies/mL (E/C/F/TAF, F/TAF+third agent) at confirmed virologic failure or last visit. Outcomes were determined by HIV-1 RNA at last on-treatment visit.

Results: Overall, 341 participants were enrolled and treated (122 B/F/TAF, 179 E/C/F/TAF, 40 F/TAF+third agent). Median (IQR) age was 12 (9, 15) years; 15% were TN (50 E/C/F/TAF). Baseline genotypic data were available for 100% (50/50) of TN and 28% (82/291) of VS participants; 39% (132/341) had protease/reverse transcriptase data and 35% (121/341) had integrase data. In total, 30% (39/132) had ≥1 preexisting primary resistance substitution (31 B/F/TAF, 8 E/C/F/TAF; *Table*). Median (IQR) treatment duration was 157 (104, 202) weeks; 95% (323/341) had virologic suppression at last visit, including 92% (36/39) with and 95% (88/93) without preexisting resistance. Altogether, 9% (32/341) met the criteria for postbaseline testing (9 B/F/TAF, 19 E/C/F/TAF, 4 F/TAF+third agent). There was no treatment-emergent resistance to B/F/TAF or E/C/F/TAF. Study drug resistance was detected in four participants without baseline data receiving F/TAF+efavirenz: all had NNRTI resistance and two

had K65R, one with M184V. All four switched third agents; three achieved virologic resuppression (including two with K65R+/-M184V).

Baseline category	Pooled pediatric participants, % (n/n with data)	HIV-1 RNA <50 copies/mL at last visit, % (n/n with resistance)	P-value (Fisher exact test)
No baseline resistance	70 (93/132)	95 (88/93)	0.69
Any baseline resistance	30 (39/132)	92 (36/39)	
NRTI resistance	15 (20/132)	90 (18/20)	NA
z1 TAMs	10 (13/132)	92 (12/13)	
M184V/I	9 (12/132)	83 (10/12)	
NNRTI resistance	20 (27/132)	83 (25/27)	
PI resistance	7 (9/132)	100 (9/9)	
INSTI resistance	4 (5/121)	80 (4/5)	

ART, antiretroviral therapy; F/TAF, emtricitabine/tenofovir alafenamide; INSTI, integrase strand transfer inhibitor; NA, not applicable; NNRTI, non-nucleoside reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitor; PI, protease inhibitor; TAM, Tumor Associated Mutation.

Table. Pre-existing resistance in pediatric studies of F/TAF-based ART and virologic suppression at last on-treatment visit.

Conclusions: High levels of virologic suppression through 157 weeks of follow-up, regardless of preexisting resistance, demonstrate the efficacy of F/TAF-based ART in children.

³University of Sydney, Sydney School of Public Health, Faculty of Medicine and Health, Sydney, Australia

Background: Studies of intravaginal SIV inoculation have shown that the clone size of individual transmitted virions may vary by up to 1000-fold in plasma virus (Deleage et al., Science Advances 2019). However, it is unclear where in the process of initial infection, local, and systemic spread this clonotype size heterogeneity arose.

In this study, we utilize multiple in vivo and in vitro infection models to characterize the contribution of cellular heterogeneity and anatomical factors in the observed heterogeneity in clonotype size.

Methods: Barcoded SIV were used for intravenous inoculation of Rhesus macaques (n=4) as well as in vitro infection of primary cells and cell lines. The relative copy numbers of individual barcodes in early plasma virus or in culture supernatant were analysed using Illumina sequencing. In some in vitro studies single cycle viral replication was analysed by blocking infection with maraviroc and anti-CD4 antibody treatment at 6 hours and FTC treatment at 24 hours post inoculation.

Results: We compared the clonotype size distribution after intravaginal and intravenous inoculation to understand the contribution of anatomical barriers to clonal heterogeneity.

Intriguingly, we observed higher variability in clonotype size after intravenous inoculation (mean interquartile range 1.76 and 1.47 log₁₀ copies/ml, respectively), indicating an anatomical barrier at the site of infection is not the primary cause for clonotype size heterogeneity.

To further examine sources of heterogeneity we analysed in vitro clonotype size distribution after single round or multiple round infection of primary cells and cell lines.

Remarkably, even in the most controlled scenarios (single round infection of the SupT1-R5 cell line) we found very similar clonotype size distribution to that observed in vivo (day 2 mean interquartile ranges of 1.34 log₁₀ copies/ml), indicating that clonotype heterogeneity is established at the first round of replication.

Conclusions: Our comparison of multiple infection models indicates that clonotype heterogeneity is established during replication within the first infected cell and is the result of the stochastic differences in viral production by individual infected cells.

and Tumor Virology, Rio de Janeiro, Brazil, ²Federal

Hospital of Ipanema, Infectious Diseases Service, Rio de

Janeiro, Brazil, ³Federal University of Rio Grande, Molecular Biology Laboratory, Rio Grande, Brazil

Background: Antiretroviral therapy (ART) has revolutionized HIV treatment, increasing quality and life expectancy of people living with HIV (PLWH). However, the expansion of treatment has resulted in an increase in antiretroviral resistant viruses, which can be an obstacle to maintenance of successful ART.

Thus, it is essential to understand the outcome of drug resistance mutations (DRM), including minority (low-frequency) variants, on treatment of PLWH with undetectable viral load.

This study analyzed the genetic composition of HIV near full-length genome (NFLG) from archived proviruses of PLWH under successful ART; determined the presence and frequency of DRM and determined the viral subtype.

Methods: Forty-six PLWH from Rio de Janeiro (RJ) and 40 from Rio Grande (RS) had their genomic DNA extracted from peripheral whole blood. HIV NFLG was PCR-amplified and ultradeep sequenced.

The presence and frequency of DRMs were analyzed in Geneious program. Phylogenetic analyses were performed using PhyML and SimPlot.

Results: All samples included in the study have been sequenced and 69 (80.2%) had the HIV NFLG determined. RJ and RS showed a predominance of HIV subtypes B (78.3%) and C (67.5%), respectively. Overall, 168 DRMs were found in 63 (73.3%) samples and 105 (62.5%) of them were minority variants.

Among the 168 DRMs, 68 (40.5%) were able to confer some degree of resistance to at least one drug in use by PLWH, yet no one showed signs of therapeutic failure.

Conclusions: Our study contributes to the understanding of the impact of DRMs on successful therapy and supports the sustainability of combinatorial ART, since all PLWH maintained their successful treatment despite the high prevalence of DRMs at low or high frequency.

EPA0005

HIV-1 Vpr drives a tissue residency-like phenotype during selective infection of resting memory T cells

A.-K. Reuschl¹, D. Mesner¹, M. Shivkumar¹, M. Whelan¹, L. Pallett¹, A. Guerra-Assunção¹, R. Madansein², K. Dullabh², A. Sigal³, J. Thornhill⁴, C. Herrera⁵, S. Fidler⁵, M. Noursadeghi¹, M. Maini¹, C. Jolly¹

¹University College London, Infection and Immunity, London, United Kingdom, ²University of KwaZulu-Natal, Department of Cardiothoracic Surgery, Durban, South Africa, ³Africa Health Research Institute, Durban, South Africa, ⁴University of Oxford, Oxford, United Kingdom, ⁵Imperial College London, Department of Infectious Disease, London, United Kingdom

Background: HIV-1 establishes cellular and tissue reservoirs, both active and latent, that prevent cure with anti-retroviral therapy. Determining how HIV-1 shapes its niche to create a permissive environment is central to informing efforts to limit pathogenesis, disturb reservoirs and ultimately achieve cure.

A key roadblock in gaining molecular level understanding of this process is the requirement to mitogenically activate T cells in vitro in order to infect them with HIV-1, which dominates changes to gene and protein expression, obscuring T cell responses driven by the virus itself.

Thus, key features of the interaction between HIV-1 and host T cells remain poorly understood.

Methods: Here we co-cultured HIV-1 infected and uninfected primary human CD4⁺ T cells, allowing for highly-efficient cell-cell spread and infection of resting T cells, without the need for confounding in vitro T cell activation. By combining viral replication assays with approaches to define T cell phenotype (flow cytometry), transcriptional responses (qPCR and RNA-Seq) and functional T cell assays, we define how HIV-1 infection reprograms resting T cells.

Results: We show that cell-cell spread allows for productive HIV-1 infection and integration into resting memory T cells. Strikingly we find HIV-1 infection primes these resting CD4⁺ T cells to gain characteristics of tissue-resident memory T cells (T_{RM}), upregulating key T_{RM} surface markers and the transcription factor Blimp-1, and inducing a transcriptional programme overlapping the core T_{RM} transcriptional signature.

Using viral mutants we show that induction of the T_{RM}-like phenotype is driven by the HIV-1 accessory protein Vpr, requires Vpr packaging into virions and its manipulation of T cell signalling and Vpr-driven transcriptional reprogramming.

Conclusions: Tissue-resident memory T cells can persist long term in vivo. Our results suggest that HIV-1 persistence and the establishment of tissue reservoirs may be driven, in part, through direct viral induction of a T_{RM}-like phenotype via transcriptional reprogramming mediated by Vpr, providing an alternate model for a tissue-associated reservoir driven by the virus itself.

This work has important implications for understanding viral replication and persistence, and how HIV-1 reservoirs are established and maintained.

Chan School of Public Health, Boston, United States, ⁵Division of Infectious Disease, Brigham and Women's Hospital, Boston, United States

Background: Long-acting injectable cabotegravir/rilpivirine (CAB-RPV) is an alternative to oral antiretroviral therapy (ART) that is currently approved for people already on suppressive ART. Pre-existing RPV-associated resistance mutations have been found to predict HIV-1 virologic failure (VF) in those switching to CAB-RPV.

There is minimal data on the prevalence of RPV-associated resistance mutations in HIV-1 subtype C(HIV-1C) predominant regions.

Methods: We evaluated the prevalence of archived RPV-associated resistance mutations among people with HIV (PWH) who had previously enrolled in the Botswana Combination Prevention Project (BCPP, from 2013-2018) from across Botswana, and who had undetectable HIV RNA viral load (VL, <400 copies/mL) on ART.

We analysed existing near full-length HIV-1 pol sequences from proviral DNA for presence of RPV-associated resistance mutations, which were defined according to the 2022 IAS-USA drug resistance mutation list and Stanford HIV drug resistance database.

Results: Of 4748 PWH on ART enrolled in BCPP, 4739 (99.8%) had VL results, 4526 (96%) of whom had VL <400 copies/mL; 3620 (87%) of 4164 individuals with viral suppression and available ART information were on NNRTI-based (nevirapine or efavirenz) ART regimens. Of the 4526 PWH with viral suppression on ART, 962 (21.3%, 95% CI 20.1%-22.5%)

had at least 1 archived RPV DRM. E138A was the most prevalent RPV-associated mutation overall (9.3%, 95% CI 8.4-10.1), followed by M230I (9%, 95% CI 8-9.7) and E138K (1.7%, 95% CI 1.3-2.1).

The rest of the mutations observed were below a prevalence of 1% (L100I, K101P, E138G, E138Q, Y181C, Y181I, Y188L and M230L). Common RPV-associated mutations patterns observed were E138A + M230I (0.8%), E138K + M230I (0.49%), E138K + G190E (0.4%), E138A + V179D (0.33%) and E138A + K101E (0.10%).

Conclusions: RPV-associated resistance mutations were present in 21.3% of PWH in Botswana with VL suppression while on predominantly first generation-NNRTI-based ART. E138A and M230I were the most prevalent RPV-associated mutations in this cohort predominated by HIV-1C.

Individuals harbouring HIV-1 variants with these mutations may be more likely to fail CAB-RPV, hence monitoring RPV-associated resistance mutations will be crucial for successful CAB-RPV treatment implementation in this setting.

Identification of a new HIV-1 BF1 intersubtype recombinant form circulating in Turkey, that has generated a secondary recombinant form with CRF56_cpx transmitted in Spain

M.M. Thomson¹, M. Moreno-Lorenzo¹, A.M. Donoso¹, S. Benito¹, G. Cilla², J. del Romero³, A. González-Praetorius⁴, M.Á. Cañizares⁵, E. Delgado¹

¹Instituto de Salud Carlos III, Centro Nacional de Microbiología, Majadahonda, Spain, ²Hospital Universitario Donostia, San Sebastián, Spain, ³Centro Sanitario Sandoval, Madrid, Spain, ⁴Hospital Universitario de Guadalajara, Guadalajara, Spain, ⁵Complejo Hospitalario Universitario de A Coruña, A Coruña, Spain

Background: In recent years, increasing HIV-1 clustering has been reported in many countries. Here we report that a BF1 recombinant cluster, originally identified by us in Spain, but comprising viruses mainly from Turkey, represents a new BF1 circulating recombinant form (CRF) and secondary recombinants of this CRF.

Methods: HIV-1 protease-reverse transcriptase (PR-RT) sequences were obtained after RT-PCR amplification from plasma RNA. Near full-length genome (NFLG) amplification of one virus was performed in 4 overlapping fragments. Similar database sequences were searched with BLAST. Phylogenetic analyses were performed via maximum likelihood. Recombinant structures were analyzed with bootscanning and phylogenetic trees of partial segments. The temporal and geographic origin of the newly identified CRF was estimated with a Bayesian coalescent method.

Results: In a HIV-1 molecular epidemiological survey in Spain, based on PR-RT sequences, we identified numerous clusters, one of which was a BF1 recombinant cluster comprising 5 individuals. After inclusion in phylogenetic

analyses of similar database sequences, it was found that the sequences of the mentioned BF1 cluster belonged to a larger cluster, comprising samples mostly from Turkey (n=84), but also from Belgium (n=3), Sweden (n=1), and United Kingdom (n=1), with 3 Spanish samples grouping in a subcluster. The Turkish sequences represented 32% HIV-1 PR-RT sequences available from Turkey at the Los Alamos HIV Sequence Database. Bootscan analyses revealed co-incident recombinant structures.

Analyses of NFLG sequences from the Belgian and Swedish samples, available at databases, revealed fully coincident BF1 structures, with 6 breakpoints. This allows to define a new CRF, provisionally designated CRF_BF1_TR.

Phylogenetic analyses of F1 subsubtype segments revealed a relation with the F1 Romanian-Angolese lineage. NFLG analysis of one virus of the Spanish subcluster identified a CRF_BF1_TR/CRF56_cpx recombinant genome. Bayesian analyses estimated CRF_BF1_TR origin in Turkey around 2005.

Conclusions: A new CRF_BF1 widely circulating in Turkey has been identified. This is the first BF1 CRF derived from the Romanian-Angolese F1 lineage (all others identified previously derive from the Brazilian F1 lineage).

The results also highlight the extraordinary recombinogenic potential of HIV-1, with secondary recombination of the Turkish CRF_BF1 with CRF56_cpx, that further derives from one CRF (CRF02_AG) and 2 subtypes (B and G).

Background: Even after extended periods of effective, suppressive immune control, HIV-1 continues to dynamically change and evolve in body compartments, suggesting persisting and continuously active viral reservoirs.

Methods: A longitudinal analysis of proviral Env sequences was performed by next-generation sequencing (NGS) in HIV-infected individuals from the Swiss-HIV-Cohort-Study right after diagnosis. HIV-1 proviral load, intracellular viral poly-A transcripts (pA) and Torque Teno Virus loads as independent marker were quantified by qPCR.

PBMCs, sorted and cultured for 3 weeks for viral outgrowth, were monitored for viral reactivation by Tat-induced LTR-activation and HIV-1 protein expression by FACS. Single-genome sequencing (SGA) analysis of the 3' half of the HIV-genomes was carried out to assess re-activated viral RNA.

Results: Specimens from nine viremic SHCS-HIV individuals with detectable HIV-1 provirus in PBMCs (median: $231/10^6$ cells) and detectable HIV-1 polyA-RNA (median: $1129/10^6$ cells) were included. In 5/9 samples a high reservoir diversity persisted even for extended periods after therapy initiation, while 4/9 presented unique virus variants (241-1454 days). Lymphocyte counts ($p=0.0068$), CD4 ($p<0.0001$), and CD8 cells ($p=0.0487$) were lower in the population with high-diversity reservoirs, and as independent marker of immune reconstitution: Torque-Teno-Virus loads were higher.

In circulating T-cell subsets, predominantly TN (naïve) and TCM (central memory) T-cells harbored replication-competent HIV-1. In TTM (transitional memory) and TEM (effector memory) T-cells, most archived proviral sequences contained inactivating mutations and, at the same time, displayed a higher genetic diversity.

Conclusions: Our study demonstrates that less immune control, evidenced by low lymphocyte counts, makes it easier for the virus to replicate to high levels and further increase its genetic diversity. The main reservoirs for replication-competent, infectious virus include TN and TCM, with single or limited numbers of intact viral variants. A distinct, smaller contribution of archived HIV sequences stems from TTM and TEM, characterized by a higher viral variability. The latter potentially form the basis for an ongoing evolution of new viral variants during therapy. These findings provide insights into the dynamics of the viral reservoir in individuals early during infection near the start of therapy and may have important implications for a better understanding of HIV-1 transmission and in vivo evolution.

EPA0009

Development of an efficient method based on Nanopore technology for sequencing of HIV-1 near full-length genomes from plasma

A. Donoso¹, M. Moreno-Lorenzo¹, S. Benito¹, P. Jiménez², Á. Zaballos², E. Delgado¹, M.M. Thomson¹

¹Instituto de Salud Carlos III, HIV Biology and Variability Unit, Majadahonda, Spain, ²Instituto de Salud Carlos III, Genomics Unit, Majadahonda, Spain

Background: HIV-1 shows high genetic diversity owing to elevated mutation and recombination rates. Due to the frequent generation of recombinant forms where multiple HIV-1 variants cocirculate, the genetic characterization of isolates requires analysis of near full-length genome (NFLG) sequences. Conventional methods for NFLG sequencing are time-consuming and labor-intensive. Therefore, the development of new methodologies

for molecular epidemiological studies is highly desirable. Here we describe a new method based on Nanopore technology.

Methods: HIV-1 NFLG genomes (8.9 kb) were amplified from plasma RNA through RT-PCR/nested PCR in two overlapping segments of 4.5 and 4.6 kb. One-tube RT-PCR was performed with Superscript III Reverse Transcriptase (Invitrogen) and Ranger mix (Bioline), and nested PCR with Ranger mix, using primers recognizing highly conserved fragments within HIV-1 group M. DNA libraries were purified with AMPure XP beads (Beckman Coulter) and were prepared following the protocol outlined by Oxford Nanopore Technologies (ONT), labelling the end-repaired DNA amplicons with the Native Barcoding Kit SQK-NBD114.24 (ONT) with subsequent loading into the R10.4.1 flow cell and sequencing with MinION Mk1B device.

Consensus sequences were obtained from the Nanopore sequencing data using a home-developed pipeline, and were phylogenetically analyzed via maximum likelihood, with analysis of recombination through bootscanning and phylogenetic trees of partial segments.

Results: Using serial dilutions of plasma-extracted RNA, we were able to amplify HIV-1 NFLGs with as few as 15 HIV-1 RNA copies per reaction. Using the described method, 22 NFLGs of subtypes A1, B, C, F1, and G, CRF02_AG, and of two new circulating recombinant forms (CRF_BC and CRF_BF1) were sequenced.

The consensus sequences obtained with the ONT method had >99% similarity to those obtained with Sanger sequencing, with sequences obtained with both methods clustering closely in phylogenetic trees.

In 4 NFLG from 2 new CRFs, analyses of recombination showed coincident mosaic structures with both sequencing methods. The turnaround time of the ONT protocol was 3 days.

Conclusions: We have developed a method for efficient HIV-1 NFLG amplification and sequencing based on Nanopore technology which allows for reliable determination of phylogenetic relationships, subtype classification, and analysis of mosaic structures. This method could be useful for HIV-1 molecular epidemiological surveillance studies.

HIV infects mesenchymal stem cells (MSC) and modulates adipocyte differentiation

R.N. Freiburger¹, C.A.M. Lopez¹, C. Cevallos¹, F.A. Sviercz¹, M.B. Palma², A.D. Guano¹, P.G. Jarmoluk¹, M.N. Garcia², J. Quarleri¹, M.V. Delpino¹

¹INBIRS/UBA-CONICET, Ciudad Autonoma de Buenos Aires, Argentina, ²INEU/FLENI-CONICET, La Plata, Argentina

Background: Mesenchymal stem cells (MSC) can differentiate into adipocytes and osteoblasts in a process that can be altered in pathological conditions, such as HIV infection. The objective was to determine if HIV could infect MSCs and modulate their differentiation into adipocytes or osteoblasts.

Methods: To determine if these cells were susceptible to HIV infection, we evaluated the expression of the CD4 receptor and the CXCR4 and CCR5 co-receptors by flow cytometry in MSC. CCR5, through its natural ligands CCL3, CCL4, and CCL5, induces the recruitment and differentiation of adipocytes. CXCL12 is the ligand of CXCR4 and increases the sensitivity of adipocytes to insulin. Therefore, we decided to study the expression of CCR5, CXCR4, and CD4 at different times during the differentiation process.

Cells were exposed to HIV (NL43 (X4) y AD8 (R5)) at an MOI of 0.5 pg (p24). The presence of the proviral genome in the MSCs was determined by Alu-PCR.

To determine if HIV could modulate the differentiation of MSCs to adipocytes, cells were infected in the presence of differentiation medium (0.5mM3-Isobutyl-1-methylxanthine; 10ug/ml insulin; 0.01 dexamethasone uM) during 10 days. Lipid droplet formation was determined by confocal microscopy by staining with Bodipy 493/503.

Results: We show that MSC expresses CD4 and low levels of CXCR4 and CCR5. Assays of infection indicated that both viral tropisms were capable of infecting MSC. After 7 days, we observed that HIV modulated the differentiation of MSCs to adipocytes, observing differences between both viral tropisms; HIV-AD8 was able to stimulate adipocyte differentiation, giving rise to larger lipid droplets, while HIV-NL43 induced the formation of smaller adipocytes with perinuclear lipid droplets. At 10 days of differentiation, both HIV tropisms gave rise to larger lipid droplets than uninfected controls.

Our results indicated that CCR5 expression remained at the same levels throughout the differentiation process, while CXCR4 expression increased from day 7 of differentiation, which could explain the differences observed between both viral tropisms.

Conclusions: Together, our results indicate that HIV is capable to infect MSCs, preserving the presence of the proviral genome, and modulating the differentiation of these cells into adipocytes, presenting differences between the viral tropisms studied.

Background: HIV-1-associated immune activation drives CD4⁺ T cell depletion and the development of acquired immunodeficiency syndrome (AIDS). Since combination antiretroviral therapy (cART) does not correct residual immune activation in patients, we aim to determine the role of nicotinamide mononucleotide (NMN), the direct precursor of nicotinamide adenine dinucleotide (NAD) co-enzyme, on modulating CD4⁺ T cell during HIV-1 infection.

Methods: We examined the intracellular HIV-1 p24 protein, viral RNA or integrated DNA, as well as T cell activation markers, in HIV-infected primary CD4⁺ T cells, PMA-stimulated resting CD4⁺ T cells derived from individuals living with HIV and HIV-infected humanized mice. RNA-seq analysis was used for identifying the gene ontology of interest.

Results: In this study, we found that NMN treatment suppressed intracellular and secretory HIV-1 p24 production in HIV-infected primary CD4⁺ T cells. NMN did not affect CD4 and CCR5 expression significantly, but suppressed HIV-1 expression at the post-transcription stage. Under the NMN treatment, CD25⁺CD4⁺ T cells rather than CD25⁻CD4⁺ T cells preferentially decreased intracellular p24 level. NMN also inhibited the expression of late T cell activation markers including CD25 and HLA-DR consistently on reactivated resting CD4⁺ T cells derived from cART-treated individuals living with HIV. At the transcriptomic level, the CD25 downregulation by the NMN treatment was associated with some downregulated gene ontology

pathways such as cell proliferation and activation. NMN treatment also reduced the proportion of proliferating p24-expressing CD4⁺ T cells which was positively correlating with activated CD25⁺ p24-expressing CD4⁺ T cells. Moreover, in HIV-infected humanized mice, we found significantly reconstituted CD4⁺ T cell frequency along with suppressive T cell hyperactivation and apoptosis after the combined NMN and cART treatment compared with cART alone.

Conclusions: Our results highlight the suppressive role of NMN in CD4⁺ T cell activation during HIV-1 infection. These findings warrant clinical investigation of NMN as a supplemental treatment in combination with cART in people living with HIV, especially those with persistent low CD4⁺ T cell count.

Background: Th17 cells are rapidly depleted during HIV infection and contribute to viral persistence, whereas their frequencies and functions are not fully restored by antiretroviral therapy (ART). However, molecular mechanisms underlying these alterations are understudied.

Methods: RNA-sequencing (Illumina Technology) was performed in freshly FACS-sorted Th17 cells (CD4⁺CD25⁺CD45RA⁺CCR6⁺) from successfully ART-Treated (ST, n=6), elite controllers (EC, n=3) and uninfected controls (HD, n=5).

Results: Th17 cells from STs vs. HDs showed alterations in the TGF-β1/smad2-3 pathway, indicative of impairments in their generation and stability. Other pathways related to Th17 differentiation were downregulated in STs vs. HDs, including p38, PTEN, RUNX1, NFAT, and Notch.

Consistently, the RORC2 repressor NR1D1 was upregulated, while Semaphorin 4D, a RORC2 inducer, decreased in STs vs. HDs. Migration markers CCR9, α4β1, CXCR5 and CCR7 decreased in STs vs. HDs, indicating diminished migration potential towards the gut and inflammatory tissues. Metabolic alterations were observed in STs vs. HDs, comprising decreased expression of mitochondria genes, energy metabolism, and PI3K-AKT-mTOR pathway.

Furthermore, in STs, sphingolipids synthesis and amino acid transport were downregulated. In STs vs. HDs, decreased expression of transcription factors RUNX1, NFAT, and CREB, along with lower CDK6 expression and in-

creased expression of EED and TP53BP1, are associated with increased HIV persistence/latency. Downregulation of HIV restriction factors (BST2, SERINC3, RNF115, and RNF125) and HIV inhibitors (FOXO1/4, Wnt/β-catenin, Notch, and tetraspanins), along with increased expression of MRE11 and TRA2B, suggest higher Th17 cell's susceptibility/permissiveness to HIV infection in STs vs. HD donors.

Similarly to the ST group, Th17 cells in ECs showed decreased expression of Semaphorin 4D and downregulated PI3K-AKT-mTOR pathway. Decreased synthesis of sphingolipids and amino acid transport and higher expression of NR1D1 were also observed in Th17 cells from EC and ST vs. HD donors.

Furthermore, compared to HD donors, Th17 cells in ECs showed a unique metabolic profile related to an increase in the TCA cycle, fatty acid β-oxidation, cellular response to hypoxia, and decreased inositol phosphate metabolism.

Conclusions: Despite successful ART, the Th17 transcriptional signature revealed impaired differentiation, stability, migration, metabolism, and higher susceptibility to HIV infection.

EPA0013

Impact of chronic HIV Infection and Smoking on dynamics of pulmonary mucosal tissue resident CD8 T-cells and regulatory CD4 T-cells during antiretroviral therapy

Y. Alexandrova^{1,2}, A. Yero¹, R. Olivenstein³, M. Orlova², E. Schurr², C.T. Costiniuk^{2,3}, M.-A. Jenabian¹

¹Université du Québec à Montréal (UQAM), Department of Biological Sciences, Montreal, Canada, ²Research Institute of the McGill University Health Centre, Montreal, Canada, ³McGill University, Department of Medicine, Montreal, Canada

Background: People living with HIV (PLWH) continue to suffer from a high burden of infectious and non-infectious pulmonary diseases despite antiretroviral therapy (ART), which suggest that their lung immunity is not fully restored. The balance between effector and regulatory T-cells is essential for the maintenance of lung mucosal tissue integrity and immune defense. As such, excessive CD8 T-cell activation during HIV infection can contribute to pulmonary mucosal tissue damage.

Furthermore, tobacco smoking changes the lung environment and induces pulmonary inflammation and tissue fibrosis. Additionally, regulatory T-cells (Tregs) control CD8 tissue-resident memory (Trm) cell homeostasis.

Herein, we first validated CD8Trm and Non-Trm markers from animal models in the human lung, then, we characterized the effects of HIV and smoking on pulmonary cytotoxic CD8 T-cells and Tregs.

Methods: Bronchoalveolar lavage (BAL) fluid and matched blood were obtained from asymptomatic ART-treated smoking (n=4) or non-smoking (n=6) PLWH and seronegative controls (smokers: n=4; non-smokers: n=8).

Lymphocytes were isolated and CD8 and Treg subsets were characterized by multiparametric flow cytometry.

Results: Human lung CD8^{Trm} cells consisted of primarily CD69⁺ subsets expressing CD103 and/or CD49a. In line with previous mice studies, CD8^{Trm} were largely CXCR6⁺CXCR3⁺, while CD8 non-^{Trm} were largely CXCR6⁺CXCR3⁺. Levels of CX3CR1 and KLRG1 were highest in CD8 Non-^{Trm}. Most airway CD8 T-cells expressed Gzma/B but very little Perforin.

Both smoking and HIV infection were associated with an increase in total CD8 T-cells in BAL. HIV and smoking were associated with increased expression of Perforin and GzmB respectively. GzmA⁺ and GzmB⁺ CD8 T-cells showed higher expression of CD103 and CXCR6 in smokers and higher frequencies of CX3CR1⁺KLRG1⁺ and Ki67⁺ cells in PLWH. Pulmonary mucosal Tregs were mainly CD69⁺. In smokers, higher frequencies of total Tregs and Helios⁺Tregs were observed.

Conclusions: Smoking and HIV could promote cytotoxic CD8 T-cell retention in small airways through different mechanisms. While smoking likely increases recruitment and retention of CD8^{Trm} via CXCR6 and CD103 respectively, HIV is associated with CD8 non-^{Trm} recruitment via CX3CR1 from the periphery, which could contribute to increased tissue damage.

Lastly, smoking could promote local Treg differentiation, favoring increased levels of effector CD8^{Trm} in smokers.

EPA0014

Accelerated biological aging is associated with intestinal barrier permeability and microbial translocation during antiretroviral therapy suppressed HIV infection

S. Singh¹, L. B. Giron¹, M. W. Shaikh², S. Shankaran³, Z. R. Bogin², S. A. Bambi², J. Koshy¹, J.L. Lima Calandrini De Azevedo¹, P. A. Engen², J. Martinson^{2,3}, M. Tsapekos⁴, L. Orgaz⁴, N. de Pedro⁴, P. González⁴, I. Vasile-Pandrea⁵, Q. Liu¹, A. Landay^{2,3}, A. Keshavarzian^{2,3}, M. Abdel-Mohsen¹

¹The Wistar Institute, Philadelphia, United States, ²Rush University, Rush Center for Integrated Microbiome and Chronobiology Research, Chicago, United States, ³Rush University, Department of Medicine, Chicago, United States, ⁴Life Length, Madrid, Spain, ⁵University of Pittsburgh, Pittsburgh, United States

Background: HIV infection has been associated with accelerated biological aging even after suppressive antiretroviral therapy (ART); however, the underlying mechanisms are unclear and likely multifactorial. In the general population, a decrease in intestinal barrier integrity has been linked to accelerated biological aging by leading to microbial translocation that causes systemic inflammation.

However, the potential links between intestinal barrier integrity and biological aging during ART-suppressed HIV infection are unknown.

Methods: Colon biopsies and blood were collected from 25 HIV+ ART-suppressed individuals and 23 age, gender, and ethnicity-matched HIV-negative controls. The PBMCs' telomere length was quantified using high-throughput quantitative fluorescence in situ hybridization (HT-Q-FISH). Colon epithelial cadherin (E-cadherin) was quantified by immunofluorescence. Plasma markers of gut damage, microbial translocation, and inflammation were measured using multiplex arrays and ELISA.

Results: Despite similar chronological age (Fig. 1a), HIV+ ART-suppressed individuals exhibited an average of 474 bp shorter telomeres, higher cell percentages with shorter telomeres, and lower cell percentages with longer telomeres ($P<0.05$; Fig. 1b). E-cadherin (a tight junction protein and a marker of intestinal barrier integrity) levels were lower in the colon of HIV+ ART-suppressed individuals than controls (Fig. 1c; $P=0.036$). Consistently, markers of gut damage (Reg3A), bacterial translocation (LBP), fungal translocation (β -glucan), and inflammation/immune dysfunction were higher in the plasma of HIV+ ART-suppressed individuals than controls ($P<0.05$; Fig. 1d-e). Correlation network analysis (Fig. 1f) showed significant associations between lower intestinal barrier integrity, higher gut damage, higher microbial translocation, higher inflammation, and the higher percentage of short telomeres (a marker of biological aging; $P<0.05$).

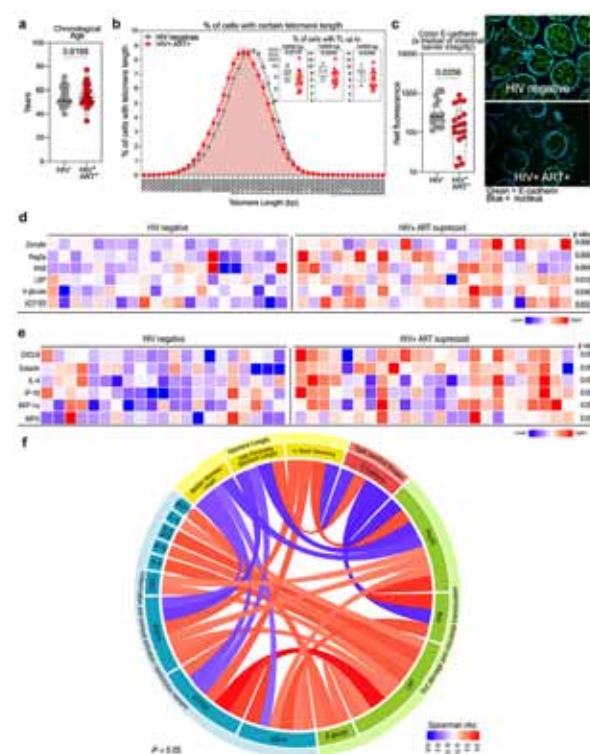

Fig. 1 a-f

Conclusions: Intestinal barrier permeability, gut damage, and microbial translocation are linked to accelerated biological aging during ART-suppressed HIV infection. Further studies are warranted to investigate the mechanistic links between intestinal barrier integrity and biological aging and the utility of using approaches to fortify the intestinal barrier to prevent aging-associated diseases during ART-suppressed HIV infection.

EPA0015

Simultaneous transcriptome and miRNome profiling of CD4+ T cells from elite controllers identify that miR-99b and miR-125a are implicated in viral replication in vitro

R. Ayala-Suárez¹, F. Díez-Fuertes¹, E. De la Torre-Tarazona², M. Bermejo¹, E. Calonge¹, L. Leal³, M.E. Bargalló³, M.J. Maleno³, F. García³, M. Planá³, J. Alcamí¹, ECRIS integrated in the Spanish AIDS Research Network
¹Instituto de Salud Carlos III, AIDS Immunopathology Unit, Madrid, Spain, ²Hospital Ramón y Cajal, Madrid, Spain, ³Hospital Clínic - IDIBAPS, Sida e Infección por VIH, Barcelona, Spain

Background: Elite controllers (EC) maintain viral loads below 50 cp/ml for long periods without antiretroviral therapy (ART) and represent a natural model for a functional HIV cure. Previous works describe miRNA expression profiles associated to EC.

Our objectives are to describe the miRNome and transcriptome of CD4+ T cells from ECs, to study its role in the regulation of gene expression and to assess miRNA antiviral activity in functional assays.

Methods: We performed miRNA-Seq and RNA-Seq in CD4+ T cells from EC (n=10, 60% males), non-treated (NT) people living with HIV (PLWH) (n=8, 87.5% males) and PLWH receiving ART (n=9, 77.8% males) recruited in the Spanish EC-RIS cohort. The reads were aligned to miRbase-v22 and human transcriptome (GRCh38). The pairs of differentially expressed miRNA-targets were represented using Tarbase-8.0, miRTarBase-v8 and Cytoscape, and they were functionally annotated with KOBAS. To assess miRNA downregulation effect in HIV-1 infection cycle, miRNA miR-CURY inhibitors (Qiagen) were transfected into CEM-NKR. CCR5 cells and later infected with the replication competent NL4-3 Ren HIV-1 clone.

Results: Two miRNAs were downregulated (FDR<0.05) in EC compared to PLWH receiving ART, miR-99b-5p (log2FoldChange(LFC)=-1.00) and miR-125a-5p (LFC=-0.76). In contrast, comparing NT and EC groups, ECs presents upregulation of miR-27a-5p (LFC=1.11) and downregulation of six miRNAs, including miR-99b-5p (LFC=-1.36) and miR-125a-5p (LFC=-0.97) among them.

Accordingly, we found upregulation in EC of miR-99b-5p targets (TIMP2, MAFB, MMP9, DUSP1, or CCL3), miR-125a-5p targets (LAMP1, CDKN1A, NBEAL2, BBC3, CSRN1P, SOD2) and targets from both miRNAs (THS1, DPM2, RSP2, FLNA).

Treatment with miRNA inhibitors in CEM cells reduced viral replication by 17.6% (p<0.05) when miR-99b-5p was downregulated whereas miR-125a-5p downregulation resulted in a 16.3% reduction in viral replication (p<0.01). The combined suppression of miR-99b-5p and miR-125a-5p decreased viral replication by 21.4% (p<0.001).

Conclusions: Both miR-99b-5p and miR-125a-5p were downregulated in EC compared to NT or ART. Accordingly, gene targets of these miRNAs were upregulated and participate in p53 signaling route and TNF pathway. The downregulation of these miRNAs in CEM.NKR.CCR5 cells

reduced the viral production of HIV pointing to a protective role of these miRNA in HIV infection in EC, which can be used to identify new therapeutic targets.

EPA0016

Elevated plasma galectin-9 among vertically infected youth with HIV on ART is associated with inflammation and cognitive performance

P. Moar¹, K. Linn², T.A. Premeaux¹, U. Kaur³, B.P. Gopalan⁴, E.E. Shwe⁵, T. San⁵, C.S. Hlaing², E.H. Kyu², C. Thair², Y.Y. Mar², N. Nway², J. Mannarino⁶, J. Bolzenius⁶, S. Mar⁷, A.M.M. Aye², R. Tandon⁸, R. Paul⁶, L.C. Ndhlovu¹

¹Weill Cornell Medicine, Department of Infectious Disease, New York, United States, ²Yangon Children's Hospital, Institute of Medicine 1, Department of Pediatrics, Yangon, Myanmar, ³University of Nebraska, Department of Food Science and Technology, Lincoln, United States, ⁴St. John's Research Institute, Division of Infectious Disease, Bengaluru, India, ⁵Yangon Children's Hospital, Institute of Medicine 1, Department of Pathology, Yangon, Myanmar, ⁶University of Missouri, Missouri Institute of Mental Health, St. Louis, United States, ⁷Washington University School of Medicine, Department of Neurology, St. Louis, United States, ⁸Jawaharlal Nehru University, School of Biotechnology, New Delhi, India

Background: Perinatally infected adolescents with HIV are distinct from adults living with HIV in terms of rapid disease progression, increased viral burden and depletion of CD4 T cells. We previously showed that the levels of plasma and CSF Galectin-9 (Gal-9), a lectin immunomodulator, are elevated during adult HIV infection and this was compounded by age and HIV viremia.

Here we investigated the influence of Gal-9 in HIV disease indices among adolescents with perinatal HIV infection and sought to determine links to cognitive performance.

Methods: Blood was obtained from two independent cohorts of perinatally infected adolescents in the southern region in Asia.

Cohort I included adolescents with HIV (AWH) on suppressive ART (n=15), ART-naïve (n=15), and adolescents without HIV (AWOH; n=10) from India with median age of 10yrs. Cohort II from Myanmar included AWH on ART (n=54) and AWOH (n=22) with median age of 12yrs.

Cohort II also completed standardized cognitive tests adapted for cultural relevance. We measured plasma Gal-9 by immunoassay, inflammatory mediators by Luminex and T-cell activation based on HLA-DR and CD38 co-expression by flow cytometry. Data were analysed using Mann-Whitney t-tests and Spearman correlations.

Results: Gal-9 levels were found to be elevated in ART-treated AWH on ART when compared to AWOH in both cohorts (all p<0.05).

Higher Gal-9 levels correlated with increased levels of sCD14, IP-10, TNFα, MCP-1, IL-10 and measures of CD8 T cell activation (HLA-DR⁺CD38⁺). In Cohort 2 it was notable that in AWH higher Gal-9 levels correlated with higher

TNFA and MCP-1 (all $p < 0.05$) and with lower cognitive performance on visual learning and memory test ($r = -0.31; p < 0.05$). [Fig.1]

Conclusions: Similar to adults, Gal-9 remains elevated among vertically infected youth with HIV receiving ART and correlated with persistent inflammation. The association with cognition suggests that Gal-9 may serve as a marker of neuroinflammation and brain injury in AWH.

EPA0017

Plasma derived extracellular vesicles modulate monocyte function in adults with HIV-related cognitive impairment

S. Yeung¹, E. Marques de Menezes^{2,3,4}, C. Friday¹, J. Liu¹, S. Bowler¹, M. Abdel-Mohsen⁵, C. Shikuma⁶, P. Norris^{3,4,2}, L. Ndhlovu¹

¹Weill Cornell Medicine, New York, United States, ²Vitalant Research Institute, San Francisco, United States, ³University of California, San Francisco, Department of Laboratory Medicine, San Francisco, United States, ⁴University of California, San Francisco, Department of Medicine, San Francisco, United States, ⁵The Wistar Institute, Philadelphia, United States, ⁶University of Hawaii, Hawaii Center for AIDS, Honolulu, United States

Background: HIV-associated neurocognitive dysfunction persists despite suppressive antiretroviral therapy (ART). Extracellular vesicles (EVs) are emerging modulators of immunological responses and we have published that observations that EVs expressing monocyte activation and neuronal markers are related to the degree of cognitive impairment (CI) in people with HIV (PWH) on ART. Whether these EV changes observed in people with HIV (PWH) influence innate cellular function among those with CI remains unclear.

Methods: EVs were purified from blood derived from 58 PWH on suppressive ART with either cognitive impairment (CI, n=48) or normal cognition (NC, n=10) and 8 participants without HIV (PWOH) were isolated using differential centrifugation.

EVs were co-cultured with PBMCs from a single uninfected donor for 18 hours. Monocyte (mono) function was assessed for 8 cytokine responses and 13 surface chemo-

kines and myeloid differentiation markers by spectral flow cytometry. Furthermore, Mono migration capacity was assessed from 12 hour co-cultures prior to exposure to MCP-1 for 3 hours to allow chemotaxis in a subgroup of donors. Non-parametric statistical T tests were used.

Results: We found differential effects of EVs on multiple mono cytokine responses and cell surface receptors irrespective of HIV status. Levels of mono IL-18 were significantly lower after incubation with EVs derived from PWH compared to PWOH. B

ased on cognitive status, EVs from HIV-CI group significantly lower % of IL-18 mono responses and lower IFN- α and higher IL-10 responses on a per cell basis when compared to the NC group. No differences in Mono migration were observed across the groups.

Conclusions: These results suggest EVs can modulate mono function irrespective of HIV status. PWH with CI exhibited altered EV driven mono cytokine responses. Our data support interventions that target EVs to reverse or restore mono perturbations and limit neuropathology in PWH on ART.

EPA0018

HIV-induced mitochondrial ROS and cell death in hepatic stellate cells contribute to a profibrotic profileHIV-induced mitochondrial ROS and cell death in hepatic stellate cells contribute to a profibrotic profile

C. Cevallos¹, P. Jarmoluk¹, F. Sviercz¹, A. Lopez¹, N. Freiburger¹, A. Guano¹, V. Delpino¹, J. Quarleri¹

¹Institute for Biomedical Research on Retroviruses and AIDS (INBIRS, School of Medicine, University of Buenos Aires), Buenos Aires, Capital Federal, Argentina

Background: Hepatic stellate cells (HSC) are susceptible to HIV infection. Whether HIV is able to activate HSCs by damage-related stimuli to secrete excessive extracellular matrix, leading to collagen deposition, is undefined. Since the level of reactive oxygen species (ROS) increases sharply in activated HSCs and HIV exposure may trigger ROS early after viral exposure, our goal is to define the HIV role in propitiating a profibrotic profile by inducing ROS imbalance and cell death among HSC.

Methods: Both cell-free X4-tropic HIV (pNL43-GFP 100ng/ μ L p24 antigen) and HIV-infected T lymphocytes (HIV-GFP+ Jurkat cells labeled with violet proliferation dye, 5:1 ratio) were used to examine the LX-2's permissiveness to HIV replication.

Additionally, LX-2 were subjected to conditioned media (supernatant from HIV-infected T lymphocytes). Viral replication and HIV infection effectiveness were measured 3 days after exposure (dpe) using HIV-p24 antigen by ELISA in supernatants and GFP+ cells by flow cytometry, respectively. In LX-2, cell-death (PCD, Annexin-V/7AAD) and mitochondrial ROS (MitoSox™) levels were measured using flow cytometry, using staurosporine (1 μ M) and rotenone (10 μ M) as positive controls, respectively.

Collagen deposition in the extracellular matrix was determined by Sirius Red staining and spectrophotometric (O.D. 550nm) quantification. All experiments were carried out in triplicate.

Results: At 3 dpe, neither the cell-free virus nor the cell-to-cell contact challenge produced HIV progeny. Cell-to-cell contact with HIV-infected T-lymphocytes significantly enhanced necrosis (7AAD+ only) in LX-2 compared to control (1.4% vs. 2.0%; p 0.01).

However, no significant differences were observed early (Annexin-V+ only) and late apoptosis (Annexin-V+/7AAD+) (3.6% vs 3.2% and 2.4% vs 3.8% $p > 0.05$) respectively. This was also accompanied by a very early (2 hpe) increase in mitochondrial ROS generation (1.3% vs. 2.3%, p 0.01).

Additionally, the extracellular matrix of these cells revealed a 1.6x change in collagen deposition ($p = 0.01$). When LX-2 were exposed to conditioned media, these anomalies were not observed.

Conclusions: Although HSCs are susceptible but not permissive to HIV-X4 tropic infection, their cell-to-cell contact with HIV-infected T lymphocytes results in oxidative stress and enhanced cell death that favors an exacerbated deposition of extracellular matrix, ultimately resulting in a profibrotic profile.

EPA0019

Both HIV-1 expression and germinal center B cells reduce CXCR5 expression on T follicular helper cells

M.T. Ollerton¹, J.M. Folkvord¹, D. Parry², E. Connick¹

¹University of Arizona, Medicine, Division of Infectious Diseases, Tucson, United States, ²University of Arizona, Otolaryngology, Tucson, United States

Background: CD4+ T follicular helper cells (TFH) are important sources of HIV RNA (vRNA) in secondary lymphoid tissues during chronic untreated HIV-1. TFH express the follicular homing receptor, CXCR5, and its ligand CXCL13. The impact of HIV expression and/or germinal center B cells (GCB) on CXCR5 expression, and the distribution of vRNA+BCL6+PD-1+TFH in lymph nodes of PLWH are not well characterized.

We hypothesized that HIV expression and GCB reduce CXCR5 expression on TFH, and that some vRNA+TFH are located in extrafollicular sites in vivo.

Methods: TFH (7-AAD-CD3+CD8-CXCR5hiPD-1hi) and GCB (7-AAD-CD19+IgD-CD38+) were sorted from tonsils of individuals at low risk of HIV acquisition, spinoculated with X4-GFP reporter virus and cultured 3 days alone or with GCB ($n=11$). CXCL13 neutralizing antibody was added in a subset of experiments ($n=10$). CXCR5 median fluorescence intensity was measured.

Supernatant CXCL13 was quantified in a subset of experiments ($n=6$). ISH for vRNA and BCL6, and immunofluorescent antibody staining for PD1 and CD20 were performed on 10 μ m sections of inguinal lymph nodes (LN) from 6 antiretroviral-naïve PLWH. Slides were imaged, follicles

were defined as CD20+ regions, and the distribution of vRNA+ cells and vRNA+ TFH (BCL6+PD-1+) quantified. Statistical significance was determined using nonparametric Wilcoxon tests.

Results: In in vitro experiments, GFP+TFH expressed less CXCR5 than GFP-TFH when cultured alone ($p=0.002$) or with GCB ($p=0.002$). CXCR5 was further reduced on GFP+ cells in the presence of GCB ($p=0.04$). CXCL13 was elevated in cultures of TFH with GCB compared to TFH alone ($p=0.03$).

Addition of CXCL13 neutralizing antibody increased CXCR5 expression on GFP+TFH cultured alone ($p=0.002$) or with GCB ($p=0.002$), and ablated differences in CXCR5 expression associated with GCB ($p=0.23$). In LN, 221 (range, 9-134) vRNA+ PD-1+BCL6+TFH were detected and constituted 32% (range, 15-40%) of vRNA+ cells. Eight percent (range 0-23%) of PD-1+BCL6+TFH were located outside follicles and represented 7% (range 0-28%) of extrafollicular vRNA+ cells.

Conclusions: HIV expression and GCB reduced CXCR5 expression on TFH, the latter likely through a CXCL13 related mechanism. CXCR5 downregulation on TFH in follicles may facilitate immigration of TFH to extrafollicular regions and dissemination of these cells within secondary lymphoid tissues.

Maria Nuova-IRCCS, Reggio Emilia, Italy, ⁵Department of Infectious Diseases, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy, ⁶Division of Infectious and Tropical Diseases, ASST Spedali Civili Hospital, University of Brescia, Brescia, Italy

Background: Ineffective viral control in Heavily Treatment-Experienced (HTE) fuels inflammation which may be increased in HTE with vertical transmission (VT), given that viral acquisition at birth may alter immune homeostasis. We investigated inflammation in HTE with and without VT, according to viral load (VL) status.

Methods: Matched cohort study including individuals of the Prestigio Registry with resistance to NRTIs, NNRTIs, PIs and INSTIs, with or without VT, VL <50 copies/mL or VL >200 copies/mL. GM-CSF, IFN- α , IFN- γ , IL-2, IL-4, IL-5, IL-6, IL-9, IL-10, IL-12p70, IL-17A, TNF- α (Cytometric Bead Array) and sCD14 (ELISA) were determined.

Propensity score was used to match VT and no-VT for sex, HIV duration, CD4 nadir and VL at plasma sampling. Mann-Whitney test and Spearman's correlation were calculated.

Results: We evaluated 16 VT and 16 no-VT (Table); in each group, 8/16 had VL<50 copies/mL and 8/16 VL>200 copies/mL. VT were younger than no-VT ($p<0.0001$). VT and no-VT showed comparable cytokines, with the exception of lower IL-6 in VT (median=0.526 pg/mL, IQR=0-2.85) vs 2.198 pg/mL, IQR=0.94-6.17; $p=0.04$; 1A) and a trend to lower IL-10 ($p=0.08$). IL-6 did not differ between VT and no-VT, within viremia strata (1B-C), while a tendency to lower IL-10 was retained in viremic VT ($p=0.06$; Figure1, D). IL-6 correlated with age ($r=0.362$, $p=0.04$; 1E); no other correlations between cytokines and demographic/viro-immunologic parameters were found.

	VT (N=16)	no-VT (N=16)	p-value
Age at sampling, (years), median (IQR)	31 (27-33)	56 (54-59)	<0.0001
Sex female, [n (%)]	10 (62.5)	10 (62.5)	1.000
Time since HIV diagnosis, (years), median (IQR)	31 (27-33)	30 (25-32)	0.724
CD4+ nadir, (cells/mm ³), median (IQR)	90 (16-186)	127 (21-200)	0.745
CD4+ at sampling, (cells/mm ³), median (IQR)	394 (179-1011)	547 (149-770)	0.545
CD8+ at sampling, (cells/mm ³), median (IQR)	806 (571-1117)	672 (510-949)	0.406
HIV-RNA at sampling, [n (%)]			
<50 copies/mL	8 (50%)	8 (50%)	1.000
>200 copies/mL	8 (50%)	8 (50%)	

Table 1.

Figure 1.

Conclusions: HTE with VT feature comparable inflammation to that of HTE without VT, regardless of VL. The correlation between IL-6 and age suggests that age, rather than mode of transmission and viremia, drives inflammation in treated HIV.

EPA0021

Urethral microbiome of South African cis-gender men and transwomen with and without bacterial sexually transmitted infections

B.S. Maust^{1,2}, C. Feng¹, C.L. Rametse³, M. Mndini³, B. Alinde³, Y. Ganief³, E. Muller⁴, V. Maseko⁴, R. Lorenzo Redondo⁵, T. Amaral Russo⁵, C.M. Gray^{6,3}, T.J. Hope⁵, H.B. Jaspan^{1,2,3}

¹Seattle Children's, Center for Global Infectious Disease Research, Seattle, United States, ²University of Washington, Pediatrics, Seattle, United States, ³University of Cape Town, Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, ⁴National Institute for Communicable Diseases, Centre for HIV and STIs, Johannesburg, South Africa, ⁵Northwestern University, Medicine (Infectious Diseases), Chicago, United States, ⁶Stellenbosch University, Immunology, Stellenbosch, South Africa

Background: Anaerobic bacterial dysbiosis of the foreskin and urethral sexually transmitted infections (STIs) are independently associated with mucosal inflammation and increased risk of HIV acquisition.

Methods: Participants aged 18 to 45 in Cape Town, South Africa provided penile swabs prior to surgical penile circumcision. The V3-V4 segment of the bacterial 16S rRNA gene was sequenced using DNA extracted from urethral swabs to characterize bacterial communities in participants with and without a concomitant sexually transmitted infection (STI), diagnosed by a custom multiplex PCR assay. Absolute 16S copies were assayed from each swab by BactQuant qPCR.

Results: The median age of participants was 25 years old, and 79% reported being sexually active with a median of 3 lifetime sexual partners. STIs were diagnosed in 18 of the 85 participants with sequencing data, *Chlamydia trachomatis* (CT) in 16 participants.

Analyses of the within-participant and between-participant bacterial community diversities showed no differences by STI diagnosis.

Absolute 16S copy number also showed no difference between participants with or without an STI diagnosis. Differential abundance testing confirmed the increased relative abundance of CT in specimens from participants with positive PCR testing (10.5-fold higher, FDR-adjusted p-value 3.6×10^{-10}), and also showed an increase in *Acinetobacter* (8.6-fold higher, FDR-adjusted p-value 6.4×10^{-3}).

Conclusions: We found that detection of a bacterial STI was associated with minimal differences in the quantity, diversity, or composition of the penile urethral bacterial community. This suggests that CT cohabitates with the existing microbial community of the penile urethra rather than requiring or causing a disruption to establish an environmental niche.

Furthermore, we did not detect changes in microbial abundances to suggest that the increased inflammation and risk of HIV acquisition reported with CT infection

are mediated by associated changes in the urethral microbiome, implying they may result intrinsically from CT infection. Sequencing of larger numbers of STI positive samples is ongoing to confirm these findings.

EPA0022

Microbial dysbiosis is associated with peripheral inflammation in vertically infected youth with HIV on stable anti-retroviral therapy

S. Bowler¹, K. Linn², E. Shwe², T. Premeaux¹, J. Bolzenius³, N. Thong⁴, P. Moar¹, J. Mannarino³, A. Pang¹, S. Mar⁵, A.M. Aye², R. Paul³, L. Nhdlovu¹

¹Weill Cornell Medicine, Department of Medicine, New York, United States, ²Yangon Children's Hospital, Department of Pathology, Yangon, Myanmar, ³University of Missouri-Saint Louis, Saint Louis, United States, ⁴United States Army Pacific, Honolulu, United States, ⁵Washington University, Pediatric Neurology, Saint Louis, United States

Background: Vertically HIV-infected children experience rapid disease progression and increased HIV replication compared to adults. Differences in microbial populations found within the gastrointestinal tract (gut) affects host immune regulation and significant shifts in these communities are observed during HIV infection and may influence health outcomes despite anti-retroviral therapy (ART).

We examined gut microbial communities within a cohort of youth with or without HIV in a socio-economically controlled setting in Myanmar and examined for relationships with markers of immune dysregulation.

Methods: A cross-sectional study design with perinatally HIV-infected adolescents on ART (AWH, n=9, median age 13 years) and without HIV (AWOH, n=6, median age 16 years) recruited from two orphanages in Yangon, Myanmar had plasma and stool collected.

Stool DNA underwent 16S ribosomal-RNA sequencing and bacterial relative abundance was quantified using Qiime2. 13 plasma biomarkers associated with inflammation (TNF- α , TNF receptor I, IL-6, galectin-9, CRP), myeloid activation/migration (sCD14, sCD163, neopterin, MCP-1), and endothelial activation (E-Selectin, P-Selectin) were measured by immunoassay. Analyses were assessed using Spearman correlation.

Results: In stool we identified an increase of *Veillonellas-Selenomonadales* and a trend towards a decrease in *Lachnospirales* abundances in AWH compared to AWOH ($p<0.001$ and 0.09).

High relative abundance of *Veillonellas-Selenomonadales* correlated with elevated IL-6, TNF α , and sCD14 (all $r>0.73$, $p<0.05$) levels in AWH but not in AWOH.

Furthermore, higher IL-6 levels correlated with low relative abundance of *Lachnospirales* ($r=-0.77$, $p=0.016$) and *Veillonellas-Selenomonadales* ($r=-0.67$, $p=0.050$) only in the AWH group.

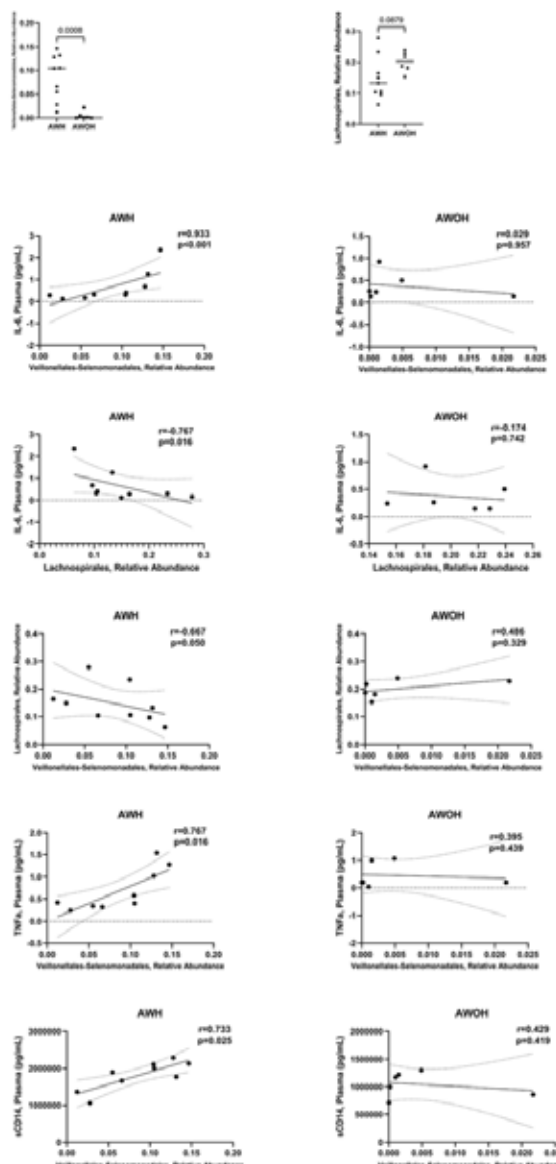

Figure.

Conclusions: From this pilot study, we report an expanded gut microbial population linked to persistent inflammation among youth with perinatal HIV, despite stable ART, in a controlled environment, potentially informing new mechanisms to direct interventions in AWH. Further investigation into these pathogens is warranted.

Massive HIV infection abrogates osteoclastogenesis by influencing CCR5 and CD9 expression

F.A. Sviercz¹, P. Jarmoluk¹, C. Cevallos¹, A. Adamczyk¹, N. Freiburger¹, A. López¹, A. Guano¹, M. Ostrowski¹, M.V. Delpino¹, J. Quarleri¹

¹Institute of Biomedical Research on Retroviruses and Aids, University of Buenos Aires, Argentinean National Research Council, CABA, Argentina

Background: Mature bone-resorbing osteoclasts (OC) and their precursors (macrophages) are structurally and functionally affected by HIV-influencing bone loss. The membrane CCR5 and tetraspanins play an essential role in bone-destructive conditions through the functional regulation of osteoclasts that could be altered directly by R5-tropic HIV infection.

Methods: Macrophages (OC precursors) were obtained in cell culture from human monocytes isolated from buffy coats and differentiated with M-CSF (30 ng/mL) for 6 days. Then, by adding RANKL (50 ng/mL) for 9 days mature OC were obtained. At 3 days of MDM differentiation, HIV infections (R5-tropic AD8, and BaL strains; pseudo-typed pNLAD8-VSV-G strain) were performed using two inoculums (high:1pg/cell vs. low:0.01pg/cell). HIV Infection efficiency and replication were assessed at 3, 6, 9, and 12 dpi by measuring intracellular p24-expressing cells (flow cytometry), and soluble p24 in cell supernatants (ELISA). Multinucleated tartrate-resistant acid phosphatase-positive cells with ≥3 nuclei were considered mature osteoclasts. Using flow cytometry in cells detached, cell-death (annexin-V/7-AAD) and CCR5/CD9 expression were measured. Bone resorption activity was measured by light microscopy on bovine cortical bone slices.

Results: An HIV replication peak was found earlier with the high inoculum (42-fold change from 3 to 6 dpi), whereas this peak (30-fold change) occurred between 6 and 9 dpi with the low inoculum. At 12 dpi, both inoculums depicted similar infection efficiency (p24-expressing cells: 57.7±12.8% vs. 46.0±10.6%) and cell-death level (11.9±4.7 vs. 8.6±3.3). High but not low HIV-inoculum abrogates markedly OC number (x200; control:37.2±12.4; HIV-low:32.3±13.3; HIV-high: 10.8±3.4). Besides, two CCR5-ligands (TAK-779, and recombinant-AD8-gp120), and HIV-VSV-G infections (R5-independent cell entry) significantly impaired osteoclastogenesis, as well. OC precursors and early OC challenged with high (but not low) HIV inoculum triggered a significant increase in membrane CCR5 (1056.0±97.6MFI) and CD9 expression (4196.0±277.2MFI). The number of osteoclasts formed on bone slices correlated directly with bone resorption (by examinations of the resorbed area). When HIV replication was inhibited using nevirapine (1 mM), osteoclastogenesis was recovered.

Conclusions: Osteoclasts differentiation is impaired by R5-tropic HIV strains when a massive replication and CCR5 blocking occurs in their precursors, altering both CCR5 and tetraspanin expression and its resorptive functions.

EPA0024

Impact of the synthetic opioid fentanyl on HIV replication in vitro

J. Madhuravasal Krishnan¹, R. Karns², K. M. Roskin^{3,4}, M. Medvedovic⁵, K. E. Sherman^{1,6}, J. Blackard^{1,6}

¹University of Cincinnati College of Medicine, Internal Medicine, Cincinnati, United States, ²Cincinnati Children's Hospital, Digestive Health Center, Cincinnati, United States, ³Cincinnati Children's Hospital Medical Center, Cincinnati, United States, ⁴University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States, ⁵University of Cincinnati College of Medicine, Department of Environmental & Public Health Sciences, Cincinnati, United States, ⁶University of Cincinnati College of Medicine, Center for Addiction Research, Cincinnati, United States

Background: The illicit use of synthetic opioids such as fentanyl has led to a serious public health crisis in the US. People with opioid use disorder are more likely to contract infections such as HIV and viral hepatitis and experience more severe disease. While several drugs of abuse are known to enhance viral replication and to suppress immunologic responses, the effects of synthetic opioids on HIV pathogenesis have not been investigated thoroughly. Thus, we examined the impact of fentanyl on HIV-susceptible and HIV-infected cell types and chemokine receptor expression *in vitro*.

Methods: HIV susceptible cell lines (TZM-bl and U937) and HIV-infected lymphocyte cells (ACH-2, H9, and J-Lat GFP) were exposed to varying concentrations of fentanyl. Expression levels of the CXCR4 and CCR5 chemokine receptors were measured in cell lysates. HIV p24 antigen was quantified in culture supernatants by ELISA, and HIV proviral DNA was quantified in cells using SYBR real-time PCR targeting the *pol* gene. RNAseq was performed to characterize cellular gene regulation in the presence of fentanyl.

Results: Fentanyl enhanced significant expression of CXCR4 protein levels in ACH-2 and H9 cells and CCR5 in TZM and all HIV-infected lymphocyte cell lines in a dose-dependent manner. Fentanyl led to a non-significant decrease in CXCR4 and CCR5 protein levels in U937 cells. Fentanyl induced HIV p24 expression and proviral DNA levels in HIV-exposed TZM-bl cells, U937 cells, and several HIV-infected lymphocyte cell lines. Multiple genes associated with apoptosis, antiviral / interferon response, chemokine signaling, and NFκB signaling were differentially regulated by fentanyl.

Conclusions: These data demonstrate that the synthetic opioid fentanyl increases HIV replication and chemokine co-receptor expression in HIV-susceptible and HIV-infected lymphocyte cell lines, as well as different regulate genes relevant to HIV infection and disease progression. Increased virus levels also suggest that opioid use in vivo may increase the likelihood of transmission to others and accelerate disease progression.

EPA0025

Role of transcriptionally-active „defective“ HIV-1 proviruses in immunological non-responders: a case-control study

F. Scrimieri¹, E. Bastian², M. Smith², C. Rehm², C. Morse³, J. Kuruppu³, M. McLaughlin³, J. Kovacs³, H.C. Lane², H. Imamichi²

¹Frederick National Laboratory for Cancer Research, Frederick, United States, ²National Institutes of Health, National Institute of Allergy and Infectious Diseases, Bethesda, United States, ³National Institutes of Health, Critical Care Medicine Department, Bethesda, United States

Background: Despite being placed on suppressive antiretroviral therapy (ART), HIV-positive immunological non-responders (INRs) fail to recover their CD4⁺ T-cell count and have increased T-cell activation and inflammation compared to immunological responders (IRs). The involvement of “defective” HIV-1 proviruses in immune activation has recently been suggested.

In the present study, we investigated the potential contribution of transcriptionally-competent “defective” HIV-1 proviruses to poor immune recovery observed in INRs.

Methods: 26 INRs (CD4 <250 cells/ μ L, pVL<50 for on average 2.7 yrs) and 25 IRs (CD4 \geq 250 cells/ μ L, pVL<50 for on average 3.9 yrs) on ART were studied. Age, sex, ART regimen and years of ART were matched between the two groups. Activation phenotypes of T-cells were analyzed by 8-color flow cytometry. Levels of HIV-DNA and cell-associated (CA) HIV-RNA were determined by a quantitative PCR/RT-PCR for the Psi-LTR region. Sequences of HIV-DNA (n=677) and CA HIV-RNA (n=209) were assessed by 5'LTR-to-3'LTR single-genome amplification and direct sequencing. Differences in HIV-1 quasispecies profiles of INRs and IRs were assessed by proportion of near full-length intact HIV-1 and number of viral protein-coding regions.

Results: INRs had higher %CD4⁺HLA-DR(+) (23.0 vs. 12.5, p<0.01) and %CD8⁺HLA-DR(+) (41.5 vs. 32.0, p=0.04). Levels of HIV-DNA were similar between INRs and IRs (median 1827 vs. 1575 copies/million CD4⁺, p=0.84). In contrast, levels of CA HIV-RNA were higher in the INR-group (median 1593 vs. 580 copies/million CD4⁺, p=0.03). Proportions of near full-length intact HIV-1 proviruses in INRs and IRs were 5.1% and 5.9%, respectively. No full-length HIV-RNA transcripts were detected in either group, suggesting that ongoing HIV replication is an unlikely explanation for the poor CD4⁺ recovery. All HIV-RNA transcripts were in novel unspliced forms and frequently encoded for Gag and Nef. These transcripts were expressed in similar proportions in INRs and IRs (50% vs. 32% for Gag; 27% vs. 24% for Nef).

Conclusions: Levels of sub-genomic HIV-RNA transcripts were higher in the INRs than the IRs, suggesting a possible role for biologically-active “defective” proviruses in the INRs. Further work in studying whether or not these levels are correlated with the observed increases in CD4⁺ and CD8⁺ T-cell activation is warranted.

Frequencies of CD4⁺ and CD8⁺ T cells immune activation are reduced in PLWH after 5 years of antiretroviral therapy

L. Maddaloni¹, L. Santinelli¹, G. Bugani¹, A. Lazzaro¹, C.M. Lofaro¹, S. Caiazzo¹, L. Sorrentino², A. D'Auria², C. Scagnolari², G. Ceccarelli¹, C.M. Mastroianni¹, G. d'Ettore¹

¹Sapienza University of Rome, Public Health and Infectious Diseases, Rome, Italy, ²Sapienza University of Rome, Virology Laboratory, Department of Molecular Medicine, Rome, Italy

Background: Chronic immune activation represents one of the main determinants of a senescent immune phenotype in people living with HIV-1 (PLWH). To address the effectiveness of antiretroviral therapy (ART) in reducing chronic CD4⁺ and CD8⁺ T cells immune activation, an observational study comparing peripheral blood immune activation status between ART-naïve, less than 5 years and more than 5 years ART-treated PLWH was conducted.

Methods: Peripheral blood mononuclear cells (PBMC) were collected from ART-naïve (n=14), less than 5 years (n=13) and more than 5 years (n=26) ART-treated PLWH recruited at the Department of Public Health and Infectious Diseases of “Sapienza” University of Rome (Italy) and Immunophenotype and activation levels were evaluated by multiparameter flow cytometry on CD4⁺ and CD8⁺ T cell subsets [naïve, central memory (TCM) and effector memory (TEM)] by the following anti-human monoclonal antibodies: CD3-PerCP, CD4-APC-Vio770, CD8-FITC, CD45RO-PE-Vio770, CD27-VioBlue, CD38-APC, and HLA-DR-PE. Statistical analyses were performed using Prism and p<0.05 were statistically significant.

Results: Frequencies of CD4⁺ naïve and CD8⁺ naïve T cells expressing CD38, HLA-DR or both markers were similar between the three groups. PLWH treated for more than 5 years exhibited lower frequencies of CD38⁺ (p = 0.0074 and 0.0021) and CD38⁺ HLA-DR⁺ CD4⁺ TCM and TEM cells (p = 0.0152 and p = 0.0002, respectively), CD38⁺ CD8⁺ TCM cells (p = 0.0358), CD38⁺ HLA-DR⁺ CD8⁺ TCM and TEM cells (p = 0.0068 and p = 0.0026, respectively) as compared to ART-naïve PLWH.

Moreover, PLWH ART-treated for less than 5 years had increased levels of CD38⁺ (p = 0.0058) and CD38⁺ HLA-DR⁺ CD4⁺ TEM cells (p = 0.0018) compared to PLWH treated for more than 5 years.

By contrast, no differences in the percentages of the other T cell subsets (HLA-DR⁺ CD4⁺ TCM and TEM cells, CD38⁺ HLA-DR⁺ and HLA-DR⁺ CD8⁺ TCM cells, HLA-DR⁺ CD8⁺ TEM cells) were recorded among the three groups.

Conclusions: These findings suggest the efficacy of ART in reducing the immune activation levels of distinct CD4⁺ and CD8⁺ T cell subsets in PLWH after 5 years of ART.

States

Background: Innate immunity predictors of HIV risk are modulated by levels of progesterone (P4) and β -estradiol (E2) and by pregnancy and lactation status. The epigenetic mechanisms, including post-transcriptional regulation by small non-coding (micro) RNAs, underlying these associations are unknown.

Methods: We utilized longitudinal serum specimens collected in 3-month intervals from 162 women who became pregnant during follow-up in a large prospective study of hormonal contraception and HIV acquisition in Uganda and Zimbabwe.

We used the EdgeSeq platform coupled with Illumina sequencing to obtain the global miRNA transcriptome before, during and after pregnancy. miRNAs levels were voom-transformed and normalized in the linear regression modelling R package limma to log2 counts per million.

We used paired analysis in limma to identify differentially expressed miRNAs that distinguished pregnancy from pre-conception or breastfeeding following pregnancy, with batch and country as covariates.

We tested association of hormonally regulated miRNAs with Box-Cox-transformed levels of P4, E2, and sex-hormone binding globulin (SHBG) in limma with country, batch, pregnancy/breastfeeding, and age as covariates. P-values were corrected using the Benjamini-Hochberg false discovery rate (FDR) and significant at $p < 0.05$.

We used DIANA TarBase v8 to identify experimentally validated gene targets of pregnancy/hormone regulated miRNAs and overlapped those with the HIV interactome genes. We tested these overlapped genes for enrichment in Gene Ontology (GO) biological process (BP) and in BioCarta pathways using clusterProfiler.

Results: 793 miRNAs were differentially expressed with $FDR < 0.1$ at the transition from pre-conception to pregnancy and 31 - from pregnancy to breastfeeding. We identified 223 HIV interactome genes under reproductive cycle epigenetic control, including targets of miRNAs differentially expressed in pregnancy (217), and regulated by SHBG (218), P4 (167) and E2 (32). Pregnancy-upregulated miRNAs targeted the ENV and VIF interactome conveying suppression of HIV replication (IGFR2), reactivation (AHR),

and latency (PSMD1). Pregnancy-downregulated miRNA indicated upregulation of HIV resistance genes, e.g. RAC2 and SUN2. Among the top represented pathways of the HIV interactome epigenetically suppressed by P4-upregulated miRNAs was ERAD, with most of its genes also implicated in SARS CoV2 pathogenesis.

Conclusions: Global miRNA transcriptome analysis identified hormone-regulated targets of vulnerability and resistance to viral acquisition.

EPA0028**Identification of SIV infected mast cells in early sites of viral rebound**

Y. Thomas¹, S. Arif¹, S. Samer¹, C. Rische², R. Krier², K. Walker¹, J. O'Sullivan², R. Lorenzo Redondo³, F. Villinger⁴, B. Bochner², T. Hope¹

¹Northwestern University, Cell and Developmental Biology, Chicago, United States, ²Northwestern University, Allergy and Immunology, Chicago, United States, ³Northwestern University, Infectious Diseases, Chicago, United States,

⁴Lafayette University, New Iberia Research Center, New Iberia, United States

Background: Combination antiretroviral therapeutics, suppressing viremia does not prevent the premature development of comorbidities that are reminiscent of aging such as cardiovascular disease, atherosclerosis, frailty, neurocognitive disease.

Methods: Utilizing a radiolabelled-Fab2 probe to SIV, we are able to detect early foci of viral rebound during the eclipse phase (before viremia) after analytical therapy interruption (ATI) utilizing PET/CT. With the premise that the early foci of rebound reflect certain characteristics of the reservoir of viral persistence, we have analyzed the SIV infected cells in the region of a rebound foci (Rebound Zone) and unexpectedly observed SIV infected cells with a myeloid cell morphology and no infected CD4 T Cells.

Results: We have recently identified this undefined population as mast cells, which are present at increased density within the identified Rebound Zones. We have rediscovered the HIV/SIV infection of mast cells that was initially reported by 4 groups between 2000-2009. We were able to utilize primary human mast cells derived from skin or the peritoneal lavage of a humanized mast cell mouse model. Mast cells in both models expressed CD4 and CCR5 and were able to support the replication of HIV BaL and ADA. HIV replication was blocked with antiretrovirals as expected.

Next, we examined the Rebound Zone containing tissue from multiple animals necropsied 4, 5, 7, and 10 days post ATI utilizing multiple markers of mast cells (Tryptase, FcεR1, CD117). We were able to identify SIV infected mast cells in all the rebound animals.

Conclusions: This rediscovery of HIV infection of MCs in culture and validation of the infection of MCs in a rhesus macaque early reservoir model reveal a potentially ac-

tive role of mast cells during HIV/SIV infection. Mast cells play key functions in innate and adaptive immunity and facilitate the execution of the immune and inflammatory responses and the process of tissue repair and healing their infection by SIV/HIV could have a consequential role in HIV pathogenesis.

The unique characteristics of MCs to self-renew (proliferate), regulate epithelial and endothelial barrier function, and influence systemic inflammation make them a critical focus of research to gain unique perspectives and understanding of persistence.

Early initiation of anti-retroviral therapy restores some but not all perturbations of natural killer cell functions and phenotypes in early HIV-1 infected men who have sex with men

M. Akiso¹, R. Langát², D. Muema², K. Naidoo³, G. Oino², T. Kotikot², G. Mutua², C. Tsabalala³, D. Ochiel⁴, K. Chinyenze⁴, O. Anzala^{2,1}, M. Mureithi^{1,2}

¹University of Nairobi, Department of Medical Microbiology, Nairobi, Kenya, ²KAVI Institute of Clinical Research, Department of Medical Microbiology, Nairobi, Kenya, ³University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, ⁴International AIDS Vaccine Initiative, Nairobi, Kenya

Background: NK cells play a crucial role in regulating HIV-1 infection and replication, and this regulation of HIV-1 infection and replication may determine the disease outcome. Antiretroviral therapy (ART) effectively restores CD4⁺ T cell counts and suppresses HIV-1 viral loads to undetectable levels in circulation. However, it is unclear whether or not the perturbations on NK cells are fully recovered. We hypothesized that early initiation of ART restores NK cell perturbations due to HIV-1 infection. We, therefore, sought to understand the phenotypic and functional changes that may occur to NK cells in early HIV-1 infection and whether early initiation of ART restores these possible changes.

Methods: We longitudinally evaluated NK cell functional and phenotypic changes in early HIV-1 infected Men who have Sex with Men (MSM) in Nairobi, Kenya, and who were recently initiated on ART. Blood samples were obtained fortnightly for three visits post seroconversion. Baseline blood samples collected in the SIVET study before seroconversion were also analyzed. Frozen PBMCs were thawed and stimulated overnight with K562 cell line, IL-2 and IL-15 and stained with antibodies to evaluate NK cell phenotype, activation, and functionality.

Results: Compared to the pre-seroconversion time point, there were no changes in the total NK cell frequencies across the time points. We observed significant reduc-

tions in NK cell production of IFN- γ , expression of CD69, and NK cell inhibitory receptor siglec7. However, there were significant increases in NK cell degranulation and expression of cell exhaustion marker PD-1.

Most of these changes were restored to near the pre-seroconversion level around 30 days post-ART initiation. The reduction in expression of the siglec7 receptor was, however, not restored.

Conclusions: The impairment of NK functionalities in early HIV-1 infection may enhance disease progression. This could be one way in which HIV-1 escapes the immune system. However, these impairments seem to be restored a few weeks after ART supporting the test and treat strategy.

Evaluating the mechanisms by which HIV-1 impairs NK cell effector functions would inform designing an effective HIV-1 vaccine boosting innate immunity.

EPA0030

Mitochondrial HSP₆₀ ensures optimal energy-dependent immunity in antiviral T-cells

N. Ghahari¹, H. Loucif², D. OLAGNIE³, J.-P. Routy⁴, J. Van Grevenynghe¹

¹INRS, Armand-Frappier Santé Biotechnologie, Laval, Canada, ²McGill University, Montreal, Canada, ³Aarhus University, Aarhus, Denmark, ⁴McGill University Health Centre, Montreal, Canada

Background: Immunometabolism, which refers to the crosstalk between immunology and cellular metabolism, has provided new promising therapeutic venues for treating HIV-1. Our laboratory has shown that antiviral T-cell functions in PLWH (people living with HIV) were mediated through autophagy-dependent energy production and could be a target to boost protective immunity in these individuals.

Furthermore, Autophagy provides different sources of nutrients (lipids and amino acids for CD8 and CD4 T-cells, respectively) to ensure optimal energy production.

However, it remains critical, mechanistically speaking, to have a complete picture of how antiviral T-cells use nutrients and metabolic enzymes.

Here, we aimed to assess the role of mitochondrial heat shock protein 60 (HSP60) in memory T energy production and effector function.

Methods: We assessed the expression levels and mitochondrial localization of HSP60 within T-cells (CD4 and CD8) following their cellular activation by multiparametric and imaging Flow Cytometry (Aim 1). Blockade of HSP60 within memory T-cells by gene silencing was followed by evaluating expression levels of metabolic enzymes and mitochondrial energy production using western blotting and Seahorse metabolic analyzer, respectively (Aim 2). Finally, evaluating the effector function of T-cells after HSP60 gene silencing by multiparametric Flow Cytometry (Aim 3).

Results: The results show an increase in mitochondrial HSP60 expression in an HSF-1-dependent manner within memory T cells following cell activation. We found that mitochondrial HSP60 was critical to ensure optimal energy production by stabilizing the expression of several enzymes and nutrient transporters, which were involved in lipid and glutamine catabolism.

Finally, our data vouched for our ability to rescue the energy-dependent antiviral immunity of T-cells when HSP60 expression is impaired with alpha-ketoglutarate supplementation.

Conclusions: Overall, our study demonstrates a new molecular and metabolic mechanism involving the vital role of HSP60 in providing the energy required in Memory T cells against Viruses which could be a novel therapeutic tool for PLWH.

In addition, we also show that alpha-ketoglutarate supplementation may be beneficial for boosting T-cell immunity against viruses including HIV-1.

EPA0031

Genetic signatures of HIV-infected CD4⁺ T cells that survive interactions with NK cells

P. Grasberger¹, A. Kucukural², M. Zapp², K. Clayton¹

¹University of Massachusetts Medical School, Pathology, Worcester, United States, ²University of Massachusetts Medical School, Program in Molecular Medicine, Worcester, United States

Background: *In vitro* experiments in which HIV-infected CD4⁺ T cells are co-cultured with natural killer (NK) cells yield incomplete elimination of the infected cells.

We therefore hypothesize that cell-intrinsic pathways in CD4⁺ T cells are differentially regulated in HIV-infected cells to mediate resistance to NK cell-mediated killing.

Methods: Mock-infected and HIV-89.6-infected CD4⁺ T cells from 6 donors were co-cultured overnight +/- autologous NK cells. Following co-culture, cells were stained for the surface exposed HIV envelope protein using fluorescently conjugated HIV antibodies. Fluorescence activated cell sorting was then used to isolate infected and uninfected cells, followed by bulk RNA-sequencing. Transcripts from infected and uninfected cells co-cultured overnight with versus without NK cells were compared.

Results: RNA-seq analysis of CD4⁺ T cells that survived co-culture with NK cells revealed dozens of differentially expressed genes in infected, but not uninfected cells. This included upregulation of interferon-stimulated genes, including PD-L1 (padj=310⁻⁶), and NF-kB-related genes. Additional upregulated genes in the surviving infected cells included c-Fos (padj=1.910⁻⁵), c-Jun (padj=4.910⁻⁸), and cathepsin L (padj=5.910⁻³).

Conclusions: NF-kB genes that are downregulated in infected cells, potentially through Vpu activity, are normalized in survived infected cells. This may be due to NK cell targeting of Vpu-mediated HLA-C-downregulation.

Deconvolution of relative contributions of specific genes/proteins to target cell resistance will reveal novel targets for the development of therapeutics to eliminate the HIV reservoir.

Autophagy and the acyl-coA-binding protein influence immune function in people living with HIV

S. Isnard^{1,2,3}, L. Royston^{3,2,1,4}, T. Mabanga^{1,2}, S. Bu¹, C.A. Berini^{1,2}, J. Lin¹, B. Fombuena¹, N.F. Bernard^{1,5,6}, G. Kroemer^{7,8,9}, J.-P. Routy^{1,2,10}

¹McGill University Health Centre - Research Institute, Montreal, Canada, ²McGill University Health Centre, Chronic Viral Illness Service, Montreal, Canada, ³CIHR/Canadian HIV Trial Network, Vancouver, Canada, ⁴Geneva University Hospitals, Division of Infectious Diseases, Geneva, Switzerland, ⁵McGill University, Division of Experimental Medicine, Montreal, Canada, ⁶McGill University Health Centre, Division of Clinical Immunology, Montreal, Canada, ⁷Centre de Recherche des Cordeliers - INSERM U 1138, Paris, France, ⁸Institut Gustave Roussy, Metabolomics and Cell Biology Platforms, Villejuif, France, ⁹Hopital Européen Georges Pompidou, Institute du Cancer de Paris - CARPEM, Paris, France, ¹⁰McGill University Health Centre, Division of Hematology, Montreal, Canada

Background: Through degradation of cytosolic structure, autophagy allows the establishment and maintenance of efficient anti-HIV T-cell responses, owing to the production of IL-21 by CD4 T-cells. Cytosolic acyl-coA-binding protein (ACBP) binds to activated fatty acid and favors autophagy. However, when ACBP is secreted in the extracellular milieu, autophagy is inhibited, and appetite increased.

To assess the role of ACBP in people living with HIV (PLWH) receiving antiretroviral therapy (ART), we assessed intra and extracellular ACBP levels and their link with metabolic and immune functions as well as autophagy.

Methods: ELISA were used to quantify ACBP and cytokines levels in 50 long-term ART-treated PLWH and 30 controls without HIV. Intracellular ACBP and autophagy marker LC3II levels were assessed by flow cytometry in PBMC. Metabolomic analyses were performed on serum samples by GC-MS. *In vitro* assays were performed on PBMC from donors without HIV.

Results: ACBP levels were higher in ART-treated PLWH compared to controls (medians 127.5 vs 78.1 ng/mL, p=0.03), independently of age and sex. Intracellular ACBP was detected in all leukocytes in both groups, and intracellular ACBP levels in T-cells and monocytes correlated inversely with plasma levels (r=-0.9, p=0.02 and r=-0.9, p=0.08 respectively). Intracellular levels of ACBP and LC3II were associated, in both T-cells and monocytes.

In ART-treated PLWH, plasma ACBP levels were neither associated with CD4 nor CD8 T-cell counts, but correlated

with pro-inflammatory cytokines (IFN α 2, IFN γ , IL1 β) and homeostatic factors (IL7 and IL15) ($r > 0.3$, $p < 0.05$ for all comparisons).

Plasma ACBP levels were inversely associated with plasma IL-21 levels ($r = -0.54$, $p < 0.01$). PLWH with high plasma ACBP had two-fold higher levels of glutamic acid ($p = 0.02$) and tended to have higher levels of α -ketoglutarate ($p = 0.09$) in their serum. *In vitro* addition of recombinant ACBP to culture medium for 24h decreased LC3II intracellular levels and the percentage of IL-21 producing CD4 T-cells after PMA-ionomycin stimulation.

Conclusions: Higher plasma levels of ACBP in ART-treated PLWH were associated with inflammation and markers of T-cell dysfunction. Circulating ACBP weakens anti-HIV T-cell functions, possibly through the inhibition of IL-21 production. The ACBP pathway might constitute a target for increasing autophagy and improving anti-HIV T-cell responses.

Background: A strong predictor of outcome following HIV-1 infection is the carriage of specific alleles of the human leucocyte antigen (HLA) molecule that presents viral peptides (epitopes) to T cells, with residual variation in outcome measures attributed, in part, to viral adaptation to these responses. The endoplasmic reticulum aminopeptidases (ERAPs) trim viral peptide precursors to optimal lengths for peptide presentation and functional variants of the ERAPs can affect the repertoire of T cell epitopes presented by specific HLA alleles.

Here, we propose that variations in ERAP will be associated with changes in the viral targets of HLA-restricted T cell responses affecting HIV disease outcome measures and the adaptation profile of HIV.

Methods: Host (HLA, ERAP1 and 2) genotyping and HIV sequence data on 249 anti-retroviral therapy-naïve HIV-1-infected subjects from the Western Australian HIV cohort was utilised to investigate the effect of variations in HLA, ERAP1 and ERAP2 and their interactions on disease

outcome (set-point viral load) and HIV adaptation levels. All data analyses and statistical tests were performed using R Studio.

Results: We confirmed the known association of HLA-B*27 and HLA-B*57 with lower viral load ($P = 0.0002$) and higher CD4⁺ T cell count ($P = 0.0028$) and CD4⁺ T cell percentage ($P = 0.0052$) in this study cohort. We also identified a novel association between two ERAP2 single nucleotide polymorphisms (SNPs; rs2248374 and rs2549782 that are in strong linkage disequilibrium) with viral load (P adjusted = 0.0022 for both) and CD4⁺ T cell count and percentage (rs2248374 only; P adjusted = 0.0468).

There was a significant interaction between these ERAP2 SNPs (that define haplotype B) and viral adaptation (an indicator of HLA-restricted T cell immune pressure) on viral load ($P = 0.0091$).

Conclusions: Variations in ERAP2 appear to impact HLA-restricted anti-HIV T cell immune responses most likely by altering the peptide repertoire presented to T cells or the overall anti-viral immune response.

This study provides evidence that HIV disease outcome is, in part, a result of independent and interactive effects of immune-related host factors such as HLA and ERAP and viral factors including the autologous sequence.

Improvement of B cell responses by an HIV-1 amphiphilic polymer nanovaccine

X. Xin¹, Y. Liu¹, L. Guo¹, H. Wang¹, D. Lu¹, Y. Chang², M. Wan², Y. Zhang², Y. Shan², Q. Zhang¹, X. Liu^{3,4}, F. Gao¹

¹Institute of Molecular and Medical Virology, Key Laboratory of Ministry of Education for Viral Pathogenesis & Infection Prevention and Control, School of Medicine, Jinan University, Guangzhou, China, ²National Engineering Laboratory for AIDS Vaccine, School of Life Sciences, Jilin University, Changchun, China, ³Engineering Center of Catalysis and Synthesis for Chiral Molecules, Department of Chemistry, Fudan University, Shanghai, China, ⁴Shanghai Engineering Research Center of Industrial Asymmetric Catalysis of Chiral Drugs, Shanghai, China

Background: The development of a safe and effective vaccine is critically needed to control the current devastating AIDS pandemic. One key barrier to develop HIV-1 vaccines is the challenge to improve the ability to induce broadly neutralizing antibodies (bnAbs). Thus, exploring innovative strategies to enhance neutralization breadth and potency elicited by HIV-1 vaccines will assist in developing next generation HIV-1 vaccines.

Methods: A novel HIV-1 envelope glycoprotein nanoparticle (Env/NP) vaccine was generated by embedding stable native-like Env trimers into the amphiphilic polymers, which was synthesized through the amidation reaction between the anhydride group on poly(maleic anhydride-ALT-1-octadecene) (PMHC₁₈) and the amino group on poly(ethylene glycol) (PEG). To evaluate the immunogenicity of Env/NP, we immunized New Zealand rabbits sub-

cutaneously in three groups (Env with adjuvant AS03, Env/NP alone, and Env/NP with AS03) and collected blood after each immunization. To investigate the stability of Env/NP stored under different conditions, we immunized BALB/c mice with Env/NP immunogens which were stored at 4°C or -80°C for 2.5 months or lyophilized and then stored at room temperature for 2.5 months.

Results: The final Env/NP formed irregular spheres with diameters about 20 nm and significantly reduced the negative charge of Env trimers. Env/NP with AS03 induced about four-fold higher titers of HIV-1 Env specific binding Abs as well as 3.5-7 fold higher titers of nAbs than Env with AS03 or Env/NP alone in rabbits.

Moreover, the sera from rabbits immunized using Env/NP with or without AS03 could neutralize more tier 2 viruses (3 or 4) than the sera from rabbits immunized using Env with AS03 (only 1). Furthermore, Env/NP stored at 4°C for 2.5 months or lyophilized induced similar immune responses as it was stored at -80°C.

Conclusions: An HIV-1 Env/NP nanovaccine based on amphiphilic polymers can serve as an adjuvant to enhance immune responses, increase neutralization potency and breadth as well as be stable at different storage temperatures even after lyophilization.

HIV-infected macrophages express different NK ligands compared to HIV-infected T cells

H. Kek^{1,2}, A. Pombourios^{1,3}, A. Jaworowski^{1,4}, A. Hearps^{1,5}

Australia, ³Monash University, Department of Microbiology, Melbourne, Australia, ⁴RMIT, School of Health and

Biomedical Sciences, Melbourne, Australia, ⁵Monash

University, Department of Infectious Diseases, Melbourne, Australia

Background: HIV-infected macrophages form tissue reservoirs in people with HIV which persist despite anti-retroviral therapy. Natural killer (NK) cells may be useful effector cells for eliminating HIV-infected cells through both antibody dependent and independent cytotoxicity. NK recognition of HIV+ cells is influenced by the interaction between ligands on the target cells with activating/inhibitory receptors expressed on NK cells.

HIV replication kinetics and host viral restriction mechanisms differ between macrophages and T cells, which may influence the expression of ligands for NK receptors (e.g. human leukocyte antigens, HLA) and HIV antigens which influence NK recognition.

HIV accessory proteins also regulate the expression of factors involved in NK cell engagement but their effect in HIV-infected macrophages is less clear.

Methods: Monocyte-derived macrophages from HIV-seronegative blood donors were infected in vitro with HIV (BaL and AD8/Δnef/Δvpu) and synchronised using an HIV fusion inhibitor on day 3 post-infection. Productive infec-

tion (indicated by intracellular HIV p24 protein) and surface expression of HIV envelope (Env), CD4 and HLA molecules were quantified using flow cytometry at various times post-infection.

Results: HIV+ macrophages downregulated surface CD4 and classical (A+B+C) HLA molecules relative to bystander (p24-) cells after infection (p<0.02, days 3/7/10 vs day 0). HIV-induced downregulation of HLA-ABC and CD4 were partially restored by Δnef/Δvpu HIV in macrophages but not in T cells. HIV+ macrophages upregulated HLA-C and HLA-E expression (p<0.05, bystanders vs infected) but not T cells; this was irrespective of nef deficiency but was restored to bystander levels by Δvpu HIV.

Whilst HIV Env was detected on the surface of HIV+ macrophages after 3 days, expression plateaued between 7-10 days post-infection even though p24 expression continued to increase.

Conclusions: A proportion of HIV+ macrophages down-regulate HLA-A/B and can be opsonised by anti-Env antibodies, suggesting increased susceptibility to antibody-dependent NK cytotoxicity. However, specific upregulation of HLA-C/E on HIV+ macrophages may impair NK responses and/or influence the types of NK cells which recognise HIV+ macrophages.

These data indicate that HIV+ macrophages are a unique and dynamic reservoir that express a different array of NK ligands to HIV+ T cells, which may influence their ability to be targeted by subpopulations of NK cells.

EPA0036

Pomalidomide drives expansion of HIV-specific CD8+ T-cells by promoting transcriptional activity of E2F1 and PRMT3

Background: HIV-specific CD8+ T-cells in chronic HIV infection have reduced cytolytic and proliferative capacities. Therapeutics that reinvigorate HIV-specific CD8+ T-cell responses are therefore highly relevant to HIV cure strategies. Pomalidomide is an immunomodulatory drug that has pleiotropic effects on multiple immune cells including production of IL-2. We investigated the capacity of pomalidomide to enhance HIV-specific CD8+ T-cell responses.

Methods: PBMCs from ART-suppressed people living with HIV (PLHIV) were treated *ex vivo* with pomalidomide or DMSO control for 13 days in the presence of HIV immunodominant peptides, Gag (SL9, RK9, EI8) or Pol (IV9). HIV-specific CD8⁺ T-cell responses were evaluated using HIV peptide loaded-MHC-I tetramers. The frequency and cytotoxic profile of HIV-specific CD8⁺ T-cells were measured by intracellular staining for degranulation, granzymes, perforin and IFN γ by flow cytometry. Finally, sorted tetramer-positive CD8⁺ T-cells underwent bulk RNA-sequencing followed by transcriptomic analyses using KEGG pathway analysis and Reconstruction of Transcriptional regulatory Networks and analysis of regulons (RTN).

Results: In the presence of HIV peptides, pomalidomide significantly expanded both total and HIV-specific CD8⁺ T-cells, producing a 9.26-fold increase ($p=0.0156$) in HIV-specific CD8⁺ T-cell absolute numbers relative to DMSO. When restimulated with the cognate antigen, degranulation, and expression of granzymes, perforin and IFN γ in the degranulating tetramer positive cells were similar in PBMC treated with pomalidomide and DMSO.

Transcriptomic analyses demonstrated that pomalidomide-treated HIV-specific CD8⁺ T-cells clustered separately from DMSO-treated cells. Pomalidomide was associated with an upregulation of pathways involved in carbon metabolism, cell cycle and DNA replication in HIV-specific CD8⁺ T-cells, and strongly increased expression of MYB, a transcription factor implicated in CD8⁺ T-cell stemness, polyfunctionality and survival (5.36-fold $p=3.84E-20$). When analysed against a CD8⁺ T-cell 'core exhaustion profile', pomalidomide-treated HIV-specific CD8⁺ T-cells displayed less exhaustion than those treated with DMSO. RTN analysis identified E2F1 and PRMT3 as key regulators of the pomalidomide-associated responses in HIV-specific CD8⁺ T-cells. E2F1 and PRMT3 have been implicated in promoting proliferation, with E2F1 a cell cycle effector regulated by Ikaros.

Conclusions: We show that pomalidomide enhances HIV-specific CD8⁺ T-cell responses and provides a compelling justification for the investigation of pomalidomide as an immune-enhancing therapeutic agent as part of HIV cure approaches.

Zinc protein inhibitor SAMT-247 modulate immune response generated by ALVAC-based HIV vaccine candidate and improve the vaccine efficacy

M.A. Rahman¹, M. Bissa¹, I. Silva de Castro¹, S. Helmod Hait¹, J. Stamos¹, F. Bhuyan², R. Hunegnaw¹, S. Sarkis¹, A. Gutowska¹, M. Doster¹, R. Moles¹, T. Hoang¹, L. Miller Jenkins³, E. Appella⁴, D. Venzon⁵, H. Choo-Wosoba⁵, T. Cardozo⁶, M. Baum⁷, D. Appella⁸, M. Robert-Guroff¹, G. Franchini¹

¹National Institutes of Health, Vaccine Branch, CCR, NCI, Bethesda, United States, ²National Institutes of Health, National Institute of Allergy and Infectious Diseases, Bethesda, United States, ³National Institutes of Health, Collaborative Protein Technology Resource, Laboratory of Cell Biology, NCI, Bethesda, United States, ⁴National Institutes of Health, Chemical Immunology Section, NCI, Bethesda, United States, ⁵National Institutes of Health, Biostatistics and Data Management Section, Bethesda, United States, ⁶New York University School of Medicine, NYU Langone Health, New York, United States, ⁷Oak Crest Institute of Science, Monrovia, United States, ⁸National Institutes of Health, Synthetic bioactive Molecules Section, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, United States

Background: The HIV epidemic remains unabated in sub-Saharan Africa, particularly in adolescent women who have limited access to antiretroviral therapy. The deletion of the Env V1 region of the DNA/ALVAC/gp120 vaccine regimen has improved vaccine efficacy compared to RV144 trial. Furthermore, the antiretroviral agent SAMT-247 formulated as vaginal gel has been shown to have an anti-HIV effect.

Here, we tested the hypothesis that the SAMT-247 microbicide targeting the HIV/SIV nucleocapsid protein in combination with DNA/ALVAC/gp120 Δ V1 vaccination would provide benefit and augment protection against SIVmac251 vaginal challenge.

Methods: Thirty-eight macaques were vaccinated with the Δ V1 DNA/ALVAC/gp120/alum vaccines, and 12 animals remained naive. All animals received up to 14 consecutive weekly intravaginal SIVmac251 challenges in the presence (20 vaccinated & 6 naive) of 0.8% SAMT-247 in HEC gel, or HEC gel only (18 vaccinated & 6 naive) dosed vaginally 4-hours before each challenge until infection was confirmed. Immunological assays such as ADCC, effero-cytosis, ELISA, immunohistochemistry, flowcytometry to measure cell frequencies and cytokine production, with an emphasis on immune responses correlating with vaccine efficacy.

Results: Vaccine alone decreased the risk of virus acquisition by 65% ($p=0.0074$). Strikingly, the vaccine+SAMT-247 combination afforded a 92.7% reduction in the risk of virus acquisition when compared to controls ($p<0.0001$). The vaccine+SAMT-247 combination differed significantly from the vaccine-only group ($p=0.006$;) and protected

from highly pathogenic SIVmac251 infection in 16 of 20 animals (80%). At the dose used, treatment with SAMT-247 alone did not significantly decrease risk of virus acquisition. Vaccine efficacy results from V2 antibody responses, recruitment of Nkp44 IL-17⁺ cells to mucosal sites and efferocytosis.

In vitro experiments suggested that the protective responses by vaccine such as ADCC, efferocytosis, IL-17⁺Nkp44⁺ responses, CCR5 $\alpha_4\beta_7$ Th1 and Th2 cell responses were augmented by the presence of SAMT-247.

Further data suggested that SAMT-247 mobilize cellular zinc, a master regulator of immunity, which might play an important role in the augmented vaccine efficacy.

Conclusions: SAMT-247 is safe and does not induce mucosal inflammation, suggesting that delivery methods aimed to maintain effective drug concentrations in the vaginal mucosa, such as a controlled release intravaginal ring, combined with the DNA/ALVAC/gp120/alum vaccine regimen, may result in durable protection against HIV.

Duration of antiretroviral therapy is a determinant of the frequency of NKG2C⁺CD57⁺ adaptive NK cells in persons living with cytomegalovirus and HIV infections

K. Alsulami^{1,2,3}, F.P. Dupuy^{1,3}, L. Gilbert^{1,3}, M. Durand⁴, C. Tremblay^{5,4}, J.-P. Routy^{1,3,6,7}, J. Bruneau^{4,8}, N.F. Bernard^{1,2,3,7,9}

¹Research Institute of the McGill University Health Centre, Medicine, Montreal, Canada, ²McGill University, Division of Experimental Medicine, Montreal, Canada, ³Research Institute of the McGill University Health Centre, Infectious Disease, Immunology and Global Health Program, Montreal, Canada, ⁴Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CR-CHUM), Montreal, Canada, ⁵Université de Montréal, Department of Microbiology, Infectiology and Immunology, Montreal, Canada, ⁶McGill University Health Centre, Department of Hematology, Montreal, Canada, ⁷McGill University Health Centre, Chronic Viral Illness Service, Montreal, Canada, ⁸Université de Montréal, Family Medicine, Emergency Medicine, Montreal, Canada, ⁹McGill University Health Centre, Division of Clinical Immunology, Montreal, Canada

Background: Of the people living with HIV (PLWH) enrolled in the Canadian HIV and Aging Cohort Study (CHACS), 94% were cytomegalovirus (CMV) co-infected. CMV drives the expansion of NKG2C⁺CD57⁺ Natural Killer cells with memory-like features. The frequency of adaptive NK (adapNK) cells did not differ in CMV⁺PLWH and CMV⁺HIV⁺ persons enrolled in the CHACS who were all >40 yrs of age.

In contrast, the frequency of adapNK cells was higher in CMV⁺PLWH enrolled in the Montreal Primary Infection (PI) cohort than in CMV⁺HIV⁺ persons who were <40 yrs of age. However, age and time on antiretroviral treatment (ART) are positively correlated in PLWH. We questioned whether age or time on-ART influenced adapNK cell frequency.

Methods: We evaluated the frequency of CD3⁺CD14⁺CD19⁺CD56^{dim}NKG2C⁺CD57⁺ adapNK cells in 3 groups of CMV⁺PLWH and 2 groups of CMV⁺HIV⁺ persons by multiparametric flow cytometry.

Groups	1 CMV ⁺ PLWH	2 CMV ⁺ HIV	3 CMV ⁺ PLWH	4 CMV ⁺ PLWH	5 CMV ⁺ HIV
Cohort/Age category	CHACS older	CHACS older	PI younger	PI older	younger
Age	55.7 (51.1,59.3)	57.7 (50.8,62.4)	33.2 (30.8,38.2)	54.1 (52.9,60.1)	31.5 (25.2,36.6)
ART duration	Long	None	Short	Short	None
Years on-ART	16.0 (8.6,19.1)		1.4 (1.0, 2.2)	1.94 (1.8,2.0)	
% adapNK cells	15.9 (5.8,39.4)	13.7 (3.7,33.9)	39.8 (18.8,58.2)	27.5 (18.8,52.85)	15.6 (2.5,33.3)

Table.

Results: AdapNK cell frequency did not differ significantly in older CMV⁺PLWH and CMV⁺HIV⁺ persons (group 1 versus 2). Younger CMV⁺PLWH had a higher frequency of adapNK cells than similarly aged CMV⁺HIV⁺ (group 3 versus 5 (p=0.003, Mann-Whitney). The CMV⁺PLWH in groups 1 and 4 were of similar age and significantly older than those in group 3. CMV⁺PLWH PI subjects in groups 3 and 4 were on-ART for a similar duration that was shorter than those in group 1.

The frequency of adapNK cells was similar in the two CMV⁺PLWH groups on ART for similar times despite their significant difference in age (group 3 and 4). This frequency was higher than in the CMV⁺PLWH CHACS subjects in group 1. Time on-ART was negatively correlated with adapNK cell frequency.

Conclusions: The absence of significant differences in the frequency of adapNK cells in older CMV⁺PLWH on-ART and untreated CMV⁺HIV⁺ CHACS participants (groups 1 and 2) and in groups 3 and 4 who differed in age but had a similar time on-ART, is consistent with a time on-ART dependent decline in the frequency of adapNK cells.

EPA0039

IL-15 treatment rescues perturbations to NK cell mitochondrial fitness and effector function driven by acute SIV infection

B. Hueber¹, A. Hudson¹, P. Rasclé¹, C. Manickam¹, R.K. Reeves¹

¹Duke University School of Medicine, Surgery, Durham, United States

Background: As one of the earliest responders to HIV infection, NK cells play a central role in blocking transmission and virus-dissemination. Unfortunately, their global functional and capacity to infiltrate tissues is compromised during infection, limiting their effector response.

The primary objective of this research was to determine how acute SIV infection impacted the metabolic fitness of NK cells, elucidate the relationship between fitness, function and trafficking to virus replication sites and whether the NK cell homeostatic cytokine IL-15 could rescue the perturbations driven by infection.

Methods: Peripheral lymph nodes (PLN), PBMCs and spleen samples from SIV-naïve and infected rhesus macaques were used to analyze metabolic and functional profiles of NK cells. NK cells were supplemented with/without IL-15 and co-cultured with the classical NK cell targets, K562 cells.

Samples were analyzed for functional, lineage, activation, and nutrient transporter markers by multiparametric flow cytometry as well as MitoTracker Red CMXRos and MitoSOX, to measure mitochondrial membrane polarization ($\Delta\Psi_m$) and the presence of superoxides.

Results: Our results indicated that acute SIV infection increased the frequency of NK cells that displayed perturbed mitochondrial phenotypes (i.e., decreased $\Delta\Psi_m$ $p = 0.0003$ and higher superoxide accumulation $p = 0.0027$). This metabolic dysfunction was most evident in NK cells from PLN post-infection. Treatment with IL-15, reversed these phenomena in SIV+ samples, increasing $\Delta\Psi_m$ ($p < 0.0001$) and decreasing superoxide accumulation ($p = 0.0001$). CXCR5 expression, a B cell follicle trafficking marker, strongly correlated with $\Delta\Psi_m$ ($p = 0.0024$) indicating that expression may be tied to mitochondrial health. IL-15 also increased the expression of the amino-acid transporter CD98 ($p < 0.0001$), and decreased the frequency of CD56-CD16- NK cells ($p < 0.0001$). Functionally, NK cells with higher or rescued $\Delta\Psi_m$ produced stronger cytokine responses (TNF- α , IFN- γ , and MIP1-b).

Conclusions: These findings indicate that lentivirus infection induces systemic mitochondrial dysfunction in NK cells, a fundamental pathology undermining their ability to infiltrate tissues and respond to infection, and that IL-15 exposure reverses these phenomena.

These data highlight the importance of understanding and treating metabolic perturbations caused by infection and supports IL-15 as a candidate to augment NK cell-based HIV eradication treatments.

EPA0040

Ibalizumab and CD4 domain 2 exert an allosteric effect on HIV envelope binding to CD4 domain1

C. Cicala¹, D. Van Ryk¹, J. McMurray¹, S. Vimontpatranon¹, I. Licavoli¹, S. Wertz¹, A. Girard¹, D. Wei¹, A.S. Fauci¹, J. Arthos¹
¹NIAID, NIH (USA), Laboratory of Immunoregulation, Bethesda, United States

Background: HIV infection of CD4⁺ T cells is mediated by a high affinity interaction between the HIV envelope (gp120/41) and the CD4 receptor. To date, Ibalizumab, a CD4 domain 2 (D2) mAb, is the only CD4 mAb widely used to treat people living with HIV. Ibalizumab does not block gp120 binding to CD4 but is believed to interfere with post-binding events (figure 1).

gp120 binds to CD4 domain 1 (D1), while ibalizumab binds to CD4 domain 2 (D2). There appears to be no direct contact between D1 and D2, and ibalizumab does not interact with the gp120 binding site in D1. In this study we inves-

tigated unrecognized properties of the CD4 receptor that may impact mechanisms by which Ibalizumab blocks HIV entry into CD4⁺ cells.

Figure 1.

Methods: Our studies relied upon mass photometry, surface plasmon resonance and flow-cytometry to characterize the impact of ibalizumab on gp120 binding to CD4.

Results: Results from three independent techniques, mass photometry, SPR, and flow-cytometry provide evidence of unexpected cross-talk between CD4 domains 1 and 2. Mutations in the CD4 binding site in D1 significantly enhance ibalizumab binding to D2. Although ibalizumab does not compete with gp120, preincubation with CD4 inhibits gp120 binding. Cross-talk is bidirectional. Mutations in CD4 D2 impact gp120 binding to CD4 D1. We further show that CD4 D2 may impact gp120 CD4 interactions in ways that were not previously recognized.

Conclusions: We identified a new way in which CD4 D2, and drugs that target this domain, can impact the HIV envelope binding to its principal receptor. These observations may assist in the further development of HIV entry inhibitors.

Institute of Allergy and Infectious Diseases, Laboratory of Immunoregulation, Bethesda, United States

Background: The primary correlate of reduced risk in the RV144 Phase III trial was the level of IgG binding to the V1/V2 variable loops of gp120 scaffolded on gp70. V2 contains cryptic RDK and LDI/V binding motifs for the gut-homing host $\alpha_4\beta_7$ integrin receptor.

Further insight on the role of anti-V2 binding, non-neutralizing antibodies has been provided by the recent demonstration that V2 binding to $\alpha_4\beta_7$ on CD4⁺ T-cells co-stimulates CD4⁺ cells and, by upregulating CCR5 expression, facilitates HIV/SIV infection.

Methods: NCI05 and NCI09 were cloned from a vaccinated macaque that resisted 22 low-dose intrarectal challenges of SIV_{mac251} for over a year, both targeting an overlapping, conformationally dynamic epitope in SIV-envelope V2.

We characterized the ability of NCI05 and NCI09 to mediate ADCP, trogocytosis, antibody-dependent cellular cytotoxicity (ADCC), and inhibition of gp120 costimulation of CD4⁺ T cells.

We treated two groups of 9 macaques each with NCI05 or NCI09 at a dose of 20 mg/kg, beginning at four days prior to the first SIV_{mac251} challenge. Levels and effector functions of V2 mAbs were assessed in plasma rectal secretions and correlated with time of SIV acquisition.

Results: Here, we show that NCI05 recognizes a CH59-like coil/helical epitope whereas NCI09 recognizes a b-hairpin linear epitope. *In vitro*, NCI05 and, to a lesser extent, NCI09 mediate the killing of SIV infected cells in a CD4-dependent manner. Compared to NCI05, NCI09 mediates higher ADCC titers to gp120-coated cells, as well as higher lev-

els of trogocytosis, a monocyte function that contributes to immune evasion. Strikingly, mucosal levels of NCI05 strongly correlated with a decreased risk of SIV_{mac251} acquisition and there was a similar trend for ADCC mediated by plasma samples from NCI05-treated animals.

Conclusions: Passive administration of NCI05 or NCI09 to macaques did not affect the risk of SIV_{mac251} acquisition compared to controls, demonstrating that these anti-V2 antibodies alone are not protective.

However, NCI05 but not NCI09 mucosal levels strongly correlated with delayed SIV_{mac251} acquisition, and functional and structural data suggest that NCI05 targets a transient state of the viral spike apex that is partially opened, as compared to its prefusion conformation.

EPA0042**Identification and characterization of HIV-1-specific CD8⁺ T cells in highly HIV-1 exposed but uninfected MsM in Vietnam**

H. The Nguyen¹, C. Takayuki¹, N. Kuse¹, Y. Zhang¹, N.D. Thi Pham², N. Thi Do², N. Bich Lung², B. Thanh Nguyen², D. Van Nguyen², G. Minh Le², S. Oka³, M. Takiguchi¹

Background: Several studies reported that HIV-1-specific cytotoxic T lymphocytes (CTLs) were detected in a part of individuals called highly exposed seronegative (HESN) individuals who remained uninfected despite repeated exposures to HIV-1. However, it is unknown whether these T cells can recognize HIV-1-infected cells and contribute to prevention of HIV-1 infection.

Methods: We analyzed HIV-1-specific T cells among HESN men who are sex with men (MSM) in Vietnam where the subtype AE is epidemic. We recruited 249 seronegative MSM and analyzed T cell responses to overlapping 17-mer peptides spanning the consensus sequences of Nef, Gag and Pol proteins among HIV-1 subtype A/E in Vietnam.

We stimulated PBMCs from these individuals with 281 overlapping HIV-1 peptides and tested the responses of the cultured cells to these peptides after 3 weeks culture by performing ICS assay. Responses of HIV-1-specific T cells to HIV-1-infected cells were tested by using target cells infected with HIV-1 subtype AE clone derived from a Vietnamese.

Results: Responses of CD8⁺ T cells to five 17-mer peptides were detected in 5 of 249 individuals. We attempted to identify T cell epitopes recognized by these T cells using truncated peptides of these 17-mers as well as HLA restriction of the responses. Three HIV-1 epitopes, HLA-A*02:01-restricted Nef, HLA-B*15:02-restricted Gag, and HLA-B*58:01-restricted Pol epitopes, were identified in 3 individuals.

To clarify the ability of these T cells to recognize HIV-1-infected cells, we analyzed CD8⁺ T cell responses to target cells infected with HIV-1 subtype AE clone. HLA-B*15:02-restricted GagHL9-specific CD8⁺ T cells effectively recognized HIV-1 infected cells. These results indicated that HIV-1-specific T cells in HESN individuals can recognize HIV-1-infected cells.

Conclusions: The present study demonstrated that HIV-1-specific CD8⁺ T cells were detected in approximately 2 % of HESN individuals in Vietnam. Some of them effectively could recognize HIV-1-infected cells. Further study is expected to clarify the role of these T cells in HIV-1 protection.

Favourable transcriptomic signature of HIV-specific CD8 T cells in response to single anti-PD1 dose in people with HIV on ART and cancer

C. Gubser¹, C. Chiu¹, L. Rajdev², J. Schroeder³, C. Tumpach¹, R.D. Pascoe¹, C. Durand⁴, J. Chang¹, A. Solomon¹, R. Cao¹, L. Martelotto⁵, J. Bethony⁶, D. Utzschneider⁷, A. Kallies⁷, M. Davenport⁸, J. Anderson³, T.A. Rasmussen⁹, S.R. Lewin^{1,10,11}
¹Peter Doherty Institute, University of Melbourne, Department of Infectious Diseases, Melbourne, Australia, ²Mount Sinai Hospital, New York, United States, ³Peter Doherty Institute, University of Melbourne, CSI, Melbourne, Australia, ⁴John Hopkins University, Baltimore, United States, ⁵University of Adelaide, Adelaide, Australia, ⁶George Washington University, AIDS Malignancy Consortium, Washington, United States, ⁷Peter Doherty Institute, University of Melbourne, Department of microbiology, Melbourne, Australia, ⁸The Kirby Institute, Infection Analytics Program, Sydney, Australia, ⁹Aarhus University Hospital, Department of infectious disease, Aarhus, Denmark, ¹⁰Alfred Hospital and Monash University, Department of infectious disease, Melbourne, Australia, ¹¹Royal Melbourne Hospital, Victorian Infectious Disease Service, Melbourne, Australia

Background: In people with HIV (PWH), immune dysfunction persists with elevated expression of the exhaustion marker programmed death (PD-1) despite suppressive antiretroviral therapy (ART). Anti-PD1 in people with cancer can reinvigorate exhausted tumor-specific T cells through the proliferative burst of exhausted effector T cells (TEX) that originate exclusively from T precursor exhausted (TPEX) cells. There is high interest in whether anti-PD1 can also drive recovery of HIV-specific T-cell cytolytic function in PWH.

Methods: PWH on ART with cancer were enrolled in the AIDS Malignancy Consortium (AMC)-095 Study and received anti-PD1 (nivolumab) every 3 weeks. Blood was collected prior to and following the first, fourth and subsequent infusions. In a subset of 8 participants, we sorted HIV-tetramer⁺ CD8 T-cells and performed single cell RNA sequencing using the Chromium 10X platform.

We analysed antigen-specific cytokine production using intracellular cytokine staining (ICS) following incubation with gag and nef peptides.

Results: Following the first dose of anti-PD1, we observed a significant increase in the frequency of Tex cells ($p=0.028$) in 3 out of 8 participants. In these three participants, central memory T- cells (TCM) showed differentially expressed genes (DEG) associated with molecular pathways of the HIV-1 viral cycle, type I interferon signaling and cytokine response.

We identified HIV specific TCRs through their TCR beta chain and found that among TCM, expanded clonotypes compared to non-expanded clonotypes displayed differential expression of genes with effector-like functions, while hallmarks of memory were downregulated.

The expanded clonotypes accumulated only in the 3 participants with an increase in TEX and were not associated with increased production of antiviral cytokines. There was minimal additional impact on the transcriptome following subsequent doses of anti-PD1.

Conclusions: A distinct and favorable transcriptional response to anti-PD1 is seen within HIV- antigen specific CD8 T-cells in PWH on ART.

This response was evident in a subset of participants following the initial dose of anti-PD1 with no further enhancement after subsequent infusions.

Collectively, this shows that HIV-specific T-cell exhaustion can be perturbed using therapeutic blockade of PD1.

EPA0044

CX3CR1⁺ macrophages as guardians of the intestinal barrier: lessons learnt from non-human primates exposed to SIV or SARS CoV-2

K. Latha¹, S. Hua¹, K. Benmezi¹, R. Marlin¹, P. Maisonnasse¹, N. Bosquet¹, R. Le Grand¹, M. Cavarelli¹
¹Université Paris-Saclay, Inserm, CEA, Center for Immunology of Viral, Auto-immune, Hematological and Bacterial Diseases (IMVA-HB/IDMIT), Fontenay-aux-Roses & Le Kremlin-Bicêtre, Fontenay-aux-Roses, France

Background: Maintenance of gut homeostasis is critical to efficient immune responses and is dependent on a population of *lamina propria* (LP) resident macrophages (M ϕ) expressing the fractalkine receptor CX3CR1, which play a pivotal role in the maintenance of the intestinal epithelial barrier, microbial translocation and the host response to microbiota changes.

Humans exposed to HIV-1 and Cynomolgus macaques (CMs) exposed to SIV show highly persistent immune activation and inflammation in their gut, which are strong predictors of disease progression and are prevalent despite antiretroviral therapy.

Moreover, people diagnosed with COVID-19 also presented with symptoms of gastrointestinal (GI) disruption like diarrhea, vomiting and nausea; along with detectable rectal viral load and various long-term sequelae like intes-

tinal dysbiosis. Thus, understanding the immune response to SIV and SARS CoV-2 in the GI tract is crucial to develop strategies targeted towards improving host outcomes.

Methods: Hypothesizing that the loss of intestinal CX3CR1⁺ Mø homeostasis contributes to the sustained immune activation seen during SIV or SARS CoV-2 exposure, we analyzed the frequency, phenotype and functionality of colonic Møs expressing CX3CR1 in the following cohorts of CMs: 12 controls, 12 chronically SIV_{mac251}-exposed (SIV+), and 11 animals examined either at acute (7-9 days, n=5) or at the resolved phase (43 days, n=6) post exposure to SARS CoV-2.

Results: The control colons had a predominant population of mature tissue-resident CD64⁺CD14⁺CD11c⁺CX3CR1^{high} Mø. In SIV+ CMs, we observed a significant accumulation of CD14⁺, CD11c⁺, CX3CR1^{low} pro-inflammatory Mø, along with the upregulation of soluble inflammation markers like calprotectin and fractalkine.

Meanwhile, in CMs exposed to SARS CoV-2, colonic CX3CR1^{low} Møs accumulated in the acute phase and correlated with an increase in the intestinal fatty acid binding protein (iFABP) levels, with a concomitant reversal to the CX3CR1^{high} Mø population observed in the resolved phase. However, this reversal seems to be defective with a significant reduction in total Mø frequency at resolution, accompanied by high levels of soluble CD14, fractalkine and calprotectin.

Conclusions: Our results suggest that the maintenance of macrophage homeostasis is vital to the preservation of the GI barrier and the short and long-term response to viral exposures, be it with HIV-1 or SARS CoV-2.

EPA0045

Longitudinal humoral and celular immune responses to mRNA SARS-CoV-2 vaccination in adolescents living with HIV

A. Berzosa Sánchez^{1,2}, M. Illán^{1,2}, S. Villanueva³, A. Ruedas⁴, I. Callejas¹, S. Sánchez-Ramón¹, K. Mohamed¹, L.M. Prieto⁴, C. Epalza⁴, S. Guillén^{5,2}, A.B. Jimenez⁶, S. Jimenez de Ory^{7,2}, R. Sanchez del Hoyo¹, M.L. Navarro^{7,2}, J.T. Ramos Amador^{1,2}
¹Clínico San Carlos Hospital, Paediatrics, Madrid, Spain, ²CIBERINFEC, Madrid, Spain, ³Gomez Ulla Hospital, Madrid, Spain, ⁴Doce de Octubre Hospital, Madrid, Spain, ⁵Getafe Hospital, Madrid, Spain, ⁶Fundación Jiménez Díaz, Madrid, Spain, ⁷Gregorio Marañón Hospital, Madrid, Spain

Background: Children and adolescents living with HIV (ALHIV) might be at risk of severe COVID-19 and candidates for booster vaccines doses. Data on immunogenicity and durability of SARS-CoV-2 vaccines in ALHIV are scarce. More knowledge is needed on the immune response and their protection correlate against SARS-CoV-2 variants. Our aim was to assess the longitudinal evolution of humoral-cellular responses after mRNA vaccination in ALHIV.

Methods: A prospective observational study was performed after mRNA vaccination. Samples were drawn 3-8 weeks (T1) and 6 months (T2) after second dose of mRNA

vaccines in 26 ALHIV and compared to 20 healthy Spanish controls. Humoral response was assessed by SARS-CoV-2 antibodies (chemiluminescent microparticle immunoassay: Alinity® Quant assay-Abbott) detecting IgG against S1 spike protein (≥50 U/mL reactive). T Cell response was measured by IGRA (Euroimmun) of S1 peptide-stimulated T-cells in whole blood (≥200 mIU/ml reactive).

Results: Twenty-six ALHIV (16 female, 25 perinatally-transmission, 14 Spanish origin) were included from 5 hospitals in Madrid, after mRNA vaccination (89% 2 doses) (10 Moderna, 16 Pfizer/BioNTech), between August 2021-March 2022. Median age was 17 (ALHIV) and 15.5 years (controls) (p:0.04). Median baseline CD4 count/nadir were 698/345 cells/ul. All on integrase inhibitors (24 undetectable viral load) ART regimen. 47% ALHIV and 44% controls had documented COVID-19 between T1-T2. All subjects elicited reactive humoral and cellular immune responses. ALHIV had lower anti-Spike titers at T1 (median:14662) than controls (31854)(p:0.018), but not at T2 (11275, controls 10917; p:0.32). IGRA titers were lower in ALHIV (median:1689) than controls (1873) at T1 (p:0.004), but not at T2 (2078, controls 2114; p:0.4). By logistic regression no differences were observed regarding vaccine type, COVID-19 infection between T1-T2 or HIV status.

Conclusions: ALHIV elicit an appropriate humoral and cellular immune response that is maintained at 6 months after mRNA vaccination. Although ALHIV appears to mount a short-term lower quantitative immune response, in the setting of ongoing SARS-CoV-2 infections, the degree of protection at 6 months appears to be similar to healthy controls. Larger and more prolonged studies are needed to determine the need for additional doses of SARS-CoV-2 in ALHIV and the immune correlates for protection.

Immunogenicity of conjugate meningococcal ACWY-TT vaccine in adolescents living with HIV

A. Berzosa Sánchez^{1,2}, S. Guillén^{3,2}, C. Epalza⁴, L. Escosa^{5,2}, M.L. Navarro^{6,2}, L.M. Prieto⁴, T. Sainz^{5,2}, S. Jimenez de Ory^{6,2}, M. Illán^{1,2}, R. Abad⁷, J.T. Ramos Amador^{1,2}
¹Clínico San Carlos Hospital, Paediatrics, Madrid, Spain, ²CIBERINFEC, Madrid, Spain, ³Getafe Hospital, Madrid, Spain, ⁴Doce de Octubre Hospital, Madrid, Spain, ⁵La Paz Hospital, Madrid, Spain, ⁶Gregorio Marañón Hospital, Madrid, Spain, ⁷Microbiology National Centre, Madrid, Spain

Background: Adolescents living with HIV (ALHIV) are at increased risk of meningococcal infection. Conjugate meningococcal vaccines are recommended, but no studies have been conducted on the immunogenicity of MenACWY-TT in ALHIV and a two dose booster schedule might be needed. Aim: to assess MenACWY-TT vaccine response in ALHIV.

Methods: Prospective study conducted in ALHIV in Madrid with the administration of 2 doses of MenACWY-TT(2 months apart) and the assesment of serum bactericidal

antibodies (SBA) assays using rabbit complement. Sera were scheduled to be assessed at baseline, one month and 10 months after second dose. A threshold of hSBA titres of $>1:8$ against C, W-135 and Y groups was considered protective.

Vaccine response was defined as a postvaccination SBA titre of $>1:32$ in initially seronegative subjects ($<1:8$) and a 4-fold increase in titre from pre- to post-vaccination in initially seropositive subjects ($>1:8$). Most adolescents had been previously immunized with a primary series of MenC-conjugate-vaccine in the first year of life.

Results: Twenty-nine adolescents living with HIV were included (17 females (58.6%), median age 16.6 years (IQR 11.4–21.6), 22 (75.8%) perinatally HIV-acquired). At baseline, all on ART, 27 (93%) presented undetectable viral load, median CD4+count was 902 cells/ml (645 – 1070).

Overall, 7 (24.1%), 9 (31%) and 8 (27.6%) subjects had protective antibodies against capsular groups C, W-135 and Y, respectively, at baseline.

One month postvaccination, 25 (86.2%), 26 (89%) and 25 (86.2%) adolescents showed vaccine response for C, W-135 and Y serogroup. Most of them, 21 (72.4%) showed vaccine response to all vaccine serogroups.

After one year, among 24 adolescents who maintained follow-up, 17 (70.8%) had protective antibodies against C capsular group and 23 (95.8%) against W-135 and Y groups. There were no significant differences on viral load, CD4+ count or CDC-classification among adolescents who presented vaccine response (or not), neither among those who maintain (or not) protective antibodies after one year.

Conclusions: Adolescents living with HIV with good immuno-virological status achieve appropriate antibody-mediated protection against serogroups C, W-135 and Y after 2 booster doses of Men ACWY-TT. At 12 months, more than two-thirds of adolescents presented protective antibodies, being this percentage higher for W-135 and Y groups than for C capsular group.

EPA0047

Cryo-EM analysis provide structural insights for broad HIV-1 neutralization by a heavy chain matured antibody from an Indian pediatric elite-neutralizer

S. Kumar^{1,2}, S. Singh², A. Chatterjee³, R. Lodha⁴, S. Dutta³, K. Luthra²

¹International Centre for Genetic Engineering and Biotechnology, ICGEB-Emory Vaccine Center, New Delhi, India, ²All India Institute of Medical Sciences, Biochemistry, New Delhi, India, ³Indian Institute of Science, Molecular Biophysics Unit, New Delhi, India, ⁴All India Institute of Medical Sciences, Pediatrics, New Delhi, India

Background: The structural information of HIV-1 broadly neutralizing antibodies (bnAbs) are currently being used to guide rational vaccine design. The functional and structural features of HIV-1 bnAbs from adults are known

whereas there is a paucity of such information on bnAbs identified from children living with chronic HIV. We previously reported the discovery of a singular pediatric HIV-1 bnAb AIIMS-P01, from an Indian pediatric elite-neutralizer AIIMS_330.

This study aimed to delineate the structure and functional characteristics of AIIMS-P01 matured lineage member(s) to understand the effect of somatic hypermutation in pediatric HIV-1 bnAbs and to provide structural information for vaccine design.

Methods: Herein, we first performed the deep sequencing of total B cells isolated from the peripheral blood mononuclear cells of AIIMS_330 samples collected during 2015–2018 at AIIMS hospital, New Delhi, India. The sequence analysis led to the identification of a heavy chain matured AIIMS-P01 lineage members.

One of the AIIMS-P01 lineage member 44m was further characterized to determine its HIV-1 binding and neutralization potential followed by structural analysis by Cryo-EM in complex with BG505.SOSIP trimer.

Results: In comparison to its wild-type AIIMS-P01 bnAb, 44m exhibited moderately higher level of somatic hypermutations (SHM) of 15.2%. 44m neutralized 79% of HIV-1 heterologous viruses tested, with a geometric mean IC50 titer of 0.36 μ g/ml. The cryoEM structure of 44m Fab in complex with fully-cleaved glycosylated native-like BG505.SOSIP envelope trimer at 4.4 Å resolution revealed that 44m targets the V3-glycan N332-supersite and GDIR motif to neutralize HIV-1 with improved potency and breadth.

Conclusions: Our results showed that broad HIV-1 neutralisation potential exhibited by 44m, is plausibly attributed by a matured heavy chain as compared to that of wild-type AIIMS-P01 bnAb.

This study advances our understanding on the evolution of pediatric HIV-1 bnAbs. The structural basis of broad HIV-1 neutralization by 44m may be useful blueprint for vaccine design in future.

Further studies in this direction are required to be conducted to understand the antigenic triggers in children living with chronic HIV that can elicit bnAbs targeting other HIV-1 bnAb epitopes which in turn can provide simpler blueprint to guide HIV-1 vaccine design.

**EPA0048****Feasibility of iNKT cells as an immunotherapeutic HIV cure intervention**

M. Khan¹, C. Herrera², H. Ren³, M. Pardons⁴, A. Rowan²,
A. Karadimitris³, S. Fidler², J. Thornhill¹

¹Queen Mary, University of London, Immunobiology, Blizard Institute, London, United Kingdom, ²Imperial College London, Department of Infectious Disease, London, United Kingdom, ³Imperial College London, Department of Immunology and Inflammation, London, United Kingdom, ⁴Ghent University, Faculty of Medicine and Health Sciences, Ghent, Belgium

Background: Innovative approaches are needed to achieve a functional HIV cure. Invariant-natural-killer T-cells (iNKTs) are an innate-like T-cell subset that express an invariant T-cell receptor which are not restricted to polymorphic HLA and therefore may provide an allogenic or "off the shelf" immunotherapy.

Understanding the anatomical distribution and the potential for HIV infection of iNKTs is essential to assess the feasibility of their use in HIV.

Methods: Peripheral Blood Mononuclear Cells (PBMCs) were collected from people with HIV (PWH) and controls. Colonic tissue from controls undergoing bowel resection was digested into a single cell suspension using collagenase. Flow cytometry was used to assess the expression of TCR Vα24-Jα18, TCR Vβ11, CD3, CD45 & CXCR5. iNKTs were expanded and used for in vitro infection by HIV_{BAL}. p24 was measured by Flow Cytometry and ELISA.

Results: The frequency of iNKTs in PBMCs as a proportion of CD45+CD3+ single cells (n=43) varied widely by donor (mean 0.08%; SD 0.13%; range 0.01-0.68%).

The median frequency of iNKTs in PBMC was similar in PWH (n=33; median 0.04%) compared to controls (n=10; median 0.02%, P=0.25). iNKT cells were more frequent in colon tissue (n=7; median 0.31%) compared to peripheral blood (n=43; median 0.03%, P<0.0001).

Median CD4 expression on iNKTs was 43% on PBMCs and 27% in colon, with increased CXCR5 in tissue. In vitro infection of expanded iNKTs demonstrates p24 positive iNKT cell populations primarily in the CD8 negative iNKTs but not in CD8+ iNKTs (Figure 1).

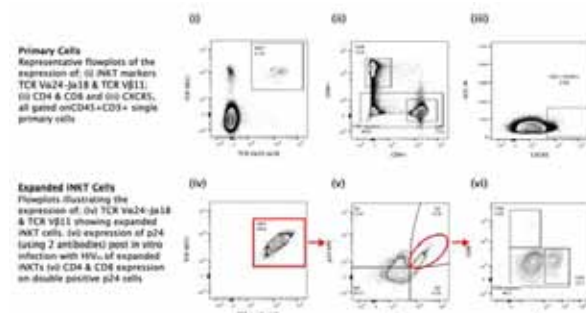

Figure 1.

Conclusions: iNKTs are present at higher frequencies in the HIV reservoir of the gut with expression of markers which facilitate access to the germinal centre.

However, CD8 negative iNKT are potential targets for HIV infection. These data suggest that CD8+ iNKT cells are a potential immunotherapeutic agent.

EPA0049**HIV vaccine candidate efficacy mediated by epigenetic changes in CD14⁺ cells and cAMP-dependent efferocytosis**

M. Bissa¹, S. Kim², S. Fourati³, S. Sarkis¹, I. Silva de Castro¹,
M.A. Rahman¹, S. Fujiwara², M. Vaccari¹, J.A. Tomalka³,

G.L. Hager², G. Franchini¹

¹National Institutes of Health, NCI CCR VB AMRVS, Bethesda, United States, ²National Institutes of Health, NCI CCR LRBGE, Bethesda, United States, ³Emory University, Department of Pathology, Atlanta, United States

Background: The DNA/ALVAC-SIV/gp120 vaccine significantly decreased the risk of SIV_{mac251} acquisition. CD14⁺ monocytes and the Antibody-dependent cellular cytotoxicity to the V2 (V2-ADCC) of SIV were correlated with reduced risk of acquisition, indicating the central role of innate response in mounting an effective response to vaccination.

We hypothesized that in-depth understanding of the innate and adaptive responses to vaccination will elucidate mechanisms of protection and will allow to increase vaccine efficacy.

Methods: To test this hypothesis, we integrated different analyses conducted in two separate macaque studies to elucidate how the innate and adaptive responses cooperate in reducing the risk of SIV_{mac251} acquisition. Animals were immunized with the DNA/ALVAC-SIV/gp120 based-vaccines and exposed to SIV_{mac251}.

Analyses of samples collected from vaccinated macaques included canonical assays (ADCC, cell analysis by flowcytometry and CD14⁺ efferocytosis) together with multi-omics (RNA- and ATAC-sequencing).

Results: The study of the vaccine-induced changes of transcriptome and the epigenetic landscape of CD14⁺ cells showed that epigenetic reprogramming of enhancer region surrounding *CREB1* gene was associated with reduced risk of acquisition and V2-ADCC.

Additionally, we found that, efferocytosis, a cyclic AMP (cAMP)-dependent process of CD14⁺ monocytes that clear engulfed apoptotic cells, is a novel correlate of reduced risk of SIV_{mac251} acquisition that complements V2-ADCC. The study of CD4⁺ T-cells responses elicited by vaccination identified that the frequency of CD4⁺ T-cells expressing the chemokine receptor CXCR3⁺ is a correlate of decreased risk of acquisition and that these cells could migrate in the mucosa where they lower the susceptibility to infection.

Additionally, these cells were associated with the V2-ADCC and the increased accessibility to *CREB1* gene identified in the CD14⁺ cells, suggesting the ability of vaccine-induced innate and adaptive responses to influence each other.

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

The study of the vaccine-induced changes of transcriptome and the epigenetic landscape of CD3⁺ cells identified 35 genes whose expressions and accessibility were either decreased or increased in the animals with delayed acquisition.

Conclusions: All together these data suggest that epigenetic reprogramming in immune cells, and their effect on V2-ADCC and efferocytosis, contribute to vaccine efficacy by decreasing inflammation and maintaining tissue homeostasis, and therefore counteract the SIV acquisition.

EPA0050

Post-treatment controllers exhibit distinct CD8⁺ T cell features before and after ART interruption

T. Ma^{1,2}, A. George^{1,2}, R. Thomas³, M.-G. Shin³, B. Etemad⁴, Y. Li⁴, S. Deeks⁵, J. Li⁴, N. Roan^{1,2}

¹Gladstone Institutes, Virology, San Francisco, United States, ²University of California, San Francisco, Urology, San Francisco, United States, ³Gladstone Institute, Data Science and Biotechnology, San Francisco, United States, ⁴Brigham and Women's Hospital, Medicine, Boston, United States, ⁵University of California, San Francisco, Medicine, San Francisco, United States

Background: Rare individuals, termed HIV post-treatment controllers (PTCs), can exhibit prolonged periods of viral control upon ART withdrawal, but the mechanisms by which this occurs remain poorly understood.

In this study, we assessed whether PTCs exhibit unique T-cell properties.

Methods: A 40-parameter CyTOF panel was developed to characterize the differentiation, activation, and other phenotypic features of T cells. The panel was applied to PBMCs collected on ART and prior to treatment interruption from clinically matched PTC (n=20) and non-controller (NC) participants (n=32).

In addition, post-interruption specimens were analyzed to characterize differential features between PTCs and NCs off ART. CyTOF datasets were gated on T cells, and clustered and mixed effects models were used to identify associations with PTC/NC status.

Results: By implementing cluster-resolution optimization, we identified nine distinct T cell clusters. Prior to ART interruption, one cluster was significantly less abundant in subsequent PTCs than NCs. This cluster consisted of memory CD8⁺ T cells expressing high levels of PD1 and TIGIT, suggesting immune exhaustion.

After ART interruption, a separate cluster comprised predominantly of activated CD8⁺ Temra cells expressing high levels of the pro-survival factor BIRC5 significantly increased in abundance in PTCs, while it exhibited the opposite pattern in NCs.

We also found post-ART that NCs harbored a larger proportion of a cluster that was comprised of CD4-CD8- T cells expressing high levels of Tfh marker CXCR5 and activation marker CD30, both previously shown to be increased on HIV-infected cells.

Conclusions: Our data suggest that prior to interrupting ART, people who subsequently control HIV exhibit lower frequencies of exhausted CD8⁺ T cells, which may enable these individuals to better control HIV replication upon ART cessation. After ART interruption, a population of activated CD8⁺ Temra expressing BIRC5 expands in PTCs but not NCs; theoretically, these cells might persist longer and be able to maintain more direct virus control.

Post-ATI viremia in NCs is associated with a population of CD4-CD8- T cells expressing antigens associated with HIV-infected cells; ongoing work seeks to determine whether these cells are productively-infected with HIV.

EPA0051

Specific immunological response after administration of anti-meningococcal quadrivalent conjugate vaccine MENVEO® in a population of vertically HIV-infected children, adolescents and young adults

M. Stracuzzi¹, C. Vanetti², C. Fenizia³, F. Ardizzone⁴, I. Saulle⁴, M. Biasin⁴, M. Clerici³, G. Zuccotti⁵, D. Trabattoni¹, V. Giacometti¹

¹Università degli Studi di Milano, Luigi Sacco Hospital, Pediatric Infectious Diseases, Milan, Italy, ²Università degli Studi di Milano, Luigi Sacco Hospital, Department of Biomedical and Clinical Sciences, Milan, Italy, ³Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy, ⁴Università degli Studi di Milano, Department of Biomedical and Clinical Sciences, Milan, Italy, ⁵Università degli Studi di Milano, V. Buzzi Hospital, Pediatric Department, Milan, Italy

Background: It is recommended that PLWH aged ≥2 months should routinely receive meningococcal conjugate vaccine. However, HIV-subjects, because of immune abnormalities, may undergo impaired vaccine response. Our study aims to assess humoral and cell-mediated immune responses after the administration of a quadrivalent meningococcal conjugate vaccine Menveo® (MenAC-WY-CRM, GlaxoSmithKline Vaccines) in HIV-infected young patients.

Methods: We carried out a controlled, non-randomized, observational and prospectively study, involving 27 HIV-infected patients aged 9–30 years, reporting vertically-transmitted HIV infection and followed at the Pediatric Infective Disease Clinic of Luigi Sacco Hospital, Milan.

All patients enrolled were on ART, and 25 out of 27 presented optimal immunological and viral response. Each subject received the vaccine Menveo (0,5 ml i.m.).

MenACWY-specific Ab titer, viral load, and CD4⁺ T cells count were measured at baseline (T0), T3, T6 and T12 months post vaccination. MenACWY-specific cell-mediated immune responses were evaluated at the same time points.

Results: Menveo induced seroconversion in 26 out of 27 subjects. We divided our cohort in different subgroups: Responders (R), reporting seroconversion at T3, Highly-

Responders (HR) with a high Ab titer at T0, and Non-Responders (NR). The administration of the vaccine induced MenACWY-specific immunological memory mainly in R and HRs: CD4+ (at T12) and CD8+ (at T3 and T12) T Central Memory. MenACWY-specific TNF α -, IFN γ - CD8+ T cells and IL2-secreting CD4+ T cells were increased in Rs and HRs at T3 and T6.

However, at T12, this effect was slightly decreased. In the NR group, terminally-differentiated CD4+ and CD8+ T cells were the only parameters modified.

Conclusions: The administration of Menveo® vaccine induced a valid antibody-mediated protection in both the R and HR subgroups. We observed the development of a stable T cell-mediated immune memory that lasted robustly up to one year since vaccination in most of the subjects analyzed. Furthermore, we observed increased CD8+ CTL functions specifically in Rs and HRs, with significant increases of TNF α and IFN γ secretion.

The lack of Menveo-specific immune response, observed in the NR subject, is associated with a low compliance to the therapy and high viremia. Our data indicate that alternate immunization schedules need to be considered in ART-non-responder patients.

EPA0052

Costimulation with MAdCAM and retinoic acid generates the formation of gut tissue resident memory CD8 T cells that express E-cadherin

C. Cicala¹, S. Vimontpatranon², D.W. Huang³, A. Jiang², C. Huang³, K. Virtaneva², L. Goes², A. Chan², I. Licavoli², J. McMurry², D. Wei², A. Fauci², J. Arthos²

¹NIH, NIAID, Bethesda, United States, ²NIAID, Bethesda, United States, ³NCI, Bethesda, United States

Background: Tissue resident memory cells (T_{RM}s) function as a first line of defense against invading pathogens. Although they hold the potential to play an important role in preventing HIV acquisition, they are difficult to study. Sampling these cells is difficult, and there is no established method to generate them in vitro.

The two principal markers of T_{RM}s are CD69 and CD103 (in the form of $\alpha_E\beta_7$). We have established a system to generate CD8+ T_{RM}s in vitro.

Methods: Primary CD8+ T cells isolated from healthy donors were costimulated with a panel of non-canonical costimulatory ligands including CD80, CD86, MAdCAM and VCAM to generate memory CD8+ T cells with distinct differentiation patterns. Retinoic acid (RA) and TGF- β were also employed. Gene expression profiling (RNAseq), cytokine profiling (Luminex) and multi-parameter flow cytometry were employed to characterize differentiated cells. We employed FRET (FLIM) imaging to evaluate CD103 association with E-cadherin.

Results: Among the different costimulatory ligands we evaluated, MAdCAM and anti CD28, when combined with RA and TGF- β , both generated CD8+ cells that expressed CD69, CD103, CCR9 and $\alpha_E\beta_7$, indicating T_{RM}s with a gut

homing phenotype. Transcriptional profiling by RNAseq provided further evidence that these cells adopted a T_{RM}-like phenotype. Of note, a subset of these cells also expressed E-cadherin, the natural ligand of CD103. The presence of E-cadherin suggests the upregulation of an inhibitory ligand as a regulatory mechanism.

Conclusions: This study provides a novel way to generate CD8+ T_{RM}s from primary peripheral blood CD8+ T cells. MAdCAM, when combined with RA and TGF- β generated cells with a phenotype consistent with gut homing. Up-regulation of E-cadherin suggested a novel regulatory mechanism for T_{RM} residency. These findings can provide new ways to evaluate immune-based mechanisms to prevent HIV acquisition.

Understanding and targeting persistent HIV reservoirs

EPA0053

Identification of novel PTPN1/PTPN2 inhibitors to target latent HIV reservoirs

C. Levinger¹, J.N. Howard¹, C. Holmberg¹, D. Copertino², E. McMahon¹, R.B. Jones², A. Bosque¹

¹The George Washington University, Microbiology, Immunology and Tropical Medicine, Washington DC, United States, ²Weill Cornell Medicine, Department of Infectious Diseases Division of Medicine, New York, United States

Background: 3-Hydroxy-1,2,3-Benzotriazin-4(3H)-one (HODHBt) is a latency reversal agent (LRA) that enhanced γ c-cytokine signaling by increasing phosphorylation and transcriptional activity of STAT5. We have shown that HODHBt increases IL-2 and IL-15 activation of STAT5, promoting reactivation from latency in a primary cell model and cells isolated from people living with HIV. Furthermore, we have shown that HODHBt enhances IL-15 mediated NK and CD8T cell effector function.

Recently, we used cellular-thermal shift assay followed with mass-spectrometry (CETSA-MS) to uncover the HODHBt target. We have found that HODHBt binds and inhibits the catalytic domain of the phosphatases PTPN1 and PTPN2. In spite of the positive properties of this class of compounds towards developing HIV cure approaches, their activity in the high micromolar range hinders further pharmacological development.

In here, we aimed to identify novel inhibitors and/or novel scaffold molecules targeting PTPN1/PTPN2 that could be further developed towards HIV cure strategies

Methods: We used an *in vitro* fluorogenic enzymatic assay to screen for compounds that inhibit PTPN1 and PTPN2. We tested 52 HODHBt derivatives and 94 known phosphatase inhibitors. Those with higher activity than HODHBt were then tested for their ability to enhance IL-2 mediated STAT5 transcriptional activation in the HEK-Blue IL-2 cell line.

Results: From the 146 tested compounds, we have identified one HODHBt derivative and two phosphatase inhibitors with enhanced activity relative to our lead compound HODHBt. These compounds inhibit both PTPN1 and PTPN2 *in vitro* and have increased activity to enhance STAT5 transcriptional activity compared to HODHBt in the low micromolar range.

Figure. Identification of novel phosphatase inhibitors to target PTPN1 and PTPN2.

Conclusions: In conclusion, we have identified novel PTPN1/PTPN2 inhibitors with improved pharmacological capabilities that our lead compound HODHBt. Further medicinal chemistry and validation in *ex vivo* and *in vivo* models of HIV latency is currently underway.

P400/Tip60 chromatin remodeling complex in HIV transcription and latency establishment

S. Valente¹, C. Li², L. Mori², T. Venables², R. Bronson², P. Mathew²

¹UF Scripps Biomedical Research, Immunology and Microbiology, Jupiter, United States, ²UF Scripps Biomedical Research, Jupiter, United States

Background: Current HIV cure approaches, such as the block-and-lock and shock-and-kill strategies, depend on a complete understanding of the regulation of HIV transcription and the surrounding chromatin environment. There are ~320 chromatin regulatory factors (CRFs) that alter chromatin structure in a complex process, and characterization of chromatin regulators' roles in HIV transcription will potentiate development of multiangled approaches towards HIV transcriptional regulation.

Methods: We performed a pooled RNAi screen utilizing shRNAs embedded in a microRNA backbone (shRNAmirs) to probe all human CRFs simultaneously in the J-Lat 10.6 HIV latency model. Following hit identification, we validated the role of EP400 complex (TIP60/NuA4 complex) in various latency models by a combination of knockdown, overexpression, and mutational studies. The binding of the EP400 complex on HIV DNA were analyzed by native ChIP-PCR, and ChIP-seq and RNA-seq were used to characterize genome-wide EP400 complex transcriptional regulation.

Results: EP400 was identified in our pooled RNAi screen as a key regulator of HIV latency. RNAi of EP400 and the other components of the EP400 complex (DMAP1, BRD8, KAT5, EPC1, TRRAP) led to significant HIV reactivation, suggesting this complex is involved in maintaining transcriptional silencing of HIV provirus. RNA-seq analysis revealed that

HIV transcripts were the highest and most significantly upregulated genes upon EP400 and DMAP1 RNAi. A dual colour HIV vector (HIVGKO) was used to segregate active and latent HIV infected cells. A significantly larger proportion of integrated cells were found to be actively transcribing HIV, while a smaller proportion was latent upon EP400 complex RNAi, suggesting that EP400 complex regulates HIV latency establishment. EP400 complex associates with the proviral DNA with a peak at the HIV 5'LTR, suggesting this complex may regulate HIV transcription directly.

Interestingly, there was a high degree of concordance between RNAPII, EP400 and DMAP1 binding genome-wide by ChIP-seq, suggesting this complex might directly associate with and regulate RNAPII. This result is supported by Co-IP studies revealing an association of EP400 complex with RNAPII.

Conclusions: EP400 complex plays a previously unappreciated important role in silencing HIV transcription, it appears to act directly at the HIV LTR to negatively regulate HIV transcription.

EPA0055

Developing an ultrasensitive assay to quantify HIV-1 envelope protein in different matrixes

S. Deletsu¹, T. Murphy¹, R. Lynch¹, A. Bosque¹

¹The George Washington University, Microbiology, Immunology and Tropical Medicine, Washington, United States

Background: Recent advances have enabled the discovery, characterization, and commercial development of broadly neutralizing antibodies (bNAbs), a promising immunotherapy in HIV-1 treatment and/or cure research. One important mechanism of action of antibodies is their ability to opsonize and tag infected cells for antibody-dependent cellular cytotoxicity or phagocytosis (ADCC/ADCP) by immune effector cells.

Although the role for ADCC in protection from and control of HIV-1 infection has been demonstrated, bNAb mediated clearance of infected cells during analytic treatment interruption (ATI) has not been clearly shown to date, likely from lack of Env protein expression during suppressive ART.

Inadequate knowledge about the level of viral protein expression during HIV latency prevents effective use of therapeutics to target latent reservoirs. The ability to detect low level Env protein expression in cells will fill this gap.

Methods: Using the Quanterix SP-X platform, we have developed a homebrew assay to detect and quantify envelope protein in diverse matrixes. This is an assay that can be modified in-house to use any two sets antibodies and therefore is customizable.

Results: First, with an assay reproducibility of R²>0.99, we successfully detected monomeric YU-2 gp120 at LODs of 45-70fg/mL using a 3BNC117/10-1074 capture and detector antibody pair.

Next, we tested our ability to detect trimeric envelope spike on 2 pseudoviruses with neutralization sensitive and resistant IC80s to 10-1074. As expected, Env on the neutralization resistant pseudovirus was undetected. Finally, we evaluated detection of Env in cell lysates of ex vivo CD4⁺T cells infected with an infectious molecular clone expressing YU-2 Env or mutant YU-2 Env resistant to 10-1074. Infected cells were lysed in NETN lysis buffer, evaluated for Env expression and the IV signal normalized to the p24 levels in the lysates. We detected HIV Env protein in wild-type virus infected cells, but not in the resistant virus infected CD4T cells.

Conclusions: This assay will be an additional molecular tool which can be used to determine the expression of Env within the latent reservoir.

Importantly, the binding phenotype matches the neutralization sensitivity of the detector bNAb. This assay will provide more insight into the effectiveness of latency reversal agents.

HIV proviral reactivation is impaired in effector memory CD4⁺ T cells by immunometabolic reprogramming with dasatinib

G. Casado Fernández^{1,2,3}, M. Martínez Velasco⁴, S. Rodríguez Mora^{1,3}, M. Torres¹, C. Sánchez Menéndez^{1,5}, A. Simón Rueda^{1,6}, M. Cervero⁷, C. Hoffmann⁸, C. Wyen⁹, E. San José⁴, V. Planelles¹⁰, M. Coiras^{1,3}

¹Instituto de Salud Carlos III, Immunopathology Unit-National Center of Microbiology, Madrid, Spain, ²Universidad de Alcalá, Faculty of Sciences, Madrid, Spain, ³Biomedical Research Center Network in Infectious Diseases (CIBERINFEC), Madrid, Spain, ⁴Universidad Europea de Madrid, Health Sciences Department, Faculty of Biomedical and Health Sciences, Madrid, Spain, ⁵Hospital Universitario Ramón y Cajal, Hematology and Hemotherapy Service, Madrid, Spain, ⁶Universidad Complutense de Madrid, Faculty of Sciences, Madrid, Spain, ⁷Hospital Universitario Severo Ochoa, Internal Medicine Service, Madrid, Spain, ⁸ICH Study Center, Hamburg, Germany, ⁹University Hospital of Cologne, Department of Medicine I, Cologne, Germany, ¹⁰University of Utah School of Medicine, Division of Microbiology and Immunology, Department of Pathology, Salt Lake, United States

Background: We evaluated the use of dasatinib as latency promoting agent (LPA) by reducing the metabolic activity of viable CD4 cells to interfere with HIV reservoir replenishment.

Methods: CD4 from PLWH and healthy donors were isolated and provirus was reactivated \pm dasatinib 75nM 72h. Phosphoproteome was analyzed by LC-MS/MS. Mitochondrial ATP was quantified every 24h. Phosphoglucose-2 (PGM2), pyruvate kinase M1/2 (PKM), aldolase (ALDOA), glyceraldehyde-3-phosphate dehydrogenase (GAPDH) activities were analyzed by ELISA.

Fluorescent glucose analog 2-NBDG uptake, GLUT-1 expression, T-cell memory subpopulations distribution, and T-cell viability were determined by flow cytometry.

Results:

1. Dasatinib decreased proviral reactivation 2.47-fold ($p=0.0469$) in CD4 from PLWH.
2. Dasatinib modified phosphorylation of >130 proteins involved in metabolic pathways: energy metabolism, glycolysis/glyconeogenesis, inositol-phosphate metabolism, fatty-acid synthesis.
3. Dasatinib interfered with phosphorylation of 4 essential enzymes that belong to irreversible steps of glycolysis and tricarboxylic acid (TCA): PKM (-4.63 ; $p=0.002$), PGM2 (-1.74 ; $p=0.020$), ACS2 (Acyl-CoA Synthetase Short Chain Family Member 2) (-3.48 ; $p=0.031$), and ACACA (Acetyl-CoA Carboxylase Alpha) (-3.06 ; $p=0.017$).
4. Three proteins from reversible steps of glycolytic pathway showed increased phosphorylated status after dasatinib treatment: Aldolase ($+4.34$; $p=0.040$), GAPDH ($+2.76$; $p=0.033$), and Enolase-1 (ENO1) ($+1.94$; $p=0.014$).
5. Dasatinib decreased the activity of GAPDH (3.15-fold; $p=0.0379$) and ALDOA (4.70-fold; $p=0.0416$); PKM and PGM2 enzymatic activity was unmodified.
6. Dasatinib reduced 2.1-fold ($p=0.0112$) mitochondrial ATP in viable CD4 cells in correlation with reduced susceptibility to provirus reactivation.
7. Dasatinib interfered with GLUT-1 expression (Figure 1) and glucose uptake in all CD4 memory subpopulations, including TEM and TEMRA. NK remained metabolically active.
8. PLWH on ART and dasatinib showed reduced CD4 TEM and TEMRA subpopulations with decreased metabolic activity.

Figure 1.

Conclusions: Dasatinib acts as LPA by inducing resting state in viable CD4 cells with stalled glycolysis and mitochondrial ATP synthesis, impeding both HIV infection and reservoir reactivation, while NK cells remained unaffected. Treatment with dasatinib and ART may silence the viral reservoir as a block&lock strategy.

EPA0057

Mauritian cynomolgus macaques are a unique model of post-treatment control of SIV replication

S. O'Connor¹, O. Harwood¹, R. Moriarty¹, A. Ellis¹,
L. Matschke¹, A. Balgeman¹, M. Reynolds¹

¹University of Wisconsin-Madison, Madison, United States

Background: Maintaining control of HIV replication without antiretroviral treatment (ART) is the goal of a functional HIV cure. The underlying virologic and immunologic mechanisms of post-treatment control (PTC) are poorly understood. SIV+ rhesus macaques rarely become PTCs, hindering this research.

We discovered that SIV+ Mauritian cynomolgus macaques (MCMs) that started receiving ART at two weeks post-SIV infection frequently become PTCs. This serendipitous discovery occurred when evaluating if a therapeutic vaccine could prolong viral rebound.

Methods: We infected 8 MCMs intravenously with a high dose of barcoded SIVmac239M. We started treating the animals with ART at two weeks post-infection to minimize the size of viral reservoirs while initiating antiviral immune responses. None of the animals expressed MHC alleles associated with spontaneous SIV control. Four animals received the therapeutic vaccine regimen, while four did not. We suspended ART after ~eight months and measured SIV plasma viremia. After stopping ART, we intravenously challenged animals with SIVmac239, and then all animals were depleted of CD8a+ cells after SIVmac239 challenge.

Results: Remarkably, 7 of 8 MCMs either had undetectable or low level (<1e4 copies/ml) transient viremia for six months after stopping ART, independent of the vaccine regimen. Plasma viremia was largely unaffected by SIVmac239 rechallenge.

After receiving the CD8a-depleting antibody, all eight animals developed high levels of SIV plasma viremia (>5e5 copies/ml), demonstrating that SIV PTC was mediated by CD8a+ cells.

We performed intact proviral DNA assays from 14 days after infection to estimate the viral reservoir. We found that the number of cells with intact proviral SIV DNA during acute infection was ~1 log smaller than in similarly infected SIV+ rhesus macaques.

Conclusions: We find that SIV+ MCMs can develop PTC that does not depend on host MHC genetics. Two features contributed to PTC in MCMs:

1. A small number of cells containing intact proviral DNA during acute infection and;
2. The presence of antiviral CD8a+ cells capable of suppressing SIV replication after ART cessation.

We suggest that SIV+ MCMs are a unique model of PTC to understand the immune-mediated mechanisms of post-ART control of SIV/HIV replication.

EPA0058

Impact of IL-15 neutralization on neuropathogenesis in acute HIV/SIV infection

C.S. Tan¹, R. Gopalakrishnan², M. Aid¹, N. Mercado²,
C. Davis², R. Jones³, V. Varner², M. Lifton², K. Knoll³,
S. Bosinger⁴, D. Barouch¹, B. Keele⁵, D. Ram¹, R.K. Reeves³

¹Harvard Medical School, Boston, United States, ²Beth Israel Deaconess Medical Center, Boston, United States, ³Duke University, Durham, United States, ⁴Emory University, Atlanta, United States, ⁵Frederick National Laboratory for Cancer Research, AIDS and Cancer Virus Program, Frederick, United States

Background: Immune responses mounted in the CNS during acute HIV/SIV infection are insufficient to prevent viral seeding and reservoir establishment. The pleiotropic cytokine IL-15 plays a crucial role in anti-viral immune response by stimulating NK and CD8+ T cells to control HIV/SIV infection.

However, the effects of IL-15 on the CNS are largely unknown. Experimental neutralization of IL-15, leading to the depletion of NK and T cells, could significantly influence the viral pathogenesis in the brain, alter reservoir formation, and clarify the role of IL-15 in lentivirus disease.

We comprehensively evaluated brain immune and inflammatory responses to acute SIV infection with and without IL-15 neutralization in a nonhuman primate model.

Methods: Rhesus macaques (*Macaca mulatta*) were administered two doses of rhesusized monoclonal antibodies against IL-15 (anti-mRh-IL-15) at days -21 and -7 prior to challenge with SIVmac239X (day 0) and necropsied at 7 and 14 days post-infection (dpi). Peripheral and brain viral load were quantified by qPCR and RNAscope.

Sequencing analysis of viral clones were obtained from several brain regions and compared to those in blood and peripheral lymph nodes. CNS histopathology were analyzed by immunohistochemistry in combination with in situ hybridization. Transcriptomic analyses were performed on brain tissue.

Results: While anti-mRh-IL-15 treatment depleted NK cells from blood and increased virus replication, there was no significant differences in the quantities of SIV RNA or DNA in the brain on either 7 and 14 dpi. Barcoded virus detected in the blood and brain showed clonal expansion restricted to anatomical brain regions.

For brain resident cells, peripheral neutralization of IL-15 resulted in increased microglial activation with infection. While blood T cells were unaltered with IL-15 neutralization, CD8+ T cells decreased in brain, which may have led to an altered balance of local pro- and anti-inflammatory responses, where significantly fewer microglia cells expressed the proinflammatory cytokine - IL-6, and higher numbers of macrophages expressed the anti-inflammatory cytokine- TGF- β , and decreased M2 macrophage gene pathway activation.

Conclusions: IL-15 neutralization altered CNS immune and inflammatory responses to acute SIV infection by

Effect of sex and HCV on microRNA profile as a biomarker of HIV viral reservoir

S. Grande García¹, D. Valle Millares¹, V. Lara Aguilar¹, C. Crespo Bermejo¹, M.J. Llamas Adán¹, L. Martín Carbonero², P. Ryan³, I. de los Santos⁴, L. Domínguez Domínguez⁵, V. Briz¹, A. Fernández Rodríguez¹

¹National Center of Microbiology, Carlos III Health Institute, Viral Hepatitis Reference and Research Laboratory, Majadahonda, Spain, ²Hospital La Paz, Institute for Health Research, Madrid, Spain, ³Infanta Leonor Teaching Hospital, Internal Medicine Service, Madrid, Spain, ⁴Hospital Universitario de la Princesa, Internal Medicine Service, Madrid, Spain, ⁵Research Institute Hospital 12 de Octubre, HIV Unit Internal Medicine Service, Madrid, Spain

Background: Identifying reliable and non-invasive biomarkers of the HIV reservoir size, a major barrier to functional HIV cure, is crucial. MicroRNAs are key regulatory molecules that play a relevant role in HIV expression, latency and reactivation. HCV acquisition is common in PLWH, modifying both the host expression profile of microRNAs and the functional phenotype of the immune system. We aim to identify microRNAs as biomarkers of HIV reservoir, considering factors such as HCV coinfection and sex.

Methods: We massively sequenced the microRNA profile of PBMCs from 119 PLWH recruited from 5 Public hospitals from Madrid, Spain:

- i. 36 PLWH never exposed by HCV;
- ii. 36 PLWH who spontaneously eradicated HCV;
- iii. 47 PLWH chronically infected with HCV.

Nested Alu-LTR-PCR was used to measure HIV-reservoir size in resting CD4⁺ T cells. A linear regression model was applied to study the association of microRNAs with the reservoir size, considering HCV exposure and sex.

For those microRNAs involved in significant associations with reservoir size (p-value < 0.05 and arithmetic mean ratio AMR >1.1 or <0.9) pathway enrichment analysis was performed to identify their target routes.

Results: All PLWH showed similar characteristics (mean age =49.83 years, 55% male). 26 microRNAs were associated with HIV reservoir in rCD4⁺ T cells in all PLWH. Pathway enrichment analysis showed potential target routes for these microRNAs such as fatty acid metabolism, prion diseases, and cancer development. After analyzing PLWH by HCV exposure, we identified different microRNA profiles associated to reservoir size in each HIV group.

In addition, we found that sex significantly influences the reservoir size of non HCV exposed PLWH, where women showed significantly smaller levels (AMR=0.3; p=0.041)

than men. Analysis by sex showed different microRNAs associated with reservoir size among sexes, where men showed higher SDE miRNAs. Each of the association analysis pointed to miR-29, which has been previously characterized interacting with HIV.

Conclusions: HCV exposure and sex deeply influence the association of PBMCs-derived miRNAs with HIV reservoir. miR-29 isoforms could act as a generic biomarker of reservoir size in PLWH regardless of HCV co-infection and sex as it directly interacts with the HIV genome.

EPA0060

Distinct detection of intact and defective proviruses for people living with HIV subtype B and C

N.V. Buchholtz¹, M.M. Nühn¹, D. de Jong¹, A.M. Wensing^{1,2}, J. Symons¹, M. Nijhuis^{1,3}

¹University Medical Center Utrecht, Translational Virology, Department of Medical Microbiology, Utrecht, Netherlands, ²University of the Witwatersrand, Ezinthsa, Faculty of Health Sciences, Johannesburg, South Africa, ³University of Witwatersrand, HIV Pathogenesis Research Unit, Faculty of Health Sciences, Johannesburg, South Africa

Background: To increase equity in HIV cure strategies it is important to study the dynamics and size of the intact and defective reservoir of the dominant HIV-1 subtype C. Monitoring the impact of cure interventions demands an assay that offers sensitive and specific quantification of large numbers of clinical samples and can be implemented in resource limited settings. We adapted the Intact Proviral DNA Assay (IPDA) for the detection of HIV-1 subtype B and C.

Methods: Primers and probes were strategically positioned at conserved regions of packaging signal (psi) and envelope (env) for both subtypes. DNA G-blocks and clinical isolates were used to test the efficacy of the primers. Various annealing temperatures were explored to address the impact of HIV sequence variability. Reconstruction experiments were performed with PBMCs to determine the limit of blank (LoB) and dilution series of G-blocks to determine the limit of detection (LoD).

Results: Comparable efficacy in detection of both subtypes was found for the primers and probes tested on G-blocks and clinical isolates. The LoB of intact DNA was 0 copies, and LoD 6 copies with >95% certainty at 60°C, quantification of 2-5 copies had a certainty of 83%-93% (n≥40). Comparable LoBs and LoDs were observed for detection of 5'-defective and 3'-defective DNA.

Lowering the annealing temperature from 60°C to 55°C resulted in a minor increase of defective LoB but improved detection of samples with polymorphisms.

Mixture experiments with intact and defective DNA demonstrated correct quantification when the mixture contained 5% intact in the background of defective DNA.

Oral
abstractsPoster
exhibition

E-posters

Late-breaker

Conclusions: This robust pan-subtype B-C IPDA enables detection of intact and defective DNA with >95% certainty when at least 7 DNA copies are present at an annealing temperature of 60°C. Lowering the annealing temperature to 55°C might be helpful, depending on the desired specificity of the study.

As the number of intact DNA copies decreases after start of treatment, it is important to note that 2-5 copies can still be quantified with >80% certainty. Thus, the pan-subtype B-C IPDA is an ideal candidate to monitor the impact of cure-interventions in (large-scale) clinical studies.

Young adults with perinatally-acquired HIV from Argentina present differential IPDA-determined HIV reservoir composition and immune phenotype: distinctive strategies needed for HIV cure?

L. Baquero¹, M. Armani-Tourret², A. Perbelis¹, S. Stover¹, A. Urioste¹, A. Sisto³, M.J. Rolon³, J. Lattner³, P. Coll³, A. Czernikier¹, V. Gonzalez Polo¹, P. Benencio¹, A. Osegueda¹, Y. Ghiglione¹, M. Lichterfeld², G. Turk¹, N. Laufer^{1,3}

¹CONICET-Universidad de Buenos Aires. Instituto de Investigaciones Biomédicas en Retrovirus y Sida (INBIRS), Ciudad Autónoma de Buenos Aires, Argentina, ²Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, ³División de Infectología. Hospital General de Agudos Dr. Juan A. Fernández, Ciudad Autónoma de Buenos Aires, Argentina

Background: Overall data on young adults with perinatally-acquired HIV (p-HIVYA) is scarce. We have previously reported that p-HIVYA exhibited lower frequencies of PD-1+ T-cells, and higher rates of naïve CD4 T-cells (n-CD4TC) compared to people with HIV (PWH, non-perinatally-acquired). Here, we aimed to perform a deeper characterization of their immune phenotype and HIV-reservoir composition.

Methods: Total, intact and defective proviral (TP, IP and DP) HIV-DNA/1M CD4TC were measured by IPDA in 16 p-HIVYA (20-30-years-old) and 27 PWH: 12 age-paired controls (AC) and 14 time from HIV-diagnosis paired controls (TDC). All participants were Argentinians enrolled between April-2019/December-2022; all on suppressive ART. Immune phenotype (differentiation, exhaustion, activation, PTK-7 and Ki-67 expression) was evaluated by flow cytometry. Data was analyzed using Kruskal-Wallis, Mann-Whitney, and Spearman-correlation tests.

Results: Non-significant lower frequencies of TP- and IP-DNA were observed in p-HIVYA compared to AC and TDC. Lower IP-DNA/CD4TC ratios were observed in p-HIVYA compared to AC (p=0.007). Furthermore, lower IP-DNA/n-CD4TC ratios were found in p-HIVYA compared to AC (p=0.031) and TDC (p=0.006).

In addition to the previously reported increased nCD4TC proportion and decreased PD-1 expression, lower frequencies of effector- and transitional-memory and ter-

минал-effector CD4TC were found in p-HIVYA compared to AC (p=0.035, p=0.008, p=0.028) and TDC (p=0.001, p=0.018, p=0.004), respectively. No differences were found in Ki-67 and PTK-7 expression.

n-CD4TC negatively correlated with set-point viral load logarithm [log₁₀(sVL)] in the cohort as a whole (r=-0.411; p=0.026). Also, log₁₀(sVL) directly and inversely correlated with percentages of DP-DNA and IP-DNA (r=±0.709; p=0.018), respectively, in p-HIVYA but not in AC and TDC.

Furthermore, Ki-67+CD4TC inversely correlated with TP-DNA in p-HIVYA (r=-0.809; p=0.021).

Conclusions: As expected, p-HIVYA presented greater reservoirs in association with higher sVL. The higher n-CD4TC frequency observed in p-HIVYA cannot be explained by elevated present thymic activity (PTK-7 expression).

This disbalance could have been generated early in life and persists during adulthood. Lower IP-DNA/n-CD4TC ratio suggests that n-CD4TC may not serve as a main viral reservoir in p-HIVYA.

These findings suggest that acquiring HIV perinatally may imply different challenges for reaching a cure.

EPA0062

Viral rebound dynamics in SHIV-infected infant macaques are predicted by distinct immunovirologic features measured before and after one year of antiretroviral therapy

V. Obregon-Perko¹, A. Awasthi², R. Barfield², S. Berendem², B. Yagnik³, T. Styles³, G. Tharp³, P. Gupta³, M. Kumar⁴, E. Fray⁴, F. Bu², J. Siliciano⁴, R. Siliciano⁴, M. Mavigner¹, R. Amara³, S. Bosinger³, G. Fouda⁵, S. Permar⁵, C. Chan², A. Chahroudi¹

¹Emory University School of Medicine, Atlanta, United States, ²Duke University School of Medicine, Durham, United States, ³Emory National Primate Research Center, Atlanta, United States, ⁴Johns Hopkins School of Medicine, Baltimore, United States, ⁵Weill Cornell Medicine, New York, United States

Background: Ethical considerations and clinical unknowns make ART interruption challenging in children with perinatal HIV who participate in cure-related studies.

Uncovering predictors of time to viral rebound (TTR) and post-treatment control (PTC) of viremia following ART cessation in a pediatric preclinical model may inform trials testing novel cure interventions in children.

Methods: We performed staggered ART initiation in 30 infant rhesus macaques (RMs) orally infected with SHIV.C.CH505 followed by analytical treatment interruption (ATI) after 52 weeks.

Cox proportional-hazards model with LASSO regularization was used to identify and rank parameters predicting TTR and Leave-One-Out Cross Validation (LOOCV) deviance was applied to selected variables.

Penalized multinomial regression and RNA-Sequencing were used to investigate rebound phenotypes.

Results: Rebound occurred in 26/30 infants within 7-98d of ATI, with TTR significantly delayed in the Early ART group vs Intermediate and Late ART groups (median 84d, 18d, and 17d post-ATI, respectively; $p < 0.001$).

Through multivariate regression modeling of 82 potential biomarkers, we constructed a predictor inclusion rank table where peak viremia pre-ART best described TTR, with increased predictive strength through successive inclusion of six additional variables in blood, lymph nodes, and rectal tissue pre-ART or pre-ATI.

Over 32 weeks of ATI, we observed sustained viremia ($n=7$), PTC ($n=18$), and no-rebound ($n=5$). With sustained viremia as the reference group, the odds of PTC increased by 31% for each unit increase in Ki67+CD8+TEM cells in lymph nodes pre-ATI.

Transcriptomic analysis of CD4+ T-cells pre-ATI from 18 Mamu*A01- infants showed heme metabolism and IFN γ response pathways to be upregulated in the 5 non-rebounders compared to RMs with sustained viremia or PTC. A restricted analysis of the Early ART group (3 rebounders and 4 non-rebounders) also implicated TGF β pathway genes in the no-rebound phenotype.

Conclusions: This investigation into biomarkers to predict viral rebound dynamics, conducted for the first time in the pediatric setting, demonstrates that plasma viral load pre-ART is the primary determinant of TTR, confirming the importance of early treatment.

We also identified Ki67+CD8+TEM cells in lymph nodes pre-ATI as a biomarker of PTC in infant RMs and revealed key roles played by TGF β and IFN γ in lack of rebound.

EPA0063

Meta-analysis of 5'-Leader defective proviruses persisting in people on ART

J. Duan¹, H. Wilkins¹, M. Lichterfeld², R. Siliciano¹, F. Simonetti¹

¹Johns Hopkins School of Medicine, Medicine, Baltimore, United States, ²Brigham and Women's Hospital, Infectious Disease Division, Boston, United States

Background: Proviruses with defects in the 5'-Leader (5'-L) are found in virtually all people on ART, represent 5-10% of the proviral landscape, and are often detected in expanded clones, including those contributing to residual viremia. However, how these defects are formed and how they can affect proviral persistence is poorly understood.

Methods: We compiled a dataset of proviruses with 5'-L deletions from previous studies and newly generated sequences. We investigated the distribution of deletions, the impact of the primers used, and which functional RNA secondary structures are involved.

Finally, we investigated whether repeated elements and polymeric regions could contribute to the formation of these deletions.

Results: We retrieved more than 1500 sequences from 12 studies. After quality control and removal of clonal sequences, we obtained a final dataset of 574 unique provi-

rases. Deletions had a significantly asymmetrical distribution that peaked at the major splicing donor site (MSD). Although different PCR methods did not impact the deletion size and 3' end positions, the location of forward primers affected 5' end distribution of deletions, suggesting that current assays fail to detect proviruses with deletions extending further into the 5'-L. The most frequently affected discrete structure was the MSD (91%), followed by the dimerization initiation signal (71%), and the packaging signal (61%). The IPDA would correctly exclude as defective 100% of these deletions.

Interestingly, ~45% of the proviruses retained an intact gag ORF, potentially contributing to the expression of antigens and viral particles. The analysis of deletion junctions identified 64 deletions with microhomology and 85 with polymeric regions.

However, both features had a minor role in explaining the genesis of deletions compared to the proximity to the 5'-L secondary RNA structure. Of note, we found one insertion-in-deletion pattern with a Lys3a-tRNA sequence, caused by RT during plus-strand priming.

Conclusions: This is the first large meta-analysis of proviruses with 5' Leader small deletions. We show that primer design can affect the characterization of the proviral landscape. Although non-infectious, almost half of proviruses can express Gag.

Finally, the highly structured 5'-L RNA likely drives these deletions at the end of minus-strand cDNA synthesis.

EPA0064

Adaptation of the intact proviral DNA assay to the QIAcuity digital PCR platform

C. Tumpach¹, C. Cochrane², Y. Kim¹, J. Ong¹, A. Rhodes¹, M. Churchill², S. Telwatte¹, S. Lewin¹, M. Roche¹

¹The University of Melbourne at the Peter Doherty Institute of Infection and Immunity, Department of Infectious Diseases, Melbourne, Australia, ²RMIT University, School of Health and Biomedical Sciences, Melbourne, Australia

Background: Quantification of intact proviruses is a critical measurement in HIV cure studies both *in vitro* and *in vivo*. The widely adopted 'Intact Proviral DNA Assay' (IPDA) was originally validated using Bio-Rad's droplet digital PCR system (ddPCR). This system has limited multiplexing capability (2-channel), is labor- and time intensive. Qia-gen's QIAcuity digital PCR platform (dPCR) is a fully automated system which partitions samples into nanowells rather than droplets. The self-contained instrument primes, thermocycles, and optically detects fluorescence of each sample with up to 5-plex capability, requiring minimal sample preparation thereby reducing hands-on time and error. In this study we adapted the IPDA assay to the QIAcuity platform and assessed its performance relative to ddPCR.

Methods: Full-length HIV plasmids containing 5' and 3' deletions were used as controls for quantification. Intra- and inter assay variability was assessed using genomic

DNA (gDNA) isolated from Jlat10.6 cells. Full-length HIV plasmid and Jlat10.6 gDNA with an assay input ranging between 10^4 to 1 HIV copies were used to investigate the sensitivity of the IPDA on the QIAcuity platform.

Comparison to the ddPCR IPDA was determined using gDNA isolated from CD4 T cells from people with HIV on ART (n=11). *Ex vivo* samples were assayed using 500ng DNA input in quadruplicate wells for the HIV assay, 25ng DNA was loaded into the RPP30 assay to determine cell number and DNA shearing.

Results: Based on plasmid controls the QIAcuity could differentiate between defective and intact proviruses and could accurately quantify intact proviruses down to single HIV copy input. The intraplate and interplate variability was within acceptable ranges (%CV at or below 10).

When comparing the two assays in *ex vivo* CD4 T cells from people with HIV on ART we observed no significant difference in the quantification of intact ($r=0.93$; $p<0.001$); 5' defective ($r=0.7$; $p=0.04$); and 3' defective proviruses ($r=0.96$; $p<0.001$).

Conclusions: We demonstrate that the QIAcuity dPCR platform enables sensitive and accurate quantification of likely genetically-intact proviruses similar to the IPDA assay.

This flexible system will allow for an expansion of detection of up to 5 targets enabling a more comprehensive analysis of intact and potentially replication-competent proviruses.

Background: Currently no scalable cure for HIV exists due to the presence of long-lived and stable viral reservoirs in blood and tissue sites throughout the body that are not eradicated by treatment with antiretroviral therapy (ART). We recently demonstrated the first evidence of an intact, potentially replication competent HIV reservoir in the frontal lobe of people with HIV (PWH) who were duly suppressed with ART.

Here we provide the first characterization of the HIV intact and detective reservoir throughout multiple regions in the brain.

Methods: Total, intact and defective HIV proviral DNA was quantified in matched fresh frozen autopsy frontal lobe, cerebellum and basal ganglia brain tissue from viremic or ART-suppressed PWH or HIV-seronegative controls by droplet digital PCR approaches including the intact proviral DNA assay (IPDA).

Results: HIV *pol* DNA was detected in all brain tissues tested from PWH and levels were similar between virally suppressed (n=16) vs viremic PWH (n=24), demonstrating the widespread presence of HIV proviral DNA in the brain that is not influenced by long-term ART treatment. Frontal lobe tissue contained higher levels of HIV *pol* DNA relative to either cerebellum ($P<0.05$) or basal ganglia ($p<0.06$).

Further assessment of HIV proviral DNA in CNS tissues demonstrated that a higher proportion of ART-sup-

pressed PWH harbored intact proviral DNA in frontal lobe tissue (6/8 PWH) relative to matched cerebellum (3/8 PWH) and basal ganglia tissue (2/8 PWH).

Conclusions: Here we provide the first characterisation of intact and defective HIV proviral DNA across multiple regions of the brain. These data demonstrate that the frontal lobe is a major site of intact potentially replication competent HIV proviral DNA in the brain which persists despite ART treatment.

CTL epitopes from structurally important HIV proteins are identified in rebound HIV

E. Lee¹, G. Duette¹, K. Fisher^{1,2}, S. Deeks³, A. Kelleher⁴, S. Palmer^{1,2}

¹The Westmead Institute for Medical Research, Centre for Virus Research, Westmead, Australia, ²The University of Sydney, Sydney Medical School, Westmead Clinical School, Faculty of Medicine and Health, Westmead, Australia, ³University of California San Francisco, Department of Medicine, San Francisco, United States, ⁴Kirby Institute, The University of New South Wales, Sydney, Australia

Background: During an analytic treatment interruption (ATI), the elimination of HIV-infected cells by HIV-specific cytotoxic CD8 T-cells (CTLs) is required to control viral infection. However, unless treatment is initiated during acute infection, the HIV reservoir becomes dominated by CTL escape variants resistant to the immune response. Therefore, we applied a novel **IM**munoinformatics **A**nalysis **P**ipeline (IMAP) to identify CTL epitopes within structurally important HIV protein regions that avoid CTL immune escape mutations.

Methods: Employing the IMAP, we generated 8-14 mer overlapping peptides containing amino acid residues (aa) essential for HIV Gag, Pol, Vif, Vpr, and Env protein structure and function. We excluded the peptides containing CTL escape mutations and those found within <85% of global HIV-1 subtypes/recombinants.

Using the Immune Epitope Database and NetMHCpan analysis tools, we selected the peptides that are predicted to be immunogenic and are binders to the most prevalent HLA-I alleles. These peptides were compared to the five protein regions extracted from HIV-RNA sequences of five participants who underwent multiple ATIs.

Results: We selected 128 peptides from the Gag, Pol, Vif, Vpr, and Env proteins. These peptides were identified within the protein regions containing aa that form many physicochemical interactions with other residues. These peptides had 0-3 aa variations at 0-2 sites which were not associated with HLA-I anchoring or CTL immune escape. We found that 85-98% of viral sequences derived from worldwide HIV-1 subtypes/recombinants contained our selected peptides. The Gag-, Pol-, Vif-, and Env-derived peptides were predicted to bind to multiple HLA-A/B/C alleles, resulting in 88-97% worldwide population cover-

age. For the Vpr-peptides, despite the prediction that these peptides bind to multiple HLA-I alleles, population coverage was 58%. Importantly, the selected peptides, including the aa variant forms, were found within 97-100% of plasma-derived HIV-RNA sequences from five participants who had three successive ATIs.

Conclusions: Applying the IMAP, we selected novel HIV peptides within structurally essential regions of five HIV proteins. These peptides were genetically conserved and lacked known CTL escape mutations.

Notably, the peptides were identified within ATI-derived plasma HIV-RNA sequences, indicating that these peptides as a pool are highly promising for eliciting a CTL immune response during treatment interruption.

The cellular factor UHRF1 silences HIV-1 transcription in infected myeloid reservoirs

M. Santangelo^{*1}, M. Bendoumou^{*1}, A. Ait-Ammar¹, L. Nestola¹, M. Nijhuis², C. Van Lint¹,

^{*}These authors contributed equally to this work¹

¹University of Brussels (ULB), Molecular Virology, Gosselies, Belgium, ²University Medical Center Utrecht, Medical Microbiology, Utrecht, Netherlands

Background: There is increasing evidence for the physiological relevance of myeloid HIV-1 reservoirs such as brain microglia (the main central nervous system (CNS) reservoir) and urethral macrophages. However, the molecular mechanisms of HIV-1 gene expression in myeloid infected cells are still poorly understood and understudied. We have previously reported that UHRF1 is a new epigenetic repressor of the latent HIV-1 promoter in T lymphocytes (Verdikt R. *et al.*, 2022, eBioMedicine).

Here, we demonstrated that UHRF1 also plays an important role in HIV-1 latency by silencing viral transcription in infected cells of myeloid origin.

Methods: Electrophoretic mobility shift Assay, ChIP-qPCR, RNA interference, p24 ELISA, use of infected human primary Monocytes-derived Macrophages (MaM) and microglial cells (the CNS resident macrophages) and HIV-1-infected microglia-containing human 3D cerebral organoids.

Results: Using the HIV-1 latently-infected monocytic cell line THP89GFP as a myeloid model system for HIV-1 infection, we demonstrated that UHRF1 was recruited *in vivo* to the 5'LTR promoter and that the recruitment of UHRF1 was strongly decreased after HIV reactivation with TNFa. Genetic downregulation of UHRF1 by RNA interference induced an increase in HIV gene expression accompanied by decreased recruitments of DNMT1, G9a and HDAC1 to the viral promoter, thereby demonstrating the role of UHRF1 in HIV-1 transcriptional silencing in myeloid cells. Moreover, pharmacological inhibition of UHRF1 by the green tea polyphenol EGCG (EpiGalloCatechin-3-Gallate) caused an increase in HIV-1 transcription. We are currently studying the role of UHRF1 in infected human primary

Monocytes-derived Macrophages (M ϕ M) and microglial cells (the CNS resident macrophages), as well as in HIV-1-infected microglia-containing human 3D cerebral organoids.

Conclusions: We thus demonstrated that UHRF1 is involved in HIV-1 latency in cells of myeloid origin, in addition to cells of T-lymphoid origin. Considering the role of UHRF1 in HIV-1 silencing in the two main reservoirs of virus, our findings reinforce the relevance of UHRF1 as an attractive therapeutic target for anti-HIV-1 cure strategies.

EPA0068

Long-term protection against HIV infection after discontinuation treatment with ponatinib for 1 year

M. Manzanares¹, F. Ramos-Martín¹, G. Casado-Fernández^{1,2,3}, M. Torres¹, C. Sánchez-Menéndez^{1,4}, E. Mateos¹, L. Vigón¹, S. Rodríguez-Mora^{1,3}, V. García-Gutiérrez⁴, V. Planelles⁵, M. Coiras^{1,3}

¹Instituto de Salud Carlos III, Immunopathology Unit-National Center of Microbiology, Majadahonda, Spain, ²Universidad de Alcalá, Faculty of Sciences, Madrid, Spain, ³Biomedical Research Center Network in Infectious Diseases (CIBERINFEC), Madrid, Spain, ⁴Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Hospital Universitario Ramón y Cajal, Hematology and Hemotherapy Service, Madrid, Spain, ⁵University of Utah School of Medicine, Division of Microbiology and Immunology, Department of Pathology, Salt Lake City, United States

Background: PLWH on ART and dasatinib show reduced reservoir size resistant to reactivation. We evaluated if treatment with ponatinib for 1 year may protect CD4 from HIV infection and if this protection was maintained during treatment-free remission (TFR).

Methods: 12 participants with chronic myeloid leukemia (CML) of NCT04043676 were recruited. They were on treatment with imatinib for 14 (IQR 5.25-15.75) before discontinuation and then received 1 year-consolidation treatment with ponatinib 15mg/day.

Blood samples were collected before starting ponatinib, after 1 year-treatment, and 3, 6 and 12 months after discontinuation. PBMCs were infected with NL4-3_wt 72h. HIV-p24, pSAMHD1, CD4 memory and cytotoxic cell populations were analyzed by flow cytometry. PBMCs antiviral activity was evaluated by measuring caspase-3 activity in NL4.3_wt-infected TZM-bl cells.

Results:

1. 8 participants (66.6%) did not relapse from CML 12 months after ponatinib interruption (Non-relapsed); 4 participants (33.3%) relapsed after 5.5 months (IQR 4.25-6.75) of ponatinib interruption (Relapsed).
2. CD4 were susceptible to HIV infection in all participants while treatment with imatinib; 1 year-treatment with ponatinib reduced 5.75-fold HIV infection (Figure 1)

and this protection was maintained 6 (p=0.0313) and 12 months (p=0.0313) during TFR in Non-relapsed, which correlated with pSAMHD1 interference.

3. After CML relapse and imatinib reintroduction, all CD4 memory subpopulations regained susceptibility to HIV replication, including TEM (>3.79-fold;p=0.0485) and TEMRA (>4.93-fold;p=0.0317).

4. Antiviral cytotoxicity increased 4.22-fold (p=0.0156) in PBMCs from Non-relapsed after 1-year of ponatinib and remained enhanced for 12 months of TFR.

5. NK cells increased 1.86-fold (p=0.0061) after 1-year on TFR in Non-relapsed, with 3.51-fold (p=0.0476) increased degranulation capacity.

Figure. 1

Conclusions: One-year treatment with ponatinib preserved SAMHD1 in CD4 and induced sustained cytotoxic effect, impeding HIV infection and reservoir formation. Antiviral protection was maintained 12 months during TFR in correlation with sustained antileukemic response. Short-term intensification treatment with dasatinib or ponatinib could be used for HIV cure strategies.

A case of persistent low-level viremia during ART fueled by a clonally expanded provirus with a 3 base deletion in HIV's major splice donor site

F.H. Omondi^{1,2}, C.J. Brumme^{2,3}, W. Dong², H. Lapointe², E. Barad^{1,2}, S. Speckmaier², N. Kinloch^{1,2}, C. Beelen², D. Kirkby², M. Harris^{2,4}, J.S.G. Montaner^{2,3}, S. Guillem^{1,2,4}, Z.L. Brumme^{1,2}

¹Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, ²British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, ³University of British Columbia, Department of Medicine, Vancouver, Canada, ⁴University of British Columbia, Department of Family Practice, Vancouver, Canada

Background: Historically, persistent low-level viremia (pLLV) during ART has been attributed to incomplete anti-retroviral adherence or *de novo* emergence of drug resistance, but recent evidence indicates that it can originate from the reservoir.

We investigated the potential reservoir origin of plasma virus in an individual with pLLV.

Methods: The participant, who acquired a recombinant HIV strain primarily comprising subtype A-like regions, was diagnosed with HIV in 2003 and initiated ART in October 2006.

With the exception of two "blips", pVL was suppressed until February 2020, after which all 30 subsequent pVL were detectable (between 50-709 copies/ml) despite receiving four active drug classes. No adherence concerns were noted and the presence of drug in plasma was confirmed by mass spectrometry.

We integrated sequencing, phylogenetics, and the intact proviral DNA assay (IPDA) to elucidate the reservoir origin of pLLV by analyzing historical longitudinal plasma samples alongside a PBMC sample collected in December 2022.

Results: Drug resistance genotyping of 12 plasma samples from February 2021-December 2022 during the pLLV revealed an essentially clonal population with no resistance mutations, that was distinct from prior genotypes performed in 2003, 2005 and 2013. Bulk sequencing of 5' and *gp41* regions confirmed that the pLLV was clonal with occasional limited diversity.

To date, 188 near full-length proviruses have been single-genome-sequenced. Of these, 8 were classified as genetically intact by the bioinformatics pipeline (the remaining 180 were defective, where 3' deletions were the most common defect). Four of these intact proviruses were genetically identical and exactly matched the pLLV sequence across all query regions.

Both the pLLV and matching proviruses had a unique 3 base deletion in the major splice donor site that all other plasma and proviral sequences lacked. This deletion, which may render this provirus defective, will allow us to design a custom IPDA probe to specifically quantify its within-host abundance. Reconstruction of within-host HIV evolutionary history from pre-ART plasma to infer pLLV age and lineage origin is also underway.

Conclusions: Our observations provide additional evidence that clonally-expanded reservoir cells harboring deletions within HIV's major splice donor site can fuel persistent low-level viremia during ART.

EPA0070

Myeloid production of GDF15 influences HIV reservoir size in ART-treated people living with HIV

S. Isnard^{1,2}, L. Royston^{1,2,3,4}, F.P. Dupuy¹, J. Lin¹, B. Fombuena¹, S. Bu^{1,5}, C. Tremblay⁶, M. Durand⁶, N.F. Bernard^{1,7}, J.-P. Routy^{1,2,8}

¹McGill University Health Centre - Research Institute, Montreal, Canada, ²McGill University Health Centre, Chronic Viral Illness Service, Montreal, Canada, ³CIHR/Canadian HIV Trial Network, Vancouver, Canada, ⁴Geneva University Hospitals, Division of Infectious Diseases, Geneva, Switzerland, ⁵McGill University, Division of Experimental Medicine, Montreal, Canada, ⁶Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montreal, Canada, ⁷McGill University Health Centre, Division of Clinical Immunology, Montreal, Canada, ⁸McGill University Health Centre, Division of Hematology, Montreal, Canada

Background: Growth differentiation factor-15 (GDF15) is an atypical member of the transforming growth factor- β family. Circulating GDF15 levels increase with mitochondrial stress, age, cardiovascular diseases, cancer and severe COVID-19.

We assessed whether plasma GDF15 levels were associated with inflammation markers and HIV reservoir size in people living with HIV (PLWH) taking antiretroviral therapy (ART).

Methods: Plasma and peripheral blood mononuclear cells (PBMCs) were obtained from 55 ART-treated PLWH and 30 people without HIV with similar age as controls. Plasma levels of GDF15 and validated markers of inflammation were quantified by ELISA. HIV reservoir size was estimated by measuring integrated HIV DNA by nested-qPCR in sorted CD4 T-cells. Intracellular levels of GDF15 were assessed by flow cytometry. In vitro assays were performed on PBMC or sorted CD4 T-cells.

Results: PLWH were on ART for a median of 14.5 years and had undetectable viremia. Median age of PLWH and controls was 54 and 53 years, respectively. Plasma GDF15 levels were higher in PLWH ($p < 0.0001$) and correlated with age ($r = 0.4$, $p < 0.01$). In ART-treated PLWH, GDF15 levels were not associated with CD4 count, CD4/CD8 ratio, weight, gut permeability, nor inflammatory markers. GDF15 levels were associated with levels of the non-AIDS comorbidity marker suPAR ($r = 0.68$, $p < 0.0001$). GDF15 levels were also strongly associated with integrated HIV DNA levels in CD4 T-cells ($r = 0.49$, $p < 0.001$) independently of age, sex, and CD4 count. GDF15 was only found in monocytes, but not in T-, B- or NK-cells or dendritic cells. Intracellular levels of GDF15 correlated strongly with plasma levels ($r = 0.9$, $p < 0.01$). *In vitro*, addition of recombinant GDF15 to culture medium increased TNF- α expression in CD4 T-cells as observed by RNA-sequencing and RT-ddPCR.

In preliminary experiments, addition of recombinant GDF15 to previously HIV-infected CD4 T-cells increased infected cell survival by 2-fold after 5 days of culture.

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

Conclusions: GDF15 levels were higher in ART-treated PLWH compared to controls and were associated with risk of non-AIDS comorbidities and HIV reservoir size, independently of classical inflammatory markers. Myeloid production of GDF15 might directly influence infected CD4 T-cell survival and represent a potential target for HIV cure strategies.

Background: Despite long-term combination antiretroviral therapy (cART), viral reservoir elimination in humans infected with HIV-1 remains elusive, due to the presence of latently infected cells and their sequestration in immunologic sanctuaries. During infections with HIV-1 and SIV of macaque species, CD4⁺ TFH cells in B cell follicles (BCF) of lymph nodes (LN) are a major reservoir for latent virus that remain largely inaccessible to CD8⁺ T cell-mediated killing.

In prior work, we have demonstrated that BCFs in the SIV natural host African Green Monkey are generally virus free, and in vivo depletion of NK cells induces elevated plasma viremia and recrudescence of viral foci in lymph nodes. The goal of this study was to determine whether NK cell-mediated clearance of virus replication in LNs is a

conserved feature of nonpathogenic SIV infection by analyzing NK cell depletion and viral dynamics in another SIV natural host, sooty mangabeys.

Methods: We depleted NK cells from eight chronically SIVsmm infected sooty mangabeys by administration of recombinant anti-IL-15 (clone M111, 20 mg/kg, i.v.) and monitored plasma viral loads. NK cell function in blood and lymph nodes was assessed by flow cytometry and single-cell RNA-Seq.

Results: Efficient depletion of NK cells was observed by 14 days post-infusion. Plasma levels of SIVsmm increased significantly from a mean of 2.06×10^5 copies/ml prior to depletion to 7.74×10^5 copies/ml at seven weeks post NK cell depletion ($p < 0.0001$ by linear trend test). A significant increase in cell-associated SIV RNA was observed in the LNs at day 42 post-infusion.

To assess NK cell function, we sorted subpopulations of NK cells from LN based on CD16, CXCR5 and NKG2A expression and conducted single-cell RNA-Seq. Strikingly, within the CXCR5⁺ NKG2A⁺ population, we observed elevated expression of perforin, granzyme, and restriction factors.

Conclusions: This study demonstrated for the first time that NK cells contribute to control of viral replication in LNs of sooty mangabeys. This function of NK cells appears to be a general feature of nonpathogenic SIV infections. These findings further warrant the investigation of NK cell-based immunotherapies as part of cure and vaccine strategies for HIV-1.

EPA0072

Characterisation of HIV latency and reactivation in human macrophages

M.E. Wong¹, C. Tumpach², A. Jaworowski^{1,3,4}, A.C. Hearps^{1,3}

¹Burnet Institute, Melbourne, Australia, ²Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, ³Monash University, Infectious Diseases, Melbourne, Australia, ⁴RMIT University, School of Biomedical Sciences, Melbourne, Australia

Background: HIV-infected macrophages persist in people with HIV in tissue such as the brain, gut and lung despite suppressive antiretroviral therapy and can contribute to viral rebound when therapy is stopped. What governs the establishment and reactivation of latent HIV infection in different types of tissue macrophages is poorly understood, but essential to inform HIV elimination strategies which adequately target this reservoir.

Methods: An *in vitro* model of HIV latency in human macrophages was utilised, where primary human serum-derived monocyte-derived macrophages (MDM), GM-CSF-derived alveolar like-macrophages (AlvMDM) or multiple cytokine-differentiated monocyte-derived microglia were infected with a GFP-HIV reporter virus.

Non-productively infected cells were FACS sorted and latency reactivation quantified longitudinally using fluorescence microscopy.

The impact of stimulation with M1 (TNF + IFN γ) and M2 (IL-4) polarising cytokines was assessed. HIV-infected MDM from 3 donors were further analysed using single cell transcriptomics.

Results: MDM and AlvMDM harboured comparable levels of latent HIV and exhibited a similar rate of spontaneous reactivation (+0.27 vs 0.15% cells/day respectively, $p=0.3$). Modulation of macrophage phenotype using M2 polarising conditions enhanced HIV reactivation in both MDM and AlvMDM ($p=0.02$ and 0.01 respectively), whilst M1 polarising conditions inhibited reactivation in MDM ($p=0.03$). HIV reactivation from non-productively infected microglial cells trended lower than for MDM ($p=0.06$). Single cell transcriptomic analysis of non-productively infected (GFP-) MDM revealed substantial numbers of cells (>10%) expressing HIV transcripts, indicating latent HIV infection. Productively HIV-infected MDM were distinguished with 20 differentially expressed host genes. Unique cellular markers identifying latently infected macrophages were not identified.

Conclusions: Tissue-specific macrophage sub-populations may differ in their ability to harbour reactivatable latent HIV reservoirs. The ability of polarising cytokines to modulate HIV reactivation suggests local tissue microenvironments may influence latency in macrophages, but also indicates the potential for macrophage reservoirs to be reactivated by exogenous stimulation as part of shock and kill cure approaches.

Unique data from single cell analysis of latently infected macrophages indicates a substantial proportion of macrophages can harbour latent HIV infection but remain phenotypically 'silent' and evade immune recognition. Productively-infected macrophages displayed a distinct gene signature, which may identify targets for novel therapeutics targeting the productive HIV macrophage reservoir.

EPA0073

Developing triplex forming oligonucleotides as a 'block and lock' strategy for an HIV cure

H. Liu¹, C. Tumpach², J. Symons^{2,3}, S. Lewin^{2,4,5}, M. Roche²

¹The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ²The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Department of Infectious Diseases, Melbourne, Australia, ³University Medical Center Utrecht, Translational Virology, Department of Medical Microbiology, Utrecht, Netherlands, ⁴Royal Melbourne Hospital at the Peter Doherty Institute for Infection and Immunity, Victorian Infectious Diseases Service, Melbourne, Australia, ⁵Alfred Health and Monash University, Department of Infectious Diseases, Melbourne, Australia

Background: The main barrier to an HIV cure is the persistence of long lived and proliferating latently infected T cells. Virus can integrate in the host genome, stay tran-

scriptionally silenced, and re-emerge upon reactivation of transcription. Triplex formation oligonucleotides(TFO) are single stranded DNA that can bind in the major groove of duplex DNA with high specificity and affinity.

We hypothesized that TFO can bind to the integrated provirus and inhibit viral transcription leading to a 'block and lock' strategy for an HIV cure.

Methods: We designed multiple TFOs targeting HIV *gag* ($n=3$), *env* ($n=4$) and to GFP ($n=4$). TFOs were delivered by lipofectamine or a novel nanoparticle to HEK 293T transfected with plasmids expressing *gag*, *env*, green-fluorescent-protein (GFP) and full length HIV NL-4.3.

TFO impact on full length proviral transcription was assessed by incubating supernatant with the reporter TZM-bl cell line which contains an integrated HIV LTR, a portion of *gag* and the luciferase gene and quantification of cell associated unspliced HIV RNA by RT-qPCR. TFO activity on integrated provirus was assessed by transfection of TFOs and subsequent stimulation of TZM-bls.

Results: In the plasmid transfection system, GFP-specific TFOs inhibited GFP expression (mean \pm SEM inhibition for 2uM GFP-TFO2 was $96.8\pm0.45\%$, $p<0.001$) and HIV-specific TFOs inhibited either HIV *gag*(reduction with 4 uM HIV-TFO7, $67.26\pm9.19\%$, $p=0.03$) or HIV *env* expression (reduction of *env* expression ranging from 75 to 88%).

In HIV NL-4.3 transfected cells, 2uM HIV TFO4 potently reduced the infectivity of supernatant by $97\pm0.59\%$ ($p<0.001$) and reduced unspliced HIV RNA 400 ± 35.02 fold ($p=0.03$) consistent with the TFO inhibiting transcription initiation. Inhibition of HIV gene expression was achieved by both lipofectamine and nanoparticle delivery of TFO.

In TZMBL cells, transfection of four different TFOs by lipofectamine had no effect on either basal or induced HIV transcription.

Conclusions: TFOs can potentially inhibit HIV gene expression, however we were unable to demonstrate inhibition of transcription from an integrated provirus. This may be due to the lack of nuclear penetration by TFOs or target inaccessibility due to the chromatin environment.

Further work to address these limitations is underway. TFOs present a novel HIV 'block and lock' option to limit HIV transcription.

EPA0074

Assessment of monovalent and bivalent SMAC mimetics to both shock and kill the HIV reservoir

K. Tanaka¹, Y. Kim¹, C. Tumpach¹, J. Ong¹, M. Roche¹,
M. Pelligrini², S. Lewin^{1,3,4}

¹The University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Department of Infectious Diseases, Melbourne, Australia, ²The Walter and Eliza Hall Institute of Medical Research, Infectious Diseases and Immune Defence, Melbourne, Australia, ³Royal Melbourne Hospital at The Peter Doherty Institute for Infection and Immunity, Victorian Infectious Diseases Service, Melbourne, Australia, ⁴Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia

Background: Latently infected CD4+ T-cells are primed for survival due to the over-expression of factors that regulate apoptosis such as inhibitors of apoptosis proteins (IAPs). This may explain why 'shock and kill' efforts to date have largely failed. SMAC mimetics (SMACm) have been shown by others to increase binding of non-canonical NfκB (ncNfκB) complex to the HIV long terminal repeat and can potentially reverse HIV latency. SMACm can also inhibit IAPs leading to an increase in tumor necrosis factor alpha (TNF-α) mediated extrinsic apoptosis. We hypothesised that SMACm would increase death of latently infected cells in the presence of TNF-α.

Methods: We assessed bivalent (AZD5582, BV6 and Birinapant) and monovalent (GDC0152, GDC0197, xevinapant and LCL161) SMACm in the presence and absence of TNF-α (20ng/ml) in peripheral blood mononuclear cells (PBMC) and sorted CD4+ T-cells from uninfected donors and people with HIV (PWH) on antiretroviral therapy. Latency reversal was assessed using a cell line containing integrated HIV with a mutation in *env* and *vpr* and a green fluorescent protein (GFP) reporter (J-Lat clone 10.6). GFP expression and cell death using a live dead stain were quantified by flow cytometry. NFκB activation and cIAP1 degradation was measured by western blot.

Results: The bivalent compared to monovalent SMACm showed higher levels of GFP expression in J-Lat10.6 (100nM; mean±SEM GFP expression 1.3%±0.14% vs 6.0%±1.9% respectively, p=0.03) and induced greater cIAP1 degradation and induction of p52 from p100 cleavage in PBMC from uninfected donors. Both bivalent and monovalent SMACm demonstrated similar toxicity profiles in CD4+ T-cells isolated from uninfected PBMC (100nM; 8.5%±3.3% vs 9.9%±0.4% cell death, p=0.52). Addition of TNF-α to SMACm led to no difference in cell toxicity and cIAP1 degradation in CD4+T-cells from uninfected donors and PWH.

Conclusions: Bivalent compared to monovalent SMACm induce greater latency reversal and also cell death in cell lines but have similar levels of toxicity in primary cells. The additional of TNF-α did not increase cell death. Further work is continuing on the impact of these compounds on CD4+ T-cells from PWH on ART.

Background: One strategy to eliminate latently infected CD4+ T-cells that persist in people living with HIV (PLWH) on suppressive antiretroviral therapy (ART) is to activate virus expression to induce immune-mediated clearance or virus induced cytolysis using latency reversing agents (LRAs). To date, evaluation of LRAs alone or in combination with antibodies or vaccination has not resulted in a substantial decrease in the frequency of infected cells or increased time to viral rebound once ART is stopped. Thus, additional strategies to kill reactivated cells are needed. Given phosphoinositide 3-kinases (PI3K) promote the survival of virus-infected cells, here we investigated whether PI3K inhibitors could be combined with LRAs to kill latently infected cells.

Methods: We assessed the effects of three different PI3K inhibitors (IPI-443, IPI-3063 and wortmannin) alone and in combination with LRAs (romidepsin, panobinostat, JQ1 and PMA/PHA as a positive control) to determine if these pro-apoptotic agents enhanced death of HIV-infected cells using CD4+ T-cells isolated from blood from n=6 PLWH on ART.

Results: We found that the histone deacetylase inhibitor romidepsin together with either IPI-443 or wortmannin PI3K inhibitor led to significant declines in the frequency of infected cells, measured as integrated HIV DNA (p=0.0312 in both cases). Both drug combinations were also synergistic (mean Bliss independence score 0.15 and 0.37, respectively).

Interestingly, we found that the PI3K inhibitors alone could reactivate cell-associated HIV RNA (mean fold change of 1.43, 2.32 and 1.81, for IPI-443, IPI-3063 and wortmannin, respectively).

Conclusions: Taken together, the data suggests that sensitisation of latently infected CD4+ T-cells with pro-apoptotic compounds combined with latency reversal to drive expression of viral pro-apoptotic proteins can enhance the clearance of latently infected cells.

The combination of romidepsin and select PI3K inhibitors could inhibit multiple cell survival pathways, ultimately leading to the production of ROS and an increase in pro-apoptotic molecules.

**EPA0076****Tat diversity in intact versus defective proviral HIV-1 DNA genomes across viral subtypes**

P. Khadka¹, Z. Tang¹, M.R. Arikatla¹, E. Benko², C. Kovacs², M. Caskey³, T. Kityamuweesi⁴, P. Buule⁴, S. Tomusange⁴, A. Anok⁴, S.J. Reynolds⁵, T.C. Quinn⁵, J.L. Prodger⁶, A.D. Redd⁵, R.B. Jones¹, G.Q. Lee¹

¹Weill Cornell Medicine, Department of Medicine, New York, United States, ²Maple Leaf Medical Clinic, Toronto, Canada, ³Rockefeller University, New York, United States, ⁴Rakai Health Sciences Program, Kalisizo, Uganda, ⁵Johns Hopkins University School of Medicine, Baltimore, United States, ⁶Western University, Department of Microbiology and Immunology, London, Canada

Background: Tat is a transcription trans-activator protein that binds to the TAR region of the HIV-1 promoter in the LTR region, and recruits positive transcription elongation factor b (P-TEFb) to the viral promoter to stimulate transcription elongation of HIV-1 genes and therefore plays a major role in virologic rebound during therapy cessation. Here, we examine Tat length and sequence diversity associated with genome-intact versus defective HIV-1 DNA genomes across viral subtypes.

Methods: Near-full-length HIV-1 DNA genomes (2107 sequences, HXB2 638-9632) were sequenced from 42 individuals living with HIV-1 subtype A1 (n=4), AE (n=2), B (n=15), D (n=9) and inter-subtype recombinants (n=12) via single genome amplification. Genomes were classified as intact or defective using HIVSeqinR software. HIV-1 *tat* exon 1 and 2 nucleotide sequences were extracted and translated into amino acids using an in-house adaptation of Gene Cutter in R-language.

Results: Of the 2107 HIV-1 proviral DNA genomes analyzed, 268 *tat* sequences from 30 donors were not associated with hypermutated nor truncated-genomes. Amino acid length polymorphisms ranged from 75 to 106 residues, where Tat amino acid length was associated with viral subtypes (Kruskal-Wallis $p=6.4 \times 10^{-12}$).

The 101-residue variant was the most common variant in both intact and defective genomes and was observed in 20/30 donors across subtypes A1, AE, B and recombinants, whereas subtype D exclusively harbored the 86-residue variant.

The 106-residue variant was found exclusively in intact, not defective, subtype B and B-recombinant genomes.

Of the 30 donors, three individuals had more than one Tat length variants within their intrahost intact genome pools.

Phylogenetic analysis showed intermingling of *tat* sequences of intact and defective genomes within each donor, suggesting a lack of selection.

In eight individuals on suppressive antiretroviral therapy who had >5 intact proviral genomes, within each person, Tat associated with intact proviral genomes were up to 8% different in amino acid identity relative to other intra-host variants.

Conclusions: Our results revealed that Tat associated with intact HIV-1 DNA proviral genomes displays polymorphisms within host, across hosts and across HIV-1 subtypes, which could be associated with varying likelihoods of viral transcription reactivation within and across hosts upon treatment interruption.

EPA0077**Upregulation of TCF1 improves the efficiency of latency reversing agents for HIV-1 transcriptional reactivation**

H. Huang¹, T.Y. Luk², J. Wang², Z. Chen²

¹University of Hong Kong/AIDS Institute, Microbiology, Hong Kong, China, ²University of Hong Kong/AIDS Institute, Microbiology, Hong Kong, Hong Kong, SAR of China

Background: HIV-1 latently persisted in CD4⁺ T cells is the major barrier to cure people living with HIV. Since latency reversing agents (LRAs) tested in clinical trials showed only partial effects, it is critical to investigate factors that may improve the potency of LRAs.

Previous studies indicated that T-cell factor 4 (TCF4), one of members in the TCF/lymphoid-enhancer factor (LEF) family of transcription factors, inhibits HIV-1 transcription. The role of TCF1 in the same TCF/LEF family remains incompletely understood.

Methods: We investigated the expression of TCF1 in primary CD4⁺ T cells derived from healthy donors and ART-treated people living with HIV. The involvement of TCF1 in regulating HIV-1 latency reactivation was investigated in the T cell line model ACH2 latently infected with HIV-1.

Results: We found that the amount of TCF1 mRNA was significantly higher than that of TCF4 in purified primary CD4 T cells derived from healthy donors by RT-PCR.

Moreover, CD4⁺ central memory T cells displayed significantly higher expression of TCF1 compared with naive, effector memory, and CD45RA⁺ effector memory cells in healthy donors.

Critically, the amount of TCF1 expression was significantly decreased in both CD4⁺ naive and memory T cells derived from ART-treated people living with HIV comparing with healthy donors. Unlike TCF4, overexpression of TCF1 in ACH2 cells enhanced HIV-1 transcription compared with conventional ACH2 cells.

Moreover, overexpression of TCF1 in ACH2 promotes HIV-1 reactivation significantly by LRAs including the PKC agonist PMA and the BET inhibitor JQ1. 6-bromoindirubin-3'-oxime (6BIO), a potent inhibitor of Glycogen synthase kinase 3 β (Gsk-3 β), enhanced the expression of TCF1 in conventional ACH2 cells and consistently promoted the efficiency of PMA and JQ1.

Conclusions: Our results demonstrate that upregulated TCF1 may improve the efficiency of latency reversing agents for HIV-1 transcriptional reactivation.

Genetic diversity of HIV-1 long terminal repeat in proviral populations during long-term antiretroviral therapy

T. Nguyen¹, M.-E. Zipparo¹, L. Adams¹, A. Glassey¹,
E. Madeen¹, U. Santamaria², C.A. Rehm³, J. Earhart¹,
C.-Y. Lau¹, F. Maldarelli¹

¹National Cancer Institute, NIH, USA, HIV Dynamics and Replication Program, Frederick, United States,

²Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc, Frederick, United States,

³National Institute of Allergy and Infectious Diseases, Clinical Research Section, Bethesda, United States

Background: HIV proviral populations remain dynamic after long-term antiretroviral therapy (ART) but responsible mechanisms are uncertain. During ART, most proviruses are transcriptionally silent, and levels of expression from the HIV-promoter may contribute to the differential dynamics of intact and defective proviruses.

To investigate the effects of long-term ART on HIV promoter sequences, we characterized genetic variability of HIV-LTR in total, intact, and near-full length (NFL) defective proviruses prior to and during long-term ART

Methods: Peripheral blood lymphocytes from 11 participants were obtained prior to and during long-term ART (range 4-20y). Single genome sequences (SGS) of NFL proviruses (>7kb) were obtained by Illumina MiSeq and genetic intactness was determined by analysis of open reading frames and regulatory genes. The total proviral LTR population was obtained by SGS of the LTR alone (450bp).

We measured the genetic diversity by average pairwise distance (APD) and assessed population structure by phylogenetics and Slatkin-Maddison analyses. We predicted the promoter activity of LTR transcription factor binding sites (TFBS) based on the TRANSFAC database

Results: We obtained 0-50 intact, 2-46 NFL defective, and 10-36 LTR sequences/timepoint. No significant differences were detected in LTR genetic diversity (APD range: 0.83-2.17%) in total, intact, or NFL-defective proviruses prior to or during long-term ART.

From pretherapy to long-term ART, no changes in proviral population structures of intact were observed but significant changes were observed in 2/11 participants for NFL-defective and total proviruses.

LTR populations in intact and NFL-defective were, however, distinct from the total proviruses in 6/11 patients, either due to population shifts only at pretherapy (2/6 cases), only after long-term ART (3/6) or at both (1/6).

Differences in genetic variations in TFBS between NFL vs total proviruses were present in a minority of individuals, with changes in CCAAT-box binding (3/8 participants), NF-KappaB (3/11), CP2 and SP1 (2/11), Pit-1A and Oct-1 (1/11) sites.

Conclusions: HIV-LTR derived from NFL proviruses undergoes population shifts from total proviruses in the majority of participants observed both at pretherapy and after long-term ART.

These results suggest differential levels of host-specific pressure on the transcriptional activities of NFL and highly deleted proviruses and ART does not significantly contribute to this difference.

Delineating the role of transcription factor BRD9 in HIV-1 latency reactivation

T.Y. Luk¹, L.Y. Yim¹, H. Chu², Z. Chen¹

¹AIDS Institute, The University of Hong Kong, Department of Microbiology, Hong Kong, Hong Kong, SAR of China,

²The University of Hong Kong, Department of Microbiology, Hong Kong, Hong Kong, SAR of China

Background: AIDS remains incurable despite in search for treatment regimens in the past decades. The major obstacle is the HIV-1 latent reservoir in infected immune cells, especially in resting memory CD4+ T cells. The "Shock and Kill" strategy combines the administration of latency reversal agent (LRA) and anti-retroviral treatment (ART) to induce HIV-1 reactivation from infected cells and stimulate immune response against them.

Since current LRA treatments in clinical trials are suboptimal, drug screening for novel LRA remains a promising strategy to eliminate HIV-1 latent reservoirs.

This study therefore aims to reveal the potential of epigenetic drugs as new LRA specifically applicable in CD4+ T cells.

Methods: We first screened an epigenetic drug library consisting of 280 compounds using the latent HIV-1-infected T cell line model ACH2 and ranked the drugs according to their HIV-1 reactivation effects. Selected drug candidates were tested in different cell models to validate their functions. Measurements included qPCR, HIV-1 p24 ELISA and flow cytometry to identify the changes in HIV-1 production.

Gene knockout experiment was utilized to elucidate the ability of the target proteins of drug candidates in controlling HIV-1 gene expression.

ChIP-qPCR experiment was used for identifying the DNA-binding regions of target proteins to confirm their interactions with HIV-1 genome.

Results: We found that the inhibitor of transcription factor BRD9, namely I-BRD9, was an encouraging LRA candidate. BRD9 protein belongs to the BET protein family that consists of BRD4 protein that is known to mediate HIV-1 gene expression. I-BRD9 reactivated HIV-1 production not only in ACH2 T cells but also in infected resting memory CD4+ T cells and PBMC samples isolated from HIV-1 patients undergoing ART treatment.

Furthermore, knocking down BRD9 gene in ACH2 T cells increased HIV-1 production significantly. ChIP-qPCR experiment then demonstrated that BRD9 protein could bind to LTR and Gag gene region of HIV-1 genome, which integrated into host cellular genome, and it might regulate HIV-1 gene transcription via direct interaction.

Effect of combination latency reversing agents and bNAbs in SHIV-infected rhesus macaques on antiretroviral therapy

A. Solis Leal¹, N. Bobby¹, S. Mallick¹, A. Goodroe¹, J. Kaur², F. Wu¹, G. De La Torre¹, C. Fennessey³, Y. Cai², J. Murry², B. Keele³, B. Ling⁴

¹Texas Biomedical Research Institute, San Antonio, TX, United States, ²Gilead Sciences, Inc., Foster City, United States, ³Frederick National Laboratory, AIDS and Cancer Virus Program, Frederick, United States, ⁴Texas Biomedical Research Institute, San Antonio, TX, United States

Background: The combination of latency reversing agents (LRA) with antiretroviral therapy (ART) has been proposed as an HIV cure strategy. However, no therapy combination has demonstrated the capacity to clear latent HIV reservoirs.

This study assessed the impact of an LRA in combination with the broadly neutralizing antibody PGT121 on viral reservoirs in ART-suppressed rhesus macaques.

Methods: Eight macaques were infected with the bar-coded virus SHIVAD8E0M and underwent ART starting at 4 weeks post-infection (wpi). These ART-suppressed animals were divided into 2 groups at 49 wpi. The active arm (n=5) was dosed with AZD5582, then ctipavir prior to a 6-week ART interruption (ATI-1). At 80wpi, ART was re-initiated with a combination of AZD5582 and PGT121.

The control group received daily ART only. At 87 wpi, animals from both groups entered a 2nd ATI (ATI-2) for up to 11 weeks before necropsy. Changes in cellular and tissue viral reservoirs were evaluated using deep sequencing and quantitation methods, immunofluorescence and cell sorting.

Results: Plasma viral loads (pVL) were consistently <81 copies/ml while on ART in both groups. The active arm experienced viral rebound with detectable virus in plasma and cerebrospinal fluid during ATI-1; all animals showed a similar reservoir size in multiple tissues and organs at necropsy.

Viral DNA was detected in multiple regions of the brain, with low intact proviral reservoirs ranging between 75 and 374 intact proviruses/10⁶ cells in either temporal or parietal lobes, hippocampus, and/or hypothalamus in both groups. The active arm did not rebound during ATI-2, while all control animals rebounded within 6 weeks of ATI-2.

Conclusions: Sustained viral suppression after receiving AZD5582 and PGT121 suggests that PGT121 exposure prevented viral rebound. More data collection is ongoing and will provide further insights regarding cell types and anatomic sites that harbor reservoir.

These preliminary data also suggest that intact viruses in certain brain regions may serve as HIV reservoirs that could be challenging for eradication. Thus, future HIV cure strategies may need to include drugs that specifically target these resilient reservoirs.

EPA0081

Transient upregulation of CD4 increases permissibility of Vδ1 T cells to HIV-1 infection

B. Mann¹, M. Sanz¹, K. Langlands¹, M. Siegel¹, N. Soriano-Sarabia¹

¹George Washington University, Washington, United States

Background: The human gammadelta (γδ) T lymphocyte subset Vδ1 cells populate both peripheral blood and tissues with high rates of HIV replication such as lymph nodes (LNs). During early HIV infection peripheral Vδ1 cells expand.

Although the majority of γδ T cells do not express CD4, we previously demonstrated that other subsets upregulate CD4 following activation and becoming permissive to HIV infection. Therefore, we hypothesized that activated Vδ1 cells also upregulate CD4 expression increasing their permissibility to HIV entry and subsequent latent infection.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from ART-suppressed people living with HIV (PLWH) and HIV-seronegative donors. LNs were obtained from the National Disease Research Interchange. A single cell suspension was obtained from LNs after mechanical disruption. Modulation of CD4, CCR5, and CXCR4 on circulating Vδ1 cells was assessed in time-course experiments by flow cytometry.

Separately, both PBMCs and LN cells were activated with 3 mg phytohemagglutinin and 100U/mL IL-2 for 72 hours prior to exposure to HIV variant JR-CSF for six days. In some cultures, CD4 was blocked using a monoclonal antibody prior to infection. HIV DNA was measured within Vδ1 cells and resting CD4 T cells from PLWH by droplet digital PCR (ddPCR).

Results: Vδ1 cells had a mean *ex vivo* expression of 5.6% CD4, 21.1% CCR5 and 93.7% CXCR4 compared to conventional CD4+ T cells which had mean CCR5 of 5.7% and CXCR4 of 86.9%. CD4 expression increased in Vδ1 T cells following activation, peaking at 5-6 days and declined thereafter. We found that both peripheral and tissue Vδ1 cells were permissive to infection *in vitro*. Infection was inhibited by the presence of αCD4. HIV *pol* DNA was detected in Vδ1 cells in ART-suppressed PLWH.

Conclusions: Our results indicate that HIV infection of Vδ1 T cells is CD4-dependent similar other T cell populations. Upregulation of CD4 within Vδ1 cells is transient following activation suggesting a potential window of opportunity where they are most susceptible to infection.

Successful infection of tissue and circulating Vδ1 cells *in vitro* and detection of HIV DNA *ex vivo* necessitates further investigation into their potential role as a latent viral reservoir.

EPA0082

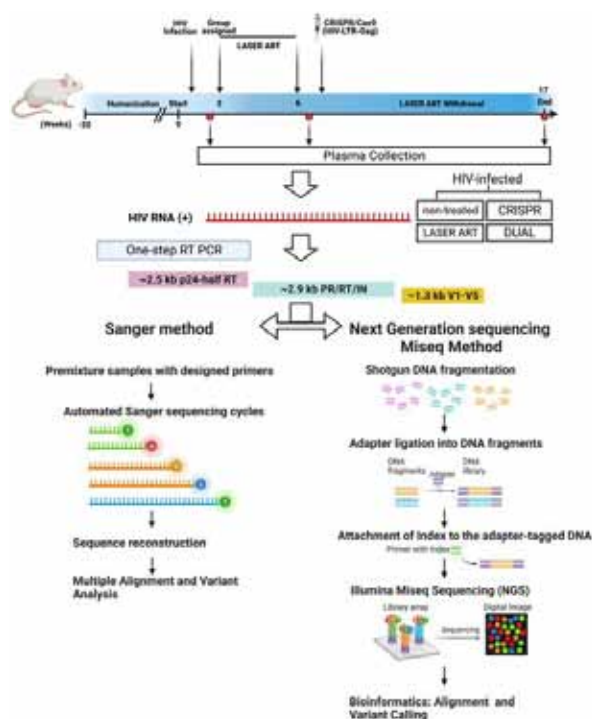

Molecular deep sequencing analysis of rebound viruses from antiretroviral drug and CRISPR-treated HIV-infected humanized mice

C. Zhang¹, H. Gendelman¹, P. Dash¹

¹University of Nebraska Medical Center, Department of Pharmacology and Experimental Neuroscience, Omaha, United States

Background: The elimination of human immunodeficiency virus type-1 (HIV-1) was achieved from infected humanized mice following combination antiretroviral and CRISPR-Cas9 therapies. However, viral rebound was observed in more than two-thirds of dual-treated animals. Single-genome and next-generation sequencing (SGS and NGS) were deployed to determine the molecular signature of these viral variants.

Methods: Plasma-derived replication-competent viral RNA was collected before and after combinational antiretroviral therapy (cART is defined by dolutegravir, lamivudine, abacavir, and rilpivirine), and CRISPR/Cas9 targeting HIV-1-LTR-gag treatment. One-step reverse transcriptase polymerase chain reaction (PCR) was performed from humanized HIV-1 infected mice plasma as controls (untreated) or replicate animals treated with cART (-; CRISPR- treated; or both cART and CRISPR).

Results: Sequencing and bioinformatics analysis revealed low-frequency non-salient mutations across the untreated samples at different time-points confirming the existence of host selection pressure. The env region demonstrated the greatest evolution divergence compared to other viral regions in the same treatment group. Importantly, the longitudinal analysis showed that the treatment (ARV and/or CRISPR) was responsible for the new mutations/indels in the env region over the course of study. No CRISPR-mediated indels or nucleotide substitu-

tions were observed at or near the gRNA-targeted cleavage site. Using Stanford drug-resistance database and IAS Drug Resistance Mutation List, accessory mutations not belonging to any major drug-resistant mutations were found utilizing SGS, while both major and accessory mutations were detected by NGS in samples from cART and dual treatment groups.

Conclusions: Collectively NSG-humanized mice paralleled viral evolution previously identified in ART-treated patients living with HIV. We detected drug-resistant mutations in four out of eleven cART-treated samples using NGS at 2% high-sensitive threshold analysis, suggesting drug resistance-mediated escape mutants may have contributed to the viral rebound.

Additional mechanisms which may have contributed to the viral rebound in dual-treated samples remain under investigation.

Novel treatment and prevention strategies

EPA0083

Engineering macaque B cells for persistent anti-HIV broadly neutralizing antibodies production

A.-S. Kuhlmann¹, N. Madkhali¹, E. Moskovitz¹, J.E. Parrott¹, M.D. Gray², J.J. Taylor², C.W. Peterson¹, H.-P. Kiem¹

¹Fred Hutchinson Cancer Center, Stem Cell and Gene Therapy Program, Clinical Research Division, Seattle, United States, ²Fred Hutchinson Cancer Center, Vaccine and Infectious Division, Seattle, United States

Background: Recent clinical trials conducted in people living with HIV (PLWH) have shown that the administration of anti-HIV broadly neutralizing antibodies (bNAbs) is safe, significantly decreases the plasma viremia and potentiates HIV-specific host immune responses. However, waning levels of injected bNAbs are frequently associated with viral rebound and bNAb resistance during analytical treatment interruption (ATI).

These challenges significantly hamper bNAbs potential. To address this issue, we are interested in applying CRISPR-based gene editing methods to permanently reprogram B cells to express one or more bNAbs from the endogenous immunoglobulin heavy chain (IGH) locus.

To facilitate rapid translation to PLWH, we have focused on studies in our well-established nonhuman primate (NHP) model of acquired HIV-1 and anti-HIV gene therapy. Here we present foundational NHP B cell manufacturing data that will be applied in upcoming NHP experiments.

Methods: Rhesus macaque B cells were isolated and activated in culture before *ex vivo* editing with IGH-directed CRISPR-Cas9 ribonucleoprotein and adeno-associated virus (AAV). CRISPR targeting promotes the insertion of AAV-delivered homology donor template encoding an

engineered VRC01 bNAb into an intronic region of the IGH locus, replacing the endogenous heavy chain expression. IGH editing efficiency and specific integration of VRC01 in the targeted locus were assessed by Inference of CRISPR Edits (ICE) and in-out PCR, respectively. Cell surface VRC01 expression was quantified by flow cytometry.

Results: CRISPR RNP edited the IGH locus in 80-90% of NHP B cells. These edits facilitated the insertion of our VRC01 donor sequence, which was confirmed by in-out PCR.

Five to eight days post-editing, flow cytometry assays identified up to 15% of NHP B cells expressing VRC01 bNAb at the cell surface. Our editing approach did not impact NHP B cell proliferation, consistent with successful expression and trafficking of the engineered VRC01 bNAb.

Conclusions: Our data demonstrate that NHP B cells can be efficiently engineered to express anti-HIV bNAbs. This ongoing study paves the way for further *in vivo* evaluation in our immunocompetent NHP model.

In addition to adoptive transfer of *ex vivo*-manufactured B-cells, we are developing *in vivo* editing approaches to accelerate efficacious, scalable and feasible B cell-based therapies for PLWH.

EPA0084

(5R)-5-Hydroxytriptolide inhibits immune activation in SIV-infected ART-treated rhesus macaques

X. Liu^{1,2}, T. Lv³, J. Xue⁴, L. Lin³, L. Lu², X. Li², Y. Yang², Y. Wu², Q. Wei⁴, W. Cao², T. Li^{1,2}

¹Tsinghua University, Tsinghua-Peking Center for Life Science, Beijing, China, ²Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Department of Infectious Diseases, Beijing, China, ³Beijing Friendship Hospital, Capital Medical University, Department of Infectious Diseases, Beijing, China, ⁴Institute of Laboratory Animal Science, Chinese Academy of Medical Sciences and Comparative Medicine Center, Peking Union Medical College, Beijing Key Laboratory for Animal Models of Emerging and Remerging Infectious Diseases, Beijing, China

Background: Chronic immune activation significantly contributes to HIV pathogenesis and disease progression, while the available interventions are limited. Triptolide has been identified as the primary active ingredient of Tripterygium wilfordii Hook F (TwHF), which has shown promising clinical benefits in PLWH.

Here, we investigated the efficacy of (5R)-5-hydroxytriptolide (LLDT-8), a novel triptolide derivative, to reduce immune activation in rhesus macaques (RMs).

Methods: 8 RMs were infected with SIVmac239 and ART was initiated 14 weeks after infection. At the same time, RMs were randomly allocated to receive daily LLDT-8 (Shanghai Pharmaceuticals Holding Co., Ltd., Shanghai, China; 0.2 mg/kg, n= 4) or placebo (n= 4) in alliance with continuous ART. During the 24-week follow-up, T cell

subsets, SIV RNA, and SIV DNA were measured to monitor treatment efficacy. PBMCs were collected to conduct transcriptomic analyses by RNA-seq.

Results: Following SIV infection, the CD4⁺ T cell percentage significantly decreased from 26.2% (15.7, 39.9) to 6.5% (3.5, 9.5) and the co-expression of CD38 and HLA-DR on CD8⁺ T cells also increased from 1.4% (0, 5.8) to 14.4% (10.4, 21.5) of all RMs at 12 wpi. LLDT-8 treated RMs experienced a much faster-descending percentage of HLA-DR⁺CD38⁺CD8⁺ T cells than the placebo group (wk16-wk 12: LLDT-8, -9.5% vs. placebo, 1.5%; *P*= 0.029).

The RNA-seq results showed that LLDT-8 treatment significantly inhibited immune activation and proliferation-related pathways, including the E2F targets, the G2M checkpoint, and the mitotic spindle, the spermatogenesis, and the IFN- α response pathways.

The expression of *MKI67* was continuously differentially expressed at different time points throughout the LLDT-8 treatment, and significantly correlated to CD8⁺ T cell activation level (Pearson's *r*= 0.23, 95%CI 0.04-0.41, *P*= 0.017). These results were validated in human PBMCs, LLDT-8 significantly suppressed the expression of Ki-67, CD38, and HLA-DR on CD8⁺ T cells in a dose-dependent manner *in vitro*.

Conclusions: LLDT-8 treatment significantly inhibited CD8⁺ T cell activation in SIV-infected RMs and human PBMCs, providing a potential therapeutic option for PLWH.

EPA0085

Dual therapy of Interleukin-21 and anti- $\alpha\beta 7$ antibody administration during ART-treated SIV promotes immunological responses and ameliorates dysbiosis in rhesus macaques

S.D. Johnson^{1,2}, M. Pino³, A. Acharya¹, K. Nguyen³, F. Villinger⁴, M. Paiardini^{3,5}, S.N. Byraredy^{1,6,7}

resultant sequelae, even during ART. Both IL-21 and anti- $\alpha 4\beta 7$ administration modulate gut lymphocyte milieu improving mucosal barrier function, thus limiting inflammation and plasma viral loads (VLs). We hypothesized that combining these interventions would synergistically further improve outcomes.

Methods: Sixteen rhesus macaques (RMs) were inoculation with 300 TCID₅₀ SIVmac239. Six weeks post acquisition (p.a.), ART (TDF+FTC+DTG) was initiated and administered until interruption at week 72 p.a. (ATI). Starting week 64 p.a., the experimental group (n=7; one excluded for remaining viremic during ART) was administered seven rounds of 100 μ g/kg subcutaneous IL-21-IgFc weekly and 50 mg/kg intravenous anti- $\alpha 4\beta 7$ antibody every three weeks. Animals were sacrificed at week 92 p.a. VLs, intact proviral DNA assays in CD4⁺ T-cells, flow cytometry, and fecal 16S rRNA sequencing were performed longitudinally.

Results: All RMs rebounded after ATI. Controls experienced progressive increases in VL reaching pre-ART setpoints after day 100 ATI.

In contrast, and despite higher initial rebound, dual-treated RMs controlled viral replication better compared to pre-ART setpoints, with log₁₀ 2.2 copies/mL lower VLs by sacrifice (P<0.0001).

At endpoint, dual-treated RMs had log₁₀ 1.4 copies/mL lower VLs than controls. Reservoir size was not different between groups. Following ATI, controls experienced increases in PD-1 expression on CD4⁺ TCMs (P<0.0001), with no significant changes in dual-treated RMs. Notably, reservoir size at dual therapy baseline correlated with PD-1⁺ TCMs (P=0.04) and predicted VLs ATI (P=0.007).

Finally, dual therapy facilitated SIV-associated dysbiosis recovery (increased Firmicutes (P=0.001), decreased Spirochaetes (P=0.02), decreased Proteobacteria (P=0.02)) compared to controls (week 72 p.a.). *Roseburia* (a butyrate-producing Firmicute) abundance was predictive of PD-1⁺ TCMs after therapy (P=0.004) and subsequent viral loads (P=0.004).

Conclusions: We demonstrate that combining IL-21 and anti- $\alpha 4\beta 7$ treatments inhibits PD-1 expression on CD4⁺ TCMs, ameliorates dysbiosis, and limits VLs after ATI. These findings highlight the importance of targeting PD-1 and microbiome composition for improving immune responses against SIV and provide a roadmap for future mucosal immunotherapies in ongoing cure efforts.

⁵Emory University, Center for Human Health, Atlanta, United States,

⁶Harvard Medical School, Center for Bioethics, Boston, United States,

⁷Arizona State University, Psychology, Tempe, United States,

⁸Emory University, Dermatology, Atlanta, United States

Background: Regardless of combined antiretroviral therapy (ART), mild HAND still commonly occur due to the incompetence of ART to eradicate brain HIV, and consequential persistent viral infection in the brain. Pathologically HAND appears to correlate with immune dysregulation, and ongoing presence of neurotoxic HIV proteins, which lead to progressively deteriorated neurocognitive function.

Eventually, more severe forms of neurocognitive impairment, such as dementia may take place, and, in aging people with HIV (PWH) comorbidities likely increase susceptibility to HAND and accelerate progression.

Therefore, adjunctive therapies need to be developed that reduce or eliminate brain HIV or limit cognitive impairment.

Methods: Honokiol is known to exhibit anti-inflammatory and neuro-protective effects. CH is a synthetic Honokiol analogue and was administered in a SCID HAND mouse model in order to determine its ability to reverse cognitive and pathological features of HAND.

Mice (n=24) were firstly intracerebrally inoculated with HIV-infected human monocyte derived macrophages (MDMs). Control group of mice (n=12) were injected with uninfected MDMs.

Then half of the HAND mice (n=12) were administered 3mg of CH intraperitoneally daily for 6 days, the other HAND mice were given saline. Cognition was assessed through object recognition testing (ORT) among three groups of mice before and after treatment.

Mice were sacrificed after 1 week of treatment and the severity of neuroinflammation, including astrogliosis (GFAP), dendritic arborization (MAP2), microgliosis (MHCI⁺/CD45⁺), was evaluated by both histopathology and flow cytometry.

Results: CH treatment reversed ORT abnormalities. Flow cytometry revealed that the percentage of activated astrocytes were significantly decreased in CH-treated HAND mice compared to untreated HAND mice. Densitometric analysis of MAP2 indicated that CH largely restored the

changes of neuronal dendritic arborization compared to untreated HAND mice. Also, CH promoted mouse mononuclear phagocyte infiltration into the CNS.

Conclusions: CH ameliorated brain histopathology in HAND mouse model, and elicited protection via reducing HIV-induced neuroinflammation.

Future investigations will focus on characterizing the molecular and immunological profiling of monocytes and microglia in this HAND mouse model.

L. de Chaisemartin⁴, O. Binois⁵, N. Achour Chneiweiss⁵, M.-T. Nugeyre^{2,1}, R. Le Grand¹, E. Menu^{2,1}

¹Center for Immunology of Viral, Autoimmune, Hematological and Bacterial Diseases, UMR 1184, Université Paris-Saclay, Inserm, CEA, IDMIT, Fontenay-aux-Roses, France, ²Institut Pasteur, Université Paris Cité, Mucosal Immunity and Sexually Transmitted Infection Control (MISTIC) Group, Virology, Paris, France, ³Life and Soft, Fontenay-aux-Roses, France, ⁴INSERM UMR 996, Inflammation, Chemokines and Immunopathology, Université Paris-Saclay, Châtenay-Malabry, France, ⁵Service de Biologie de la Reproduction, Préservation de la Fertilité, CECOS, Hôpital Antoine Bécère, Clamart, France

Background: Heterosexual transmission from male to female is the major route of sexually transmitted infections (STI) and occurs mainly via the female reproductive tract (FRT) mucosae. Environmental factors present within the FRT play a role in the control against pathogens. An increase inflammation is rather in favour of a high risk of STI acquisition.

To have a better understanding of the interaction between the local environmental factors within the FRT in physiological conditions and during a STI, we have conducted three *in vivo* studies in the female cynomolgus macaque model.

Methods: Firstly, we have studied the interplay between the vaginal microbiota and the local inflammation during the menstrual cycle. Secondly, the impact of vaginal microbiota manipulation on the inflammatory immune response and on *Chlamydia trachomatis* (CT) acquisition was analysed. Finally, semen being the main STI vector, we analysed the impact of seminal plasma (SP) and CT infection on the vaginal microbiota and inflammation. For all the studies, the menstrual cycle (progesterone measurement), cytokine production (blood and vaginal

fluids) by Luminex[®], neutrophil subpopulations (blood and vaginal cytobrushes) by flow cytometry and the vaginal microbiota (16S rRNA V3/V4 regions or full 16S) were analysed longitudinally.

Results: We characterized for the first time the main cervicovaginal neutrophil subpopulations and demonstrated that local innate markers and vaginal microbiota composition are influenced by hormonal cycle phases.

We highlighted an impact of the vaginal microbiota composition on the local and systemic immune responses induced by CT infection and a significant and persisting alteration of the vaginal microbiota upon antibiotics and CT infection/inoculation.

We have shown that a single SP inoculation induced a higher inflammatory profile, with an increase production of cytokines and neutrophil extracellular traps (NET), compared to repeated SP inoculations.

Furthermore, the immune responses to CT infection varied in the presence or absence of SP.

Conclusions: Our studies support the idea that strategies aiming at modulating the FRT inflammation could be effective to prevent adverse genital health outcomes such as STI acquisition. However, such strategies must remain efficient during semen exposition and during the entire menstrual cycle to have a significant effect on the genital health.

TB-associated microenvironment represents a barrier for HIV curative strategies

G. Duette^{1,2}, A. De Vries-Egan¹, Z. Vahlas³, C. Melucci⁴, P. Pereyra Gerber⁵, A. Czernikier⁴, A. Pereyra Casanova¹, M. Sharabas¹, G. Turk⁴, A. Kelleher⁶, C. Verollet³, L. Balboa⁷, S. Palmer^{1,2}

¹The Westmead Institute for Medical Research, Centre for Virus Research, Westmead, Australia, ²University of Sydney, Faculty of Medicine and Health, Sydney, Australia, ³Institut de Pharmacologie et Biologie Structurale, Université de Toulouse, CNRS, Toulouse, France, ⁴Instituto de Investigaciones Biomédicas en Retrovirus y SIDA, Universidad de Buenos Aires-CONICET, Buenos Aires, Argentina, ⁵Cambridge Institute for Therapeutic Immunology and Infectious Disease, Jeffrey Cheah Biomedical Centre, Cambridge, United Kingdom, ⁶The Kirby Institute, The University of New South Wales, Sydney, Australia, ⁷Instituto de Medicina Experimental-CONICET, Academia Nacional de Medicina, Buenos Aires, Argentina

Background: Tuberculosis (TB), the most frequent opportunistic co-infection in HIV-positive individuals, enhances the infectivity of each pathogen and worsens the clinical outcomes in persons living with HIV/TB. However, it is unclear how the TB-associated microenvironment affects HIV latency and the efficacy of CD8+ T-cells in eliminating HIV-infected cells. Therapeutically aspirated pleural effu-

sions from TB participants (TB-PE) can reflect the microenvironment found in human respiratory cavities impacted by TB infection.

Therefore, we investigated the effects of TB-PE on latently HIV-infected CD4+ T-cells and HIV-specific CD8+ T-cells.

Methods: For HIV latency studies, CD4+ T-cells from 4 healthy donors were infected with a dual-fluorescent reporter HIV in the presence or absence of TB-PE. The proportion of latently and productively HIV-infected cells was quantified by flow cytometry.

To test whether TB-PE affects HIV latency reversal, CD4+ T-cells from two HIV-positive donors on antiretroviral therapy were exposed to PMA with or without TB-PE. Levels of HIV reactivation were determined by quantifying unspliced HIV-RNA expression by qRT-PCR. The effector CD8+ T-cell response from 3 HIV-positive participants was assessed by measuring intracellular effector cytokine (IFN- γ /TNF- α) production and degranulation (CD107a/b) after stimulation with HIV-peptides in the presence or absence of TB-PE.

In addition, the impact of TB-PE on the transcriptomic profile of CD8+ T-cells was characterized by RNAseq in cells from 3 healthy donors. Differential gene expression analysis was performed to investigate the cellular pathways modulated by TB-PE.

Results: The incubation with TB-PE significantly increased the proportion of latently HIV-infected cells ($p=0.012$). In addition, PMA-induced latency reversal was inhibited by TB-PE in CD4+ T-cells ($p<0.001$). Moreover, the expression of IFN- γ , TNF- α and CD107a/b in HIV-specific CD8+ T-cells was significantly diminished by TB-PE ($p<0.05$).

In addition, cellular pathways involved in T-cell activation, and inflammatory response were downmodulated by TB-PE in CD8+ T-cells ($p<0.01$).

Conclusions: We observed that the presence of TB-PE negatively impacts latency reversal in CD4+ T-cells. Moreover, the effector functionality of HIV-specific CD8+ T-cells was impaired. Importantly, our results suggest that the TB-associated microenvironment may pose a challenge to HIV curative strategies, such as shock and kill, which rely on latency reversal and CD8+ T-cell-mediated clearance in persons living with HIV/TB.

Support vector machine classification modeling identifies composite biomarkers predictive of non-AIDS events in people with HIV on suppressive anti-retroviral therapy

T. Premeaux¹, S. Bowler¹, C. Friday¹, C. Moser², M. Hoenig³, M. Lederman⁴, A. Landay⁵, S. Gianella³, L. Ndhlovu¹

¹Weill Cornell Medicine, Medicine, New York, United States,

²Harvard T.H. Chan School of Public Health, Biostatistics, Boston, United States, ³University of California San Diego, Medicine, San Diego, United States, ⁴Case Western Reserve University, Medicine, Cleveland, United States, ⁵Rush University Medical Center, Internal Medicine, Chicago, United States

Background: People with HIV (PWH) experience an increased risk of non-AIDS events (NAEs), including cancer and cardiovascular disease, despite effective antiretroviral drug therapy (ART), partly driven by chronic inflammation and immune activation. While select immune biomarkers are predictive of NAEs in PWH, composite panels may provide a more effective and accurate means for monitoring adverse outcomes.

Using a support vector machine (SVM) learning approach and a nested case-control study from the AIDS Clinical Trials Group ALLRT cohort, we aimed to identify composite predictors for NAEs.

Methods: Study participants were evaluated at baseline (pre-ART), one-year post-ART at viral suppression, and immediately preceding an event. NAEs (cases), include myocardial infarction/stroke, malignancy, serious bacterial infection, and non-accidental death. Controls were matched for age (median 45 years), sex (84% male), pre-ART CD4+ T-cell count (median 213 cells/mm³), and ART regimen at 48 weeks.

Parameters for model generation included age, sex, pre-ART CD4 count, and 49 plasma biomarkers associated with inflammation, myeloid/lymphocyte activation, coagulopathy, or microbial translocation.

Recursive Feature Elimination identified model parameters which carried significant power to classify cases/controls. SVM classification models were used to predict NAEs and area under the curve of the receiver characteristic (AUC-ROC) measured model accuracy. To reduce data noise, outlier values were adjusted and age range for cases was restricted (30-50 years). 3-fold cross validation was conducted to reduce the risk of overfitting.

Results: SVM modeling did not demonstrate case-control classification at baseline. However, a classification model consisting of 4-1BBL (lymphocyte activation) and CD163 (myeloid activation) identified NAEs with high accuracy one-year post-ART (AUC=0.96, $p<0.0001$).

At pre-event, classification model exhibited decreased accuracy (AUC=0.75, $p=0.0127$) with highest model contributions being 4-1BBL, indoleamine-2,3-deoxygenase 1, VISTA (lymphocyte activation), and D-dimer (coagulopathy).

Impact of HCV clearance on metabolism biomarkers in people living with HIV

A. Deza de la Casa¹, D. Valle-Miralles², S. Grande-Garcia², V. Lara-Aguilar², C. Crespo Bermejo², M. Llamas-Adan², L. Martin Carbonero³, L. Dominguez⁴, P. Ryan⁵, I. De Los Santos⁶, V. Briz², A. Fernandez-Rodriguez¹
¹National Center of Microbiology Carlos III Health Institute, Viral Hepatitis Reference and Research Laboratory, Majadahonda, Spain, ²National Center of Microbiology, Carlos III Health Institute, Viral Hepatitis Reference and Research Laboratory, Majadahonda, Spain, ³Hospital Universitario La Paz, Internal Medicine Department, Madrid, Spain, ⁴Research Institute Hospital 12 de Octubre, HIV Unit Internal Medicine Service, Madrid, Spain, ⁵Infanta Leonor Teaching Hospital, Internal Medicine Service, Madrid, Spain, ⁶Hospital Universitario de la Princesa, Internal Medicine Service, Madrid, Spain

Background: Co-infection with hepatitis C virus (HCV) and human immunodeficiency virus (HIV) alter lipid and glucose metabolism mediated by cytokines release. Our aim was to assess the evolution in metabolic plasma markers of people living with HIV (PLHV) after HCV elimination either spontaneously or with direct active antivirals (DAAs).

Methods: Multicenter prospective study of 116 HIV patients from four Public Spanish Hospitals in Madrid Autonomous Community. Samples were processed at the National Center for Microbiology, Institute of Health Carlos III, Madrid (Spain);

- HCV chronically infected patients (CHR) HIV+/HCV+= 45;
- Spontaneous clarifiers (SC) HIV+/HCV-=36; and;
- HIV control group, HIV+=35.

HCV-exposed patients were all studied at baseline and 48 weeks after achieving sustained virological response (SVR). Plasma levels of 15 metabolic biomarkers were measured by Multiplex Immunoassays. Differences between

groups were evaluated by generalized linear mixed model (GLMMs) for longitudinal series or generalized linear model (GLMs) for non-paired comparisons.

Results: The main metabolic characteristics of the study population are summarized in Table 1. At baseline, CHR patients showed higher levels of adiponectin (aAMR (IC95%) = 1.29 (1.06-1.57) p=0.014), NGAL (aAMR = 1.57(1.08-2.29); p=0.021), and sICAM-1 (aAMR = 3.45(1.86-6.40); p<0.001), than the control group.

After achieving SVR, the CHR group showed a significant decrease in the 3 cytokines that were increased at baseline: adiponectin (aAMR = 0,54 (0,40 - 0,74); p<0.001), NGAL (aAMR = 0,41 (0,21 - 0,77) and sICAM (aAMR = 0,17 (0,06 - 0,44). In contrast, there was an increase in cortisol levels (aAMR = 1.71 (1.31-2.22), p<0.001).

After the end of the follow-up CHR showed normalization of all measured markers that were increased at baseline. Any changes were observed in the same follow-up period for the SC group.

Conclusions: Chronically coinfecting HIV+/HCV+ patients showed altered levels in lipid and glucose metabolism compared to HIV monoinfected subjects and spontaneous clearers. The elimination of chronic HCV infection by DAAs normalized the lipid and glucose metabolism profile except for cortisol that remains increased after reaching RSV compared to levels observed in the HIV group. Spontaneous clarification of HCV did not modify metabolism biomarkers in these patients.

EPA0091

Faster disease progression and increased viral replication among HIV-TB co-infected individuals via *Mycobacterium tuberculosis* mediated modulation of host intrinsic anti-viral factors

U. Khan¹, A. Sharma², S.K. Arora¹

¹Post Graduate Institute of Medical Education and Research, Immunopathology, Chandigarh, India, ²Post Graduate Institute of Medical Education and Research, Internal Medicine, Chandigarh, India

Background: *Mycobacterium tuberculosis* infection in HIV-1 infected individuals enhances HIV-1 viral loads, HIV diversity and also changes the cytokine /chemokine levels, resulting in rapid HIV disease progression and mortality, despite higher CD4 T-cell counts. Many speculations, yet the exact mechanisms are yet not known. The host intrinsic anti-viral factors act directly at different stages of HIV virus life cycle. These factors including APOBEC3G, TRIM5, BST2 and SAMHD1 are interferon inducible and various studies have highlighted their role in HIV infection. We hypothesised that the *M. tuberculosis* mediated immune activation and viral diversity modulate the expression of intrinsic factors as well as the host-viral interactions among HIV-TB co-infected individuals.

Methods: The differential gene as well as protein expression levels of host intrinsic anti-viral factors was evaluated among therapy naïve patients including HIV (n=22),

HIV-TB co-infected (n=22) and TB infected (n=19) cohorts using qRT-PCR and western blotting respectively and correlated with disease progression.

RNA sequencing analysis was carried out for further elucidation of associated pathways. The characterisation of viral *vif* and *vpu* genes was also carried out to understand the host-viral interactions among co-infected individuals.

Results: The gene expression of APOBEC3A, APOBEC3H, and BST2 was significantly up-regulated ($p < 0.0001$) among HIV-TB co-infected patients compared to only HIV or TB infected individuals. A positive correlation with IFN- γ expression in HIV-TB co-infected individuals was observed.

The protein expression of SAMHD1 and BST2 was significantly down-regulated in HIV-TB co-infected individuals indicating the modulation of SAMHD1 and BST2 at post-translational level. The RNA sequencing analysis further confirmed the differential gene expression among HIV-TB co-infected and mono-infected individuals in various innate immune pathways associated directly or indirectly with intrinsic anti-viral factors.

The enhanced APOBEC3A levels and higher number of G-A hypermutations in viral genes of co-infected patients further suggests the role of MTB in HIV viral diversity and hence disease progression.

Conclusions: The study suggests the role of MTB mediated modulation of different intrinsic antiviral factors among HIV-TB co-infected individuals that potentiates the accelerated disease progression.

The findings further indicate the possibility of novel therapeutic strategies targeting host-intrinsic anti-viral factors for better management of co-infected individuals.

In vitro modelling to monitor pathogenic implications of viral co-infections

C. Vanetti¹, S. Zecchini¹, G. Cappelletti¹, M. Garziano², I. Saulle², S. Strizzi¹, F. Limanaqi¹, C. Fenizia², M. Clerici³, D. Trabattoni¹, M. Biasin¹

¹Università degli Studi di Milano, Department of Biomedical and Clinical Sciences, Milan, Italy, ²Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy, ³IRCCS, Fondazione Don Carlo Gnocchi, Milan, Italy

Background: Concurrent infection with two or more pathogens is common and can seriously affect the course of each infection from its own natural history. Co-infecting pathogens may antagonize or facilitate each other—for example, by altering cross-protective host immune responses—modulating host disease outcomes and microbe transmission relative to a single infection. However, experimental testing of co-infection models is extremely limited. Herein, we propose two different *in vitro* co-infection models to assess HIV-1/SARS-CoV-2, and RSV/SARS-CoV-2 immune and viral evolution.

Methods: HIV-1/SARS-CoV-2 co-infection model: PBMCs from 10 healthy volunteers were infected with 1ng HIV-1_{BoL}/1×10⁶ cells and subsequently co-cultured with Calu-3 cells pre-seeded in the bottom side of a transwell. After 24 hours, Calu-3 cells were challenged with SARS-CoV-2 (MOI= 0.015). Ninety-6 hours post-HIV-1 infection, PBMCs and Calu-3 supernatants were harvested for viral load quantification (RT-qPCR) and proteomic analysis (Multiplex Cytokine ELISA).

RSV/SARS-CoV-2 co-infection model: 0.7×10⁵ A549-ACE2 expressing cells were co-infected with RSV and SARS-CoV-2 (MOI=0.01). SARS-CoV-2 and RSV replication was determined 72 hours post infection by RT-qPCR and immune-fluorescent analyses. Type-I interferon release (ELISA) was evaluated on cell culture supernatants.

In both models, immune and anti-viral gene expression was assessed on cells (RT-qPCR). All the experiments were performed in the BSL3 facility.

Results: In the HIV-1/SARS-CoV-2 model, SARS-CoV-2 replication in Calu-3 cells was significantly reduced when exposed to HIV-pre-infected PBMCs. IL-10 expression and production were significantly higher in the co-infected condition, in both Calu-3 and PBMCs. The upregulation of IL-10 was associated to higher STAT3 expression levels. RSV/SARS-CoV-2 co-infection was characterized by an increased replication rate of both viruses compared to single infection, mainly for RSV ($p < 0.001$).

Notably, it was accompanied by a significant rise in the expression of ACE2 ($p < 0.01$) and the main Interferon Stimulated Genes (ISG) (single SARS-CoV-2 vs co-infection: MX2 $p < 0.001$; single RSV vs co-infection: MX1 $p < 0.05$; MX2 < 0.01 ; IFITM3 < 0.05 ; IFN β < 0.05). These results were confirmed by analyzing IFN β release in supernatants.

Conclusions: The HIV-1/SARS-CoV-2 and RSV/SARS-CoV-2 co-infection models display a unique and specific viral and molecular fingerprint. Co-infection models may represent an attractive cost/effective approach to mimic both viral dynamics and host immune responses providing readily-measurable targets predictive of co-infection progression.

EPA0093

HIV infection enhances EBV replication and EBV-associated tumorigenesis *in vivo*

A. Wahl¹, C. Whitehurst¹, M. Rizk¹, A. Teklezghi¹, R.A. Spagnuolo¹, J. Pagano¹

¹University of North Carolina at Chapel Hill, Chapel Hill, United States

Background: Although the incidence of AIDS-associated malignancies has declined, the prevalence of certain types of EBV-associated cancers in people living with HIV (PLWH) has increased.

A clear understanding of how HIV co-infection affects EBV replication and EBV-associated tumorigenesis *in vivo* would accelerate the development of novel therapeutics to reduce EBV-associated cancers.

Methods: First, we established a humanized mouse model of HIV/EBV co-infection. Humanized mice were generated by transplantation of human CD34+ hematopoietic stem cells into irradiated immunodeficient mice. Mice were exposed to EBV then injected intravenously with HIV. Mice exposed only to EBV served as controls. HIV and EBV infection were monitored longitudinally in blood with real-time PCR. The levels of T cells, T cell activation, and memory T cells were also measured in the blood of mice with flow cytometry. At necropsy, tumor incidence and EBV-DNA, T cell, T cell activation, and memory T cell levels in blood and tissues were analyzed.

Results: HIV-RNA was detected in the plasma of all mice exposed to HIV. While no significant difference in EBV acquisition was observed between groups ($P=0.5007$), as demonstrated in PLWH, we observed higher EBV-DNA levels in the blood of EBV/HIV co-infected mice. Peak cell-free and cell-associated EBV-DNA levels were 15-fold ($P=0.0082$) and 5-fold ($P=0.0350$) higher respectively. EBV infection resulted in CD8 T cell expansion, activation, and acquisition of memory phenotype in the blood EBV/HIV co-infected mice and controls.

At necropsy, significantly higher levels of EBV-DNA were observed in the blood ($P=0.0022$), spleen ($P=0.0047$), lymph nodes ($P=0.0140$), bone marrow ($P=0.0350$), liver ($P=0.0082$), and lung ($P=0.0221$) of EBV/HIV co-infected mice.

The levels of activated CD8⁺ T cells were significantly higher in the blood ($P=0.0087$), spleen ($P=0.0221$), liver ($P=0.0140$), and lung ($P=0.0047$) of EBV/HIV co-infected mice.

Macroscopic tumors were observed in all (7/7) EBV/HIV co-infected mice but in only 57% (4/7) of controls. Tumors were also located in more distinct body sites in EBV/HIV co-infected mice compared to controls ($P=0.0023$).

Conclusions: Collectively, these results demonstrate a direct effect of HIV co-infection on EBV replication and pathogenesis *in vivo*. They provide an *in vivo* model that can be used for the study of other HIV co-infections.

SARS-CoV-2 virology, pathogenesis, and host immune responses, vaccines and immunotherapies

EPA0094

A panel of RBD-specific broadly neutralizing antibodies against SARS-CoV-2 variants

Z. Wang¹, D. Li¹, Z. Yuan¹, C. Hu², L. Ren², Y. Hao¹, B. Zhu², Y. Shao¹

¹National Center for AIDS/STD control and prevention, Chinese Center for Disease Prevention and Control, Department of Viral immunology, Beijing, China, ²The First Affiliated Hospital, School of Medicine, Zhejiang University, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China

Background: SARS-CoV-2 has developed into multiple variants, including Alpha, Beta, Gamma, Delta, Lambda and Omicron. Compared to the WT isolate, the Alpha, Delta and Omicron propagated faster, and the Beta, Gamma and Omicron variants showed stronger neutralization resistance to neutralizing antibodies and vaccine-immunized sera.

As a result, developing novel drugs, vaccines or neutralizing antibodies to prevent or treat COVID-19 is vital to completely contain the emergence and prevalence of SARS-CoV-2 variants.

Methods: In this study, single receptor binding domain (RBD)-specific memory B cells were sorted by flow cytometry from one COVID-19 convalescent and paired V_H/V_L regions were acquired by RT-PCR. Then paired V_H and V_L PCR products were cloned into the corresponding expression vectors respectively and antibodies were produced by co-transfecting paired heavy chain and light chain vectors into 293F cells. Antibodies were purified from the supernatant using protein A column in five days.

Furthermore, the neutralizing activity of these antibodies against multiple pseudotyped SARS-CoV-2 variants were evaluated.

Results: We identified five potent RBD-specific neutralizing antibodies (ZHC8, ZHC11, ZHD2, ZHD7 and ZHD11) that neutralized SARS-CoV-2 WT, Gamma (P.1), Alpha (B.1.1.7), Beta (B.1.351), Kappa (B.1.617.1) and Delta (B.1.617.2), with IC_{50} values below 0.3 μ g/mL.

Particularly, three of them (ZHC11, ZHD2 and ZHD7) presented broadly neutralizing activity against Omicron (B.1.1.529) and BA.2 with IC_{50} values below 0.2 μ g/mL. However, it seems that BA.4 escapes the neutralization of these three antibodies.

Antibody ID	Neutralizing activity against variants (IC_{50} , μ g/mL)								
	WT	P.1	B.1.1.7	B.1.351	B.1.617.1	B.1.617.2	B.1.1.529	BA.2	BA.4
ZHC8	0.027	0.015	0.022	0.044	0.147	0.034	NA	NA	NA
ZHC11	0.063	0.027	0.079	0.054	0.225	0.027	0.024	0.062	>0.667
ZHD2	0.007	0.002	0.009	0.004	0.014	0.005	0.045	0.199	>0.667
ZHD7	0.006	0.003	0.011	0.005	0.020	0.008	0.025	0.104	>0.667
ZHD11	0.020	0.015	0.037	0.038	0.037	0.021	0.351	NA	NA

Table.

NA: Not assessed.

Conclusions: In conclusion, we have got broadly neutralizing antibodies against multiple SARS-CoV-2 variants. These antibodies will provide candidate for promising cocktail therapy as well as valuable information for vaccine design to treat or prevent SARS-CoV-2 transmission.

Fc-modified HIV-1 broadly neutralizing monoclonal antibody, VRC01LS, shows enhanced biodistribution in human genital and rectal mucosal tissue compared to VRC01

M.P. Lemos¹, R.D. Astronomo¹, Y. Huang², S. Narpala³, M. Prabhakaran³, P. Mann¹, C.A. Paez¹, Y. Lu¹, G.J. Mize¹, H. Glantz¹, K. Westerberg¹, H. Colegrove¹, K.S. Smythe⁴, M. Lin⁵, R.H. Pierce⁴, J. Hutter⁶, I. Frank⁷, J.R. Mascola⁶, J. Ledgerwood³, A. McDermott³, L.-G. Bekker⁸, M.J. McElrath⁹

¹Fred Hutchinson Cancer Center, Vaccine and Infectious Diseases, Seattle, United States, ²Fred Hutchinson Cancer Center, Vaccine and Infectious Diseases, Seattle, United States, ³Vaccine Research Center, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, United States, ⁴Fred Hutchinson Cancer Center, Clinical Research Division, Seattle, United States, ⁵Fred Hutchinson Cancer Center, Human Biology, Seattle, United States, ⁶National Institute of Health, National Institute of Allergy and Infectious Diseases, Bethesda, United States, ⁷University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States, ⁸University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa, ⁹University of Washington, Department of Medicine, Seattle, United States

Background: The Antibody Mediated Prevention studies demonstrated that infusion of a broadly neutralizing monoclonal antibody (mAb), VRC01, could prevent HIV-1 acquisition in humans. Follow-up analyses suggested that serum mAb concentrations 200-fold above the *in vitro* neutralization titer are needed for 90% prevention efficacy against sensitive circulating strains.

Thus, a combination of mAbs with greater neutralization potency-breadth profiles and extended half-life are critical. Importantly, infused mAbs must reach mucosal areas to block the earliest steps of sexually transmitted HIV-1 infection, before extensive viral replication and reservoir establishment occurs.

Methods: We examined biodistribution, concentration and localization of VRC01 and a variant with enhanced FcRn binding, VRC01LS, in healthy cisgendered adults (12 male, 14 female), followed for 1-52 weeks post-intravenous mAb administration. Participants donated blood serum, cervicovaginal and rectal secretions, semen, as well as cervical, vaginal, and rectal biopsies.

We measured mAb concentrations in the samples using idiotype antibody 5C9 via ultra-sensitive Singulex technology. We assessed sub-anatomical localization of the mAbs in mucosal biopsies by immunohistochemistry.

Results: A single 30mg/kg infusion of VRC01 or VRC01LS was well tolerated. In rectal and cervicovaginal tissues, both localized primarily in the lamina propria and stroma, with low and variable epithelial distribution.

At 1-2 weeks post-infusion, VRC01LS levels were at least ~3-4 times higher than VRC01 in blood serum, rectal, vaginal and cervical tissue and remained higher throughout the study. VRC01LS half-life in serum and tissues was 3-fold higher (60-68 days) than VRC01 (20-27 days). We did not observe enhanced bioaccumulation of VRC01LS in rectal secretions, cervicovaginal secretions or semen. No differences were observed between VRC01 and VRC01LS in terms of penetration into tissues, as a percentage of blood levels. At 5-6 weeks, the penetration of both mAbs into rectal tissue was 8-16% of that in blood, into cervical and vaginal tissue was 22-28%, and <2% penetrated into rectal secretions and seminal plasma.

Conclusions: These results demonstrate benefits of VRC01LS for durable mAb distribution at HIV-1 exposure sites. Both monoclonals reach the lamina propria where most HIV target cells lie. More potent, LS-modified broadly neutralizing mAbs could be a promising, long-acting component for preventing sexually transmitted HIV-1.

EPA0096

COVID-19 vaccination uptake among adolescents and young people living with HIV in Kenya, 2021-2022

I. Mutisya¹, K. Muthoka², K. Masamaro¹, D. Kimanga¹, E. Ngugi¹, J. Odhiambo², P. Mwele², A. Katana¹, L. Nganga¹

¹U.S. Centers for Disease Control and Prevention (CDC), Nairobi, Kenya, ²Palladium Kenya, Nairobi, Kenya

Background: People living with HIV (PLHIV) are at increased risk of morbidity and mortality due to infection by SARS-CoV-2, virus that causes COVID-19. COVID-19 vaccines are both safe and effective in preventing SARS-CoV-2 infection and deaths in PLHIV. Kenya was among early adopters of COVID-19 vaccination in Africa in March 2021.

As of September 2022, 34% of adults of ages 18 years and above in Kenya are fully vaccinated and 8% were partially vaccinated. Vaccination among PLHIV is lower than the general population.

We evaluated COVID-19 vaccine uptake among adolescents and young people living with HIV (AYPLHIV), 15-24 years old during June 2021 and May 2022.

Methods: We analysed data from 1,550 facilities using electronic medical records reported to the national data warehouse from 40 counties. AYPLHIV were defined as those aged between 15-24 years while 25+ years were defined as adults living with HIV. Vaccine uptake was defined as those who had received 1 or 2 doses; fully vaccinated were those who received 1 dose of Johnson and Johnson vaccine or 2 doses of the other vaccines. Outcome variables of interest were uptake of vaccination and completion of the recommended vaccine doses.

We compared outcome measures for AYPLHIV, and adults living with HIV and tested for the difference using chi-square tests.

Results: A total of 1,000,100 records reported from 40 counties were included in the analysis. Overall, 74,120 (7.4%) were AYPLHIV. Vaccine uptake among AYPLHIV was 11.2% (8,284/74,120) compared to 22.7% (210,109/925,980) among adults ($p < 0.001$). AYPLHIV were less likely to be fully vaccinated (7.3%) than adults PLHIV (17.7%) ($p < 0.001$).

Vaccine uptake among male AYPLHIV (9.0% [2,411]) was significantly lower compared to female AYPLHIV 12.4% [5,873] ($p < 0.001$). Vaccine uptake among AYPLHIV varied by geography.

Four counties had the vaccine uptake of $> 20\%$ namely, Nyeri (29%), Siaya (21%), Homa bay (21%) and Kirinyaga (21%).

Counties with high AYP vaccine uptake had a similarly higher vaccine uptake among adults living with HIV.

Conclusions: AYPLHIV have low COVID-19 vaccine uptake and completion of the recommended vaccine doses. Greater advocacy, education, and care navigation could increase COVID-19 vaccine access and uptake among AYPLHIV.

Comparison of immunogenicity and neutralizing antibody response of CoronaVac (Sinovac) and Vaxzevria (AstraZeneca) between people living with HIV with $CD4 \leq 200/\mu L$ and $CD4 > 200$ cells/ μL

S. Chittrakarn¹, S. Chusri¹, P. Siripaitoon¹, S. Kanchanasuwan¹, N. Kositpantawong¹, B. Charoenmak¹, P. Kantiki²

Background: SARS-CoV-2 infection in people who living with HIV (PLWH) is associated with worse outcome. The emergency authorized of COVID-19 vaccines are globally used; therefore, vaccination in PLWH with low CD4 T cell count demonstrated the lower immunogenicity. Heterozygous administration of COVID-19 vaccine triggers higher immunogenicity. Moreover, the immune response of heterozygous vaccine in PLWH is unknown.

Our study aims to compare the immune response of CoronaVac (Sinovac) and Vaxzevria (AstraZeneca) between PLWH with $CD4 \leq 200$ cells/ μL and $CD4 > 200$ cells/ μL .

Methods: A prospective cohort study was conducted to compare the immunogenicity and neutralizing antibody (nAb) of CoronaVac and Vaxzevria between PLWH with $CD4 \leq 200$ cells/ μL (low CD4 group) and $CD4 > 200$ cells/ μL (high CD4 group).

All of the participants received antiretroviral therapy and had undetectable HIV viral load. The anti-RBD IgG level and percentage of nAb inhibition were analyzed at 2 weeks and 12 weeks after complete vaccination.

Results: Thirty participants were included. 15 participants in low CD4 group had a median age of 47 (IQR 33, 55) years and mean CD4 of 139 (IQR 129, 149.5). While 15 participants with high CD4 group had a median age of 47 (IQR 43.5, 50.5) years and mean CD4 of 575 (IQR 476.5, 681).

At 2 weeks and 12 weeks after vaccination in low CD4 group, the median anti-RBD-IgG was 159 IU/ml (IQR 35.8, 492) and 143 IU/ml (IQR 77.3, 344.5), while nAb was 71% (IQR 49.4, 92.9) and decrease to 47.2% (42.3, 85), respectively.

In contrast to high CD4 group, the median anti-RBD-IgG was 273 IU/ml (IQR 154, 791) and 294 IU/ml (IQR 140, 551.5) while nAb was 89.3% (IQR 72.4, 93.8) and relatively stable of 81.6% (61.8, 86.9), respectively.

However, the anti-RBD IgG level and percentage of nAb inhibition were not statistically significant between two groups.

Conclusions: Immune response to heterozygous vaccination with CoronaVac-Vaxzevria between PLWH with $CD4 \leq 200$ cells/ μL and $CD4 > 200$ cells/ μL were not different.

Although, the decline of nAb was observed at 12 weeks after immunization in PLWH with $CD4 \leq 200$ cells/ μL . Therefore, adding a booster dose of COVID-19 vaccine is suggested.

¹Kumamoto University, Joint Research Center for Human Retrovirus infection, Kumamoto, Japan, ²National Hospital Organization, Kyushu Medical Center, Fukuoka, Japan, ³Hiroshima University Hospital, Division of Transfusion Medicine, Hiroshima, Japan

Background: Although People Living with HIV (PLWH) could be at a relatively higher risk of suboptimal immune responses to COVID-19 vaccination, vaccine immunogenicity remains undercharacterized.

Here, in a cohort of PLWH on antiretroviral therapy (ART), we investigated antibody responses to SARS-CoV-2 and variants of concern (VOCs) following primary and booster COVID-19 vaccination.

Methods: We recruited 82 PLWH, with a median age of 48 (IQR, 40-56) years and $CD4^+$ count of 470 (IQR, 314-643) cells/ μL , in Fukuoka and Hiroshima, Japan. Participants had received 2 or 3 doses of either mRNA-1273 (Moderna) or BNT162b2 (Pfizer) mRNA vaccines 2-3 months before plasma was obtained. Plasma IgG was purified by protein A resin and neutralizing activity quantified by SARS-CoV-2 wildtype and VOC spike protein pseudotyped on a lentiviral reporter assay system.

Results: We confirmed that IgG purification could preclude inhibitory activity by non-antibody factors, including residual ART. Following primary vaccination, Neutral-

izing antibody (NAb) potency against wildtype spike was quantitatively detected in 75 (91%) IgG samples at a median IC_{50} of 44.5 (IQR, 27.4– 92.4) μ g/mL. Given NAb potency negatively correlated with age in multivariate analysis ($r=0.33$, $p=0.01$), but not with other host factors, we disaggregated the participants into younger (≤ 48 yrs, $n=42$) and older (> 48 yrs, $n=40$) age groups.

Interestingly, in the younger age group, NAb potency positively correlated with subnormal CD4+ count (≤ 500 cells/ μ L) ($r=-0.63$, $p=0.02$), in contrast with the older age group ($r=0.04$, $p=0.84$).

Similarly, NAb potency negatively correlated with the inflammation biomarker, hs-CRP, in the younger ($r=0.44$, $p=0.01$), but not older ($r=0.09$, $p=0.64$) age group. In a subset of 18 (22%) participants who had received booster vaccination, NAb potency against wildtype, Delta, and Omicron BA.1 and BA.2 subvariants was enhanced >7 -fold ($p<0.001$) except in 2 participants.

Finally, NAb potency against wildtype spike following primary vaccination predicted VOC cross-neutralization post-booster vaccination ($r>0.6$, $p<0.01$).

Conclusions: Our data suggest heterogeneous immune correlates of COVID-19 vaccine immunogenicity in different age groups, peripheral inflammatory, and CD4+ recovery states, hence underscoring the importance of disaggregating cohorts of PLWH by clinical and immune recovery parameters.

Chan School of Public Health, Immunology and Infectious Diseases, Boston, United States, ³London School of Hygiene and Tropical Medicine, London, United Kingdom, ⁴University of Botswana, Medical laboratory Sciences, Gaborone, Botswana, ⁵Ministry of Health, Clinical Services, National Health Laboratory, Gaborone, Botswana, ⁶Botswana-Baylor Children's Clinical Center of Excellence, Gaborone, Botswana, ⁷Baylor College of Medicine, Pediatrics, Houston, United States, ⁸Ministry of Health, Gaborone, Botswana, ⁹University of Botswana, Internal Medicine, Gaborone, Botswana

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) binding antibody titers have been shown to positively correlate with neutralizing antibodies in neutralization assays and have good utility in quantifying immune protection against SARS-CoV-2.

We assessed levels of antibodies post-vaccination using a quantitative binding antibodies analysis in a cross-sectional cohort in Botswana.

Methods: We measured binding antibody responses to SARS-CoV-2 spike (Anti-S) in adults with at least 14 days post-full doses of primary series vaccination with either Oxford/AstraZeneca (Vaxzevria), Johnson & Johnson (Jcovden), Pfizer/BioNTech or Sinovac (CoronaVac), using the Elecsys Anti-SARS-CoV-2 S quantitative immunoassay. We compared log Anti-S responses using multivariable linear regression, analysis of variance (ANOVA) and Student t-tests.

Results: Overall, 1013 participants were enrolled with a median age of 38 years (Q_1 , Q_3 : 31,47), mostly female (78%) and 31% were people with HIV. A total of 438, 450 and 125 participants were within the <3 months, 3 to <6 months and ≥ 6 months post-vaccination, respectively.

Overall, vaccine responses decline over time and there were statistically significant differences observed between vaccine products. Sinovac had the lowest mean responses across all time points.

Significant lower mean Anti-S levels for AstraZeneca ($p=0.004$) and Sinovac ($p=0.049$) were recorded after 3–6 months as compared to <3 months, and no statistically significant change for Pfizer/BioNTech and Johnson & Johnson (Jcovden) vaccine (Fig1A). Anti-S titres were higher in participants with a history of natural SARS-CoV-2 infection and COVID-19 vaccination (either before, after the first or second dose) as compared to those with no history of previous infection. Anti-S responses did not differ by HIV status ($p=0.35$, Fig1B) and age ($p=0.8$).

Figure 1. Anti-Spike Antibody Response A. Overall and B. by HIV status.

Conclusions: SARS-COV-2 Anti-S responses vary by vaccine product but did not differ by HIV status. History of natural infection SARS-CoV-2 infection and COVID-19 vaccination was associated with higher levels of Anti-S responses.

EPA0100

Serum level of Macrophage migration Inhibitory Factor (MIF) is elevated during acute COVID-19 but not associated with severity, in donors from a biobank from Buenos Aires, Argentina

P. Benencio¹, Y. Longueira¹, L. Cruces¹, L. Baquero¹, A. Czernikier¹, V. Gonzalez Polo¹, M.F. Quiroga¹, N. Laufer¹, G. Turk¹, BBEI Working Group

¹Institute of Biomedical Research in Retroviruses and AIDS (INBIRS / CONICET-UBA), University of Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina

Background: MIF is a proinflammatory cytokine, fundamental to innate immunity. Elevated MIF plasma levels have been reported in acute and chronic viral infections, such as influenza and HIV. MIF also promotes the expression of inflammatory cytokines such as TNF- α , IFN- γ , IL-2, IL-6 e IL-8.

Here, we aimed to test whether MIF is also elevated during the acute phase of COVID-19, and whether it has a role in shaping the cytokine response to this virus.

Methods: Serum samples were obtained from 135 individuals with COVID-19 diagnosis that donated blood to the Argentinean Biobank of Infectious Diseases, Buenos Aires, Argentina. CCL2/5, CXCL8/9/10, TNF α , IFN γ e IL-2/4/6/10/17A were evaluated using the Human chemokine and the Human Th1/Th2/Th17 kits (from BD) and MIF was evaluated by ELISA (Biolegend).

Individuals were classified into acute (Ac; <15 days since symptom onset, DSO, N=40), early convalescent (EC; 15-60 DSO; N=62) and late convalescent (LC; >60 DSO; N=33); and mild or severe depending on whether they had pneumonia or required respiratory assistance. Data was analysed using Mann-Whitney, Kruskal-Wallis and Spearman correlation tests.

Results: Age (median=41 years) and sex (female-to-male ratio=0.93) did not differ significantly between the groups. Ac and EC samples had significantly higher MIF serum levels than LC (p=0.0003 and p=0.0024, respectively).

The same differences were observed when comparing only mild Ac and EC versus LC (p=0.0074 and p=0.0333, respectively) or severe Ac, EC versus LC, although the latter differences were not significant.

When comparing MIF levels between mild or severe presentation intra-group (i.e. mild Ac versus severe Ac, etc), no statistically significant differences were observed.

Surprisingly, in severe Ac COVID19, serum MIF levels inversely correlated with CCL2 and CXCL8 (r=-0.490, p=0.0331 and r=-0.495, p=0.0313, respectively), as opposed to mild convalescent COVID19, where MIF directly correlated with CXCL-9, CXCL-10, TNF and IL-2 (r=0.361, p=0.0029; r=0.267, p=0.0305; r=0.237, p=0.049; r=0.249, p=0.042).

Conclusions: Our results suggest that MIF is elevated during acute COVID19 together with other cytokines that participate in the cytokine storm that contributes to SARS-CoV-2 pathogenesis. However, at least in this cohort, it was not associated with a more severe clinical outcome limiting its use as biomarker or therapeutic target.

Background: The main focus of this project is to study the role of UV-C induced irradiation in SARS-CoV-2 Spike protein modifications, so as to employ this technology in order to identify the molecular mechanisms and domains that are crucial in making pathogens more susceptible to this wavelength. The first step is to understand which are the dynamics of UV-C (273 nm) efficacy in viral inhibition: the two components (intensity and exposure time) could have different roles in the efficacy of the 4mJ/cm² dose. Next questions are:

- Can UV-C also exert its antimicrobial effect by directly damaging viral proteins?
- Is it possible to predict whether alterations in structural domains may have consequences in maintaining protein structure/function?
- Is there a correlation between SARS-CoV-2 inhibition by UV-C exposure and its ability to infect cells?

Methods: Following UV-C (273 nm) viral inhibitory dose assessment (4mJ/cm²) through an *in vitro* SARS-CoV-2 infection assay, we performed an in-depth analysis on UV-treated/untreated (UV⁺/UV⁻) S protein by means of mass spectrometry (MS), computational analyses and surface plasmon resonance (SPR).

Results: We document that UV-C antiviral effect is dependent on the total irradiation dose alone, regardless of the time required to provide such dose. Among the UV⁺ altered peptides identified by MS, we focused on a

sequence located in a conserved structural region within the S2 subunit where UV-C irradiation causes the oxidation of one of the two cysteines, disrupting the disulphide bond.

Computational analysis revealed that this disulphide bond breakage generates a long-distance correlation motion in the S1 subunit containing the RBD domain. Accordingly, SPR analysis demonstrated that UV⁺ S binds ACE2 with a significantly lower affinity compared to UV⁻ S protein.

Conclusions: This multidisciplinary approach pinpoints, for the first time, the S2 domain of the S protein as the putative target for the virucidal effect of UV-C, underlining its potential as a therapeutic target to prevent SARS-CoV-2 infection.

The workflow employed in this study could be used to screen viral molecular domains, resulting in a precise molecular fingerprint while providing new insights to adequately address future epidemics.

Background: Long-COVID shows undefined underlying mechanisms such as sustained inflammatory response likely caused by SARS-CoV-2 persistence or to the development of autoimmune-like processes.

In this study, we monitored during 6 months the immune response of a Spanish cohort of individuals who showed signs and symptoms compatible with Long-COVID, in comparison with individuals who fully recovered from infection.

Methods: Prospective, observational, longitudinal study with 33 individuals with persistent symptoms of COVID-19 for 49 weeks post-infection (9 individuals were hospital-

ized during COVID-19). 20 individuals who recovered completely in the first 12 weeks after infection were controls. Peripheral blood samples and clinical data were collected at baseline and after 6 months. Antibody-dependent (ADCC) and direct cytotoxic activity (DCC) were measured against rituximab-coated Raji cells and Vero E6 cells infected with pseudo-typed SARS-CoV-2, respectively. Release of IFN γ , TNF α , and Granzyme B (GZB) was measured in response to SARS-CoV-2 peptides pool. PBMCs were analysed phenotypically by flow cytometry.

Results:

1. Median age of Long-COVID participants was 45 years (IQR 39.5-49.5) and most of them were female (91%). Median age of recovered individuals was 46 years (IQR 29.75-54.75), 90% were female.
2. CD4 from Long-COVID significantly decreased in the 6-months period (1.2-fold; $p=0.0405$), while CD8 remained increased during this time and they produced 1.2-fold ($p=0.0342$) more GZB than CD8 from recovered.
3. NK cells were also increased in Long-COVID but with reduced degranulation capacity (-1.5-fold; $p=0.0330$).
4. Tregs remained significantly increased (3.5-fold; $p=0.0028$) in individuals with Long-COVID after 6 months.
5. ADCC was significantly reduced (1.4-fold; $p=0.0440$) in Long-COVID who were hospitalized, while no significant changes were observed in DCC.

Conclusions: Individuals with Long-COVID showed persistently high populations of Tregs and reduced CD4 during a 6-months period, as well as increased cytotoxic populations with reduced antiviral capacity.

More studies are necessary to develop immunotherapies able to restore normal levels of immunity that may reduce Long-COVID symptoms.

EPA0103

Humoral immune responses to ancestral SARS-CoV-2 wild type and variant strains following COVID-19 vaccination in people with HIV

¹Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia, ²Monash University, Central Clinical School, Melbourne, Australia, ³Burnet Institute, Viral Entry and Vaccines Group, Melbourne, Australia, ⁴Peter Doherty Institute for Infection and Immunity, Department of Microbiology and Immunology, Melbourne, Australia, ⁵Monash University, Department of Microbiology, Clayton, Australia, ⁶Monash University, Department of Immunology, Melbourne, Australia, ⁷Alfred Hospital, Allergy, Asthma and Clinical Immunology Service, Melbourne, Australia

Background: People with HIV (PWHIV) have reduced humoral responses to multiple vaccines compared with controls. Moreover, SARS-CoV-2 variants of concern (VoC) have the potential to evade immunity provided by ancestral COVID-19 vaccines.

We sought to describe humoral immunity to ancestral SARS-CoV-2 and multiple VoCs in PWHIV after 2 and 3-doses of COVID-19 vaccine.

Methods: We prospectively recruited PWHIV receiving antiretroviral therapy, and collected blood samples before commencing vaccination, at 1- and 6-months after the second dose, and 1-month after the 3rd vaccine dose. We measured SARS-CoV-2 receptor binding domain (RBD) and nucleocapsid IgG responses by an ELISA (microg/mL) and neutralising antibodies (nAb) against ancestral SARS-CoV-2 virus, Delta, and Omicron (BA.2, and BA.4/5) variants in a pseudovirus assay expressed as the dilution of plasma required to inhibit 50% viral entry (ID50)

Results: We enrolled 22 PWHIV (95% male, median age 50.6 [IQR 43.4-58.9]) on antiretroviral therapy. Eleven received mRNA vaccines for their primary and first booster doses. The median concentration of RBD-specific IgG was 21.7 (IQR 4.6-38.2) microg/mL after two, and 61.2 (IQR 54.7-83.3) microg/mL after three doses of COVID-19 vaccine. Recipients of two mRNA vaccine doses had higher concentration of RBD-specific IgG (39.9 microg/mL, IQR 17.1-44.2) than those receiving adenoviral-vector vaccines (16.8 microg/mL, IQR 9.7-23.6). While ancestral COVID-19 vaccines generate robust nAb responses to wild type and Delta variants, nAb titres to BA.2, and BA.4/5 were reduced.

Figure: Neutralisation responses to Wildtype, Delta, BA.2 and BA.4/5 in PWHIV following dose two and three COVID-19 vaccines.

Conclusions: PWHIV on antiretroviral therapy mount serological responses to COVID-19 vaccines, which increase after a third dose. Neutralisation of contemporary COVID-19 variants is reduced compared with wildtype and Delta strains, following ancestral vaccination. More data are needed to better understand the role of additional booster doses, particularly with bivalent COVID-19 vaccines, to enhance humoral immunity to circulating COVID-19 strains.

Background: The immune response to COVID-19 vaccine in PLWH may be affected by low CD4 count and immune exhaustion. Most studies are focused on the humoral responses but not on the cellular response.

This is a longitudinal study to evaluate the cellular responses elicited by PLWH after six months of receiving the complete vaccination schedule against SARS-CoV-2.

Methods: Blood samples of 23 PLWH and 16 healthy donors (HD) were collected before receiving the first vaccine dose and then 4-6 weeks and 6 months after two doses of COMIRNATY or Spikevax, or one dose of Ad26.COV2-S. Direct cellular cytotoxicity (DCC) was analyzed by measuring caspase-3 activity in pseudotyped SARS-CoV-2-infected VeroE6 cells after co-culture with PBMCs.

Antibody-dependent cellular cytotoxicity (ADCC) was analyzed by measuring annexin V levels in rituximab-coated Raji cells. Cell subpopulations were analyzed by flow cytometry.

Results:

1. CD4 count in PLWH was 864 (IQR 631-1035) cells/mm³ and CD4/CD8 ratio was 0.97 (IQR 0.69-1.2).
2. DCC against SARS-CoV-2 was increased 3.45-fold (p=0.0361) in PLWH before vaccination, in comparison with HD. After 6 months of receiving the second dose, DCC decreased 9.6-fold (p=0.0313) in HD and 2.4-fold (p=0.1475) in PLWH, but it was 5.25-fold higher in PLWH (p=0.0028).
3. ADCC response decreased 2.49-fold (p=0.0156) in HD but remained unchanged in PLWH.
4. CD8 count was increased 1.42-fold (p=0.0330) in PLWH before vaccination and this level was maintained after vaccination. CD8 degranulation capacity increased 1.3-fold (p=0.0408) one month after vaccination in PLWH but remained unchanged in HD.

5. CD3+CD8-TCR $\gamma\delta$ + subpopulation increased 2.41-fold ($p=0.0011$) in PLWH one month after vaccination but it decreased to similar levels between both groups six months after vaccination.

6. NK levels decreased 9.16-fold ($p=0.0156$) in HD and 3.66-fold ($p=0.0020$) in PLWH six months after vaccination; no differences were found in NKT cells.

7. Six HD (36.5%) and three PLWH (13.0%) had breakthrough infections that did not require hospitalization.

Conclusions: Cellular responses from PLWH after receiving the complete schedule of COVID-19 vaccines were comparable or even better than those developed by HD, mostly based on increased levels of CD8 and NK cells. This cytotoxic activity showed a progressive reduction six months after receiving the second dose of COVID-19 vaccine.

High levels of soluble endothelial cell protein C receptor in plasma of individuals with Long-COVID proves the role of endothelial dysfunction in the persistence of COVID-19

A. Simón-Rueda^{1,2}, C. Sánchez-Menéndez^{1,3}, M.A. Murciano-Antón⁴, O. de la Calle-Jiménez^{1,5}, G. Casado^{1,6,7}, E. Mateos^{1,6}, S. Rodríguez-Mora^{1,6}, M. Torres^{1,6}, M. Coiras^{1,6}

¹Instituto de Salud Carlos III - National Center of Microbiology, Immunopathology Unit, Majadahonda, Spain, ²Universidad Complutense de Madrid, Faculty of Sciences, Madrid, Spain, ³Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Hematology and Hemotherapy Service, Madrid, Spain, ⁴Centro de Salud Doctor Pedro Laín Entralgo, Family Medicine, Alcorcón, Spain, ⁵Universidad Europea de Madrid, Faculty of Sciences, Madrid, Spain, ⁶Biomedical Research Center Network in Infectious Diseases (CIBERINFEC), Madrid, Spain, ⁷Universidad de Alcalá, Faculty of Sciences, Madrid, Spain

Background: Individuals with Long-COVID show persistent inflammatory responses that are compatible with autoimmune-like processes triggered by SARS-CoV-2 acquisition. However, the presence of the virus is usually undetectable, indicating that other factors such as the endothelial dysfunction and/or the loss of integrity in the intestinal mucosa may be causing this syndrome.

This study was aimed to determine if the presence of markers for bacterial translocation and endothelial and/or intestinal mucosa damage may be related to the persistence of Long-COVID.

Methods: Prospective, observational, transversal study with 32 individuals with persistent symptoms of COVID-19 for 49 weeks post-acquisition (3 individuals were hospitalized during COVID-19).

32 individuals who recovered completely in the first 12 weeks after acquisition were used as controls. Residual SARS-CoV-2 viremia was determined by RT-qPCR. Levels of lipopolysaccharide (LPS), lipopolysaccharide-binding protein (LBP), occludin, fatty acid-binding protein 2 (FABP2),

tissue-type plasminogen activator (TPA), and soluble endothelial cell protein C receptor (sEPCR) were determined by ELISA (Abcam) in the plasma of the participants.

Results:

1. Median age of Long-COVID participants was 49 years (IQR 45.0-52.5) and most of them were female (97%). Median age of recovered individuals was 49 years (IQR 37.5-59.0), 69% were female.

2. No detectable viremia was detected in any participant.

3. Plasma levels of sEPCR, which increases during endothelium activation, were enhanced 3.9-fold ($p<0.0001$) in individuals with Long-COVID who were non-hospitalized during COVID-19.

However, sEPCR was undetectable in individuals with Long-COVID symptoms who were hospitalized during COVID-19, indicating that this marker could differentiate between Long-COVID and COVID-19 sequelae. 4) Levels of LPS, LBP, occludin, FABP2, and TPA were similar in individuals with Long-COVID and recovered.

Conclusions: No direct signs of intestinal mucosa damage were observed in plasma of individuals with Long-COVID. However, high levels of sEPCR were observed, in the absence of detectable viremia and negative nasopharyngeal RT-qPCR, in individuals who were non-hospitalized during COVID-19 and show signs and symptoms compatible with Long-COVID.

High levels of sEPCR have been related with thromboinflammatory processes and pulmonary findings during COVID-19 but this is the first report of EPCR persistence during Long-COVID.

EPA0106

Characterization of SARS-CoV-2 diagnostic and subgenomic RNA viral dynamics and seroconversion via Bayesian hierarchical modeling

T. Dong¹, E. Brown^{1,2}, R. Barnabas^{3,4}

¹Fred Hutchinson Cancer Center, Vaccine and Infectious Disease Division, Seattle, United States, ²University of Washington, Biostatistics, Seattle, United States, ³Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States, ⁴University of Washington, Epidemiology, Seattle, United States

Background: While SARS-CoV-2 viral load (VL) measured by diagnostic RT-PCR tracks viral RNA, the detection of subgenomic RNAs (sgRNA) may more accurately identify viral replication.

Understanding both types of viral dynamics and their relationship to immunizing antibodies is crucial for devising better therapeutic and prevention strategies for COVID-19.

Methods: A Bayesian hierarchical model was developed to jointly estimate the diagnostic and sgRNA VL trajectories and rate and timing of seroconversion for a sub-cohort of the COVID-19 PEP Study, a randomized trial conducted in the US between March and August 2020.

Participants self-collected daily mid-turbinate swabs for 14 days and some provided dried blood spot (DBS) samples on day 1, 14 and 28. Swabs were tested for SARS-CoV-2 RNA via RT-PCR and samples with detectable diagnostic RNA were further tested for sgRNA. DBS samples were tested for IgG anti-spike antibodies. 80 participants had sustained viral shedding with at least 2 positive sgRNA samples and were included in this analysis.

Results: On average, the diagnostic VL reached a peak of 8.0 (95% credible interval, CI: [7.8, 8.1]) log₁₀ copies/ml after 3.8 (95% CI: [3.2, 4.7]) days and then cleared after 10.5 (95% CI: [10.1, 10.9]) days. The sgRNA VL reached a peak of 6.0 (95% CI: [5.9, 6.2]) log₁₀ copies/ml approximately 0.6 (95% CI: [0.3, 0.8]) day after the peak diagnostic VL and then cleared after only 5.7 (95% CI: [5.3, 6.1]) days. The estimated infectious period was 10.1 days (95% CI: [9.4, 11.0]).

The overall seroconversion rate was 75.0% (95% CI: [62.5%, 85.0%]) and the peak diagnostic VL was positively associated with seroconversion (odds ratio = 1.24, 95% CI: [1.00, 1.54], for every 10-fold increase in diagnostic peak VL). When seroconverted, the mean time from infection to seroconversion was 14.4 days (95% CI: [12.5, 16.6]).

Conclusions: In this cohort, SARS-CoV-2 viral dynamics were characterized by a rapid rise to reach viral peak and subsequent slower decline.

On average, viral replication terminated after 10 days while SARS-CoV-2 RNA was detectable in respiratory samples for 14 days. Anti-spike IgG seroconversion was positively associated with VL, and the average time of seroconversion since infection was 14 days.

Methods: To assess this issue, by using iPSC-derived-human brain organoids (HBO) we evaluated: the expression of SARS-CoV-2 main receptors: ACE2, CD147, NRP1, Furin, TMPRSS2 (qPCR, IF); their infectability by SARS-CoV-2 over-time (QPCR, TCID₅₀, IF); and the effect of SARS-CoV-2-infection and S exposure on HBO transcriptome (qPCR) and secretome (Multiplex ELISA).

Results: All the main SARS-CoV-2 receptors are expressed by HBO with lower NRP1 levels compared to CD147 and ACE2. By analyzing viral N1 and N2 gene sequence over time, infectability of VeroE6 cells by SARS-CoV-2 infected HBO supernatants, and nucleocapsid expression by IF we confirmed that HBO may be productively infected by the virus.

Furthermore, SARS-CoV-2 infection was accompanied by the activation of apoptotic and stress pathways (caspase3, caspase8, Bcl2, S100B), inflammatory process (CCL2, NLRP3) Interferon Stimulated Genes (IFITM1, IFITM3, STAT1, NFkB) and antigen presentation pathway (ERAP1, ERAP2, HLA-A, TAP).

Notably, the trend of the different targets was comparable following SARS-CoV-2 infection and S-stimulation.

Conclusions: These results confirm that SARS-CoV-2 infect HBO probably by binding CD147 and ACE2 receptors and indicate that the exposure to the S protein can affect their homeostasis and exert neurotoxic effects presumably driving the so called long-COVID symptoms.

Background: COVID-19 typically causes respiratory disorders, but several COVID-19 patients (30-60%) manifest also a wide range of neurological conditions, advocating for detrimental effects of SARS-CoV-2 or Spike (S) protein on the central nervous system.

However, the molecular mechanisms responsible for these dysfunctions as well as the potential neurotropism of SARS-CoV-2, are still under investigation.

Course of HIV disease

EPB0108

A description of the characteristics and causes of HIV related in-patient mortalities at two tertiary children's hospitals in Zambia for the period January – December 2021

K.D. Zyambo¹, S. Sivile¹, B. Nduna², M. Matthew³, M. Mwamba⁴, L. Mulenga⁵, D. Kampamba⁵, J. Mutukwa⁵

¹Ministry of Health, Infectious Diseases – UTH, Lusaka, Zambia, ²Ministry of Health, Arthur Davison Children's Hospital, Ndola, Zambia, ³Ministry of Health, Children's Hospital – UTH, Lusaka, Zambia, ⁴Mwamba's Biostatistics, Research and Data Analysis Services, Lusaka, Zambia, ⁵Ministry of Health, Infectious Diseases – MoH, Lusaka, Zambia

Background: Zambia has made significant progress in improving the ART coverage for children living with HIV (51% in 2016 to 71 in 2022), however, the number of new acquired HIV and HIV related mortalities among children seems to have plateaued over time (after a significant decline from 24,000 in 2010 to 19,000 in 2019). Some of the reasons include delayed diagnosis of HIV and sub-optimal ARV initiations in hospital care.

The aim of the study was to describe the characteristics associated with HIV related in-patient mortalities among paediatric deaths.

Methods: All available mortality case files of children that satisfied the criteria for inclusion were selected from the only two children's hospitals in Zambia. The primary inclusion criterion was mortality cases between January and December 2021 with documented evidence of HIV or exposure to HIV.

We identified and selected 148 cases from 770 reviewed files. Relevant data were abstracted from the case files and uploaded to an online database hosted on the RED-CAP platform. The data were cleaned and analyzed using Microsoft Excel and R programming language. A 5% significance level was assumed for statistical analysis and descriptive statistics were generated.

Results: There was an equal sex distribution of the 148 case files reviewed and of these approximately 59.5% were HIV exposed. About 53.4% of the exposed children did not receive ARV's for PMTCT. An estimated 40.5% of the sample were confirmed HIV positive with up to 28% of these not started on ART. The median age at admission was 10 months (IQR 17). Approximately 33.8% and 33.1% experienced mixed breastfeeding and breastfeeding only practices, respectively. Respiratory diseases were the major cause of death (58.1%) followed by infectious (or parasitic) diseases with about 10.1%.

Conclusions: Most HIV in-hospital related mortalities occurred in children aged less than 24 months and slightly below half had not received either ART or PMTCT. The ma-

jority of deaths in the sample were caused by respiratory diseases. There is need to strengthen early diagnosis and rapid initiation of ART to prevent deaths in children in the two tertiary hospitals.

EPB0109

Factors associated to AIDS deaths among people living with HIV/AIDS on antiretroviral therapy between 2019 and 2021 in Brazil: a retrospective study of programmatic data

A.F. Kolling¹, A.R. Pati Pascom¹, J. Givisiez¹, P.C. dos Santos¹, R. de Almeida Coelho¹, A. Espinosa Barbosa Miranda¹

¹Ministry of Health of Brazil, Department of HIV/AIDS, Tuberculosis, Viral Hepatitis and STIs, Brasília, Brazil

Background: Since the beginning of the AIDS epidemic, 371,744 deaths from HIV/AIDS were reported in Brazil. Despite the advances achieved by the Brazilian government in adopting and incorporating best care practices for PLWHA, such as the adoption of treatment for all, increased antiretroviral coverage, multi-month dispensation, and rapid ART initiation. Reduction of mortality due to HIV/AIDS remains a challenge, considering the country's continental dimensions and substantial differences related to access of PLWHA to health services.

Our study aimed to assess demographic and clinical factors associated to AIDS deaths among PLWHA on ART, between 2019 and 2021, in Brazil.

Methods: We linked programmatic data from the national ART, viral load (VL), CD4 exams, and AIDS mortality information systems from the Ministry of Health of Brazil. PLWHA on ART, from 01/01/2019 and 12/31/2021, aged ≥18yo, were included in this study.

We estimated AIDS deaths rates stratified by demographic characteristics and clinical conditions (ART regimen, CD4, and VL). Univariable and multivariable logistic regression models were performed to access the likelihood of dying from AIDS according to the analyzed characteristics and conditions.

Variable	n	%	OR (95% CI)	p-value

Support systems for HIV self-testing: a global scoping review

A. Tran¹, N. Tran¹, J. Tapa², W. Tieosapjaroen^{2,3}, C.K. Fairley^{2,3}, E.P.F. Chow^{2,3,4}, L. Zhang^{2,3}, C.C. Johnson⁵, M.S. Jamil⁵, J.J. Ong^{2,3,6}

¹The University of Melbourne, Faculty of Medicine, Dentistry and Health Sciences, Melbourne, Australia, ²Alfred Health, Melbourne Sexual Health Centre, Melbourne, Australia, ³Monash University, Central Clinical School, Faculty of Medicine, Nursing and Health Sciences, Melbourne, Australia, ⁴The University of Melbourne, Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, Melbourne, Australia, ⁵World Health Organization, Global HIV, Hepatitis and STI Programmes, Geneva, Switzerland, ⁶London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom

Background: HIV self-testing (HIVST) is a safe and accurate way to increase access to and uptake of testing, particularly amongst key populations. Supporting the use of self-tests and onward linkage to appropriate prevention and care following HIVST remains a critical part of successful implementation.

To understand the current landscape of systems and tools supporting HIVST usage and linkage, we aimed to qualitatively synthesise the available global data on HIVST support systems.

Methods: We conducted a scoping review following the PRISMA guidance and searched five databases between January 2000 and March 2022. Included studies reported on one or more systems supporting: HIVST usage, interpretation of results, or linkage to follow-up services. We used thematic analysis to inductively identify themes.

Results: We screened 14,385 articles and included 316 for analysis, including 109 (34%) randomised controlled trials. Many included key/priority populations such as men who have sex with men (n=96, 30%), female sex workers (n=24, 8%) and pregnant people (n=20, 6%). Most were conducted in Africa (n=176, 56%).

Across 280 (89%) articles, 640 systems supporting self-test use were reported, most commonly: pictorial instructions (n=120, 19%), in-person demonstrations (n=100, 16%) and

in-person assistance (n=86, 13%). Digital tools included smartphone apps (n=11, 2%) and online video conferencing (n=11, 2%). Across 137 (43%) articles, 198 systems explicitly supporting result interpretation were reported, most commonly pictorial instructions (n=65, 33%). Smartphone-based automated results readers (n=7, 4%) have been used in the USA, China, and South Africa.

Across 265 (84%) articles, 1,137 post-test linkage support systems were reported, most commonly: in-person referrals/counselling (n=145, 13%), written referrals/counselling (n=80, 7%) and phone helplines staffed by professionals (n=71, 6%).

Less common linkage systems included home visits (n=35, 3%) and live video counselling (n=23, 2%). Bluetooth technology (n=15, 1%) has been used in the USA to remotely notify counsellors of HIVST kit opening.

Conclusions: Globally, systems supporting HIVST utilise a range of methods, including static media, and digital and in-person engagement. Whilst in-person and printed approaches are relatively common, emerging digital tools are rarer and should be further explored.

The effectiveness of support systems remains to be determined, especially with consideration of individual preferences and local contexts.

EPB0111

Independent analytical evaluation of the COBAS® 5800 system for HIV-1 quantitative and HIV-1/HIV-2 qualitative nucleic acid tests

S. Li¹, K. Sleeman¹, G. Zhang¹, D. Mathis¹, H. Alexander¹, C. Zeh¹

¹US Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV and TB, International Laboratory Branch, Atlanta, United States

Background: Roche Diagnostics recently announced that the COBAS® AmpliPrep/COBAS® TaqMan (CAP/CTM) system, widely used across low-and middle-income countries, will be phased out by early 2024 and replaced by the Roche cobas® 5800 System (c5800). The analytical performance of the c5800 for HIV-1 Quantitative Nucleic Acid Test for viral load (VL) using plasma and HIV-1/HIV-2 qualitative testing using dried blood spots (DBS) was independently evaluated for implementation consideration in the President's Emergency Plan for AIDS Relief (PEPFAR)-supported countries.

Methods: Analytical evaluations of the cobas® HIV-1 Quantitative Test and the cobas® HIV-1/HIV-2 Qualitative Nucleic Acid Test were conducted. HIV-negative plasma or whole blood samples were spiked with WHO 4th HIV-1 International Standard, 2nd HIV-2 International Standard, or cultured virus. Testing was performed using the HIV-1 Quantitative or HIV-1/HIV-2 Qualitative Nucleic Acid Test workflow.

Analytical performances, including precision, linearity, subtype detection, and cross-contamination, were evaluated. For the qualitative assay, reproducibility, cross-

abstractsAuthor
Index

contamination, and subtype coverage for HIV-1 A, B, C, D, CRF02-AG, and HIV-2 were determined. For both assays, the limit of detection (LOD) was calculated using PROBIT analysis, and error rates were assessed.

Results: The LOD for the HIV-1 Quantitative Test was 37.1 copies/mL, the LODs for HIV-1/HIV-2 Qualitative Test were 299 copies/mL and 1425 copies/mL for HIV-1 and HIV-2, respectively.

Testing of forty or fifty replicates of HIV-1 plasma or HIV-1/HIV-2 DBS samples over five days, by two testers with different reagent lots, showed 100% reproducibility. The five major HIV-1 subtypes evaluated were all detected.

No cross-contamination was detected. The error rate was 0% for HIV-1 Quantitative Test from 435 tests and 0.48% for the HIV-1/HIV-2 Qualitative Test from 415 tests. The correlation between the nominal and actual VL concentration of five subtypes was extremely high with the R^2 correlation coefficients were all 0.996 or higher.

Conclusions: We report here the first independent evaluation for HIV-1 Quantitative and HIV-1/HIV-2 Qualitative workflows on the new c5800. The manufacturer's claims were verified. The c5800 combines the capacity to conduct HIV-1 VL and HIV infection with differentiation of HIV-1 and HIV-2, which will prove to be a useful tool in HIV diagnosis and treatment monitoring.

Development of a low-cost ART resistance test for Nigeria's HIV population

N. Panpradist^{1,2,3}, B. Tran¹, K. Yamashita¹, I. Beck⁴, S. Gilligan-Steinberg¹, E. Kline¹, J. Campbell¹, J. Okpokwu⁵, G. Imade⁵, O. Agbaji⁵, P. Kanki⁶, B. Chaplin⁶, L.M. Frenkel^{4,1}, H. Rawizza^{6,7}

¹University of Washington, Seattle, United States, ²Chiang Mai University, Faculty of Associated Medical Sciences, Chiang Mai, Thailand, ³Ministry of Health, National Public Health Laboratory, Nairobi, Kenya, ⁴Seattle Children's Research Institute, Seattle, United States, ⁵Jos University Teaching Hospital, Jos, Nigeria, ⁶Harvard T.H. Chan School of Public Health, Massachusetts, United States, ⁷Brigham Women's Hospital, Massachusetts, United States

Background: Dolutegravir is associated with improved ART outcomes. Despite data suggesting that acquired drug resistance does not undermine efficacy of dolutegravir-ART, additional studies are needed to further evaluate the effects of extensive pre-existing nucleos(t)ide resistance on DTG-ART across subtypes. OLA-Simple is an easy-to-use oligonucleotide ligation assay (OLA), guided by interactive software that reports ART-resistant mutations as colored lines on lateral flow strips. OLA-Simple was validated in subtypes A, B, C, D, and AE, showing higher sensitivity than Sanger sequencing and compared favorably to next-generation sequencing. To expand OLA-Simple use in AG/G subtypes, we designed and tested OLA-Simple probes for a Nigerian cohort.

Methods: OLA-Simple probe sequences were designed to detect M41L, K65R, L74V/I, Y115F, K103N, Y181C, M184V, G190A, and T215F/Y based on 380 *pol* sequences from Nigerian adults' plasma from 2007-2012 with HIV-1 subtypes prevalent in West Africa including CRF02 ($n=20$), G-prime ($n=16$), G ($n=7$), A ($n=7$), CRF06 ($n=3$), C ($n=2$), and D ($n=1$). OLA conditions were optimized to detect minority frequency (10-15%) variants in each person's quasispecies, both in the plate-based OLA and OLA-Simple kit formats.

Optimized probes and plate-based OLA conditions were used to blindly analyze 56 archived RNA at 504 codons, and results were compared to Sanger sequencing.

Results: RT-PCR for OLA-Simple successfully amplified 55/56 with plasma HIV RNA between 140-8250 copies/reaction (median: 660). The one that failed had 265 copies/reaction (CRF06 subtype). Of the remaining 495 codons, 13 failed ligation (2.6%, 95%CI:1.4-4.5), 183 had drug-resistance genotypes, and 299 were wild-type.

Compared to Sanger sequencing, OLA had 93% (95%CI:91-95) concordance with 170 and 292 drug-resistant and wild-type codons, respectively. OLA detected additional 18 drug-resistant codons classified as wild-type by Sanger, presumably below Sanger's limit-of-detection.

Conversely, 2 (1.2%, 95%CI:0.1-0.4) drug-resistant mutant codons detected by Sanger were not detected by OLA due to their weak amplification, potentially due to prolonged storage of RNA. Discordant results are being evaluated by next-generation sequencing.

Conclusions: OLA-Simple was adaptable for multiple HIV subtypes, including AG/G. Our next steps include the evaluation of these probes on currently circulating specimens on-site in Nigeria as well as designing OLA probes to detect dolutegravir resistance.

EPB0113

Assessment of the performance of the plasma separation card (PSC) for HIV viral load monitoring in South Africa

L. Chimoyi¹, L. Hans^{2,3}, M. Oladimeji¹, G. Kindra⁴, K. Diallo⁴, K. Ayalew⁴, G. Setswe^{1,5}, S. Carmona⁶

¹The Aurum Institute, Implementation Research, Johannesburg, South Africa, ²National Health Laboratory Services, Johannesburg, South Africa, ³University of the Witwatersrand, Johannesburg, South Africa, ⁴Centers for Disease Control and Prevention, Pretoria, South Africa, ⁵University of South Africa, School of Health Studies, Pretoria, South Africa, ⁶FIND, Geneva, Switzerland

Background: Viral load (VL) monitoring is a critical component of clinical management of clients on antiretroviral therapy. Newer innovations are necessary in settings where logistics around plasma monitoring are challenging.

We assessed the performance of a plasma separation card (PSC) during routine patient care for VL monitoring in clinical settings.

Methods: We employed a multi-site, cross-sectional evaluation of a PSC on blood specimens collected from all consenting adult (>18 years) and assenting young (<18 years) healthcare clients living with HIV attending ten primary healthcare clinics in Ekurhuleni and Bojanala Districts, South Africa. Ethylenediaminetetraacetic acid (EDTA) anti-coagulated venous samples and PSCs made using capillary blood were collected on site. Plasma VLs were tested at three routine National Health Laboratory Services (NHLS) referral laboratories using standard of care assays.

PSCs were tested at the NHLS, Johannesburg using the COBAS® AmpliPrep/COBAS® TaqMan®. We described sample characteristics and used McNemar tests to assess the differences in agreement between the EDTA- and PSC plasma-samples.

Significance was determined at 5%. The usability of PSC associated tasks such as blood spotting, PSC preparation and analysis was assessed by collecting data on a six-point Likert-scale from healthcare and laboratory staff.

Results: We enrolled 538 healthcare clients, majority of whom were adults [n=515, 95.7% (95% CI:93.7%-97.1%)] and female [n=345, 64.4% (95% CI:60.0%-68.1%)].

Overall, 536 paired PSC- and EDTA-plasma samples were sent for viral load testing of which 503 pairs were tested. Overall, sample failure was reported in 106 [21.1% (95% CI:17.7%-24.9%)] samples. Concordance between the paired PSC- and EDTA-plasma samples was reported for 436 (86.7% (95% CI:83.4%-89.4%)) samples.

Analysis of 503-paired samples at 1,000 copies/ml threshold yielded an overall sensitivity of 87.5% (95% CI:73.2%-95.8%) and specificity of 99.3% (95% CI:97.9%-99.8%).

On the Likert-scale, healthcare staff scored most tasks above 40% ("neutral") whereas laboratory staff rated all the tasks in the pre-analytic workflow assessment as above 80% (agree).

Conclusions: There was concordance of VL counts between PSC- and EDTA-plasma samples. PSC usability by healthcare workers was less favourable. For scale-up of PSC for VL monitoring in clinical settings, addressing the challenges related to its usability is necessary to achieve the UNAIDS third 95 target in South Africa.

EPB0114

Comparing pill counts and patient self-reports with DBS tenofovir concentrations as ART adherence measurements and predictors of virologic suppression and HIV drug resistance in young people failing ART in Zimbabwe

T.J. Mtisi-Chagumaira¹, V. Kouamou¹, G.D. Morse², C.E. Ndhlovu¹

¹University of Zimbabwe Faculty of Medicine and Health Sciences, Harare, Zimbabwe, ²State University of New York at Buffalo, Translational Pharmacology Research Core, Buffalo, United States

Background: Monitoring ART adherence presents a challenge in adolescents. There is need to explore options for effective methods to determine their levels of adherence. We sought to determine adherence levels in adolescents and young adults (on a tenofovir-containing regimen) failing ART as measured by self-reports, pill counts and DBS tenofovir concentrations.

We compared levels agreement among the methods and determined the ability of each method to predict virological suppression and HIV drug resistance mutations (HIV-DRMs).

Methods: We conducted a cohort study involving 107 adolescents and young adults aged 10-24 years failing ART with viral load >400copies/ml at enrolment. Pill count (PC) records, self-reports (SR) and DBS tenofovir concentrations (done by liquid chromatography with tandem mass spectrometry, LC-MS/MS) were used to determine adherence in this group in Harare.

The latter was used as the reference method with a cut-off of 64ng/ml. Determination of drug levels was also performed to rule out inadequate viral response due to low cumulative drug exposure despite high adherence (>90%).

Longitudinal analysis was performed to determine the correlation of viral loads (VL) with adherence. The Kappa (k) coefficient was used to evaluate the level of agreement among the three methods.

Results: Mean age-at-enrolment was 17.8 years (SD± 3) with 51% participants being male. Mean duration with known HIV diagnosis was 7.3years (SD ±3.4). Mean age-at-ART-initiation was 11.8 years (SD± 3.7).

Poor level of agreement was found between PC records and DBS tenofovir concentrations (k=-0.115). Moderate agreement was found between DBS and SR methods (k=0.0557).

Slight agreement was found between PC and SR methods (k=0.0078). Adherence was dependent on age-at-HIV-diagnosis (p=0.0184) and age-at-ART-initiation (p=0.0265).

Participants who were adherent were six times more likely to be suppressed at end point than their non-adherent counterparts (OR=5.7 CI 2.1 - 16.5, p<0.0001).

Low adherence was associated presence of HIVDRMs; those who were non-adherent were 3 times more likely to have HIVDRMs (OR=3.4 CI 1.0 -13.7, p=0.03).

Conclusions: Self-reported adherence and pill counts exhibited poor agreement with the reference method used (DBS tenofovir levels) and are thus not effective methods of predicting virological suppression in this population. Low adherence is associated with presence of HIVDRMs.

Background: HIV-1 plasma viral load (pVL) is the key indicator to monitor the response to combination antiretroviral therapy. pVL of <1000 copies/mL is considered as the threshold for virological suppression (VS) by national (India) and WHO guideline. A subset of people who have attained VS experience low-level viremia (LLV- pVL 40-999 copies/mL); its overall impact on clinical outcome is largely unknown.

Methods: We conducted a longitudinal retrospective analysis of 3498 participants visiting YRGCARE, Chennai, India between 2013-2018. The participants were on ART for ≥6 months with ≥2 pVL measurements.

We stratified results for those with pVL <1000 copies/mL as follows: Fully suppressed (FS) – pVL <40 copies/mL, LLV-I – pVL 40-199 copies/mL, LLV-II – pVL 200-399 copies/mL, and LLV-III-pVL 400-999 copies/mL.

The primary outcome of the study was virological failure (VF) – pVL >1000 copies/mL. Multivariable Cox regression estimated was used to find the association with VF.

Results: The median age was 44 years (IQR 38-50 years), 60% were male, 2574 (73.6%) were on 1st-line, 865 (24.7%) were on 2nd-line, and 59 (1.7%) were on both (BL). The median follow-up duration was 111.28 weeks (IQR 63.4-169.9 weeks). There were 2965 FS (84.8%) and 533 (15.2%) LLV, which includes 225 LLV-I, 130 LLV-II, and 178 LLV-III. 360 of 533 LLV had multiple LLV episodes.

During the follow-up, 343 (9.8%) experienced VF, with 217 (6.2%) having it after LLV (41% of LLV) and 126 (3.6%) having it after FS (4.3% of FS). When compared to suppressed, LLV had a greater risk of VF (HR 12.7; 95% CI 10.2-15.9). 1st-line participants had a higher incidence of VF (HR 15.8, 95% CI 11.4-21.9) than 2nd-line (HR 5.6, 95% CI 4.1- 7.7). LLV-III had the highest risk of VF [(HR 22.856, 95% CI 15.204-34.359) vs. (HR 8.186, 95% CI 5.564-12.043)], followed by LLV-II [(HR 13.375; 95% CI 8.327-21.483) vs. (HR 6.261; 95% CI 4.044-9.695)] and LLV-I [(HR 12.976; 95% CI 7.974-21.118) vs. (HR 4.158; 95% CI 2.826-6.119)] in 1st-line vs. 2nd-line respectively.

Conclusions: LLV was associated for higher risk of VF. Close monitoring of individuals experiencing LLV may help in early identification of VF, thus preventing drug resistance.

EPB0116

Introduction of near point of care testing platform for early infant HIV diagnosis in Nigeria

Y. Timothy Nathaniel¹, F. Emerinini¹, C. Ihesiaba¹, F. Abbah¹, E.M. Shabi¹, C. Andrew¹, R. Fayomade¹, O. Olude¹, P. Anyanwu¹, U. Omo-Emmanuel², I. Iyortim², E. Atuma³, A. Akinjeji⁴, S. Strachan⁵, R. Fayorsey⁶
¹ICAP at Columbia University, RISE Project, Abuja, Nigeria, ²USAID, HIV Care & Treatment, Abuja, Nigeria, ³Jhpiego, RISE Project, Abuja, Nigeria, ⁴ICAP at Columbia University, Abuja, Nigeria, ⁵JHPIEGO, Baltimore, United States, ⁶ICAP at Columbia University, New York, Nigeria

Background: In Nigeria, only 27% of HIV-exposed infants (HEI) received early infant diagnosis (EID) by 2 months of age in 2021. The median turnaround time (TAT) of laboratory results ranged from 28 - 60 days. Multi-disease testing using a polyvalent near point-of-care (POC) testing platform provides new opportunities for reducing the TAT for EID.

This analysis describes the use of GeneXpert platform to improve the efficiency of EID in Akwa Ibom and Taraba States, Nigeria.

Description: The USAID-funded Reaching Impact Saturation and Epidemic Control (RISE) project used GeneXpert machines (previously only used for TB diagnosis) for EID. In collaboration with relevant stakeholders, we selected 8 GeneXpert sites across Akwa Ibom (2), and Taraba (6) States, and networked 83 other facilities using the hub and spoke approach.

RISE trained and mentored laboratory personnel to test dried blood spot (DBS) specimens using GeneXpert at sites, and monitored TAT and return of results weekly.

We analyzed data from 83 spokes health facilities and 8 GeneXpert hub sites before (July to September 2022) and after (October to December 2022) the intervention.

Lessons learned: Before the intervention 165 DBS samples [(51%(84/165) (<2 months), 49%(81/165) (2-12 months)] were received at 2 molecular laboratories with 64% results returned, and a median TAT of 40 days. Post-intervention, 506 DBS samples [(60%(305/506) (<2 months), 40%(201/506) (2-12 months)] were received at 8 GeneXpert sites with 88%(446/506) results returned; median TAT of 2 days. There was a 24% increase in the proportion of results returned and a 95.2% reduction in TAT. EID uptake increased by 21.9% at < 2 months (67.9%(57/84) before and 89.8%(274/305) post-intervention).

All results were returned to the caregivers (100%); the positivity was 5.3% (3/57) for <2 months and 2.1% (1/48) for 2-12 months before the intervention and 2.9% (8/274) for <2 months and 5.8% (10/172) for 2-12 months after the intervention. The linkage to treatment was 100% before (n=4) and after the intervention (n=18).

Conclusions/Next steps: The implementation of near POC EID using the GeneXpert increased access to EID, improved early case identification, and reduced TAT.

**EPB0117****Low-level viremia as a risk factor for virologic failure in children and adolescents living with HIV**K.P. McKenzie^{1,2,3}, W. Olomi⁴, M. Chodota¹, A. Kayabu⁵¹Baylor College of Medicine Children's Foundation - Tanzania, Mbeya, United Republic of Tanzania ²Baylor College of Medicine, Houston, United States, ³Baylor International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Houston, United States, ⁴NIMR-Mbeya Medical Research Centre (MMRC), Mbeya, United Republic of Tanzania ⁵Baylor College of Medicine Children's Foundation - Tanzania, Mwanza, United Republic of Tanzania**Background:** Current guidelines in the majority of developing countries use a viral load (VL) cutoff of 1000 copies/mL to define virologic failure (VF). However, research increasingly demonstrates that VL from 50-999 copies/mL or "low-level viremia" (LLV) is a risk factor for future VF.**Methods:** A retrospective chart review was performed using the health records from the Baylor College of Medicine Children's Foundation - Tanzania sites in Mbeya and Mwanza. CALHIV up to the age of 19 years who had been on antiretroviral therapy (ART) for ≥6 months (by July 2021) were included in the analysis.

Participants were followed longitudinally for at least two subsequent VLs after an initial undetectable VL (<50 copies/mL). VF was defined as ≥1000 copies/mL.

Results: A total of 670 CALHIV were included in the outcome analysis. LLV occurred in 47.5% (318/670) and of those, 52.5% (167/318) had VL 50-199 copies/mL, 27.4% (87/318) had 200-399 copies/mL, and 20.1% (64/318) had 400-999 copies/mL. The Kaplan-Meier plot (figure) shows higher risk of failure with higher LLV category ($p < 0.0001$). When looking at predictors of VF, a Cox proportional hazard model showed that there was an increased risk of VF with higher LLV when compared to <50 copies/mL: adjusted hazard ratio (AHR) 1.73 with 50-199 copies/mL (95%CI: 1.14-2.62, $p = 0.01$), AHR 2.19 with 200-399 copies/mL (95%CI: 1.36-3.51, $p = 0.001$), and AHR 3.34 with 400-999 copies/mL (95%CI: 2.09-5.36, $p < 0.0001$).On multivariable analysis, age of 10-14 years ($p = 0.03$) and immunosuppression, moderate ($p = 0.008$) or severe ($p = 0.009$), were associated with VF.

Figure. Kaplan Meier plot of cumulative probability for virologic failure by level of LLV.

Conclusions: LLV was associated with increased risk of VF with higher levels LLV corresponding to higher risk. Age 10-14 years and immunosuppression were also associated with increased risk of VF.**EPB0118****Development of a clinical prediction tool to estimate mortality within one year from antiretroviral therapy initiation in children and adolescents living with HIV to guide differentiated service delivery**A. Kay^{1,2}, S. Dlamini², T. Steffy^{1,3}, J. Bacha^{1,4}, P. Amuge⁵, A. Munthali⁶, A. Msekandiana⁶, B. Lukhele⁷, A. Kekitiinwa^{1,5}, L. Thahane^{1,3}, L. Mwita^{1,8}, H.L. Kirchner^{1,9}, A. Mandalakas^{1,10}
¹Baylor College of Medicine, Houston, United States, ²Baylor Children's Foundation-Eswatini, Mbabane, Eswatini, ³Baylor Children's Foundation-Lesotho, Maseru, Lesotho, ⁴Baylor Children's Foundation-Tanzania, Mbeya, Tanzania, United Republic of, ⁵Baylor Children's Foundation-Uganda, Kampala, Uganda, ⁶Baylor Children's Foundation-Malawi, Lilongwe, Malawi, ⁷University of Alabama at Birmingham, Birmingham, United States, ⁸Baylor Children's Foundation-Tanzania, Mwanza, Tanzania, United Republic of, ⁹Geisinger, Danville, United States, ¹⁰Research Center Borstel, Sülzburg, Germany**Background:** Differentiated service delivery for children and adolescents living with HIV (CALHIV) can improve targeted resource utilization for this vulnerable population; however, there are no clinical prediction tools focused on this group. To address this gap, we have developed a clinical prediction tool that may be used to guide the care of this vulnerable population.**Methods:** Data was evaluated using electronic medical records of CALHIV, aged 0-19 years, enrolled as clients at a Baylor Center of Excellence in Eswatini, Malawi, Lesotho, Tanzania, or Uganda between 2005 and 2020. Data for clinical prediction, including anthropometric values, physical examination, antiretroviral therapy (ART), WHO stage, and laboratory tests, were captured at ART initiation, then was split into a training and test set. Missing data was imputed using multiple imputation with chained equations. Backward stepwise variable selection and logistic regression were performed to develop predictive models for mortality within one year of ART initiation.

Predictive probabilities of one year mortality were generated and compared to true outcomes in the training set and then evaluated in the test set against the criteria for WHO advanced disease.

Results: The study population included 15,120 CALHIV. Predictive variables included: age, CD4 percent, white blood cell count, hemoglobin, platelets, and body mass index (BMI) z-score as continuous variables, and WHO Stage and edema on exam, as categorical variables. Missingness ranged from 0% for age to 32% for platelets. The area under the curve (AUC) of the predictive model was 0.847 (95% CI: 0.83-0.86) in the training set and 0.838

(95% CI: 0.82-0.86) in the test set, as compared to 0.626 (95% CI: 0.62-0.63) for the WHO HIV advanced disease criteria in both the training and test sets. When a threshold for sensitivity was set at 90% for the model, the specificity remained quite high at 53% against 26% for the WHO advanced disease criteria.

Conclusions: This study evaluated a large, multinational clinical population to develop a clinical prediction tool for CALHIV. The model more accurately predicted clinical outcomes than the WHO HIV advanced disease criteria and has the potential to improve differentiated service delivery for children entering HIV care in high-burden settings.

EPB0119

Detection of acute HIV infection on pooled Cobas plasma separation card (PSC) samples using Cepheid GeneXpert HIV-1 qualitative assay

H.R. Kihom¹, G. Misona², R. Monton¹, P.H. Bauzon¹

¹Tropical Disease Foundation, Inc., HIV Program, Makati City, Philippines, ²Philippine Children's Medical Center, Covid Laboratory, Quezon City, Philippines

Background: The Increasing daily average of HIV diagnosis in the Philippines remains to be a threat to the country's realization of the UNAIDS 95-95-95 goal. To bridge the gap between exposure and seroconversion in persons with HIV, early detection on Cobas plasma separation card (PSC) using qualitative assays for detecting HIV – RNA must be considered. To scale up HIV screening and testing, pooled testing on PSC using qualitative assays must also be explored.

This study aims to validate the diagnostic performance of PSC in our setting and determine the optimal pooling size of PSC samples that would retain the acceptable 95% analytical sensitivity in low viral load detection, applicable in resource-limited Philippine settings. This will impact early detection and prompt initiation of treatment and preventive interventions.

Description: HIV/AIDS in the Philippines is concentrated in NCR, Region IV-A, and Region III based on 2022 HIV/AIDS and ART Registry. From January-November 2022, out of 13,791 reported cases, 9,387 (68%) are from male-to-male sexual contact. Rapid HIV diagnostic algorithm (rHIVda) is currently the confirmatory test for HIV which requires series of blood collections. The use of blood spots will offer logistical advantages in terms of the collection, storage, and transportation of samples.

Moreover, the validation of a pooling strategy on PSC in the GeneXpert platform and its conventional use in our setting will reduce the cost of the test and reduction in manpower needed to run the tests.

Lessons learned: No issues were encountered with the use of the currently available GeneXpert machines in running the tests. Pools of 5 samples retained the acceptable 95% analytical sensitivity maximizing the benefit of pooled testing in a resource-limited Philippines setting.

Conclusions/Next steps: Demonstrating the diagnostic

performance of Cobas PSC samples on Cepheid GeneXpert HIV-1 Qualitative assay, we provide scientific evidence for its adoption in the Philippines. The pooling strategy with optimal pool size of 5 offers cost-savings in resource-limited settings as in the Philippines.

This innovative approach in the early detection of HIV, particularly during the acute phase is a potential solution to the current problems facing the need for an effective and efficient diagnostic tool.

EPB0120

Can HIV low level viremia predict future anti-retroviral treatment failure? A retrospective cohort analysis from Zambia

D. Mwamba¹

¹Centre for Infectious Diseases Research in Zambia, HIV, Lusaka, Zambia

Background: HIV RNA viral load (VL) remains the most reliable marker to assess HIV treatment success to date. The Zambia HIV guideline define viral load suppression as any VL test result of below 1000 copies/ml and all HIV clients on Antiretroviral Treatment for at least 6 months with VL above 1000 copies/ml should be enrolled on enhanced adherence counselling (EAC). Studies suggest that low-level viremia (LLV) was associated with increased risk of treatment failure. We hypothesized that clients who develop unsuppressed VL above 1000 copies/ml could have had a progressive increase in their VLs from previous tests. Identifying HIV clients with LLV in Lusaka could help take proactive steps in preventing treatment failure.

Methods: We extracted data from electronic medical records of clients on ART for at least 6 months with at least one VL result documented between April 2018 and January 2022 in Lusaka. We conducted retrospective cohort analysis to determine what proportion of clients with latest VL above 1000 copies had recorded LLV - defined as VL copies/ml between 60 and 999 - on their previous VL lab tests. Logistic regression model was used to measure association between LLV and demographic characteristics of clients.

Results: 8610 records showed a VL >1000 copies on the last VL test; 4836 (56.1%) were female. 2707 (31.4%) had at least one previous VL on file of which 1498 (55.3%) were male, 1761 (65%) aged between 20 and 44 years and 2169 (80%) on ART for more than 24 months. 732 (27.0%) of patients with VL > 1000 copies had a LLV in the past.

The odds of having a VL above 1000 amongst those with past LLV was 3.4 times higher than those with no LLV [aOR 3.41 (3.12, 3.72), p<0.00]. Males patients had an odd of 1.3 (aOR 1.34 - 1.4; p<0.00) compared to females.

Conclusions: Our analysis revealed that LLV is associated with risk of future raised viral load above 1000 copies. Males with LLV are at higher risk of failing treatment. It would be justifiable to provide enhanced adherence counseling to all clients with VL between 60 and 999 copies to prevent occurrence of viral mutation and treatment failure.

EPB0121

The value of National Xpert MTB/RIF Ultra trace results in context of new molecular diagnostics: more questions than answers?

L. Scott¹, P. da Silva^{2,1}, J. Tsoka¹, S. Ndlovu², G. Dor¹, P. Marokane², W. Stevens^{1,2}

¹University of the Witwatersrand, Wits Diagnostic Innovation Hub, Johannesburg, South Africa, ²National Priority Program of the NHLS, Johannesburg, South Africa

Background: South Africa implemented GeneXpert (Cepheid) technology nationally in 2011 using the Xpert MTB/RIF cartridge as a smear replacement strategy for tuberculosis (TB) disease. Transition to Xpert MTB/RIF Ultra in 2017 increased MTB detection rates by ~2%. Early in 2023, the WHO included other molecular tests for TB: viz cobas® MTB&MTB RIF/INH (Roche) and BDMAX™ MDR-TB (Becton Dickinson). Both technologies test for rifampicin and isoniazid. The Xpert Ultra is the most sensitive, although only reports Rifampicin resistance. This low level sensitivity is reported as "trace" detection of *Mycobacterium tuberculosis* complex (*M.tb*) DNA. Geographic information system (GIS) mapped national Ultra "trace" results were explored to inform appropriate implementation of additional diagnostic platforms.

Methods: Aggregated Ultra laboratory test results, reporting *M.tb* detection and "trace", stored within the National Health Laboratory Service's central data warehouse (January 2021-December 2022) were analysed to municipality level and merged with local municipality GIS shapefiles. The spatial distribution patterns of the indicators across municipalities were determined using Moran's I and Getis Ord (Gi) statistic.

Results: A total 2,121,271 tests were performed in 12 months, of which 182,449 (8.6%) reported *M.tb* and 27,473 (1.3%) reported "trace". Significant "trace hot spots" (within "*M.tb* hot spots"), (Moran's I =0.31, Z-score of 7.27, and p-value <0.001), were reported in 10 (of 13) municipalities within the Northern Cape, 8 (of 23) within the Western Cape and 5 (of 6) within the North West provinces.

An additional cluster of "trace hot spots" not within "*M.tb* hot spots" was identified in Mpumalanga province, spanning four municipalities (Figure 1).

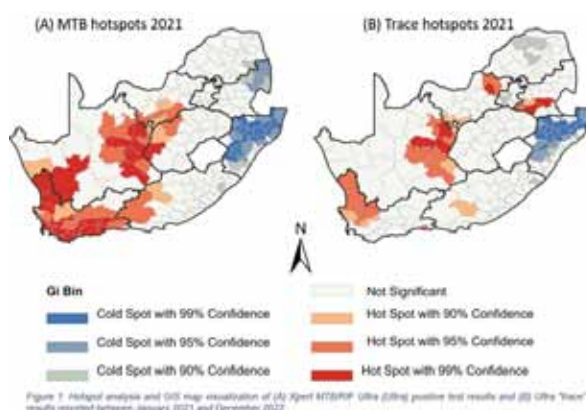

Figure 1.

Conclusions: Spatial heterogeneity of "trace" is evident in South Africa, and does not always overlay high disease burden municipalities. This could indicate direction of change in disease or the need for more granular surveillance, but does indicate areas where less sensitive molecular diagnostics may fail to identify trace amounts of *M.tb* DNA.

EPB0122

Concordance of self-reported and point-of-care biomarkers of alcohol use measures among older adults with HIV from low- and middle-income countries, the Sentinel Research Network of IeDEA

K.E. Lancaster¹, M. Stockton², J.A. Hahn³, T. Chanyachukul⁴, E. Kwobah⁵, H. Byakwaga⁶, P. Carrier⁷, G. Murenzi⁸, H. Perazzo⁹, B. Crabtree Ramirez¹⁰, A. Haas¹¹, A. Mandiriri¹², I. Marbaniang¹³, A. Jaquet¹⁴, A. Parcesepe²

¹The Ohio State University, Columbus, United States, ²University of North Carolina at Chapel Hill, Chapel Hill, United States, ³University of California San Francisco, San Francisco, United States, ⁴TREAT Asia/amfAR – The Foundation for AIDS Research, Bangkok, Thailand, ⁵Moi Teaching and Referral Hospital, Eldoret, Kenya, ⁶Mbarara University ISS Clinic, Mbarara, Uganda, ⁷Aix Marseille Univ, Marseille, France, ⁸Research for Development (RD Rwanda) and the Rwanda Military Hospital, Kigali, Rwanda, ⁹National Institute of Infectious Diseases Evandro Chagas-Oswaldo Cruz Foundation (INI/FIOCRUZ), Rio de Janeiro, Brazil, ¹⁰Instituto Nacional de Ciencias Médicas y Nutrición, México City, Mexico, ¹¹Institute of Social and Preventive Medicine (ISPM), University of Bern, Switzerland, ¹²Newlands Clinic, Harare, Zimbabwe, ¹³BJ Government Medical College-JHU Clinical Research Site, Maharashtra, India, ¹⁴University of Bordeaux, Bordeaux, France

Background: Measuring alcohol use is challenging within HIV care services, particularly in low resource settings. Self-reported measurements of alcohol use are rapid and inexpensive yet highly susceptible to mismeasurement. Understanding the use of point-of-care (POC) urine biomarkers and their concordance with self-report will inform strategies for alcohol use measurement among older people with HIV (PWH) in low- and middle-income countries.

Methods: We analyzed cross-sectional data from the International epidemiology Database to Evaluate AIDS (IeDEA) Sentinel Research Network (SRN) cohort of PWH aged ≥40 years from HIV clinics within the Asia-Pacific, Central/Latin America, and Africa regions. We assessed concordance of self-reported alcohol use and POC urine ethylglucuronide (uETG) testing (alcohol detectable up to prior 5 days).

We examined the associations between self-reported alcohol measures and uETG using mixed-effect logistic regression controlling for age and sex (fixed) and clinic site (random). We fitted 5 models of uETG positivity: alcohol use frequency, number of drinks on typical day, binge

drinking frequency, unhealthy alcohol use (AUDIT-C ≥ 3 for women, ≥ 4 for men), and possible alcohol use disorder (AUDIT ≥ 13 for women, ≥ 15 for men).

Results: Of the 2059 participants, 46% (n=945) were men, 52% (n=1,067) reported drinking alcohol, and 20% (n=406) reported unhealthy drinking. A total of 251 participants (12%) tested uEtG positive, with 140 (56%) reporting unhealthy drinking and 111 (44%) not reporting unhealthy drinking. Concordance of self-reported unhealthy alcohol use and uEtG was 82% (kappa=0.32) with differences by sex (women: 87%; kappa=0.29; men: 75%; kappa=0.17). In multivariate models, all measures of self-reported alcohol use were associated with positive uEtG.

Conclusions: Though lower among men when compared to women, the overall concordance between self-reported alcohol use and urine POC biomarker was moderate. Alternative biomarkers with longer detection windows should be used to validate and potentially augment self-reported measures.

Further approaches for incorporating objective biomarkers should be explored for both epidemiologic and interventional efforts addressing alcohol use among PWH in low resource settings.

EPB0123

Improving the diagnosis of HIV in hospitalized infants: lessons learned from the EMPIRICAL trial

mothers, and early infant diagnosis (EID) virologic testing for newly-identified HIV-exposed infants (HEI) or those with findings suggestive of HIV. On inpatient wards, HIV diagnosis is urgent given advanced disease presentation. Yet many African hospitals have implementation shortfalls due to limited resources for PITC, delays in receiving EID results, and underuse of presumptive diagnosis. The EMPIRICAL trial (#NCT03915366), which is enrolling infants with severe pneumonia and confirmed HIV, has worked to strengthen diagnostic practices at 22 recruiting hospitals across six African countries, with implementation experience that addresses these PITC/EID challenges.

Methods: HIV testing results for infants hospitalized with pneumonia and their mothers were extracted from screening logs and the trial database. Operational information detailing PITC/EID practices at each site was collected via questionnaire.

Results: Interim data after implementation of a revised, more detailed screening log (Nov. 2021-Dec. 2022) reveal that 2,673 mothers had rapid antibody tests performed, of whom 193 (7.2%) were newly HIV-positive, and 95 (49.2%) of their infants subsequently tested HIV-positive. From recruitment onset in March 2020 through December 2022, 390 HIV-positive infants were recruited, of whom 276 (70.8%) were newly diagnosed with point-of-care EID (PoC-EID) during hospitalization.

In questionnaire feedback from 19 hospitals, 18 (94.7%) reported needing counselors, often employed by partners, for timely testing of all admissions. Six sites in Mozambique (31.6%) routinely repeat PITC for breastfeeding women who tested negative in the preceding three months, diagnosing three new cases with this approach in 2022. All sites stressed the importance of PoC-EID, as turn-around-times for conventional DNA-PCRs frequently exceed 4 weeks.

Conclusions: In settings with medium-high HIV prevalence and high rates of seroconversion during breastfeeding, PITC for mothers of hospitalized infants is crucial, and dedicated counselors help improve testing coverage. Repeat PITC should be considered regardless of the time since last maternal test in the context of severe infant illness. PoC-EID expansion plans should prioritize access for pediatric wards either with on-site machines or sample referral networks to facilitate rapid diagnoses, timely opportunistic infection treatment, and prompt linkage to antiretroviral therapy.

EPB0124

Severe mpox (monkeypox) among people living with HIV in Peru: a clinical case series of hospitalized cases, 2022

R. Paredes¹, A. Lucchetti^{2,3}, M. Sihuinchu⁴, L. Martínez², E. Matos², M. Prochazka⁵

¹Universidad Peruana Cayetano Heredia, Emerge, Emerging Diseases and Climate Change Research Unit, School of Public Health and Administration, Lima, Peru, ²Hospital Nacional Arzobispo Loayza, Lima, Peru, Department of Infectious Diseases, Lima, Peru, ³Universidad Continental, Lima, Peru, ⁴Hospital Nacional Arzobispo Loayza, Lima, Peru, Department of Epidemiology and Environmental Health, Lima, Peru, ⁵World Health Organization, WHO Health Emergency Programmes, Geneva, Switzerland

Background: In the current 2022 mpox (monkeypox) outbreak, more than 3,700 cases have been identified in Peru, 55% of which were reported to be among people living with HIV (PLHIV). Although most cases experienced mild-to-moderate disease with relatively good clinical outcomes, PLHIV with advanced HIV disease (AHD) may be at increased risk of severe mpox-associated morbidity and mortality due to immunosuppression.

Methods: We conducted a descriptive clinical case series of patients hospitalized for mpox care between July and December 2022 in a tertiary hospital in Lima, Peru. We included adults (>18 years) with reactive PCR to monkeypox virus. Epidemiological, clinical, and laboratory data were collected from medical chart reviews and described along the HIV care continuum. AHD (CD4 count <200 cells/mm³) and viral suppression (viral load <1,000 copies/mL) were only reported for patients with laboratory data.

Results: Records from 36 hospitalized patients for complicated mpox were included. Patients were mostly gay, bisexual, or other men who have sex with men (33/36, 92%) and aged 31 (18-52) years. Reasons for hospitalization included secondary bacterial infection (81%, 29/36), proctitis (36%, 13/36), balanitis/orchepididymitis (14%, 5/36), necrosis of skin lesion (8%, 3/36), and generalized rash (6%, 2/36); the median length of stay was 9 (6-14) and up to 74 days. Thirty-one patients (86%) were PLHIV, and seven (23%) were newly diagnosed during hospitalization.

Of those who were aware of their HIV status, 88% (21/24) had received HIV care in the preceding year, and 83% (20/24) were on antiretroviral treatment (ART). Of those on ART, 70% (14/20) were virally suppressed. Fifteen PLHIV (48%) did not have CD4 counts since last year; the median value was 347 (111-493) cells/mm³, and 38% (6/16) had AHD. Three patients (8%) died due to severe mpox presentations, all PLHIV with AHD.

Conclusions: The severity of mpox-associated complications among immunocompromised PLHIV suggests mpox may act as an opportunistic infection. Effective access to HIV prevention and care is urgently needed to reduce the harms associated with mpox outbreaks in key populations.

EPB0125

Factors associated with non-viral load suppression in Togo

D. Mipam¹, K. Essopha¹, G. Etheredge², M. Damarly¹, A. Tamalga³, J.P. Tchupo¹

¹FHI 360, Lomé, Togo, ²FHI 360, Washington, DC, United States, ³FHI 360, Ouagadougou, Burkina Faso

Background: Progress has been made toward reaching viral load suppression (VLS) by institutionalizing viral load (VL) testing in the USAID-funded #EAWA project in Togo (82% VLS in 2019 to 93% in 2022). Understanding which characteristics are associated with non-VLS can help health care workers target their efforts toward individuals who are less likely to achieve VLS.

Methods: For this cross-sectional study, we extracted client (≥ 18 years) and site data from #EAWA's E-tracker for clients with documented VL results between January and November 2022.

We calculated differences in proportions and means by the chi-square test and Student's t-test, respectively, and odds ratios to estimate the strength of associations. P-values of <0.05 were considered significant.

Results: Our analyses included 2,424 clients (67% female, 33% male). The average age of those without VLS was 40 years vs. 41 years for those with VLS ($p<0.05$). Among those without VLS, the average age was 40 years among females and 43 years among males ($p<0.001$).

Clients without VLS were more likely to be from public clinics vs. organization-run clinics (38.1% vs. 25.5%, $p<0.001$), from the general population vs. key populations (33.2% vs. 22.5%, $p<0.05$), younger (18–35 years) vs. older (35+) (34.0% vs. 28.0%, $p<0.05$), less than one year on ART vs. more (36.3% vs. 29.1%, $p<0.05$), having interrupted treatment ≥ 3 months vs. less (38.2% vs. 27.9%, $p<0.001$), and not receiving therapeutic education (32.4% vs. 27.0%, $p<0.05$).

Multiple logistic analyses showed that non-VLS was associated with public clinic (OR=1.8, 95% confidence interval [CI]=1.4–2.2, $p<0.001$), general population (OR=1.8, CI=1.2–2.7, $p<0.05$), younger age (OR=1.24, CI=1.01–1.52, $p<0.05$), and interrupted treatment ≥ 3 months (OR=1.48, CI=1.17–1.87, $p<0.05$).

Conclusions: These analyses, the first for Togo show certain client and site level factors are associated with not achieving VLS. Clinics run by associations have more HIV-specialized care providers than public clinics. Key populations may be more likely to attend these clinics and receive more targeted care.

If care providers pay special attention to younger clients and those who have interrupted treatment, clients may have better VL outcomes. Operational modifications may lead Togo to reach its 95% VLS goal.

EPB0126

Establishing a CrAg referral testing program to expand screening for Cryptococcal Meningitis in Lesotho

T. Tarumbiswa¹, G. Saemisch², C. Nkomo³, E. Mandara³, M. Mohoanyane¹, M. Milaham³

¹Ministry of Health, Maseru, Lesotho, ²Clinton Health Access Initiative, Inc., Boston, United States, ³Clinton Health Access Initiative, Inc., Maseru, Lesotho

Background: Cryptococcal Meningitis (CM) is one of the leading causes of death among people living with Advanced HIV Disease (AHD). Guidance from World Health Organization (WHO) in 2017 recommends utilizing cryptococcal antigen (CrAg) screening to detect early infection for CM among clients with confirmed AHD. As a result of this guidance, the Lesotho Ministry of Health included CrAg screening for AHD clients in the 2020 HIV Clinical Guidelines and kicked off AHD implementation at 18 Phase I pilot sites in 2021.

Following this implementation. Lesotho expanded access to CrAg screening through an active referral screening program in 2022 for sites without access to AHD commodities. We documented the impact of this referral program on CrAg uptake and utilization rates in Lesotho.

Methods: The CrAg referral screening program utilized the already established HIV sample transport network to send blood samples for CrAg screening from sites without AHD commodities to one of the 18 AHD pilot sites in Lesotho. We collected data on CrAg screening rates through the Labs Management Information System (LMIS) for January 2021 to June 2022. Indicators included the number of CrAg tests performed and the percentage of eligible AHD clients who received a CrAg test.

Results: Access to CrAg screening for AHD clients in Lesotho increased by an average of 46% annually since the referral program was initiated, with an average of 320 AHD clients receiving CrAg screening per quarter in 2021 compared to 466 in 2022. In addition, average CrAg screening rates remained high following the implementation of the referral program, with 98% of eligible AHD clients receiving a CrAg test in H1 2022. Key enablers to the success of this program included routine supportive supervision visits, providing sites with documentation on CrAg screening algorithms and job aids, and effective utilization of the LMIS to monitor uptake and prevent stockouts.

Conclusions: The CrAg referral program has been pivotal to expanding access to CM screening for AHD clients in Lesotho and National HIV and CM programs can learn from Lesotho's experience when devising national CM screening strategies, a key component in the global effort to end CM deaths by 2030.

Effects of direct-acting antiviral therapy on immunologic and hepatic markers among people with HIV/HCV coinfections

G. Simoncini¹, Q. Hou², J. Li³, L. Battalora^{4,2}, C. Mayer⁵, K. Carlson², K. Buchacz⁶

¹AIDS Healthcare Foundation, Department of Medicine, Philadelphia, United States, ²Cerner Enviza, Kansas City, United States, ³Centers of Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States, ⁴Colorado School of Mines, Golden, United States, ⁵St. Joseph's Comprehensive Research Institute, Tampa, United States, ⁶Centers for Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States

Background: Direct-acting antiviral (DAA) treatment of hepatitis C (HCV) reduces liver-related mortality, but longitudinal effects of DAAs on immunologic and hepatic markers are not well-characterized among people coinfected with HIV/HCV in the United States (U.S.).

Methods: The HIV Outpatient Study (HOPS) is an ongoing longitudinal cohort study of persons with HIV at 8 U.S. clinics. Among persons prescribed DAAs and those of comparable age-, sex- and race/ethnicity and Fibrosis-4 (Fib-4) profiles who remained DAA-naïve, we contrasted DAA effect on longitudinal trends of immunologic and hepatic markers using generalized linear mixed models (GLM) during years 2010-2020. Cox regression models were fit to evaluate DAA effect on development of advanced fibrosis (Fib-4 score >3.25).

Results: Of 347 persons coinfected with HIV/HCV, 153 (44.1%) were prescribed DAAs during a median of 2.78 (IQR: 1.16,4.18) years of observation. In GLM, CD4 count, and Fib-4 increased faster among DAA-treated than DAA-naïve group (all $p < 0.001$), while CD4%, CD8%, and CD4/CD8 ratio did not differ (all $p > 0.30$) (Table).

Markers ¹	DAA treated (n=153)			DAA naïve (n=194)			Linear trajectory ²
	Pre DAA ³	Post DAA ⁴	Post vs. Pre ⁵	Pre-Pseudo ⁶	Post-Pseudo ⁶	Post vs. Pre ⁵	
CD4%	60.8 (59.9, 61.6)	61.5 (60.6, 62.4)	0.7 (0.1, 1.3)	60.8 (59.9, 61.6)	61.5 (60.6, 62.4)	0.7 (0.1, 1.3)	0.02 (0.00, 0.04)
CD8%	11.0 (10.8, 11.2)	11.1 (10.9, 11.3)	0.1 (0.1, 0.2)	11.0 (10.8, 11.2)	11.1 (10.9, 11.3)	0.1 (0.1, 0.2)	0.75 (0.35, 1.15)

HCV vs. (lower/high) ⁸	0.02 (0.00, 0.04)	0.02 (0.00, 0.04)	0.00 (0.00, 0.00)	0.02 (0.00, 0.04)	0.02 (0.00, 0.04)	0.00 (0.00, 0.00)	0.00 (0.00, 0.00)

Note:

1. Slope estimates (95% Confidence Interval) represent annual rate of change in marker values per year using all lab results between 1/1/2011 and 12/31/2020.
2. Pre DAA indicates prior to DAA prescription date for DAA-treated group.
3. Post DAA indicates after DAA prescription date for DAA-treated group.
4. Pre vs. Post indicates changes after DAA prescription date for DAA-treated or DAA-naïve group.
5. Pre-Pseudo indicates after propensity score matched Fib-4 data for DAA-naïve group.
6. Post-Pseudo indicates after propensity score matched Fib-4 data for DAA-naïve group.
7. Treated vs Naïve represents difference between Pre vs. Post for DAA-treated and Pre vs. Post for DAA-naïve group.
8. Logistic regression for probability of HIV viral load >100 copies/mL.
9. Logistic regression for probability of HCV viral load being greater than the lower range value.

Table. General linear mixed model estimated marker linear trajectory adjusted for age, sex and race/ethnicity variables.

In multivariable analysis, DAA treatment was associated with more rapid decline in alanine aminotransferase of -7.86 (-15.39, -0.33) $\mu\text{L}/(\mu\text{L} \times \text{year})$ [mean (95% confidence interval)] and faster increase in platelets of 6.99 (2.89, 11.09) counts/ $(\mu\text{L} \times \text{year})$, while changes in aspartate aminotransferase were comparable between two groups.

Additionally, Fib-4 decreased for the DAA-treated at -0.26 (-0.41, -0.11) per year, and did not change for the DAA-naïve group 0.02 (-0.16, 0.20) (Table).

DAA-treatment was also associated with lower rates of progressing to Fib-4 >3.25 (adjusted hazard ratio = 0.49, $p < 0.01$).

Conclusions: Among persons co-infected with HIV/HCV who were treated with DAAs in the U.S., we found comparable changes in immunologic markers and substantial improvements in hepatic markers over 4 years post-DAA treatment, highlighting the importance of DAA treatment among such persons to preserve health and prevent advanced liver fibrosis.

EPB0128

Implementation of HCV treatments among people living with HIV/HCV in Washington, DC

J. Lee¹, M. Byrne², A. Monroe², A. Castel², M. Horberg³, P. Kumar¹, A. Spence¹

¹MedStar Georgetown University Hospital, Infectious Diseases and Tropical Medicine, Washington, DC, United States, ²George Washington University Milken Institute School of Public Health, Epidemiology, Washington, DC, United States, ³Kaiser Permanente, Mid-Atlantic Permanente Research Institute, Rockville, MD, United States

Background: Direct-acting antiviral (DAA) therapies have made HCV easily treatable, preventing HCV-related morbidity and mortality. However, assessments of HCV treatment implementation among people living with HIV are limited in the post-DAA era.

Methods: Using data from the District of Columbia (DC) Cohort, a longitudinal cohort of people living with HIV receiving care at 14 sites, we identified participants with detectable HCV RNA. We examined HCV therapy in the pre-DAA (2011-2013) versus post-DAA (2014-2022) era as well as factors influencing sustained virologic response (SVR). SVR was defined as an undetectable HCV RNA within 6 months of DAA or 12 months of non-DAA initiation. Multi-variable logistic regression was used to determine factors associated with HCV treatment or SVR.

Results: 919 individuals living with HIV/HCV were identified from 11,774 participants. Only 66% of individuals living with HIV/HCV received HCV treatment, of whom, 84% had available follow-up HCV RNA. 92% of those treated received DAA. 77% achieved SVR.

After adjusting for race, age, and viral suppression (VS; HIV RNA <200 copies/mL), HCV treatment was associated with older age (aOR 1.24; 95% CI 1.06-1.46) and VS (aOR 2.53; 95% CI 1.79-3.59).

Among those treated, SVR was inversely associated with CD4 <200 (aOR 0.47; 95% CI 0.24-0.94) after adjustment for age, site, race, and pre-HCV cancer diagnosis. In the post-DAA era, people living with HIV/HCV were more likely to have evidence of HCV treatment (aOR 1.74; 95% CI 1.22-2.48). However, HCV treatment in the post-DAA era was not associated with SVR.

	OR (95% CI)	P-value	aOR (95% CI)	P-value
HCV Treatment¹				
Age per 10-year increase	1.24 (1.08-1.43)	0.0017	1.24 (1.05-1.46)	0.0093
Post-DAA (2014-2022) vs. Pre-DAA (2011-2013)	2.03 (1.49-2.75)	<0.0001	1.76 (1.23-2.51)	0.0018
HIV RNA <200 copies/mL vs. ≥200 copies/mL	2.51 (1.78-3.54)	<0.0001	2.52 (1.77-3.58)	<0.0001
CD4 <200 vs. CD4 ≥200	0.71 (0.45-1.12)	0.1368		
SVR Achievement²				
Post-DAA (2014-2022) vs. Pre-DAA (2011-2013)	1.18 (0.72-1.93)	0.5178		
HIV RNA <200 copies/mL vs. ≥200 copies/mL	0.93 (0.52-1.67)	0.8127		
CD4 <200 vs. CD4 ≥200	0.47 (0.24-0.93)	0.0299	0.47 (0.24-0.94)	0.0333

1: Multivariable model effects (aOR) were also adjusted for race. (n=848)

2: Multivariable model effects (aOR) were also adjusted for age at HCV, site of care (hospital v. community), race, any cancer diagnosis prior to HCV. (n=493)

Table 1. Factors associated with HCV treatment and achievement of SVR among PWH in the DC Cohort.

Conclusions: Among DC Cohort participants, markers of HIV treatment adherence (VS, CD4) were associated with access to HCV treatment and SVR. Gaps remain in successful HIV/HCV treatment despite receipt of HIV care. Interventions are needed to address access to HCV treatments for people living with HIV as well as facilitate treatment adherence for those at risk for unsuccessful treatment.

EPB0129

Role of low-risk HPV PCR in screening for HSIL lesions and anal cancer in men who have sex with men (MSM) living with HIV (MSM-LWHIV)

C. Hidalgo Tenorio¹, C. Garcia Martinez², R. Moya², P. Gomez Ronquillo², M. Omar Mohamed³, J. Lopez Hidalgo⁴

¹Hospital Universitario Virgen de las Nieves. Instituto de Investigación Biosanitario de Granada (IBS-Granada), Infectious Diseases Unit, Granada, Spain,

²Hospital Universitario Virgen de las Nieves. Instituto de Investigación Biosanitario de Granada (IBS-Granada), Internal Medicine Service, Granada, Spain, ³Complejo Hospitalario de Jaen, Infectious Diseases Unit, Jaen, Spain,

⁴Hospital Universitario Virgen de las Nieves. Instituto de Investigación Biosanitario de Granada (IBS-Granada), Pathology Service, Granada, Spain

Background: Anal squamous cell carcinoma (ASCC) is one of the most frequent non-AIDS-defining neoplasia in PLWHIV, mainly in MSM, and it has been associated with chronic infection by human papilloma virus (HPV).

Main: Analyze the value of low-risk HPV PCR in screening for "high-grade squamous intraepithelial lesions and anal cancer" (HSIL-plus).

Secondary objectives: To analyze the rate of patients with LSIL (AIN1) who progress to HSIL-plus and the factors associated with this progression.

Methods: This is a prospective, longitudinal study that consecutively included 493 MSM-LWHIV between May 2010 and December 2021, followed up 43 months (IQR:12-76).

At the baseline visit clinical-epidemiological, and analytical variables related to HIV were included, and anal cytology was performed to study the detection and genotyping of HPV (Linear Array HPV Genotyping Test) and cytological study using the "thin-layer technique" [Thin Prep 2000 processor (Hologic)], and high-resolution anoscopy (HRA) with the Carl Zeiss 150fc® colposcope, (Carl Zeiss, Oberkochen, Germany).

Follow-up visits were made based on the HRA results (in case of normal result or AIN1, annually; in case of HSIL-plus the HRA was carried out at the end of the treatment) during the which the HIV infection was reassessed, sexual behavior, and HPV infection.

Results: The subjects included were 36y, 23.1% had CD4 nadir <200 cells/uL. 15% had received the quadrivalent HPV vaccine >5 years ago. Mono-infection due to low-risk HPV genotypes in patients with normal cytology ruled out HSIL plus in 100% of cases (S 100%, E 91.9%, PPV 2.9% and NPV 100%). The rate of patients who progressed from LSIL to HSIL plus was 4.7% at a median time of 12 months (IQR:12-12).

Risk factors for progression from LSIL to HSIL-plus during follow-up were acquisition of high-risk HPV genotypes (HR:4.15; IC 95%:1.14-15.03), low-risk HPV genotypes [(HR:3.68 IC95%:1.04-12.94), in particular genotype 6 (HR:4.47, IC95%:1.34-14.91)] and history of AIDS (HR:5.81, 95%CI:1.78-18.92).

Conclusions: Anal mono-infection with low-risk HPV genotypes in MSM-LWHIV with normal cytology is not associated with precursor lesions or ASCC. The rate of progression from LSIL to HSIL-plus was less than 5%, which was related to the acquisition of high and low risk HPV genotypes (specifically 6) and a history of AIDS.

EPB0130

Integration of human papillomavirus-based cervical cancer screening into HIV care for women living with HIV in Ethiopia

I. Ahmed¹, F. Tefera¹, Y. Tedla¹, A. Mache¹, D. Atnafu², A. Abdulkadir², T. Moges³, D. Melese⁴, H. Petros²

¹U.S. Centers for Disease Control and Prevention-Ethiopia, Addis Ababa, Ethiopia, ²International Center for AIDS Care and Treatment Programs at Columbia University's Mailman School of Public Health-Ethiopia, Addis Ababa, Ethiopia, ³Ministry of Health of Ethiopia, Addis Ababa, Ethiopia, ⁴Ethiopian Public Health Institute, Addis Ababa, Ethiopia

Background: In Ethiopia, cervical cancer (CxCa) is the second most reported cancer (13%) among women aged 15-49 years old. However, the 2018 HIV impact assessment report showed that only 16% of women living with HIV (WLHIV) had access to CxCa screening services. To address this gap, CDC Ethiopia introduced WHO's "screen, triage

and treat" approach using human papillomavirus (HPV) testing for WLHIV followed by visual inspection with acetic acid (VIA) screening if HPV positive. We describe Ethiopia's experience and lessons learned in implementing the program.

Description: CDC in collaboration with the Ministry of Health of Ethiopia developed policy and program documents including CxCa screening guidelines and training materials. Requestion forms for laboratory testing were prepared and the electronic medical record (EMR) system was revised to integrate HPV testing into the existing HIV service database.

The initiative was introduced at 70 health facilities (HFs) providing HIV services and 15 HIV viral load testing laboratories in five regions. The HFs collect and send vaginal/cervical samples to the laboratories through a referral system. We retrospectively analyzed EMR data collected as part of routine HIV services delivery from Apr 2021 to Sept 2022.

Lessons learned: Of 14,739 samples collected and sent to laboratories, only 13,516 (92%) were tested and results were returned to HFs due to conflict in Amhara region. The average result turnaround time (TAT) was 15-days. The proportion of self-sampling and clinician sampling was 53% and 47%, respectively. Among results returned, the HPV positivity rate was 28% (3,798). All HPV positives were contacted and asked to return for screening using VIA, of which 89% (3,394) returned and had VIA screening. The proportion of WLHIV with pre-cancerous lesions was 19% (648) among HPV positives who had VIA screening; of those 95% (618) were treated with either cryotherapy, thermal ablation, or loop electrosurgical excision procedure.

Conclusions/Next steps: Integration of "screen, triage and treat approach" into HIV services was feasible and resulted in high treatment uptake, suggesting it could improve access to CxCa services in resource-limited settings. Future efforts could consider reducing TAT and ensuring VIA screening to triage women after a positive HPV test.

EPB0131

CD4+ T cell recovery in HIV/HCV co-infected patients following HCV treatment

S. Hussien¹, H. Seung², E. Wilson², L. Hynicka², P. Ryscavage¹

¹University of Maryland Midtown Campus, Baltimore, United States, ²University of Maryland, Baltimore, United States

Background: An estimated 12-30% of people living with HIV do not demonstrate robust CD4+ T cell recovery despite durable viral suppression on ART. HCV co-infection has been identified as a risk for impaired CD4+ recovery and this may be driven by HCV-mediated liver fibrosis. As HCV direct acting antiviral therapy (DAA) may partially reverse liver fibrosis, sustained HCV virologic response (SVR) may hypothetically lead to improved CD4+ T cell recovery.

Our objective was to assess the effect of HCV DAA -induced SVR on CD4 recovery among HCV/HIV co-infected patients, including immunological non responders (INR).

Methods: Subjects ≥18 years seen from 2015 - 2019 at the UMB outpatient HIV/HCV program, and who were treated with DAA and achieved an SVR were included. Pre-DAA CD4 counts were included only after sustained HIV viral suppression (<200 cpm for ≥2 years) and HIV viral suppression was maintained for the entire period of the study. Descriptive statistics were used to illustrate baseline characteristics. Segmented regression of interrupted time series analysis was used to evaluate changes in median CD4 count in the pre-DAA period (36 mo) vs post-DAA period (36 mo).

Results: 156 patients of whom 68% were male and 90% were African American were included. The mean age at DAA initiation was 56.5 years. Mean duration of HIV suppression prior to first pre-DAA CD4 assessment was 3.8 years. In the full cohort median CD4 counts increased by 15% (p=0.002, Figure 1) in the 6 month period following DAA initiation, whereafter CD4 counts decreased 2.7% per 6 month period (p=0.004). Among the 13 patients who qualified as INR, there was no immediate effect on median CD4 in the first 6 months after DAA initiation.

However, thereafter there was a sustained effect on CD4 increase (median CD4 increasing by approximately 4.1% per 6-month time interval (p=0.02). 54% of INR were able to achieve a post-DAA CD4 count of >350 cells/mm³.

Conclusions: Successful DAA therapy induced a modest immediate CD4 immunologic reconstitution among this cohort of HIV/HCV co-infected patients though this effect waned with time. By contrast, among INR, achieving HCV SVR led to more slowly gained but sustained CD4 count recovery.

J. Mwakisambwe¹, A. Kiravu¹, A. Masini¹, F. Chisonjela¹, A. Kaduma¹, T. Samatta¹, A. Kibao², F. Kibaba³, G. Msalale⁴, P. Muhone⁵, W. Mauka⁶, J. Kazitanga⁷, D. Magesa⁷, S. Mahesh⁷, D. Sando¹, G. Lyatuu¹

Background: Tuberculosis (TB) and cryptococcal meningitis (CM) account for over a third of AIDS-related deaths among people living with HIV (PLHIV). These opportunistic infections (OIs) are common among PLHIV with advanced HIV disease (AHD). We aimed to determine the magnitude of these OIs and associated outcomes among people newly diagnosed with AHD in routine healthcare in Tanzania.

Methods: We conducted a prospective cohort assessment involving newly diagnosed PLHIV with AHD, i.e. CD4 count of <200 cells/mm³ or WHO stage 3/4, across four regions of Tanzania. Upon enrollment in HIV care, clients were investigated for TB and Cryptococcal infection (CI). PLHIV diagnosed with TB/CI started treatment per the national guidelines. All PLHIV were initiated on anti-retroviral therapy (ART) and followed up for at least one year.

Our main outcomes were a TB/CI diagnosis among people newly diagnosed with AHD and their status at one-year follow-up i.e. the proportion who died, got lost-to-follow-up (no-show for >30 days since the last appointment) or had virologic failure (≥1000 copies/mL). Data were analyzed using SPSS v26.0.

Results: We identified 13,994 (19.9%) PLHIV with AHD among the 70,302 newly diagnosed PLHIV between October 2020 to September 2021 across the four regions. At diagnosis, the median age was 37.0 [IQR 16] years, with 594 (4.2%) aged <15 years and 8,183 (58.5%) females. Of these, 9.4% (1,314/ 13,994) were diagnosed with TB and 14.1% (442/ 3,125) screened positive for CI.

At the one-year follow-up, 5,172 (36.9%) had either died (n =1,354), got LTFU (n =311) or had virologic failure (n =3,507). A total of 10,869 (77.7%) PLHIV were not investigated for CI due to limited access to CI screening at that time and 1,574 (11.2%) had missing status at 1 year due to clinic transfer (n =1,292) or other reasons (n=282).

Conclusions: Despite after five years of implementing the treat-all policy, the magnitude of AHD at HIV diagnosis remains substantial in a fifth of all newly diagnosed PLHIV. AHD continues to be associated with increased risks of OIs and poor outcomes. There is a need to strengthen the clinical monitoring and management of OIs among PLHIV with AHD.

EPB0133

The impact of HIV on mortality and recurrence of rifampicin-resistant tuberculosis after successful treatment with second-line regimens: a retrospective cohort study in South Africa

H. Cox¹, S. Hlangu², P. Brown¹, J. Daniels³, L.-M. Larken⁴, A. Reuter³, M. Loveday²

¹University of Cape Town, Pathology, Cape Town, South Africa, ²South African Medical Research Council, Health Systems Research Unit, Pietermaritzburg, South Africa, ³Medecins sans Frontieres, South Africa, Cape Town, South Africa, ⁴Greytown Specialised TB Hospital, Department of Health, Greytown, South Africa

Background: The HIV epidemic continues to drive the global tuberculosis epidemic, including multi-drug/rifampicin-resistant tuberculosis (MDR/RR-TB). While TB can be cured, people living with HIV (PLHIV) have increased risk of recurrent TB, but there are limited data on recurrence after successful MDR/RR-TB treatment. High TB and/or MDR/RR-TB recurrence would erode already limited treatment success and add to the already high burdens associated with MDR/RR-TB.

Methods: To assess mortality and recurrent TB after successful MDR/RR-TB treatment, individuals who initiated second-line MDR/RR-TB treatment between 2008-2016 with a successful treatment outcome and known HIV status from two South-African districts (rural and urban) were included. Follow-up data sources included: medical/laboratory records, TB registers, healthcare utilization and deaths data. Cohort follow-up was from the end of successful treatment until TB recurrence or death (censored at date last known to be alive). Time to event analyses were used.

Results: The cohort included 595 and 836 individuals from the included districts (total=1431); 1066 (74%) were PLHIV, 740 (52%) female with median age 34 years (IQR 27-41). Overall, 1098 (77%) were recorded as cured; remainder treatment completed. 114 (8%) successfully completed treatment for MDR-TB with resistance to fluoroquinolones and/or second-line injectables (preXDR/XDR-TB). The median follow-up after treatment ended was 4.4 years. Cumulative post-treatment success mortality was 3.2%, 5.3% and 7.4% at 12, 24 and 36 months. HIV was not associated with increased mortality (HR 0.9, 95%CI 0.6-1.4), rather male sex (HR 1.5, 1.0-2.1) and older age were significant predictors.

Cumulative TB recurrence was 4.2%, 8.9% and 11.4% at 12, 24 and 36 months, while MDR/RR-TB recurrence was 1.1%, 1.9% and 2.6% respectively. Among the 40 MDR/RR-TB re-

currences, 13 (33%) subsequently died. HIV was the only factor associated with TB recurrence (HR 1.6, 1.1-1.9), but was not significant for recurrent MDR/RR-TB (HR 1.6, 0.6-4.8). MDR/RR-TB recurrence was associated with initial preXDR/XDR (versus MDR-TB, HR 8.9, 1.0-81) and with treatment completion (versus cure, HR 2.7, 1.3-5.5).

Conclusions: High TB and MDR/RR-TB recurrence were seen overall and among PLHIV. These data highlight the need for greater attention to post-treatment care and person-centred support, particularly as shorter, all oral MDR/RR-TB regimens are scaled up.

EPB0134

Integrase inhibitor-based antiretroviral treatment does not increase the risk of TB-IRIS in people with HIV treated for tuberculosis: findings from the Reflate TB2 randomized trial

Background: Antiretroviral therapy (ART) initiation in people living with HIV (PWHIV) treated for tuberculosis (TB) may be complicated due to the occurrence of tuberculosis-associated immune reconstitution inflammatory syndrome (TB-IRIS). Integrase inhibitors (INSTIs), by providing a faster HIV-RNA decline than efavirenz, could increase the risk for this complication. We sought to assess incidence and determinants of TB-IRIS in PWHIV with TB on raltegravir or efavirenz-based ART.

Methods: We conducted a secondary analysis of the ANRS 12300 Reflate TB 2 multicenter, phase 3 trial, that randomized ART-naïve PWHIV on standard TB treatment,

to receive raltegravir or efavirenz-based ART. TB-IRIS was defined according to the International Network for the Study of HIV-associated IRIS (INSHI) criteria.

Incidence rates (IR) were estimated by 100 persons-year (PY), stratified Kaplan-Meier curves (log-rank test) and cox regression models were used to assess determinants of TB-IRIS.

Results: Of 460 trial participants, 453 participants from Brazil, Côte d'Ivoire, Mozambique and Vietnam were included in this analysis. Median age 35 years (IQR: 29-43), 40% female, 69% pulmonary TB only, median CD4 102 (IQR 38-239) cells/μL and median HIV RNA 5.5 (IQR 5.0-5.8) log₁₀ copies/mL. Overall, 48 participants developed TB-IRIS (IR = 24.2/100 PY), 19 cases in the raltegravir arm and 29 in the efavirenz arm (log-rank test: p=0.123) (Figure). Factors associated with TB-IRIS were: CD4 count ≤100 cells/μL, HIV RNA ≥500,000 copies/mL, extra-pulmonary/disseminated TB (Table).

Figure. Stratified Kaplan-Meier curves for TB-IRIS-free survival probabilities by ART treatment (raltegravir arm versus efavirenz arm)

	cHR	95% CI	aHR	95%CI
Country				
Ivory Coast	1			
Brazil	1.19	0.44-3.26		
Mozambique	0.47	0.18-1.19		
Vietnam	1.97	1.02-3.81		
CD4 (cells/mm3)				
CD4 >100	1		1	
CD4 ≤100	3.17	1.65-6.16	2.48	1.27-4.84
HIV VL (copies/mL)				
VL ≥ 500 000	1		1	
VL < 500 000	0.27	0.15-0.50	0.34	0.19-0.63
TB diagnosis at enrollment				
Pulmonary only	1			
Extrapulmonary/disseminated	2.22	1.25-3.93	2.17	1.23-3.85

VL: viral load; cHR: crude hazard ratio; aHR: adjusted hazard ratio; CI: confidence interval
ART treatment was not included in the cox regression models due to violation of proportional hazards assumption.

Table. Factors associated with TB-IRIS incidence.

Conclusions: INSTI-based ART did not increase TB-IRIS risk. Low CD4 counts, high HIV RNA and extrapulmonary/disseminated TB were risk factors for TB-IRIS.

EPB0135

Standard biopsy with high-resolution anoscopy could miss potentially precancerous lesions

N. Ando¹, D. Mizushima¹, M. Takano¹, H. Kitamura¹,
D. Shiojiri¹, T. Nakamoto¹, T. Aoki¹, K. Watanabe¹,
H. Gatanaga¹, S. Oka¹

¹National Center for Global Health and Medicine, AIDS
Clinical Center, Shinjuku-ku, Japan

Background: Screening with high-resolution anoscopy (HRA) is the standard approach to anal cancer in high-risk populations. Generally, lesions suspected of being high-grade squamous intraepithelial lesions (HSIL) are biopsied and subsequent intervention such as electrocautery is performed if the lesions were anal intraepithelial neoplasia (AIN) grade 2 or 3.

However, relapse after the intervention was a clinical problem. We performed sextant biopsies to explore the reasons for recurrence regardless of abnormal findings under HRA.

Methods: Individuals were screened with both an anal pap smear and high-risk HPV genotype and those with any positive screening results were included. In the procedure, the HRA provider visually predicted whether the lesion was HSIL or not before the biopsy, and then the provider performed sextant biopsies to collect at least six samples in all directions regardless of abnormal findings. Statistics compared visually predicted and biopsy-proven lesions on a per-lesion or per-person basis.

For each lesion, whether the visually predicted HSIL was consistent with the tissue biopsy result was assessed. On the other hand, it was whether all visually predicted HSILs or non-HSILs were inconsistent with the biopsy results of at least six samples in an individual was assessed.

In this study, an HRA provider who predicted lesions completed a certified HRA course offered by the International Anal Neoplasia Society and experienced 100 person/year.

Results: A total of 112 individuals with 673 lesions were analyzed from June 2021 to September 2022. The mean age was 48 years (interquartile range 41-54), all were MSM, and 86.6% were HIV-positive. The prevalence of HSIL was 81.3%(91/112) for individuals and 43.5%(293/673) for lesions. The rate of AIN grade 3 was 46.4%(52/112) for individuals and 16.6%(117/673) for lesions.

The concordance rate between the predicted lesions and biopsy-proven results was 55.0%(371/674). The rate of the biopsy-proven HSIL that was predicted as LSIL was 36.5%(107/293) for each lesion and 19.8%(18/73) for each individual.

Conclusions: Approximately one in five HSIL cases were considered low-risk lesions based on their appearance. In conventional HRA-guided biopsy, the provider may not biopsy lesions that were not suspicious. These potentially undiagnosed lesions may explain the cause of recurrence after therapeutic intervention.

EPB0136

Dynamics of cellular senescence markers after HCV elimination spontaneously or by DAAs in people living with HIV

Background: We described that people living with HIV (PLWHIV) co-infected with HCV showed increased levels of oxidative stress (OS) and biomarkers related to the Senescence-Associated Secretory Phenotype (SASP).

Our aim was to assess the long-term evolution of senescence after HCV elimination spontaneously or by direct-acting antivirals (DAAs) in PLWHIV.

Methods: Multicenter longitudinal study (48 weeks) of 70 PLWHIV: 23 with active HCV-chronic acquisition (HIV-CHC) before and after HCV elimination with DAAs, 12 spontaneous clarifiers (HIV-SC), and 35 controls (HIV).

OS biomarkers were quantified at DNA, lipid, protein and nitrate levels, total antioxidant capacity and glutathione enzyme. The SASP was characterized by Multiplex Immunoassay and the replicative senescence was assessed by relative telomere length by qPCR.

Differences in senescence markers were evaluated by generalized mixed linear models [adjusted Mean Ratio (aMR)]. P values were adjusted by false discovery rate (q-value) using Benjamin-Hochberg correction with a cut-off point of 0.1.

Results: The median age was 50 and 47% were female. After follow-up, the SC group reduced lipid peroxidation levels (q=0.008).

Although eight SASP markers significantly increased during follow-up (Fig. 1A), they showed a significant reduction in the most prominent markers (IL-1 β , IL-2, IL-6) compared to the HIV group (Fig. 1B).

Elimination of CHC by DAAs reduced OS mainly at the level of GSSG (q=0.008) and nitrates (q=0.032). Regarding SASP, IL-13 levels decreased (q=0.078) but Gro- α and Rantes increased after treatment (q=0.065) (Fig. 1A).

Overall, they achieved a similar senescence profile to the HIV group, except for Gro- α (q=0.019) and FGF-2 (q=0.008) (Fig. 1B)

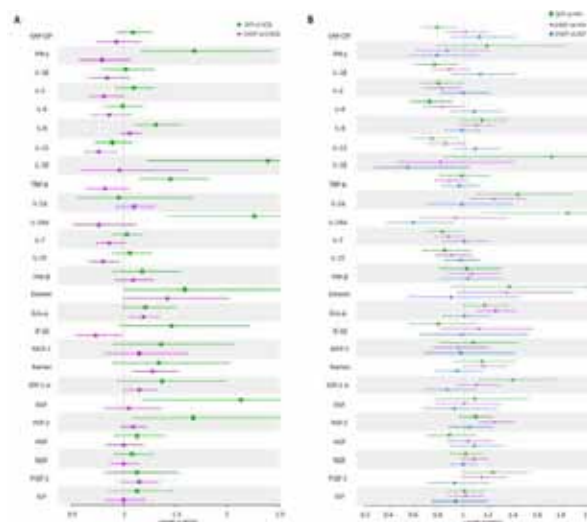

Figure 1.

Conclusions: As clearance time increases in HIV-SC individuals, they showed a greater reduction in OS and SASP markers than that observed in the HIV group, suggesting a better control of HIV-derived senescence. The elimination of CHC acquisition by DAAs partially improves the senescence profile by restoring OS levels and reducing SASP markers to levels observed in the HIV group.

Clinical presentation and outcomes of HIV-associated opportunistic central nervous system infections in the Indonesian national referral hospital: a prospective study

P.W. Andini^{1,2}, R. Estiasari¹, K. Maharani¹, D. Imran¹, A.N.M. Putri^{1,2}, A. Susanto^{1,2}, M.H. Islami^{1,2}, T. Kuntjoro^{1,2}, R.L. Hamers^{2,3}, R.v. Crevel⁴

¹Cipto Mangunkusumo Hospital, Faculty of Medicine Universitas Indonesia, Department of Neurology, Jakarta, Indonesia, ²Oxford University Clinical Research Unit Indonesia, Faculty of Medicine Universitas Indonesia, Jakarta, Indonesia, ³University of Oxford, Centre for Tropical Medicine and Global Health, Nuffield Dept of Medicine, Oxford, United Kingdom, ⁴Radboud University Medical Center, Department of Internal Medicine and Radboud Center for Infectious Diseases, Nijmegen, Netherlands

Background: Central nervous system (CNS) infections are an underrecognized cause of morbidity and mortality in HIV-infected patients, particularly in low- and middle-income countries.

We describe the clinical characteristics and outcomes of HIV-infected adults with a CNS infection in Jakarta, Indonesia.

Methods: We analysed data from a longitudinal cohort at the national reference hospital, enrolled between April 2019-September 2021. We used Cox and logistic regression to estimate in-hospital and 6-month mortality.

Results: Among 531 patients who presented with a suspected CNS infection, a CNS infection was clinically diagnosed in 340 (64%), of whom (184, 54%) were HIV-positive (76.1% male, median age 36 [IQR30-43] years, median CD4 count 37 [IQR16-125] cells/mL).

Forty-three (23.4%) patients were newly HIV-diagnosed, and of those with known HIV, only 46.8% (66/141) were receiving antiretroviral therapy. The median time from symptom onset to hospital presentation was 30 (IQR10-60) days. Cerebral toxoplasmosis was most frequent (66, 35.8%), followed by neurosyphilis (37, 20.1%), tuberculous meningitis (TBM; 35, 19%), and cryptococcal meningitis (CM; 16, 8.7%).

Disregarding asymptomatic neurosyphilis cases (n=40), in-hospital mortality was 24.5% for HIV-positives (36/147) and 22.9% for HIV-negatives (35/153) (p=0.7), and 6-month mortality was 46.5% for HIV-positives (59/127) and 42.9% for HIV-negatives (54/126) (p=0.5). In-hospital and 6-month mortality was highest for TBM (40% and 45.7%, respectively).

In multivariable Cox analysis, in HIV-positive patients, in-hospital mortality was inversely associated with lower CSF/serum glucose ratio at presentation (hazard ratio [HR] 0.04 [95%CI0.0-0.9]), whereas 6-month mortality was associated with fever (HR2.4 [1.1-4.9]), lower CSF/serum glucose ratio (HR0.1 [0.01-0.9]), and severe hyponatremia (<125 mmol/L; HR3.2 [1.1-9.5]) at presentation.

After adjusting for confounders, HIV-infection was found to double the risk of in-hospital death (odds ratio 2.1 [1.0-4.1]) and 6-month death (odds ratio 1.9 [1.0-3.4]) (p=0.04 each), compared with HIV-negative patients.

Conclusions: Most patients with a CNS infection presented late and with severe HIV-induced immunodeficiency. HIV-infection doubled the risk of early as well as long-term death. In high-burden tuberculosis countries including Indonesia, TBM remains an important cause of mortality. Our data underline the need to strengthen care cascades for HIV-positive populations at high-risk of CNS infections.

One-dose versus accelerated two-dose schedule for booster HAV vaccination among people living with HIV after primary HAV vaccination

G.-J. Chen^{1,2}, H.-Y. Sun¹, K.-Y. Lin¹, S.-H. Huang³, Y.-C. Huang³, S.-M. Hsieh¹, W.-H. Sheng¹, C.-H. Wu⁴, W.-C. Liu⁴, Y.-C. Su⁴, S.-Y. Chang⁵, C.-C. Hung^{1,6}

¹National Taiwan University College of Medicine, Internal Medicine, Taipei, Taiwan, Republic of China, ²Min-Sheng General Hospital, Infection Control Room, Taoyuan, Taiwan, Republic of China, ³National Taiwan University Hospital Hsin-Chu Branch, Hsinchu, Taiwan, Republic of China, ⁴National Taiwan University Hospital, Taipei, Taiwan, Republic of China, ⁵National Taiwan University College of Medicine, Department of Clinical Laboratory Sciences and Medical Biotechnology, Taipei, Taiwan, Republic of China, ⁶National Taiwan University Hospital Yun-Lin Branch, Yunlin, Taiwan, Republic of China

Background: People living with HIV (PLWH) are known to have inferior responses to hepatitis A virus (HAV) vaccinations as well as reduced durability of immune protection after HAV vaccination.

Currently, for PLWH who have no responses to their primary HAV vaccination or those had sero-reversion after successful primary HAV vaccination, it is unclear how should they be boosted or revaccinated.

Methods: In this open-labelled, randomized trial, PLWH who tested negative for anti-HAV antibodies >4 weeks after had received a standard adult primary HAV vaccination were included. Enrolled participants were randomized to receive either one dose (the one-dose group) of booster HAV vaccine or accelerated two doses of HAV vaccines, given four weeks apart (the two-dose group). The participants were further sub-classified as the "non-responders" (who had no response to the primary vaccination) and "sero-reverters" (who lost anti-HAV antibodies after primary vaccination).

Results: In the 153 PLWH included (77 in the one-dose group and 76 in the two-dose group), the overall serological responses rate at four weeks after completing the designated booster vaccination schedule was 79.2% in the one-dose group, which was similar to the 82.9% in the two-dose group ($p=0.56$). The response rate remained similar at week 24 (one-dose vs. two-dose, 79.2% vs. 85.5%, $p=0.31$). At week 48, the proportion of participants remained positive for anti-HAV IgG decrease slightly in both groups, but the difference remained statistically insignificant (one-dose vs. two-dose, 71.4% vs. 80.2%, $p=0.20$). However, the titer of anti-HAV antibodies were consistently higher in the two-dose group as compared to the one-dose group. In subgroup analysis, the "non-responders" were more likely to generation a positive response after two doses of HAV boosters, as compared with those in the one-dose group (68.4% vs. 44.1%, $p=0.038$). Serological responses rates and the titers of anti-HAV antibodies were compared.

Conclusions: An accelerated two dose booster HAV vaccination given four weeks apart had similar serological responses as single dose booster among PLWH who were anti-HAV negative after primary HAV vaccination. Two-dose vaccination schedule could generate higher level of anti-HAV antibodies and were more likely to elicit serological responses among PLWH who had poor response to the primary vaccination.

EPB0139

Association between high-risk human papillomavirus infections and cervical cytology results among women living with HIV in Kenya

J. Kangethe^{1,2,3}, E. Odari⁴, J. Pintye^{5,6}, S. Gichuhi⁷, K. Mutai⁸, M. Mureithi^{9,10}, A. Maiyo¹¹, L. Adbullahi¹², J. Kinuthia¹³

Background: Cervical cancer is caused by high-risk human papillomavirus (HR-HPV) and women living with HIV (WLHIV) are disproportionately affected by cervical cancer. There are limited data on the association between HR-HPV and cervical cytology in Kenya, particularly among WLHIV who are at higher risk of developing cervical cancer.

We determined the prevalence of HR-HPV infections and their association with cervical cytology findings among Kenyan WLHIV.

Methods: We conducted a cross-sectional study among WLHIV attending Kenyatta National Hospital (KNH, Kenya's national referral hospital) for HIV care and treatment. Cervical cytology was performed by KNH medical providers per standard of care.

Study nurses collected a cervical sample with a cytobrush for HPV genotyping using Gene Xpert® assays and HPV Genotypes 14 Real-TM Quant™ V67-100 FRT kits. Multivariable logistic models were used to evaluate the associa-

tion between the cytological result (normal vs. abnormal) and HR-HPV, adjusting for the duration of antiretroviral therapy (ART), CD4 count, and behavioral factors.

Results: Overall, 647 WLHIV enrolled in the study. The mean age of participants was 42.8 years (SD 8.7). All participants were on ART; 7% were initiated on ART in ≤ 12 months and 8.8% were not virally suppressed (>1000 copies/mL). The prevalence of any HR-HPV was 34.6%; 29.4% had a vaccine-preventable HR-HPV strain. The most common HR-HPV was HPV-52 (13.4%), followed by HPV16 (9.9%), and 56 (9.6%).

Half of the participants with abnormal cervical cytology had atypical squamous cells of undetermined significance while 17% had high-grade squamous intraepithelial lesions. There were higher odds of abnormal cervical cytology in women >35 years ($aOR=7.27$, 95% CI, 1.48-35.74) than in younger women. There were higher odds of abnormal cervical cytology associated with multiple HR-HPV ($aOR=0.16$, 95% CI, 0.07-0.37).

Conclusions: Over a third of WLHIV enrolled in this study at Kenya's national referral hospital had HR-HPV. There was a strong association between abnormal cervical cytology and the presence of multiple HR-HPV and older age. Cervical cancer programs for WLHIV could consider incorporating HR-HPV screening to identify women most likely to benefit from more intensive monitoring and assessment.

²Public Health Center 28, Health Department, Bangkok Metropolitan Administration, Bangkok, Thailand,

³Taksin Hospital, Medical Service Department, Bangkok Metropolitan Administration, Bangkok, Thailand, ⁴Klang General Hospital, Medical Service Department, Bangkok Metropolitan Administration, Bangkok, Thailand, ⁵Division of Infectious Diseases, Department of Internal Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand, ⁶Sirindhorn Hospital, Medical Service Department, Bangkok Metropolitan Administration, Bangkok, Thailand, ⁷Division of AIDS and STIs, Department of Disease Control, Thailand Ministry of Public Health, Nonthaburi, Thailand, ⁸Division of Tuberculosis, Department of Disease Control, Thailand Ministry of Public Health, Nonthaburi, Thailand

Background: A 2019 meta-analysis reported that 25% of the global population had latent tuberculosis infection (LTBI). Despite the Thai national HIV guidelines recommending tuberculosis preventive treatment (TPT) in newly diagnosed PLWH with CD4 <200 cells/mm³, those exposed to TB, or those who tested positive for LTBI, only 0.4% of PLWH received TPT in 2019. We assessed the prevalence of LTBI among PLWH in Bangkok using Interferon-Gamma Release Assay (IGRA) to inform policy decisions.

Methods: Since March 2022, the Thai Ministry of Public Health and PEPFAR Thailand implemented LTBI screening among PLWH using IGRA (T-SPOT.TB) in five hospitals with high HIV burden in Bangkok. Eligible clients included those with documented positive HIV test results, chest X-Ray, and IGRA test results without a history of TPT or TB treatment. Data from Thailand's HIV/TPT database during March – November 2022 was analyzed using multivariate analysis to identify factors associated with positive IGRA results.

Results: Of 888 PLWH who received IGRA screening, 20.4% (181/888) tested positive. The median age was 38 years; 612 (68.9%) were male, 667 (75.1%) were Thai, and 642 (72.3%) were ART naïve. Of 872 PLWH with CD4 results, about 20% tested positive across all CD4 categories, except those with CD4 <50 cells/mm³, in which 5.6% (1/18) tested positive. Factors associated with positive IGRA results included PLWH in the 30-44 (AOR: 2.06, 95%CI 1.24-3.52) and 45-59 (AOR: 2.44, 95%CI 1.35-4.50) age groups after adjusting for other variables. Nationality, CD4 count, gender, and ART history were not significantly associated with positive IGRA results.

¹ n (%),

² OR = Odds Ratio, CI = Confidence Interval,

³ General Population: PLWH who were not identified as men who have sex with men, transgender persons, people who inject drugs, sex workers, or pregnant women

Table 1: Characteristics of PLWH tested with IGRA and factors associated with LTBI, Bangkok, March – November 2022

Conclusions: High LTBI prevalence was found among higher age groups, and CD4 did not influence IGRA results except those with very low CD4. The feasibility of TPT implementation and cost-effectiveness of using IGRA for LTBI diagnosis in PLWH or provision of TPT to all PLWH requires further exploration.

Prevalence and associated risk factors of hepatotoxicity on tuberculosis prevention therapy in a Thai HIV cohort

H.M.S. Lwin¹, J. Sophonphan^{1,2}, S. Gatechompol^{1,3},
A. Hiransuthikul^{1,4}, W.M. Han^{1,5}, T. Apornpong^{1,2},
K. Woratanarat¹, J. Boonrungrasirap¹, S. Thammasala¹,
S. Kerr^{1,2,5}, A. Avihingsanon^{1,3}

¹HIV-NAT, Thai Red Cross AIDS Research Center, Medical Department, Bangkok, Thailand, ²Chulalongkorn University, Biostatistics Excellence Centre, Faculty of Medicine, Bangkok, Thailand, ³Chulalongkorn University, Center of Excellence in Tuberculosis, Department of Medicine, Bangkok, Thailand, ⁴Chulalongkorn University, Department of Preventive and Social Medicine, Faculty of Medicine, Bangkok, Thailand, ⁵Kirby Institute, UNSW Sydney, Sydney, Australia

Background: Tuberculosis Preventive Therapy (TPT) is an important adjunctive strategy to control tuberculosis. Antituberculosis-treatment (ATT) induced liver injury is a common and serious adverse effect of TB-related treatment. However, there is still limited data on ATT-induced hepatotoxicity in Asian people living with HIV (PLWH). We aimed to investigate the prevalence and risk factors associated with ATT hepatotoxicity on TPT in a Thai PLWH cohort.

Methods: A retrospective analysis was conducted among PLWH on combination antiretroviral therapy who received ≥7 days of TPT between 1992-2022, in Bangkok, Thailand. The participants received either nine months of daily isoniazid (9H), three months of weekly rifampentine plus isoniazid (3HP) or one month of daily rifampentine plus isoniazid (1HP) for TPT. Hepatotoxicity was defined as elevated alanine (ALT) or aspartate transaminase (AST) of 3 times upper limit of normal range with clinical symptoms. Multivariable logistics regression was used to assess factors associated with hepatotoxicity.

Results: We included 851 PLWH on TPT in the analysis (median age, 31.7 [interquartile range (IQR) 26.2-39.5] years; 80.6% male; median CD4 count 380 [IQR 254-545] cells/mm³), 35.4% on efavirenz and 40.8% on dolutegravir. 72(8.5%) participants had hepatotoxicity: 24/272(8.8%) in 9H, 25/287(8.7%) in 3HP, and 23/292(7.8%) in 1HP groups and there was lowest incidence of elevated ALT/AST Grade 3/4 in 1HP group (4/30 cases) than another 2 regimens groups (13/30 cases in both).

Those with hepatotoxicity had significant higher AST or ALT levels at the time of TPT initiation than those without hepatotoxicity (median AST: 41.5 [29-81.5] vs 30 [21-44] U/L; median ALT: 32.5 [24-64] vs 25 [20-31] U/L).

In multivariable analysis, baseline hepatitis C virus co-infection (adjusted odds ratio [aOR] 2.3, 95%CI 1.07-2.41, $p = 0.003$), baseline AST levels level of >40 U/L at TPT initiation (aOR 5.7, 95%CI 2.96-10.98, $p < 0.001$) and efavirenz use at the time of TPT initiation (aOR 2.1, 95%CI 1.11-4.00, $p = 0.02$) were associated with hepatotoxicity in patients PLWH receiving TPT.

Conclusions: HCV coinfection, efavirenz use, and elevated baseline AST were significantly associated with antituberculosis treatment-induced liver injury. Physicians should carefully monitor PLWH with these risk factors for early signs of ATT-related hepatotoxicity when initiating TPT.

High prevalence of asymptomatic Sexually Transmitted Infections in men patients living with HIV

J.A. Mata Marín¹, M.S. Rodríguez Evaristo²,
G. Barriga Angulo³, E. Pérez Barragán¹,
M. Nuñez Armendariz¹, L. Barragán Huerta⁴,
J.E. Gaytán Martínez¹

¹Hospital de Infectología Centro Medico Nacional La Raza, Infectious Disease department, Mexico City, Mexico,

²Hospital de Especialidades Centro Médico Nacional La Raza, Internal Medicine, Mexico city, Mexico, ³Hospital de Infectología Centro Medico Nacional La Raza, Clinical Laboratory, Mexico City, Mexico, ⁴Universidad Autonoma Metropolitana, Biological Science and Health Department, Mexico City, Mexico

Background: Sexually transmitted infections (STIs) occur frequently in men who have sex with men (MSM) living with HIV. Guidelines recommendations do not include

screening for asymptomatic people. The aim of the study was to identify the prevalence of asymptomatic STIs in men patients living with HIV (PLHIV).

Methods: A cross-sectional study was conducted in people with HIV infection at the Hospital de Infectología "La Raza" National Medical Center, from May to August 2022. An urethral sample was taken from PLHIV who were attended in the HIV clinic for men. Written informed consent was obtained from all participants before the sample was taken for the identification of 11 microorganisms. Detection was performed by PCR test for *Chlamydia trachomatis*, *Neisseria gonorrhea*, *Haemophilus ducreyi*, *Mycoplasma genitalium*, *Mycoplasma hominis*, *Treponema pallidum*, *Trichomonas vaginalis*, *Ureaplasma urealyticum*, *Ureaplasma parvum*, Herpes Simplex virus type 1 and 2. Participants were also asked to complete a questionnaire documenting behavioral characteristics or symptoms related to a possible STI infection (Braun STI screening ZPHI study). The data were measured in medians with inter-quartile ranges and the prevalence of detection of urethral microorganisms was presented as a percentage.

Results: We included 184 male naive treatment patients who started an antiretroviral regimen. Baseline characteristics were a median age of 26 years (IQR 22-31), CD4+ 274 cells count (IQR 183-380), and HIV-1 RNA viral load 4.36 log₁₀ (IQR 3.74 -4.83).

We detected at least one microorganism in 42 (22.8%) urethral samples; of these, *Ureaplasma urealyticum* was detected in 23 (55%), and *Mycoplasma genitalium* in 8 (20%), *Mycoplasma hominis* in 9 (21%), *Chlamydia trachomatis* in 3 (7.1%), *Treponema pallidum* 2 (4.7%), *Neisseria gonorrhoeae* in 2 (4.7%) and herpes simplex 2 in 1 (2.3%). In 5 (12%) patients, more than one microorganism was detected.

Conclusions: In PLHIV naive treatment and asymptomatic, urethral colonization with Mollicutes was high. The most frequently found microorganisms were *Ureaplasma urealyticum* and *Mycoplasma genitalium*.

The primary reason that gonorrhea and chlamydial infections are untreated is that infected people never have symptoms. Regular screening should be considered in PLHIV at least each 6 to 12 months.

EPB0143

Cryptococcal antigen (CrAg) screening a need of the hour for PLHIV of Eastern India

J. Tapadar Nee Chakravarty¹, S. Reddi¹, M. Gupta², R. Tilak²

¹Institute of Medical Sciences, Banaras Hindu University, Department of Medicine, Varanasi, India, ²Institute of Medical Sciences, Banaras Hindu University, Department of Microbiology, Varanasi, India

Background: Cryptococcal meningitis is one of the leading cause of mortality in people living with HIV (PLHIV) with advanced disease. Although the national program recommends screening for CrAg in PLHIV with CD4 < 100/

μL, it has not been implemented in practice. There is also a dearth of information regarding the prevalence of Cryptococcal antigenemia in India. Thus this study was done to assess the prevalence of cryptococcal antigenemia among PLHIV with advanced disease.

Methods: This prospective study was done in a government funded ART (Antiretroviral treatment) centre in Varanasi between January 2021- March 2022. Serum CrAg (BIOSYNEX® CryptoPS) screening was done in newly diagnosed adult PLHIV with CD4 < 200/μL after informed consent. CSF CrAg testing was done in all PLHIV who were serum CrAg positive. Serum CrAg positive PLHIV were given preemptive treatment while CSF CrAg positive were treated for cryptococcal meningitis as per WHO recommendation. All participants were followed up till September 2022.

Results: Serum CrAg was positive in 20.8% (n=20) of the 96 eligible subjects screened (Table 1). 35% (n=7/20) of CrAg positive PLHIV had CD4 count between 100-199 cells/ μL. Among the serum CrAg positive PLHIV, 45 % (9/20) were positive for CSF cryptococcal antigen. None had symptoms of cryptococcal meningitis. Serum CrAg positivity was significantly associated with low CD4 count, poor clinical stage and Pneumocystis pneumonia (PCP). At the end of follow up, 2 PLHIV among the CrAg positive and 3 in CrAg negative group died. None of the deaths were due to cryptococcal disease.

Baseline Parameter	Serum CrAg Positive (N=20) Mean ± SD (%)	Serum CrAg Negative (N=76) Mean ± SD (%)	P value
Age years	40.45 ± 10.59	38.90 ± 10.97	0.718
Sex			
Male	14 (70%)	59 (77.6)	0.496
Female	6 (30%)	17 (22.4)	
CD4 cells/ μL	74.3 ± 55.44	118 ± 57.26	0.014
WHO stage 1 & 2	5 (25)	48 (63.2)	0.02
WHO stage 3 & 4	15 (75)	28 (36.8)	
Tuberculosis	13 (65)	48(63.1)	0.878
Pneumocystis pneumonia(PCP)	7 (35)	6(8.8)	0.02
Outcome at end of follow-up			
Alive	18(90)	73 (96)	0.102
Expired	2(10) (1 PCP & 1 Tuberculosis)	3(4) (due to Tuberculosis)	

Table 1: Baseline characteristics

Conclusions: High prevalence of cryptococcal antigenemia reiterates the need for CrAg screening among PLHIV of Eastern India. As 35% of our CrAg positive PLHIV had CD4 count between 100-199 / μL the cut off for screening should be increased to CD4 200/ μL instead of the recommended CD4 <100/ μL. Appropriate management of cryptococcal antigenemia and meningitis improves survival.

Background: Delays in treating hepatitis C virus (HCV) increase the risk of loss to care and onward transmission, jeopardising HCV elimination. We describe differences in treatment initiation following HCV diagnosis among people with HIV (PHIV) in five countries with high treatment uptake in the direct acting antiviral (DAA) era.

Methods: Data were from five of 11 cohorts from the International Collaboration on Hepatitis C Elimination in HIV Cohorts (InCHEHC), including data from Australia, France, the Netherlands, Switzerland and Spain. Individuals were eligible if first HCV diagnosed after DAAs became broadly available in their country. We used Kaplan-Meier methods to estimate the probability of treatment initiation by country. Follow-up started at HCV diagnosis (first positive RNA result), and ended at first treatment initiation, cohort administrative censoring date, loss to follow up, or end of 2019, whichever came first.

Results: Of 92,626 participants in the five cohorts, 1084 were first diagnosed with HCV after broad DAA access began. Overall, 404 (37%) initiated treatment during 1120 person-years of follow up. Time to treatment initiation was shortest in the Netherlands and longest in Australia (Figure 1).

Figure 1. Time to treatment initiation since HCV diagnosis among 770 participants with first HCV RNA test after broad access to DAA therapies.

Six months and one year after diagnosis respectively, the probability of treatment initiation was 20% (95% CI: 16-24%) and 27% (95%CI: 22-31%) in Australia, and 39% (95%CI: 33-44%) and 52% (95% CI: 47-57%) in the Netherlands, with few participants treated more than one year after diagnosis (Figure 1).

Conclusions: Time to treatment initiation varies substantially between countries even among those with broad access to DAA and high treatment uptake. Those diagnosed during broad access to DAAs may be less engaged in care and therefore less likely to initiate treatment than previously treated participants. Policy differences between countries with respect to treatment of acute HCV and differences in HCV RNA testing may contribute to differences in treatment uptake.

EPB0145

The epidemiological profile of mpox cases in Rio de Janeiro, Brazil: changes over time during the 2022 outbreak

M. Secco Torres Silva^{1,1}, T. Silva Torres¹, C. Coutinho¹,

E. Mesquita Peixoto¹, A.P. Lovetro Santana¹,

M. Braga Mesquita¹, F.C. Serrão Lessa¹, R. Ismério Moreira¹,

V. Gonçalves Veloso¹, B. Grinsztajn¹,

INI-Fiocruz Mpox Study Group

¹Instituto Nacional de Infectologia Evandro Chagas

(Fiocruz), Rio de Janeiro, Brazil

Background: Mpox emerged as a public health emergency of international concern in May, 2022. By January 27, 2023, 85,382 cases were diagnosed globally;12.5% of them in Brazil. Understanding the mpox transmission dynamics in Brazil is relevant to prepare adequate responses at the country level.

This study aimed to analyze the characteristics of confirmed mpox cases and the pattern of community transmission in Rio de Janeiro according to time of diagnosis.

Methods: Prospective, observational cohort study of individuals with confirmed mpox followed at a major referral center in Rio de Janeiro, Brazil. We compared sociodemographic, clinical, and behavioral data among individuals diagnosed in two time periods:

1. June-August 2022 (first phase);
2. September-December 2022 (second phase).

Chi-squared or Fisher's tests for qualitative variables and Moods test for quantitative variables were used.

Results: Between June and December 2022, 416 participants had confirmed mpox, the majority between June and August 2022 (62.9%).

Overall, median age was 34 years (IQR:28-40), 91.9% were cisgender men (n=382/416), 62.3% self-declared as black or *pardo* (n=205/329), 87.4% were men who have sex with men (MSM) (n=326/373).

Compared to cases diagnosed during the first phase, the frequency of cases among women (cis and trans) increased during the second phase, whereas it declined

among cisgender men and MSM. Reporting sex in the 30 days before symptoms initiation and the frequency of anogenital lesions remained stable across phases. Overall, disseminated exanthema was more frequent, but localized exanthema increased during the second phase (Table).

	June – August 2022 (n = 262)	September – December 2022 (n = 154)	Total (n = 416)	p-value
Median age (IQR)	33 (28,39)	35 (28,42)	34 (28,40)	0.25
Gender				
Cisgender men	252/262 (96.2%)	130/154 (84.4%)	382/416 (91.9%)	
Cisgender women	10/262 (3.8%)	13/154 (8.4%)	23/416 (5.5%)	<0.001
Transvesti or TGW	0 (0)	11/154 (7.2%)	11/416 (2.6%)	
MSM	215/232 (93%)	111/141 (79%)	326/416 (87%)	<0.001
Reported sex in the 30 days before starting symptoms	210/231 (91%)	127/144 (88%)	337/375 (90%)	0.40
Exanthema				
Localized	69/248 (28%)	60/149 (40%)	129 (32%)	0.01
Disseminated	179/248 (72%)	89/149 (60%)	269/397 (68%)	
Anogenital lesions	191/262 (73%)	115/154 (75%)	306 (74%)	0.69

Conclusions: The intersection of sexual networks seems to play an important role in mpox transmission dynamics during community spread, as shown by the largest number of MSM in the first phase and the increased number of cases in women diagnosed over time. The increased frequency of localized exanthema might be related to greater awareness of the array of clinical presentations among clinicians. Prompt mpox identification and diagnosis are essential to fully understand the dynamics of the mpox outbreak.

EPB0146

Clinical characteristics and outcome of toxoplasma encephalitis in HIV patients from Indonesian tertiary referral hospital

A. Rakhmawati¹, P.W. Andini^{1,2}, R. Estiasari¹, K. Maharani¹, M.H. Islami^{1,2}, A.N.M. Putri^{1,2}, A. Susanto^{1,2}, T. Kuntjoro^{1,2}, D. Imran¹

¹Universitas Indonesia, Departement of Neurology, Cipto Mangunkusumo Hospital Faculty of Medicine, Central Jakarta, Indonesia, ²Universitas Indonesia, Oxford University Clinical Research Unit Indonesia, Faculty of Medicine, Central Jakarta, Indonesia

Background: Toxoplasma encephalitis (TE) is the most common brain opportunistic infection in HIV patients with low CD4 T cell counts. The mortality remains high even though the diagnosis can be made earlier. This study aims to compare the clinical characteristics, CD4 T cells count, and treatment response based on the outcome of TE patients with HIV.

Methods: The prospective cohort study was conducted at a tertiary referral hospital in Jakarta, Indonesia between April 2019–September 2021. We include all HIV patients with TE diagnosis aged ≥18 years. The diagnosis of TE was made presumptively in HIV patients with CD4 <200, having neurological deficits (hemiparesis) with compatible brain imaging features.

The data collected were demographic characteristics, clinical presentations, CD4+ T cell counts, brain imaging, and treatment response. Patients' outcome was assessed at hospital discharge and six months follow-up.

Results: Of 66 patients, the mean age was 35.76 ± 9.38 years, and 68% were male. The clinical presentations were mainly headache (78.8%), hemiparesis (63.6%), altered consciousness (63%), and fever (37%). CD4+ T cell count was observed in 63 patients with a mean of 61.94 ± 83.32 cells/mL. The results of imaging showed that 37% of patients had brain herniation. At the end of the study, 22 (33%) patients died. Nine patients (13.6%) died at the hospital and 13 patients (19.7%) died at six months of follow-up. In the dead patients' group, fever and altered consciousness were tend more frequent (50% vs 32% and 68% vs 52%). The mortality was not affected by the pyrimethamine treatment.

Figure 1. Clinical characteristics, CD4+ T-cell counts, brain imaging and pyrimethamine treatment were based on survival status at the end of the study.

Conclusions: In this study, headache, hemiparesis, and altered consciousness were the most common clinical presentation among TE in HIV patients. Half of the patients who died had a fever, altered consciousness, and low CD4+ T cell counts.

EPB0147

Efficacy and safety of different regimens in the treatment of HIV patients with latent tuberculosis infection: a systematic review and network meta-analysis of randomized controlled trials

D.G. Assefa¹, E.D. Zeleke², T. Manyazewal³¹Dilla University, Nursing, Dilla, Ethiopia, ²Bule Hora University, Midwifery, Bule Hora, Ethiopia, ³Addis Ababa University, CDT-Africa, Addis Ababa, Ethiopia

Background: Treatment of latent tuberculosis infection (LTBI) is effective in preventing progression to TB disease. This study aimed to synthesize available evidence on the efficacy, adherence, and safety of LTBI treatment in order to assist policymakers to design appropriate national treatment policies and treatment protocols.

Methods: The PRISMA statement extension for systematic reviews incorporating network meta-analysis (PRISMA-NMA) was used to review and report this research. Randomized controlled trials which compared the efficacy and safety of LTBI treatments were included.

A systematic literature search was done to identify relevant articles from online databases PubMed/ MEDLINE, Embase, and Cochrane Center for Clinical Trial database (CENTRAL). The network meta-analysis was done using R-studio Version 1.4.1103.

Results: In this review, 42 studies were included, which enrolled 52547 participants living with HIV. The incidence of TB among people living with HIV who have taken 3RHZ (RR 0.40 95% CI 0.23,0.69) as TPT was lower followed by 3RH (RR 0.56 95% CI 0.36,0.89) and 6H (RR 0.62 95% CI 0.45, 0.87). Patients' adherence to TPT was higher among patients who have taken 4R (RR1.38 95% CI 1.0,1.89) followed by 3RH (RR 1.34 95% CI 1.03,1.74) and 2RZ (RR 1.34 95% CI 1.02,1.75).

The proportion of subjects who permanently discontinued a study drug because of adverse event were higher in 3RZ (RR 9.31 95% CI 2.99,28.97), followed by 2RZ (RR7.12 95% CI 1.39, 36.57), and 3RH (RR 3.29 95% CI 1.11, 9.78). The risk of nausea and vomiting was higher among patients who have taken 3HP (RR 5.91 95% CI 2.30,15.20), followed by two months twice a week combination of HP (RR 3.51 95% CI 1.04,11.79).

Conclusions: From this review, it can be concluded that 3RHZ, 3RH, 6H has a significant impact on the reduction of TB incidence among PLWH. However, rifampicin combination either with isoniazide or pyrazinamide or both were significantly associated with adverse events which resulted permanent discontinuation.

Hence, in order to understand the efficacy and safety of TPT on children more study might needs to be done.

EPB0148

CMV co-infection and HIV disease control among children living with HIV in Canada

Y. Fougere¹, J. Brophy², L. Samson², M.T. Hawkes³, T. Lee⁴, M.-S. Kang Dufour⁵, C. Renaud⁶, S. Read⁷, A. Bitnun⁷, S. Gant⁵, H. Soudeyns⁵, F. Kakkar⁵, Epic 4 Study Group
¹CHU Sainte-Justine, Montreal, Canada, ²Children's Hospital of Eastern Ontario, Ottawa, Canada, ³University of Alberta, Edmonton, Canada, ⁴Canadian HIV Trials Network, Vancouver, Canada, ⁵Centre de Recherche du CHU Sainte-Justine, Montréal, Canada, ⁶CHU Sainte-Justine, Montréal, Canada, ⁷Hospital for Sick Children, University of Toronto, Toronto, Canada

Background: CMV co-infection among people living with HIV is associated with chronic inflammation and HIV disease progression, though data in pediatrics is limited.

The objective of this study was to determine the association between CMV viremia and HIV disease control, and to describe immunological (humoral and cell-mediated) markers of CMV control in children living with HIV (CLWH) who acquired HIV by perinatal transmission.

Methods: Sub-study of the prospective, multicenter Early Pediatric Initiation Canada Child Cure Cohort study (EPIC⁴). CLWH were followed every 3-6 months from 2014-2018. CMV serostatus (IgG) was determined at baseline (ArchitectTM CMIA) and end of study for those seronegative at baseline. CMV and HIV viral loads (VL) and lymphocyte subsets were quantified at every visit for those with IgG seropositivity. In CMV seropositive CLWH, CMV IgG avidity was quantified and CMV pp65-specific IFN-g responses were measured using ELISpot.

Results: 225 CLWH were enrolled; median baseline age was 13.9 years (IQR, 9.3-17.0 years), and median follow up was 32 months (IQR, 21-38). 192 (85.3%) were CMV seropositive at baseline (5 with documented congenital CMV infection). Thirty-four (17.7%) CMV seropositive CLWH were CMV viremic at least once during follow-up (VL range 85-1991 IU/mL). Though there was no difference in median age of cART initiation (3.7 vs 4.4 years, p=0.15) or incidence of treatment interruptions during follow-up (14.7% vs 8.2%, p=0.40) in CLWH with and without CMV viremia, those with CMV viremia were more likely to have at least one episode of detectable HIV VL during the follow-up period (64.7% vs 33.5%, p< 0.001), and to have lower CD4:CD8 ratio nadir during follow-up (0.68 vs. 0.83 p=0.043).

Those with CMV viremia had higher total CMV IgG titers (217 vs. 156 AU/mL, p<0.001) and avidity (87.9 vs. 85.6%, p=0.01), and lower though non-significant IFN-g responses (1601 vs. 2263 spot-forming units (SFU) per 10⁶ PBMC, p=0.20).

Conclusions: Among CLWH in Canada, CMV viremia is not rare and associated with HIV viremia and lower nadir CD4:CD8 ratio, higher CMV IgG titers and lower IFN-g responses. Further work is necessary to determine the potential role of CMV in HIV disease progression and chronic inflammation in CLWH.

Integration of HCV treatment at district antiretroviral therapy clinics during COVID-19 pandemic: a success story from Viet Nam

N. Do Thi¹, V. Nguyen Thi Thuy², D. Tran Anh¹, D. Vu Quoc³, C. Vu Van¹, L.A. Tong Thi⁴, H. Duong Thu⁴, H. Phan Thi Thu¹

¹Vietnam Administration for HIV/AIDS Control, Hanoi, Vietnam, ²World Health Organization, Vietnam Country Office, Hanoi, Vietnam, ³Hanoi Medical University, Department of Infectious Diseases, Hanoi, Vietnam, ⁴The Global Fund Supported Project on HIV/AIDS, Hanoi, Vietnam

Background: Estimated 1 million people are living with hepatitis C virus (HCV) in Vietnam. Majority of them are people living with HIV (PLHIV) and people who inject drugs (PWID). Hepatitis C and B are the major causes of hepatocarcinoma and liver-related deaths in Vietnam.

However, access to HCV treatment remains limited for PLHIV and PWID. To address this, an initiative on integration and scale-up HCV treatment at district antiretroviral therapy (ART) clinics for PLHIV and PWID on methadone maintenance therapy (MMT) was implemented.

Description: Between April 2021 and August 2022, a total of 16,052 patients (4,492 PWID and 11,560 PLHIV) initiated HCV treatment with direct acting antivirals (DAAs) at 210 ART clinics in 38 provinces in Vietnam. Majority (84%) of these ART clinics were at district hospitals. Data on patient demographics, ART, MMT and HCV treatment were abstracted from a web-tool designed for HIV and HCV treatment patients. Cure rate was defined as undetectable of HCV RNA at 12 weeks or more (SVR12) after completion of HCV treatment.

Lessons learned: Of 16,052 patients (including 1415 compensated and 50 decompensated cirrhosis patients) received DAAs and 98.7% patients completed the treatment course. As of 30th November 2022, there were 4,785/15,784 (30.3%) patients had a second HCV RNA test at 12 weeks or more after the treatment completion and overall rate of SVR12 was 96.6%. No difference was found in SVR12 rates between district (96.7%), provincial (95.6%) and central (98.7%) level health facilities.

However, there was a significant proportion of patients (69.7%) who had completed treatment for at least 12 weeks but did not have second HCV RNA test. The major reasons for this were patients felt well and did not want to spend their time or money for the second HCV RNA test.

Conclusions/Next steps: The findings from this real-world data demonstrated the feasibility of integration of HCV treatment at district ART clinics which brings HCV treatment services closer to PLHIV and PWID.

The results will be served as strong evidence to advocate health insurance reimbursement for HCV treatment at district health facilities to ensure sustainability of HCV treatment in Viet Nam.

Background: Limited data inform evidence-based co-administration of DTG/TDF/3TC (TLD) with daily isoniazid (H) and rifapentine (P) for 1 month (1HP) or weekly HP for 3 months (3HP) for tuberculosis preventive therapy (TPT) in people living with HIV (PWH), particularly from Asia.

Methods: A randomized control trial of 1 HP or 3 HP for TPT among PWH in 15 HIV clinics in Thailand is ongoing study from 2019 to present. At the beginning, only EFV/TDF/FTC was allowed. After the A5372 study demonstrated high DTG plasma concentrations among Thai PWH, TLD once daily was initiated from March 2022 onward. We reported the 24 weeks efficacy and safety of TLD and EFV/TDF/FTC with either 1 HP or 3HP.

Results: Of 1070 participants analysed (59% male, median body weight 62.6 kg) , 804 (75%) took EFV/TDF/FTC and 266 (25%) received TLD; 546 (51%) participants received 1HP. Median ART duration prior to TPT was 1.2 (IQR:0.6-7.2) years; the majority of participants started TPT within 3

months of TLD or EFV/TDF/FTC initiation (66%), especially in the TLD group (84%). At week 24, viral suppression (HIV VL ≤ 50 copies/mL) was high in both EFV/TDF/FTC (92.2% 1HP and 91% 3HP) and TLD (92.8% 1HP and 94.7% 3HP) (Figure 1).

Hepatotoxicity \geq grade 2, that was mainly asymptomatic and self-limited, developed in 8.8% of 1 HP and 6.4% 3HP groups. Only 0.4% and 0.2% of 1070 participants prematurely discontinued 1 HP and 3 HP, respectively, due to hepatotoxicity or hypersensitivity reactions. Only 0.8% TLD group participants prematurely discontinued TPT.

Figure. 1A-C represent median CD4 change, HIV VL suppression and grading of hepatotoxicity in each treatment group

Conclusions: Similar efficacy and safety was observed for PWH receiving dolutegravir and efavirenz based ART, co-administered with 1 HP or 3HP, suggesting once daily DTG doses are appropriate with 1 HP or 3 HP.

Hepatitis delta and liver disease among people living with hepatitis B in Senegal

A. Ramírez Mena^{1,2,3}, F. LeGal⁴, A. Badiane², M.H. Larboulette⁴, J. Tine², K. Ndiaye⁵, N.F. Ngom⁵, C. Béguelin¹, M. Seydi², G. Wandeler^{1,2}, O. Ndiaye⁶, for SEN-B
¹Department of Infectious Diseases, Bern University Hospital, University of Bern, Bern, Switzerland, ²Service des Maladies Infectieuses et Tropicales, Fann University Hospital, Dakar, Senegal, ³Graduate School of Health Sciences, University of Bern, Bern, Switzerland, ⁴Centre National de Référence des Hépatites Virales B, C et Delta, Laboratoire de Microbiologie Clinique, Hôpital Avicenne, Assistance Publique Hôpitaux de Paris; Université Sorbonne, Paris Cité, Bobigny, France, ⁵Centre de Traitement Ambulatoire de Fann, Fann University Hospital, Dakar, Senegal, ⁶Centre Régional de Recherche et Formation Clinique à la Prise en Charge de Fann, Fann University Hospital, Dakar, Senegal

Background: Hepatitis delta virus (HDV) infection is the most severe form of viral hepatitis. However, its prevalence among persons living with hepatitis B virus (HBV)

infection in West Africa, and its impact on liver-related complications is ill defined. We tested a large urban HBV cohort in Senegal for the presence of HDV infection and evaluated its association with liver cirrhosis.

Methods: We included all HBsAg-positive individuals, with or without HIV co-infection, who presented between October 2019 and September 2022 to one of two referral infectious disease clinics in Dakar, Senegal.

All participants underwent clinical and virological assessments, as well as transient elastography (TE). We tested for anti-HDV antibodies using the Anti-HD Liaison XL test (DiaSorin, Belgium) on cryopreserved dried blood spots. Anti-HDV IgG-positive specimens were tested for the presence of HDV RNA using a sensitive RT-PCR of the end of HDV-Ag region of the genome, and genotypes were determined after sequencing. We used multivariable logistic regression to explore the association between HDV-positivity and liver fibrosis, defined as TE >7.0 kPa.

Results: Among 585 participants, median age was 32 years (interquartile range [IQR] 26-41), 274 (46.8%) were women and 94 (16%) had HIV-coinfection. Eleven (1.9%) participants had anti-HDV antibodies, of whom 8 (72.7%) showed active replication. HDV-5 genotype was found in 6 of 8 individuals, while the other two had HDV-1 and HDV-7. Compared to individuals with a negative HDV serology, those with anti-HDV antibodies were more likely to have an undetectable HBV viral load (81.8% vs. 35.3%) and liver fibrosis or cirrhosis (54.4% vs 9.8%). 5 of 8 (62.5%) individuals with detectable HDV-RNA had liver cirrhosis. In multivariable analyses, HDV-positivity (adjusted odds ratio 18.91, 95% confidence interval 3.61-99.04) and male sex (5.88, 2.63-13.15) were strong predictors of liver fibrosis. **Conclusions:** Although the prevalence of hepatitis delta was low in our large cohort of persons living with HBV in Dakar, those affected had a very high risk of presenting with liver cirrhosis. Efforts to improve HDV screening and management are urgently needed in West Africa.

**EPB0152****Hepatocellular carcinoma surveillance among people living with hepatitis B in Senegal: 1-year results of a prospective cohort study**

A. Ramírez Mena^{1,2,3}, M. Thiam⁴, D. Ka², I. Niang⁴, J. Tine², L. Fortes⁵, K. Ndiaye⁶, O. Ndiaye⁷, M. Fall², A. Gaye⁶, C. Tidiane⁸, A. Jaquet⁹, N.F. Ngom⁶, M. Seydi², G. Wandeler^{1,2}, for SEN-B

¹Department of Infectious Diseases, Bern University Hospital, University of Bern, Bern, Switzerland, ²Service des Maladies Infectieuses et Tropicales, Fann University Hospital, Dakar, Senegal, ³Graduate School of Health Sciences, University of Bern, Bern, Switzerland, ⁴Department of Radiology, Fann University Hospital, Dakar, Senegal, ⁵Department of Infectious Diseases, Dalal Jamm National Hospital, Dakar, Senegal, ⁶Centre de Traitement Ambulatoire de Fann, Fann University Hospital, Dakar, Senegal, ⁷Centre Régional de Recherche et Formation Clinique à la Prise en Charge de Fann, Fann University Hospital, Dakar, Senegal, ⁸Department of Radiology, Albert Royer University Hospital, Dakar, Senegal, ⁹French National Research Institute for Sustainable Development (IRD), University of Bordeaux, Inserm, Bordeaux, France

Background: In West Africa, hepatitis B virus (HBV) infection is the most important risk factor for hepatocellular carcinoma (HCC). Although six-monthly ultrasound measurements are recommended to detect HCC at an early stage, few large-scale longitudinal studies exist to inform HCC surveillance strategies in sub-Saharan Africa.

Methods: We included antiviral treatment-naïve HBsAg-positive individuals presenting between October 2019 and September 2022 at one of two referral infectious disease clinics in Dakar, Senegal.

All participants underwent six-monthly virological assessments, transient elastography (TE) and abdominal ultrasound. In the presence of a liver lesion > 1cm on ultrasound, we performed a 4-phase CT-scan (4CT).

Results: Of 758 HBsAg-positive participants, 755 had an ultrasound measurement at enrolment. Their median age was 31 years (interquartile range [IQR] 25-39), 53% were men, 10.8% had a family history of HCC and 1.8% reported hazardous alcohol consumption. HBeAg was positive in 15/681 (2.2%) individuals, 202/755 (27%) had HBV DNA >2,000 IU/mL, and 87/755 (11.5%) had liver fibrosis or cirrhosis (TE >7 kPa).

On ultrasound at enrolment, 48/755 (6.4%) individuals had signs of cirrhosis, whereas 20/755 (2.7%) had a focal liver lesion. Of 10 patients with a lesion >1 cm, all had a 4CT, which confirmed 1 HCC, 5 liver hemangiomas, 2 biliary cysts, 1 focal nodular hyperplasia and 1 regenerative liver nodule.

In addition, 3 participants with signs of portal vein thrombosis had a 4CT performed, which confirmed the presence of an HCC. 83.2% of participants performed at least 1 additional ultrasound in the first 12 months of follow-up,

of whom 118 (18.8%) had initiated antiviral therapy. Five individuals had an incidental liver nodule <1 cm during follow-up and no incident HCC cases were found.

Conclusions: Our study highlights the feasibility of rolling out an HCC surveillance program in Senegal. Four (0.5%) participants had an HCC at an advanced stage at presentation and none during follow-up. Long-term surveillance is needed to understand the determinants of HBV-related HCC in West Africa.

EPB0153**Drug Resistant Tuberculosis (DR-TB) detection among new, previously treated TB cases, and people living with HIV in Western and Southern highlands, Tanzania**

G. Muyela¹, O. Massawa¹, A. Almeida¹, B. Chidzao¹, M. Jeremiah², E. Mwanyala³, R. Kisonga⁴, K. Mkambu¹, B. Masanja¹, S. Mathias⁵, B. Jani⁵, D. Buhili⁶, A. Simon⁷
¹Tanzania Health Promotion Support, USAID Uhuru TB&FP Activity, Dar es Salaam, Tanzania, United Republic of, ²Katavi, Regional Administrative Secretary, Health, Mpanda, Tanzania, United Republic of, ³Kigoma, Regional Administrative Secretary, Health, Ujiji, Tanzania, United Republic of, ⁴Ministry of Health, National Tuberculosis and Leprosy Program, Dodoma, Tanzania, United Republic of, ⁵USAID-Tanzania, Health, Dar es Salaam, Tanzania, United Republic of, ⁶Rukwa, Regional Administrative Secretary, Health, Sumbawanga, Tanzania, United Republic of, ⁷Songwe, Regional Administrative Secretary, Health, Songwe, Tanzania, United Republic of

Background: Tuberculosis (TB) including drug resistant Tuberculosis (DR-TB) is a major public health concern. Worldwide 649,000 people were treated for multi-drug resistance (MDR) TB from 2018-2021; 43% of the global target (WHO Global TB report 2022). Findings from the TB Drug Resistance Survey in 2018 in Tanzania, showed that MDR/rifampicin resistance (RR) TB prevalence was 0.97% among new TB clients and 4.6% for previously treated cases. Furthermore, 448 (56%) cases were diagnosed against national target of 800 in 2018. The UNAIDS estimates that people living with HIV (PLHIV) have double the risk of developing DR-TB. The USAID Uhuru TB Local Organizations Network project is implemented in Katavi, Kigoma, Rukwa and Songwe regions with overall capacity of 27 GeneXpert machines. Use of GeneXpert machine in identifying DR-TB in previously treated and PLHIV is inevitable.

Description: Between October – November 2022, the project collected and reviewed the TB clients notified from October 2020 to September 2022 from 315 health facilities in the four project supported regions. Data were then extracted from the electronic Tuberculosis and Leprosy database (DHIS2-ETL) into Ms. Excel. Collected data was disaggregated by age, sex, history of treatment, diagnostic method, laboratory test results and HIV status. Analysis was done to get descriptive information on risk of MDR/RR TB.

Lessons learned: A total of 9,416 TB cases were notified; 9,138 (97%) new and 278 (3%) previously treated. About 43% [3,972/9,138] of new TB clients were tested through GeneXpert, 56% [2,209/3,972] were MTB positive with 20 (0.9%) cases of RR TB. Among the previously treated TB clients, 75% (209/278) were tested using GeneXpert; 66% [138/209] were MTB positive and 15 (10.9%) RR TB. The proportion of RR was 10 times higher in previously treated TB clients than in new TB clients. The HIV co-infection among previously treated RR-TB clients is higher (16%) compared to new RR-TB clients (1.7%). The findings support that the risk of developing DR-TB is high among previously treated and PLHIV clients.

Conclusions/Next steps: Increasing proportion of presumptive TB cases and the access to molecular TB diagnosis for previously treated TB clients and PLHIV is an added advantage to detection of DR-TB cases.

EPB0154

Finding missing tuberculosis (TB) cases in Ugandan military health facilities through use of mobile digital X-ray services and technology (Mobile TB Clinics)

Uganda, ⁵University Research Co., LLC, Program, Maryland, United States, ⁶U.S. Embassy, Department of Defense,

Kampala, Uganda

Background: TB is the world's deadliest infectious disease, infecting about 10 million people and killing 1.5 million globally each year. Uganda is one of the 22 WHO TB high burden countries. The estimated incidence of TB in Uganda is about 223 daily, and mortality is about 30 per day. In Ugandan military bases, there is high potential of contracting TB due to overcrowded living conditions and substantially higher smoking rates. Despite implementing all routine TB case detection activities, DoD-Uganda URC project only achieved 42% of its annual TB case notification target by end of March 2022 (FY22Q2).

The major reason for this was limited investigative capacity, with only one facility having functional X-ray services and only 5 of 31 sites having onsite GeneXpert testing services. We describe the intervention used to improve TB case notification in Uganda military facilities.

Description: This was an interventional approach during program implementation. The project partnered with UPDF and Ministry of Health NTL to deploy mobile digital X-ray services to conduct mass TB screening and testing campaigns at 18 targeted military base health facilities.

The mobile digital X-ray technology uses computer assisted diagnosis for TB (CAD4TB) software and a grading system that improves presumption and diagnosis of TB cases.

Lessons learned: There was exponential increase in TB case detection from the previous quarterly average of 145 to 206 in April-June (Q3) and 236 in July-September 2022 (Q4) from 888 and 4,128 total clients screened respectively. This directly contributed to 13% (27) and 25% (59) of the total new TB cases identified during FY22 Q3 and Q4 respectively, and overall contributed to 12% (86/734) of the total TB cases identified during the year despite only being used in Q3 and Q4 of implementation.

Conclusions/Next steps: The use of mobile digital X-ray services is an effective approach for finding missing TB cases and their enrollment on treatment as part of the STOP TB initiative, especially in settings with limited investigative capacity like Ugandan military health facilities. This approach not only improves TB case detection but also raises awareness and demand for TB screening and management among health workers and the population.

EPB0155

Readiness for HCV care provision for men who have sex with men in seven countries

S. Ravishankar^{1,2}, J. Hicks³, C. James³, J.M. Zuniga^{1,2}

¹International Association of Providers of AIDS Care, Washington DC, United States, ²Fast-Track Cities Institute, Washington DC, United States, ³World Hepatitis Alliance, London, United Kingdom

Background: An estimated 58 million people have acquired chronic hepatitis C virus (HCV), and an estimated 1.5 million people newly acquire HCV annually. Although direct-acting antiviral regimens lead to sustained viral suppression (cure), the world is off-track to meet the World Health Organization (WHO) goal of eliminating HCV by 2030, particularly among key populations, including men who have sex with men (MSM).

Methods: An online survey was fielded among 1260 respondents across seven countries (Canada (160), France (171), Germany (113), Italy (203), Spain (209), United Kingdom (202), and the United States (202)) to gauge health-care providers' (HCP) HCV clinical management knowledge and preparedness. Practitioner specialties included general care (51%); nursing (20%), gastroenterology (10%), infectious diseases (9%), and hepatology (9%). Questions related to HCV care for MSM were analyzed.

Results: Globally 86% of HCPs reported that their practice provides services to MSM; and 78% reported that their practice had the expertise to provide medical services to MSM. However, only 53% of HCPs responded that they screen MSM for HCV in their practice. When asked about treatment of MSM 91% agreed/strongly agreed that MSM are treated the same as other clients in their practice.

However, only 57% reported that staff in their practice received sensitization training on provision of services to MSM; and 52% agreed/strongly agreed that stigma towards MSM is a barrier to accessing HCV care.

	Canada	France	Germany	Italy	Spain	UK	US
% HCPs that reported their practice provides services to MSM	99%	77%	95%	72%	90%	84%	81%
% HCPs that reported their practice has the expertise to provide medical services to MSM	77%	78%	76%	70%	77%	81%	88%
% HCPs that responded that they screen MSM for HCV in their practice	70%	62%	53%	42%	46%	38%	62%
% HCPs that agreed/strongly agreed MSM are treated the same as other clients in their practice	94%	94%	94%	88%	93%	88%	87%
% HCPs that reported staff in their practice receive sensitization training on provision of services to MSM	46%	50%	62%	56%	61%	56%	66%
% HCPs that agreed/strongly agreed that stigma towards MSM is a barrier to accessing HCV care	59%	48%	46%	48%	46%	53%	62%

Table 1: Responses to Questions on HCV clinical management for MSM

Conclusions: While most HCPs report that their practice provides and has the expertise to provide HCV services to MSM, it is possible that many MSM are being missed with service provision given the low levels of screening for HCV among MSM.

While most HCPs strongly agree or agree that treatment of MSM are equivalent to other clients, the unity breaks when it comes to low levels of sensitization training among staff and stigma experienced by MSM.

EPB0156

Decrease of Yellow Fever neutralizing antibody titers one year after vaccination is related to different NK cells repertoire in PLWH and non-HIV controls - ANRS12403

A. da Silva Cazote¹, L. Nery da Silva Caldas¹, D. Granato da Costa Lima¹, D. Victalina de Almeida¹, J. Henrique Pilotto¹, S.M. Barbosa de Lima², A. de Souza Azevedo Soares², Y. da Silva Mendes², A. Wagner Giacoia Gripp¹

¹Oswaldo Cruz Institute - Oswaldo Cruz Foundation, Laboratory of AIDS and Molecular Immunology, Rio de Janeiro, Brazil, ²Biomanguinhos - Oswaldo Cruz Foundation, Laboratory of Virological Technology, Rio de Janeiro, Brazil, ³Oswaldo Cruz Institute - Oswaldo Cruz Foundation, Laboratory of Flavivirus, Rio de Janeiro, Brazil, ⁴National Institute of Infectious Diseases Evandro Chagas - Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, ⁵National School of Public Health Sergio Arouca - Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, ⁶Pasteur Institute, Paris, France

Background: Yellow fever (YF) vaccine has been successfully used to control YF disease and prevent new outbreaks. The 17DD YF vaccine is considered a safe and highly effective vaccine in people living with HIV (PLWH), but the immunogenicity mechanisms are not completely understood. This study hypothesized that, despite HIV viral load (VL) suppression, PLWH could present reduced production and maintenance of YF-neutralizing antibodies (NABs) and that NK cells different repertoire could participate in this process.

Methods: This study was nested in a longitudinal study that investigated YF vaccine safety and immunogenicity in PLWH and non-HIV controls (CTRL). NK cells repertoire was evaluated in PLWH with baseline CD4⁺ T cell counts ≥ 200 cells/mm³ and suppressed VL (n=25), and in CTRL (n=16), by flow cytometry, at pre-vaccination (Day 0), and at three moments post-vaccination (Days 5, 30 and 365). YF vaccine immunogenicity was evaluated by Nab levels measured through a micro plaque reduction neutralization test (μ PRNT, cut-off $\geq 1:100$) at Days 30 and 365. For the analysis, all participants were grouped regardless HIV status and according to Nab titers at Day 365 as: low ($>1:100$ and $< 1:500$), moderate (≥ 500 and <1000) and high (≥ 1000).

Results: YF vaccine resulted in protective Nab titers at Day 30 in all participants, which decreased after one year, regardless of HIV status or CD4⁺ T cells counts. Interestingly, the frequencies of NKp30⁺ and NKG2A⁺ NK cells were significantly lower at D0 among the low Nabs participants, compared to individuals having moderate and high Nabs titers ($p<0,05$). Such lower frequencies were significant in all the moments, compared to the moderate Nabs participants ($p<0,05$).

Oral
abstracts

Poster
exhibition

E-posters

Late-breaker
abstracts

Author
Index

Conclusions: Although serological correlates of protection have not been established, higher YF NAb titers plausibly indicate longer protection against disease. Nkp30 is an important NK activation receptor while NKG2A is related to high responsive educated NK cells. Early activation of NK cells can engage pathways involving B cells response, which leads to humoral immunity against viruses (due to infections or vaccine).

Our results suggest that NK cell repertoire presented before vaccination could impact YF vaccine immunogenicity and long term duration of the NAb protection.

EPB0157

Health system strengthening approach improves national TB preventive therapy (TPT) coverage in Malawi

P. Nyasulu¹, T. Chimbandule¹, E. Kaonga², R. Nyirenda¹

¹Ministry of Health, Department of HIV, STI & Viral Hepatitis, Lilongwe, Malawi, ²KNCV Malawi, Lilongwe, Malawi

Background: Malawi dispensed TB preventive therapy (TPT) among PLHIV on ART since 2016 using continuous isoniazid monotherapy (IPT) in selected high TB/HIV burden districts. 6% of those initiated developed pellagra, uptake stalled. By end 2019, 257,334 ART clients were initiated on IPT resulting in coverage of 29%.

From 2020, Malawi commenced short course TPT regimens of rifapentine and isoniazid (3HP) and 6 monthly isoniazid monotherapy (6H) and implemented strategic interventions to improve coverage from 29% to 95% by 2025. The abstract outlines approach implemented and TPT performance till 2021.

Description: The national HIV program used health system strengthening approach to improve TPT coverage. In July 2020, 3HP was recommended as preferred regimen for PLHIV newly initiating on ART due to budget constraints. 6H dispensed to those with 3HP contraindications and drug-drug interaction. Financial support from Global Fund and UNITAID earmarked for commodity procurement ensured staggered delivery to allow phased national scale up.

Skills development activities to have competent health-care workforce included training, developed wall/desk job aids and regular supportive supervision visits.

Screening and dispensing documentation used updated manual ART patient cards or updated electronic TPT module integrated in ART EMR and e-mastercard available in 79% of all ART facilities.

Lessons learned: TPT coverage among eligible PLHIV on ART in Malawi increased from baseline of 29% (2019) to 87% (2022). Absolute figures on graph show increasing trend in TPT initiations. 3,212 providers from 512 facilities across the country were trained on TPT administration. 8 cases with moderate flu-like syndromes were reported on 3HP, no pellagra and hepatotoxicity cases reported. None of the cases needed laboratory toxicity monitoring.

Figure. TPT uptake among eligible clients in Malawi.

Conclusions/Next steps: Use of health system strengthening approach has improved TPT uptake towards achievement of NSP target. The National HIV program should use quality improvement approach, differentiated TPT dispensing services and enhanced pharmacovigilance to increase TPT coverage and improve quality.

EPB0158

Incidence of occult hepatitis B virus among people living with HIV in Botswana

M. Anderson¹, B.B. Phinius^{1,2}, B.K. Phakedi¹, L.N. Bhebhe¹, N. Tlhabano¹, P. Motshosi¹, D. Ditshwanelo^{1,3}, K. Baruti^{1,4}, G. Mpebe¹, W.T. Choga^{1,2}, D. Glebe⁵, J.T. Blackard⁶, S. Moyo^{1,7}, A. Kramvis⁸, S. Gaseitsiwe^{1,7}

¹Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, ²School of Allied Health Professions, Faculty of Health Sciences, University of Botswana, Gaborone, Botswana, ³Botswana International University of Science and Technology, Department of Biological Sciences and Biotechnology, Palapye, Botswana, ⁴University of Botswana, Department of Biological Sciences, Faculty of Science, Gaborone, Botswana, ⁵Institute of Medical Virology, University of Giessen, Giessen, Germany, ⁶Division of Digestive Diseases, University of Cincinnati College of Medicine, Cincinnati, United States, ⁷Harvard T.H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, ⁸Hepatitis Virus Diversity Research Unit, Department of Internal Medicine, University of the Witwatersrand, Johannesburg, South Africa

Background: Hepatitis B surface antigen (HBsAg) is a routine diagnostic hepatitis B virus (HBV) marker. HBsAg-negative, HBV DNA-positive occult HBV (OBI) is often missed by this approach. OBI is transmissible, can cause liver disease, and is common among people with HIV (PWH). There are limited data on the natural progression of OBI due to limited longitudinal studies of OBI, therefore we determined the incidence and risk factors for OBI in PWH in Botswana.

Methods: Plasma samples from two longitudinal HIV natural disease progression studies at the Botswana Harvard AIDS Institute Partnership which followed participants for at least 24 months from 2004 to 2009 were used. Participants with available follow-up plasma samples were selected for HBsAg testing by enzyme-linked immunosorbent assay (ELISA). HBsAg negative samples were

screened for OBI using an in-house real-time polymerase chain reaction assay. We estimated OBI incidence with 95% confidence interval (CI). Risk factors for OBI were assessed using Cox proportional hazards regression analysis.

Results: At baseline, HBsAg prevalence was 2.1% (8/382), while OBI prevalence was 14.7% (11/75). A total of 90 participants were used in the OBI incidence estimates throughout the follow-up period. Ninety participants were utilized to estimate OBI incidence over the entire follow-up period. Approximately 80% (72/90) were female, and 59% (43/73) had positive anti-HBc serology.

Participants contributed 128.82 person-years to the study and were followed for a median of 1.02 years (IQR: 1.00–2.00). Cumulatively, there were 34 incident OBI cases, giving an incidence rate of 26.4/100 person-years (95% CI: 18.9 – 36.9). The median time to incident OBI was 372 days (IQR: 365 – 730). Incident cases had slightly lower median CD4+ T-cell count compared to participants without OBI ($p = 0.05$). Being male was independently associated with a significantly higher risk of OBI [adjusted Hazard Ratio (aHR) = 3.5 (95% CI: 1.62–7.46); $p = 0.001$]. Every unit increase in CD4 cell count was associated with a lower risk of incident OBI ($aHR = 0.41$; 95%CI: 0.19 – 0.89; $p = 0.02$).

Conclusions: There was a high OBI incidence in PWH in Botswana, especially in males and immunocompromised participants. OBI screening in PWH should be considered because of the risk of transmission and reactivation.

Changes in symptoms of depression and anxiety over time in a cohort of people with HIV initiating HIV care in Cameroon

L.M. Filiatreau¹, P. Vanes Ebasone², A. Dzudie², B.W. Pence³, M. Wainberg⁴, M. Yotebieng⁵, K. Anastos⁶, R. Ajeh², D. Nash⁷, A.M. Parcesepe⁸

³University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, ⁴Columbia University, Department of Psychiatry and New York State Psychiatric Institute, New York, United States, ⁵Albert Einstein College of Medicine, Department of Medicine, Bronx, United States, ⁶Albert Einstein College of Medicine, Departments of Medicine and Epidemiology & Population Health, Bronx, United States, ⁷City University of New York, Institute for Implementation Science in Population Health, New York, United States, ⁸University of North Carolina at Chapel Hill, Department of Maternal and Child Health and Carolina Population Center, Chapel Hill, United States

Background: Abrupt changes in one's physical health, such as receiving an HIV diagnosis, can have a substantial impact on one's mental health. While it is well known that people with HIV (PWH) are disproportionately affected by poor mental health, little is known about how mental health symptoms change over time as individuals navigate the complex process of initiating and remaining in HIV care.

Methods: We conducted structured interviews with 426 PWH aged 21+ who initiated HIV care in Cameroon between June 2019–March 2020. Follow-up interviews were conducted with 303 individuals between October 2020–September 2021.

We explored changes in depression (Patient Health Questionnaire-9) and anxiety symptoms (Generalized Anxiety Disorder-7) between these two visits and socio-demographic correlates of change using chi-squared tests. Symptom changes were categorized as either no to mild symptoms at both time points, persistent or worsening symptoms at follow-up, or improved symptoms at follow-up.

Results: A total of 129 individuals (42.6%) reported no to mild depression symptoms at both time points, 57 (18.8%) reported persistent or worsening symptoms between visits, and 117 (38.6%) reported improved symptoms.

A total of 125 individuals (41.3%) reported no to mild anxiety symptoms at both time points, 73 (24.1%) reported persistent or worsening symptoms at follow-up, and 104 (34.3%) reported improved symptoms.

Gender and household hunger were the only socio-demographic correlates explored that were significantly associated with depression or anxiety symptom changes.

Men were most likely to report no to mild anxiety symptoms at both time points (51.3%) while women were most likely to report improved anxiety symptoms at follow-up (38.5%; $X^2=7.6$, $p=0.02$).

Those reporting little to no household hunger were most likely to report no to mild anxiety symptoms at both time points (45.8%) while those reporting moderate to severe household hunger were most likely to report persistent or worsening anxiety symptoms at follow-up (36%; $X^2=11.0$, $p<0.01$).

Conclusions: Over one-third of this group of individuals initiating HIV care in Cameroon reported improved mental health symptoms approximately one year after HIV care initiation. However, interventions are needed to support improved mental health in populations experiencing other forms of hardship such as household hunger.

EPB0160

Factors associated with depression and ART adherence among young people living with HIV in Lilongwe, Malawi: a mixed-methods analysis

M. Msefula^{1,2}, C. Kiruthu-Kamamia^{2,3}, J. Huwa², P. Tembo², J. Malambo², A. Thawani², S. Mbewe², E. Umar¹

¹Kamuzu University of Health Sciences, Lilongwe, Malawi,

²Lighthouse Trust, Lilongwe, Malawi, ³International Training and Education Center for Health, University of Washington, Seattle, United States

Background: Young people living with HIV (YPLHIV) face various challenges that render them vulnerable to mental health problems, including depression. Despite sundry efforts to improve mental health among YPLHIV, evidence shows that many suffer from depression. In Malawi there is limited literature on correlates of depression and how it affects ART adherence, among YPLHIV. We aim to establish the prevalence of depression and its correlates among YPLHIV in Lilongwe.

Methods: This was a cross-sectional mixed methods study using survey, in-depth interviews and health records reviews conducted at Lighthouse Trust -Martin Preuss Centre ART clinic in Lilongwe, Malawi from April 2021 to October 2022. A total of 303 YPLHIV aged 15-24 who were on ART for more than 6 months and 7 key informants (clinicians, nurses, psychosocial counsellors) providing care to the YPLHIV participated in the study. Client data was obtained from Patient Health Questionnaire 9 depression scale and Electronic Medical Records.

Bivariate analysis and multivariate logistic regression were conducted to determine the individual factors associated with depression and examine potential correlates of depression respectively. Thematic content analysis was used for qualitative data.

Results: Approximately 46% of the participants were male and 54% female. Majority (71%) were aged 20-24 and 29% were 15-19. About 23% of the YPLHIV had depression symptoms and most (79%) were ages 20-24 years. Approximately 22% had their viral load unsuppressed

and thus considered non-adherent. Most (67%) were from 20-24 age group. Source of income ($p = 0.003$), alcohol consumption ($p= 0.010$) and sexual behavior ($P = 0.014$) were associated with depression. YPLHIV with depression symptoms were 3.5 times ($p= 0.003$) more likely to be non-adherent to ART than those without depression.

Themes generated regarding associated factors with ART non-adherence were lack of basic needs, privacy, psychological trauma, incomplete disclosure, inadequate psychosocial support and knowledge deficit of ART providers.

Conclusions: Our study shows that depression is considerably high among YPLHIV in Malawi and linked to ART adherence. Strengthening provider mental health training and routinely screening YPLHIV for depression would help in early identification and management of depression thereby improving ART adherence.

EPB0161

Global pattern and trends in Kaposi sarcoma incidence: a population-based study

L. Fu¹, T. Tian¹, B. Wang¹, Z. Lu¹, Y. Gao¹, Y. Sun¹, Y.-F. Lin¹, W. Zhang¹, Y. Li¹, H. Zou¹

¹Sun Yat-Sen University, Shenzhen, China

Background: Kaposi sarcoma (KS) is a rare antiproliferative tumor caused by Kaposi sarcoma-associated herpesvirus (KSHV) and is one of the most common cancers among people living with HIV.

Methods: GLOBOCAN Cancer Today database was used to extract the incidence and mortality estimates of KS from 185 countries and regions in 2020. The time trends in KS incidence were evaluated using the cancer registry data from Cancer Incidence in Five Continents (CI5) *plus*, requiring at least 15 consecutive years of data. Joinpoint regression was used to evaluate the average annual percentage change to quantify trends in KS's age-standardized incidence rate (ASIR).

Results: In 2020, the global estimated ASIR of KS was 0.39 (per 100000), with an estimated 34 270 newly diagnosed cases. An estimated 15086 KS deaths were reported, corresponding to an age-standardized mortality rate (ASMR) of 0.29 (per 100000). In 2020, Africa accounted for 73.0% of

the incidence and 86.6% of the deaths from KS worldwide. There was a significant correlation between the ASIR ($P<0.001$) or ASMR ($P<0.001$) and Human Development Index. The incidence of KS increased in both males and females in Turkey (AAPC 11.5, 95% CI 3.2 to 20.4; 6.4, -1.8 to 15.3) and in the Netherlands males (2.5, 1.1 to 3.9) from 1998 to 2012. The incidence of KS decreased in the USA White, Israel, Uganda, Costa Rica, Colombia, Canada, and Denmark in the same period.

Conclusions: KS is a relatively rare cancer worldwide but is endemic in some countries in Southern and Eastern Africa. While a decrease in the KS incidence was noted in many countries since the introduction of antiretroviral therapy (ART), the incidence has significantly increased in both sexes in Turkey and in males in the Netherlands. Monitoring KSHV in endemic regions and high-risk populations, improving HIV/AIDS care may contribute to the prevention of KS.

EPB0162

Global prevalence of diabetes mellitus among ART-naïve adults living with HIV: a systematic review and meta-analysis

P.V. Ebasone^{1,2}, N. Peer^{3,1}, A. Dzudie^{4,2}, A.P. Kengne^{5,1,2}

¹University of Cape Town, Department of Medicine, Cape Town, South Africa, ²Clinical Research Education Networking and Consultancy (CRENC), Yaounde, Cameroon, ³South African Medical Research Council (SAMRC), Non-communicable Diseases Research Unit, Durban, South Africa, ⁴University of Yaounde 1, Faculty of Medicine and Biomedical Science, Yaounde, Cameroon, ⁵South African Medical Research Council (SAMRC), Non-communicable Diseases Research Unit, Cape Town, South Africa

Background: It has been suggested that people living with HIV (PLWH) may have a higher prevalence of type 2 diabetes, attributable to the chronic inflammation caused by the virus, the effects of antiretroviral therapy (ART), and traditional diabetes risk factors. However, existing studies have mostly focused on PLWH on ART.

We estimated the global prevalence of diabetes among PLWH prior to any initiation of ART and compared the prevalence among the ART-naïve, ART-treated and HIV-negative subgroups. PROSPERO Registration: CRD42021226001.

Methods: We searched PubMed-MEDLINE, CINAHL, SCOPUS, Academic Search Premier, Africa-Wide Information and Africa-Journals Online to identify original articles reporting on diabetes prevalence among adult ART-naïve PLWH worldwide published before September 2022.

We included cross-sectional, cohort or case-control studies with baseline information on diabetes prevalence. Two authors independently screened, selected studies, extracted data, and conducted methodological quality assessments. The prevalence estimates were combined using random-effects meta-analysis with variance stabilization through arc-sine transformation.

Results: Seventy-four studies, published between 2005 and 2022, involving 149,322 ART-naïve PLWH with a mean/median age of 32 - 49.7 years, were included. The majority of studies, 39%, were from high-income countries. The pooled prevalence of diabetes was 5.0% (95%CI: 3.9 - 6.2; p-heterogeneity<0.0001).

Among the 47 studies that used the American Diabetes Association criteria (2010) and World Health Organization criteria (2011), the pooled prevalence was 4.0% (3.2 - 5.0; p-heterogeneity<0.0001).

Prevalence significantly differed by income level: High income: 10.2% (5.6 - 16.1), Lower-middle income: 5.6% (0.0 - 22.3), Low income: 3.4% (0.0 - 22.2), Upper-middle income: 2.1% (0.18 - 5.3); $p = 0.005$. There was no significant difference in diabetes prevalence by age, CD4 count, viral load and year of publication.

Among the 11 studies that reported estimates by ART and HIV status, the prevalence was 3.6% (1.1 - 7.2; p-heterogeneity<0.0001), 3.7% (1.4 - 6.9; p-heterogeneity<0.0001) and 5.5% (2.3 - 10.0; p-heterogeneity<0.0001) in the HIV negative, ART-naïve, and ART-treated subgroups respectively ($p=0.656$). There was no evidence of publication bias (all Egger test $p>0.0701$).

Conclusions: The prevalence of diabetes in the global ART-naïve population is lower than in the general population but remains substantial. The prevalence is not significantly different to that in ART-treated PLWH.

EPB0163

What are the predictors of change in multimorbidity among people with HIV? A longitudinal observational cohort study

M. Casten¹, S. Herbert², D.J. Smith², K. Petoumenos³, C. Coorey⁴, N. Edmiston^{1,2}

¹University of Western Sydney, Sydney, Australia, ²North Coast Sexual Health Services, Mncld, Australia, ³The Kirby Institute, University of New South Wales, Sydney, Australia, ⁴Royal North Shore Hospital, Sydney, Australia

Background: Background: Multimorbidity is common among people with HIV (PWH), with numerous cross sectional studies demonstrating associations with older age and past immunosuppression. Little is known about the progression of multimorbidity, particularly in the setting of long-term access to antiretrovirals. This study aims to determine factors predictive of change in multimorbidity in PWH.

Methods: Methods: PWH who attended a regional HIV service were recruited to a consented observational cohort between 09/2016 to 03/2020. Demographic data, laboratory results and a Cumulative Illness Rating Scale score (CIRSs) were collected at enrolment and first clinical review of every subsequent year.

Change in CIRSs was calculated from enrolment to 02/2021. Associations with change were determined through univariate and multivariate linear regression.

Late-breaker
abstracts

Author
Index

Results: Of 253 people, mean age was 57.4 (SD 10.9), 91.3% were male, and HIV was diagnosed a median of 22.16 (IQR 12.1 to 30.9) years prior. Length of time in the study was a median of 134 weeks (IQR 89.0 to 179.0), in which a mean CIRSS change of 1.21 (SD 2.60) was observed. Being older ($p<0.001$), a higher body mass index ($p=0.008$) and diabetes ($p=0.014$) were associated with an increase likelihood of worsening multimorbidity. PWH with a higher level of multimorbidity at baseline were less likely to worsen over time ($p<0.001$).

Conclusions: Conclusion: As diabetes and weight predict worsening multimorbidity, routine diabetes screening, and body mass index measurement are recommended. Person centred care including multimorbidity management with a focus on weight and diabetes has the potential to improve the overall health of PWH.

EPB0164

Sleep disorder diagnoses in people with versus without HIV infection in an integrated healthcare system

J. Lam¹, C. Hou², S. Alexeeff¹, T. Levine¹, V. Sarovar¹, A. Lea¹, D. Satre^{1,3}, M. Silverberg¹

¹Kaiser Permanente Northern California, Division of Research, Oakland, United States, ²Kaiser Permanente Northern California, South San Francisco Medical Center, South San Francisco, United States, ³University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, Weill Institute for Neurosciences, San Francisco, United States

Background: Poor sleep is commonly reported in people with HIV (PWH) and has been associated with poor health outcomes and lower quality of life. Few studies have evaluated the types of sleep disorders affecting PWH versus people without HIV (PWoH).

Methods: The study included individuals ≥ 18 -years-old who were members of Kaiser Permanente Northern California (an integrated U.S. healthcare system) during 7/1/2013-12/31/2021. PWH and PWoH were frequency-matched 1:20 by age, sex, race/ethnicity, and baseline year. Sleep disorder diagnoses were identified using electronic health records. Adjusted prevalence ratios (aPR) for sleep disorders at baseline by HIV status were calculated using modified Poisson regression, adjusting for demographics (age, sex, race/ethnicity), mental health (prior clinical depression or anxiety), prior alcohol or other substance use disorder, and body mass index. aPRs were calculated for all types of sleep disorders combined, then for sleep apnea and insomnia, the most common disorders.

Results: The study included 11,326 PWH and 223,678 matched PWoH (90.0% men, mean baseline age 47.7 years, 48.3% White, 19.9% Hispanic, 17.0% Black, 14.8% Other/unknown race/ethnicity). Compared with PWoH, PWH were more likely to have had a diagnosis of depression (37.8% vs.14.4%), anxiety (36.3% v. 20.1%), or substance use disorder (62.9% vs 46.3%), but were less likely to be obese

(20.7% vs. 30.4%). At baseline, 3,808 (33.6%) PWH and 46,534 (20.8%) PWoH had at least one prevalent sleep disorder. Insomnia was the most common disorder among PWH, and sleep apnea was the most common among PWoH (Table).

	With HIV N=11,326 n (%)	Without HIV N=223,678 n (%)
Insomnia	2,583 (22.81)	21,169 (9.46)
Sleep apnea	1,152 (10.17)	25,159 (11.25)
Other/Unspecified	900 (7.95)	9,698 (4.34)
Hypersomnia or parasomnia	68 (0.60)	853 (0.38)
Leg cramps, movement disorder-related	59 (0.52)	907 (0.41)
Circadian rhythm disorder	43 (0.38)	383 (0.17)
Substance use-related	21 (0.19)	96 (0.04)
Number of sleep disorders, range	0-5	0-6
No sleep disorder diagnosis	7,518 (66.38)	177,144 (79.20)

Table.

Overall, sleep disorders were significantly more common among PWH (vs. PWoH; aPR=1.32, 1.29-1.36). PWH were more likely to have insomnia (aPR=1.56, 1.51-1.62) but not sleep apnea (aPR=0.91, 0.86-0.96).

Conclusions: Multiple types of sleep disorders are more common among PWH. Examining risk factors for specific types of sleep disorders, and potential differences by HIV status, could inform preventive or treatment strategies among PWH.

EPB0165

Preventing weight gain for people with HIV on ART in South Africa: a qualitative interview study of perspectives and potential strategies

T. Manyapelo¹, N. Mpanza¹, T. Mjilo¹, S. Nxumalo¹, G. Shazi¹, T.N. Aung², S. Mabweazara¹, M. Siedner², S. McCluskey², J. Manne-Goehler²

¹Africa Health Research Institute, Mtubatuba, South Africa,

²Massachusetts General Hospital, Boston, United States

Background: Obesity and diabetes are comorbidities of growing importance in people living with HIV (PLWH). Our aim was to assess perceptions of obesity among PLWH on dolutegravir (DTG)-based ART in rural South Africa and to elicit possible intervention targets to prevent weight gain and diabetes that could be incorporated into routine HIV care.

Methods: This study was conducted at the Africa Health Research Institute (AHRI), KwaZulu-Natal, South Africa. We recruited a subset of participants from the DISCO Study, a prospective observational cohort study of adults transitioning to DTG-based ART. We selectively recruited individuals with a BMI ≥ 30 kg/m². We conducted one-time, in-depth, semi-structured interviews in isiZulu, then audio-recorded, transcribed and translated these into English. The interview content, coding, and thematic analysis was guided by the Causal Continuum Model for Obesity in sub-Saharan Africa.

We assessed:

1. Self-perceptions of body size and the impact of HIV and its treatment on body size,
2. The perceived health threat of obesity,
3. Preferences for interventions to prevent obesity and diabetes (e.g. diet, physical activity, pharmacotherapy), and;
4. The role of social relationships in intervention design.

Results: Twenty-six participants were interviewed (Table 1). Preliminary thematic analysis revealed that, although large body size is associated with an increased risk of illness, above-average body size is viewed as "normal" and preferable to being thin. ART initiation was believed to have contributed to weight gain.

A pharmacological option to prevent weight gain was of interest if one could be identified without severe side effects. Interviewees preferred physical activity programs that were community-based and communal in nature.

Sex (N/%)	
Men	3 (12%)
Women	23 (88%)
Age (median/IQR, years)	41 (31-52)
Education (N/%)	
No formal education	1 (4%)
Primary	4 (15%)
Secondary	18 (69%)
Tertiary	3 (12%)
Body mass index (median + IQR)	33 (30-37)
Duration of dolutegravir use (median/IQR, months)	19 (17-20)

Table 1. Demographic and health characteristics of interview participants.

Conclusions: Many obese PLWH taking DTG-based ART in South Africa don't consider moderate levels of overweight to be a risk factor for poor health. If this awareness can be addressed, preferences for interventions include pharmaceutical options with minimal side effects and community-based physical activity programs.

EPB0166

Arterial stiffness and HIV: an analysis of sequential pulse wave velocity measurements in Tanzanian adults with and without HIV

K. Reis¹, S. Fadhil^{2,3}, P.F. Stephano^{2,3}, M. Willkens⁴, M.H. Lee⁴, R.N. Peck^{2,3,4}

¹Columbia University, Vagelos College of Physicians and Surgeons, New York, United States, ²Mwanza Intervention Trial Unit (MITU), Mwanza, Tanzania, United Republic of,

³Weill Bugando School of Medicine, Mwanza, Tanzania, United Republic of, ⁴Weill Cornell Medicine, Center for Global Health, New York, United States

Background: Cardiovascular disease (CVD) is a growing cause of morbidity and mortality in people with HIV (PWH)(1). This may be related to accelerated arterial stiffness promoted by HIV. Pulse wave velocity (PWV) is a validated measure of arterial stiffness and predicts CVD(2).

Our objectives were to determine longitudinal trends in PWV and risk factors for elevated PWV in PWH vs HIV-uninfected controls.

Methods: This study was conducted in a previously described cohort of PWH and HIV-uninfected controls in Mwanza, Tanzania(3). PWH were enrolled at the time of HIV diagnosis. Consecutive PWV measurements were performed ≥ 180 days apart(4). Mixed effects linear regression models with time-varying co-variables were used to determine the association between risk factors and PWV.

Results: 707 participants were included in this analysis, including 333/707 (47%) PWH. 1414 total PWV measurements were included. Mean interval between measurements was 471 days, (SD 139, range 181-905).

PWV was significantly lower in PWH than HIV-uninfected controls (Figure 1).

In mixed-effects regression models controlled for systolic blood pressure (SBP) and age, PWV was significantly associated with HIV (-0.17, $p=0.022$), months since first PWV measurement (Coefficient: -0.01, $p<0.001$), age (0.08, $p<0.001$) male sex (-0.20, $p<0.001$), SBP (0.08, $p<0.001$), diastolic blood pressure (DBP) (0.05, $p<0.001$), and months on anti-retroviral therapy (ART) (-0.009, $p=0.021$). In a multivariate model including SBP, age, sex, and months since first PWV measurement, HIV remained significantly associated with decreased PWV (-0.17, $p=0.020$).

Figure 1: PWV measurements stratified by HIV-status ($n=1404$).

Conclusions: HIV was independently associated with decreased PWV compared to HIV-uninfected controls. Among PWH, time on ART was associated with decreased PWV. While most studies have reported increased arterial stiffness in PWH(5), some data suggest that arterial stiffness may be decreased with ART use(6-8).

Understanding the dynamics of arterial stiffness in PWH is critical to controlling the growing burden of CVD in this population.

M. McLaughlin¹, M. Durstenfeld², A. Beatty³, P. Hsue⁴¹University of California, San Francisco, Division of Cardiology, San Francisco, United States, ²Zuckerberg San Francisco General Hospital, Division of Cardiology, San Francisco, United States, ³University of California, San Francisco, San Francisco, United States, ⁴Zuckerberg San Francisco General Hospital, Division of Cardiology, San Francisco, United States**Background:** Persons with HIV (PWH) have increased risk for atherosclerotic cardiovascular disease (ASCVD), and perceived cardiovascular risk among PWH is low. We sought to characterize ASCVD risk and metrics of cardiovascular health (CVH) in PWH eligible for primary prevention of ASCVD.**Methods:** We conducted a retrospective study of PWH 40 years and older without existing ASCVD who received care at three HIV clinics in San Francisco, U.S. from 2019-2022. We used ICD-10 codes and electronic health record data to assess ASCVD risk and CVH, as defined by the American Heart Association's Life's Essential 8 (LE8) metrics for nicotine exposure, body mass index (BMI), lipids, glucose, and blood pressure.

AHA Life's Essential 8 cardiovascular health metrics	Quantification of cardiovascular health metric	Score among PWH, out of 100 points – mean (standard deviation)	Score among general population*, out of 100 points – mean (standard error)
Nicotine exposure	100 points: never smoker 50 points: former smoker 0 points: current smoker (modified criteria)	55.1 (40.8)	69.2 (0.77)
Body mass index	BMI (kg/m ²): 100 points: < 25 70 points: 25.0-29.9 30 points: 30.0-34.9 15 points: 35.0-39.9 0 points: ≥ 40.0	71.3 (29.9)	57.5 (0.65)
Blood lipids	Non-HDL cholesterol (mg/dL): 100 points: < 130 60 points: 130-159 40 points: 160-189 20 points: 190-219 0 points: ≥ 220 (If drug-treated level, subtract 20 points)	70.5 (28.8)	67.4 (0.56)
Blood glucose	Hemoglobin A1c (%): 100 points: no history of diabetes and A1c < 5.7 60 points: no diabetes and A1c 5.7-6.4 40 points: diabetes with A1c < 7.0 30 points: diabetes with A1c 7.0-7.9 20 points: diabetes with A1c 8.0-8.9 10 points: diabetes with A1c 9.0-9.9 0 points: diabetes with A1c ≥ 10.0	81.7 (27.2)	78.4 (0.43)
Blood pressure	Systolic and diastolic blood pressure (mmHg): 100 points: <120/<80 75 points: 120-129/<80 50 points: 130-139 or 80-89 25 points: 140-159 or 90-99 0 points: ≥ 160 or ≥ 100 (subtract 20 points if treated level)	56.0 (32.1)	70.8 (0.45)
Average score		66.2 (16.5)	65.9 (0.41)

*Based on estimates from the National Health and Nutrition Examination Survey (NHANES) in the U.S. general population

Results: Among 2567 PWH, median age was 55 (interquartile range 48-61), 14% were female, 95% were on antiretroviral therapy, and median CD4 cell count was 530 cells/mm³. In this population eligible for primary prevention of ASCVD, 77% had undergone complete assessment of ASCVD risk factors. Half of PWH had intermediate-high estimated ASCVD risk. Risk factors for ASCVD were common (hypertension 69%, hyperlipidemia 48%, diabetes 16%, current smoking 28%). Of those with hypertension, 39% were on an anti-hypertensive. Among those eligible, 44% were on a statin. Mean LE8 CVH score (out of 100 points) was 55.1 for nicotine exposure, 71.3 for BMI, 70.4 for lipids, 81.2 for blood glucose, 56.0 for blood pressure, with an average score of 66.2 across the five metrics studied. PWH with Medicare insurance, Black PWH, and those with sleep apnea and chronic kidney disease had on average lower CVH scores; those with undetectable viral loads had higher CVH scores.**Conclusions:** PWH in this study of ambulatory HIV care in San Francisco demonstrate suboptimal cardiovascular health, especially in the areas of nicotine exposure and blood pressure control. We highlight opportunities for improving primary prevention of ASCVD among PWH.

EPB0168

Changes in weight after switching from ritonavir-boosted protease inhibitors to dolutegravir/tenofovir alafenamide/emtricitabine: results from a single arm, open-label, phase 3 clinical trial study (SPIRITED)

A. Hiransuthikul^{1,2}, W.M. Han^{1,3}, T. Ueapongsukit^{1,4}, H.M.S. Lwin¹, J. Sophonphan¹, S. Gatechompol^{1,5,6}, S. Kerr^{1,3,7}, S. Ubolyam^{1,5}, A. Avihingsanon^{1,5}, HIV-NAT 006 Study Team¹HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, ²Chulalongkorn University, Department of Preventive and Social Medicine, Faculty of Medicine, Bangkok, Thailand, ³Kirby Institute, UNSW Sydney, Sydney, Australia, ⁴Chulalongkorn University, Division of Infectious Diseases, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, ⁵Chulalongkorn University, Center of Excellence in Tuberculosis, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, ⁶University of Amsterdam, Department of Global Health and Amsterdam Institute for Global Health and Development Amsterdam University Medical Centers, Amsterdam, Netherlands, ⁷Chulalongkorn University, Biostatistics Excellence Centre, Faculty of Medicine, Bangkok, Thailand**Background:** Dolutegravir-based regimens are preferred first-line HIV treatments in all guidelines. However, studies suggest its is associated with excess weight gain. We assessed weight changes in virologically suppressed Thai people living with HIV (PLWH) who switched from ritonavir-boosted protease inhibitors (PI/r)-based regimens to tenofovir alafenamide/emtricitabine/dolutegravir (TAF/FTC/DTG).

Methods: Thai PLWH with plasma HIV RNA <50 copies/mL were switched from ritonavir-boosted lopinavir (LPV/r) or atazanavir (ATV/r) + ≥ 1 nucleoside reverse transcriptase inhibitor(s) to TAF/FTC/DTG in this 48-week, single arm, open-label, phase 3 clinical trial. Multivariate generalized estimating equations were employed to assess changes in weight, lipid profiles, and safety parameters after switching to TAF/FTC/DTG.

Results: Among 203 participants enrolled (median [IQR] age, 48.9 [38.7–54.4] years; 107 [52.7%] male; median body mass index [BMI], 22.7 [19.9–25.5] kg/m²; median antiretroviral therapy [ART] duration, 17.4 [10.3–21.5] years; 180 [88.7%] used tenofovir disoproxil fumarate [TDF] at baseline; 103 [50.7%] switched from LPV/r and 100 [49.3%] from ATV/r), 191/193 (99.0%) maintained viral suppression at week 48.

After adjusting for age, sex, ART duration, TDF used, and type of prior PI/r use, weight significantly increased from baseline at week 24 (1.7 kg; 95%CI 1.3 to 2.1, $p < 0.001$) and at week 48 (1.9 kg; 95%CI 1.5 to 2.4, $p < 0.001$) (Figure 1). No differences in weight changes were observed based on prior PI/r used.

Using the same adjustment variables, triglyceride decreased by -41.7 mg/dL (95%CI -58.2 to -25.3, $p < 0.001$) at week 24 and -47.5 mg/dL (95%CI -64.2 to -30.8, $p < 0.001$) at week 48; estimated glomerular filtration rate decreased by -9.7 mL/min/1.73m² (95%CI -12.5 to -6.8, $p < 0.001$) at week 24 and -7.5 mL/min/1.73m² (95%CI -10.4 to -4.6, $p < 0.001$) at week 48.

Conclusions: Significant weight gain increases, along with significant plasma triglyceride and eGFR decreases were evident in virologically suppressed Thai PLWH after switching from PI/r-based regimens to TAF/FTC/DTG.

Background: Although HIV-associated mortality has been greatly reduced by ART, the incidence of deaths due to non-communicable diseases remains high in PLWH. Clinical decisions regarding whether to modify ART in the

context of a HIV-RNAs50 copies/mL may be guided by current ART and specific comorbidities.

Methods: Cross-sectional analysis of the risk of ART switch (RTS) in PLWH of the IcoNa cohort with a stable VL ≤ 50 copies/mL according to *a priori* chosen co-morbidities (i.e. obesity (OB, BMI >30), dyslipidaemia (DP), kidney disease (KD, eGFR <60) and diabetes mellitus (DM)).

During episodes of >6 months with VL ≤ 50 copies/mL participants could develop the event (if there was a ART switch) or be controls (if ART remained unchanged). Four separate GEE logistic regression models were fitted. Models were repeated after stratification by anchor drug class received and after restricting to the last episode.

Results: We included 9,212 PLWH who contributed 17,109 episodes. Median (IQR) age was 48 (39–56) years, 19% females, 47% MSM, 35% of foreign nationality with a median of 734 (541–954) CD4 count. The prevalence of the main exposures was: 11% OB, 74% DP, 11% KD and 6% DM. The Table shows adjusted OR of RTS.

In the analysis controlling for confounders, DP was associated with an increased (64% higher in exposed vs. unexposed) and OB with a decreased RTS (26% risk reduction). DM was associated with a reduced RTS but only in INSTI- or NNRTI-recipients. When restricting to most recent switches, DP was associated with a lower RTS.

Conclusions: In our cohort, ART management was modified by the presence of specific comorbidities. For participants with DM, a lower risk of switching was seen only with NNRTI or INSTI-based regimens. The reduced risk of switching in those with DP in recent years may be explained by the use of therapies which are perceived as lipid-friendly.

Factor	all episodes, all reasons and all anchor drugs					
	Unadjusted	P ^a	Adjusted ^b	P ^a	Adjusted ^c	P ^a
	Odds ratio (95% CI)		Odds ratio (95% CI)		Odds ratio (95% CI)

Ambulatory blood pressure abnormalities and its determinants in people living with HIV and AIDS in an African setting

S.N.N. Ekongefeyin^{1,2}, C. Linonge Etombi³, C. Akem Dimala⁴, M.-P. Halle⁵, A. Dzudie Tamdja⁶, S.P. Choukem⁷

¹University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom, ²University of Buea, Faculty of Health Sciences, Buea, Cameroon, ³London School of Hygiene and Tropical Medicine, London, United Kingdom, ⁴John Hopkins Bloomberg School of Public Health, University of London, London, United Kingdom, ⁵University of Douala, Department of Clinical Sciences, Douala, Cameroon, ⁶Faculty of Medicine and Biomedical Sciences, University of Yaounde I, Yaounde, Cameroon, ⁷University of Dschang, Faculty of Medicine and Pharmaceutical Sciences, Dschang, Cameroon

Background: There is currently no data on ambulatory blood pressure (ABP) abnormalities and their determinants among People Living with HIV/AIDS (PLHA) in Cameroon. This study aimed to determine the proportion of PLHA with the non-dipping pattern, masked hypertension, nocturnal hypertension and white coat hypertension compared to an HIV seronegative group; to determine the factors associated with ABP profiles among PLHA, in the Buea Regional Hospital.

Methods: A hospital-based comparative cross-sectional study was carried out between January 8th, and August 8th, 2018. The study compared two groups: consecutively-selected HIV seronegatives individually matched for age and gender to HIV seropositives. 24-hour ABP measurements, sleep disturbances using the Pittsburgh Sleep quality index (PSQI) and the Epworth Sleepiness Scale (ESS), Clinic Blood Pressure (CBP), anthropometric measurements, and microalbuminuria were assessed. The data was analyzed using Epi info 7.2.2.2.1

Results: Of the 180 participants, 65.56% were females and the median age was 44 years. The average 24-hour systolic BP was lower in PLHA than the controls (117±15 vs 125±16, $p<0.001$). There was no significant difference in the proportion of systolic and diastolic non-dipping between PLHA and controls ($P = 0.370$ and 0.418 respectively).

The prevalence of masked, nocturnal and white coat hypertension was: 3%, 13%, and 9% respectively among PLHA compared to 11%, 24% and 4% in the control group ($p = 0.044$, $p = 0.152$ $p = 0.091$ respectively).

Insomnia (PSQI > 5) and daytime sleepiness (ESS > 10) were not associated with non-dipping in PLHA ($P = 0.729$, $P = 0.890$ respectively). In multivariate analysis, only ART duration > 5 years was independently associated with DBP non-dipping (aOR: 2.89, 95% CI: 1.02-8.22, $p = 0.046$).

Conclusions: Abnormal ABP measurement phenotypes were similar amongst PLHA and HIV-negative controls. Sleep disorders did not affect non-dipping BP among PLHA. ART use for more than 5 years was the only factor associated with diastolic non-dipping.

The prevalences of BP non-dipping, masked hypertension, nocturnal hypertension, white coat hypertension and sleep disorders are not as high as predicted among PLHA compared to the HIV-negative controls. general population. The findings of our study bring more arguments as to whether HIV/AIDS is an independent risk factor for abnormal blood pressure.

EPB0171

A pilot randomized controlled trial to improve depression and HIV care engagement among perinatal women with HIV in Malawi

T.R. Filipowicz¹, A.M. Bengtson², S. Mphonda³, M. Udedi⁴, K. Kulisewa⁵, B.N. Gaynes^{6,1}, V.F. Go⁷, D. Chibanda⁸, R. Verhey⁹, M.C. Hosseinipour^{3,10}, B.W. Pence¹

¹University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, ²Brown University, Department of Epidemiology, Providence, United States, ³UNC Project Malawi, Lilongwe, Malawi, ⁴Malawi Ministry of Health, Mental Health Unit, Lilongwe, Malawi, ⁵Kamuzu University of Health Sciences, Department of Psychiatry and Mental Health, Blantyre, Malawi, ⁶University of North Carolina at Chapel Hill, Department of Psychiatry, Chapel Hill, United States, ⁷University of North Carolina at Chapel Hill, Department of Health Behavior, Chapel Hill, United States, ⁸University of Zimbabwe, Department of Psychiatry & Research Support Centre, Harare, Zimbabwe, ⁹Friendship Bench Zimbabwe, Harare, Zimbabwe, ¹⁰University of North Carolina at Chapel Hill, Division of Infectious Diseases, Chapel Hill, United States

Background: Women with HIV (WHV) are at high risk for HIV care disengagement during the perinatal period. Perinatal depression (PND) affects 20-24% of WHV and creates barriers to HIV care engagement. To reduce these barriers, we adapted and enhanced The Friendship Bench (FB), an evidence-based counseling intervention, for WHV in Malawi to improve perinatal depression and HIV outcomes.

Methods: We enrolled 80 pregnant WHV with PND (defined as Self-Report Questionnaire ≥8) who were 18 years of age and 34 weeks gestation from August 2020-August 2021 in Lilongwe, Malawi. WHV were randomized 1:1 to the enhanced FB or Usual Care (UC) arm. Intervention participants received 4 individual prenatal sessions, 2 post-natal sessions, and 1 social-support session, delivered by trained and supervised counselors.

At 6-months post-delivery, we assessed feasibility, acceptability, fidelity, and preliminary efficacy of enhanced FB to improve PND and HIV care engagement. Feasibility and acceptability was assessed both quantitatively and qualitatively among a subset of 15 participants. Fidelity was assessed using a 10-item checklist in a subset counseling sessions.

We defined remission as 10 (threshold for depression) on the Edinburgh Postnatal Depression Scale (EPDS) at 6 months and a 50% reduction in EPDS score from base-

line-6 months post-partum. We defined retention as 2 HIV visits 30 days apart between delivery and 6-months post-partum.

Results: 100% (15/15) of participants indicated high satisfaction with the intervention while 93% (14/15) deemed the intervention beneficial to their health. 83% (68/82) of counseling sessions met or exceeded the fidelity threshold. WHV in the intervention arm had improved PND remission 59% vs 36% [Risk Difference (95% Confidence Interval): 23% (2%,45%)], HIV care retention compared to the UC, 82% vs 69% [RD: 13% (95% CI: -6%, 32%)], and viral suppression, 96% vs 90% [RD: 7% (95% CI: -7%,20%)] at 6-months post-partum, compared to the UC arm. There was no difference in adverse events between arms.

Conclusions: Our results indicate a counseling-based intervention is feasible and acceptable to WHV with PND in Malawi and can be delivered with high fidelity. The enhanced FB may improve PND and HIV care engagement among WHV and should be evaluated in a larger randomized trial.

Department of Medicine, David Geffen School of Medicine, Los Angeles, United States, ⁴Kamuzu University of Health Sciences, School of Global and Public Health, Blantyre,

Malawi, ⁵Partners in Hope, Department of Implementation Research, Lilongwe, Malawi

Background: Mental health (MH) disorders are highly prevalent among people living with HIV (PLHIV) and can have negative impact on antiretroviral therapy (ART) outcomes. Malawi's Ministry of Health introduced MH screening in national HIV management guidelines in December 2021. We describe early experience with integrated MH screening at ART clinics that have scarce human resources and limited capacity of specialist MH units.

Description: Partners in Hope is a Malawian, Christian, non-governmental, medical organization and PEPFAR/USAID clinical implementing partner. We trained ART staff in 15 facilities to use the PHQ-9 (depression) and AUDIT (harmful alcohol use) screening instruments, developed MH registers for tracking screening results and referrals, and engaged existing MH referral units.

Based on screening results, ART clients received counseling by lay cadre staff (for mild disorders) or intensive counseling by trained psych-social counselors and referrals to specialist MH units (for moderate to severe disorders). From April through November 2022, we screened 3,607 ART

clients, only from priority groups defined as follows: returning to care after defaulting (50%); new ART initiation (38%); viral load ≥ 1000 copies/mL (12%). 59% were female and 14% were aged 12-19 years.

Screening coverage was 83% (3,607/4,356) among the 3 priority groups. Those in the two highest risk categories of PHQ-9-scores (1.9%; n=67) and AUDIT-scores (3.0%; n=107) were eligible for specialist review (Figure).

99% of these eligible individuals were referred to specialist MH units, which was on average 9.3 individuals/month/specialist MH unit.

Figure. Categorized PHQ-9 (depression) and AUDIT (harmful alcohol use) screening outcomes at 15 ART clinics in Malawi, April-November 2022.

Lessons learned: Thorough preparation led to high MH screening coverage among ART priority groups in Malawi. The burden of cases requiring referral to specialist MH units was limited. In our setting, MH screening was feasible at ART clinics with PEPFAR support.

Conclusions/Next steps: Next steps include studying the impact of integrated MH screening on ART outcomes (retention; viral suppression) and scaling up integrated MH screening to all ART clinics.

**EPB0173****Antiretroviral treatment as a protective factor for dysplasia and HPV infection in people living with HIV (PLHIV)**

Instituto de Investigación Biosanitario de Granada (IBS-Granada), Pathology Service, Granada, Spain, ⁵Hospital Universitario Virgen de las Nieves. Instituto de Investigación Biosanitario de Granada (IBS-Granada), Microbiology Service, Granada, Spain

Background: The risk of oropharyngeal HPV infection in PLHIV is higher than in the general population, as well as that of its complications, but at present, there are few data on this issue.

The main aim was to describe the prevalence and genotypes of HPV in oropharyngeal mucosa of PLWHIV, and related factors; and to compare it with infection and dysplasia in anal and female genital mucosa.

Methods: Prospective, cross-sectional study, which consecutively included PLHIV attended consecutively in outpatient specialized consultation. During the visit, clinical and analytical variables related to HIV were collected and exudates of the oropharyngeal mucosa were taken for the carrying out of PCR for HPV and other sexually transmitted infections; the samples of anal and female genital mucosa were included in liquid medium (ThinMayer Liquid) for detection and genotyping of HPV by polymerase chain reaction (Linear Array HPV Genotyping Test) and cytology by the thin layer technique (Thin Prep 2000 Processor (Hologic)).

Results: 300 PLHIV were included with a mean age of 45.1 years, 25.3% had a history of AIDS, 99.7% were taking ART and 1% were in virologic failure. 27.3% had received the complete HPV vaccine schedule. The prevalence of HPV infection in the oropharyngeal cavity was 13%, the most frequent genotype was 16 (2.3%); and none had dysplasia. 50% of the women had genital HPV infection, genotype-high risk 51 was the most prevalent (8.9%), 1.7% had CIN1. 82.6% had anal HPV infection, the most frequent genotypes were 44/55 (19.2%), 62/81 (19.2%), 16 (14.9%) and 68 (14.6%); 29.2% had LSIL(AIN1) and 1.7% HSIL (AIN2/3). Risk factors for having oral HPV infection were, simultaneous Treponema pallidum [4.02(1.06-15.24); 0.04], and history of HSIL or anal cancer (SCCA) [21.52(1.59-291.6); 0.02]; and as a protective factor, time on antiretroviral therapy (8.8 years vs. 7.4 years) [0.989 (0.98-0.99); 0.034].

Conclusions: The prevalence of HPV infection in oropharyngeal mucosa and dysplasia were lower than those found in anal and female genital tracts. Syphilis and precursor lesions and SCCA were surrogate markers of oropharyngeal HPV infection. Increased ART exposure provided protection against such infection.

Background: Mental and substance use disorders (MSD) are common among people with HIV (PWH) and have been associated with poor HIV care outcomes. Psychiatric multimorbidity, the presence of two or more co-occurring MSD, has been associated with greater psychiatric symptom severity and worse mental health treatment outcomes. Research into the prevalence of psychiatric multimorbidity among PWH in low- and middle-income countries (LMIC) remains limited.

Methods: We analyzed baseline data from the International epidemiology Databases to Evaluate AIDS (IeDEA) Sentinel Research Network (SRN), a cohort of PWH aged ≥40 years on antiretroviral therapy at eight HIV clinics within the Asia-Pacific, Latin America, and Central, East, Southern, and West Africa IeDEA regions. Baseline data were collected between October 2020 and September 2022.

We documented the prevalence and co-occurrence of symptoms of moderate to severe depression (PHQ-9 ≥ 10), anxiety (GAD-7 ≥ 10), and post-traumatic stress disorder (PTSD) (PCL-5 ≥ 33), as well as hazardous alcohol use (AUDIT-C ≥ 3 for women, ≥ 4 for men) and hazardous drug use (ASSIST > 3 for cannabis, cocaine, amphetamines, inhalants, sedatives, hallucinogens, or opioids). Psychiatric multimorbidity was defined as the co-occurrence of symptoms of two or more disorders assessed.

Results: Among 2,074 participants, the median age was 50 (IQR: 45–56) years and 54% were female. The prevalence of symptoms of depression, anxiety, and PTSD was 15%, 10%, and 6%, respectively. The prevalence of hazardous alcohol use and hazardous drug use was 20% and 4%, respectively.

Overall, the prevalence of psychiatric multimorbidity was 12%. Among those with symptoms of at least one MSD, the prevalence of psychiatric multimorbidity was 35%. The prevalence of symptoms of psychiatric multimorbidity was as follows: hazardous alcohol use 29%, hazardous drug use 62%, depression 60%, anxiety 79%, and PTSD 89%.

Conclusions: In this cohort, psychiatric multimorbidity was common among PWH aged ≥ 40 across LMIC. Integration of MSD screening and treatment into HIV care should be prioritized. The effectiveness and implementation of transdiagnostic or multi-focus mental health treatment approaches in HIV care settings should be examined.

Background: Symptoms of mental disorders and hazardous substance use (HSU) are common among people with HIV (PWH) and associated with poor HIV care outcomes. Research into common mental disorders (CMDs) and HSU among PWH in low- and middle-income countries (LMIC) remains limited.

Methods: We analyzed baseline data from the International epidemiology Databases to Evaluate AIDS (IeDEA) Sentinel Research Network cohort of PWH aged ≥ 40 years on ART at eight HIV clinics in Brazil, Côte d'Ivoire, India, Kenya, Mexico, Rwanda, Zambia, and Zimbabwe. We estimated the prevalence of hazardous alcohol use (HAU) (AUDIT-C ≥ 3 for women, ≥ 4 for men) and hazardous drug use (HDU) (ASSIST > 3 for cannabis, cocaine, amphetamines, inhalants, sedatives, hallucinogens, or opioids), as well as symptoms of depression (PHQ-9 ≥ 10), anxiety (GAD-7 ≥ 10), and post-traumatic stress disorder (PTSD) (PCL-5 ≥ 33). Log binomial models assessed the association between sociodemographic and HIV care characteristics and HSU and symptoms of CMDs.

Results: Of 2,074 participants, the prevalence of HAU and HDU was 20% and 4%, respectively (Table 1). The prevalence of HSU and symptoms of CMDs varied by sex, age, marital status, education, and income, as well as HIV care characteristics (Table 2).

10+ years on ART (Ref: <10 years)	1.05 (0.85-1.30)	1.02 (0.78-1.31)	0.94 (0.67-1.31)	0.67 (0.56-0.80)	0.86 (0.55-1.36)
Never diagnosed with AIDS (Ref: Ever)	0.89 (0.72-1.09)	0.69 (0.54-0.89)	0.90 (0.64-1.27)	1.04 (0.86-1.24)	0.74 (0.47-1.16)

Table 2. Prevalence ratios of sociodemographic and HIV care characteristics with HSU and symptoms of CMDs

Conclusions: Routine screening and treatment for CMDs and HSU among PWH in LMICs are urgently needed, with particular relevance for groups more vulnerable to mental or substance use disorders.

EPB0176

Increase in ambient air pollution is associated with cardiovascular disease risk in youth with and without HIV in urban Uganda

H.K. Kim¹, M. Nagy¹, R. Nazzinda², V. Musiime², S. Etajak³, N. Funderberg⁴, G. McComsey^{1,5,6}, L. Atuyambe³, S. Dirajlal-Fargo^{1,5,6}

¹Case Western Reserve University, School of Medicine, Cleveland, United States, ²Joint Clinical Research Center, Kampala, Uganda, ³Makerere University, School of Public Health, Kampala, Uganda, ⁴The Ohio State University, Columbus, United States, ⁵University Hospitals, Cleveland Medical Center, Cleveland, United States, ⁶Rainbow Babies and Children's Hospitals, Cleveland, United States

Background: Ambient air pollution is a major public health concern, particularly in Sub-Saharan Africa (SSA). Both air pollution and HIV are associated with increased cardiovascular disease (CVD) risk in adults, however, longitudinal data evaluating these associations in youth in SSA are limited.

Methods: A prospective observational cohort study was performed from 2017-2021 at the Joint Clinical Research Center in Uganda. Children with perinatally acquired HIV (PHIV) and children without HIV (HIV-) between 10-18 years of age with no known active infections and who lived in and around Kampala were included. PHIVs were on ART with HIV-1 RNA level ≤400 copies/mL. Ambient concentrations of PM_{2.5} were measured with a continuous central site monitoring using a Beta Attenuation Monitor or E-Samplers from the GeoHealth Hub at baseline and 96 weeks later. Carotid intima media thickness (IMT) and pulse wave velocity (PWV) were evaluated at baseline and 96 weeks. Groups were compared using unpaired t test and potential predictors of IMT and PWV were assessed using linear regression.

Results: Sixty-nine participants were evaluated at both timepoints (38 PHIV & 31 HIV-). At baseline, median (IQR) age was 13 years (11,14) and 46% were female. The overall median yearly PM_{2.5} exposure increased from 26 (25, 38) µg/m³ at baseline to 37 (37, 39, p = <0.001) µg/m³ at week 96. Change in yearly PM_{2.5} was significantly associated with increase in IMT over 96 weeks (β:0.007, 95%CI: [0.002, 0.01], p = 0.004), after adjusting for HIV status, age, socio-economic status (p≥0.4 for all) and sex (p=0.03). There was no association between PM_{2.5} and PWV (p>0.05).

Conclusions: In urban Uganda, adolescents are exposed to PM well over the WHO recommendation of an average of 5 µg/m³ or less per year. The levels of air pollution in the Kampala region increased by 1.4 times over a 2 year period, highlighting an urgent need to rapidly scale up air quality control measures.

This is further supported by our observation that increasing PM_{2.5} exposure over 2 years was associated with elevated CVD risk, irrespective of HIV status, suggesting air pollution may be a prominent driver of CVD risk in SSA.

EPB0177

The identification of intact HIV proviral DNA in human cerebrospinal fluid

Z. Zhang^{1,2,3}, M. Reece², S. Roa², W. Tyor^{1,3}, C. Gavegnano^{2,3,4,5,6}, A. Anderson⁷

¹Emory University, Neurology, Atlanta, United States, ²Emory University, Pathology and Laboratory Medicine, Atlanta, United States, ³Atlanta Veterans Affairs Medical Center, Decatur, United States, ⁴Emory University, Pharmacology and Chemical Biology, Atlanta, United States, ⁵Emory University, Center for Human Health, Atlanta, United States, ⁶Harvard Medical School, Center for Bioethics, Boston, United States, ⁷Emory University, Medicine, Atlanta, United States

Background: The Central Nervous System (CNS) provides a sanctuary site for HIV-1 persistence, and HIV-1 RNA remains detectable in the cerebrospinal fluid (CSF) and brain tissues from people living with HIV-1 (PWH) despite peripheral virologic suppression with ART. Neu-

rocognitive impairment (HIV-associated neurocognitive disorders;HAND), develops in roughly 45% of PWH. We sought to better understand the relationship between reservoir size of replication competent virus in CNS and the periphery and their relationship to severity of neurocognitive deficits in PWH.

Methods: Exclusion criteria: ART regimen, continuously virologically suppressed; no history of any neurologic disease known to affect memory (including stroke, malignancy involving the brain, traumatic brain injury, schizophrenia, and AIDS-related opportunistic infection of the CNS). A neuropsychological (NP) testing battery was administered that included nine tests used commonly in studies of cognition and HIV acquisition. Intact proviral DNA assay (IPDA) was performed to predict the frequency of replication competent virus in CSF and peripheral blood mononuclear cells (PBMC) from PWH (n=11).

Results: Intact proviral DNA (mean=6.31x10³ copies per million cells) persists in the CSF despite ART intervention (8/11 individual PWH were detected intact proviral DNA). We further compared the frequency of intact and defective proviruses in CSF versus PBMC. CSF contains significantly higher frequency of both intact (mean 2.69x10³ vs 2.76x10²) and defective (5' defective proviral copy numbers per million cells: mean 1.44x10⁶ vs 4.36x10³, p = 0.0228) [3' defective proviral copy numbers per million cells: mean 4.07x10⁶ vs 7.96x10³, p = 0.0228] proviruses throughout all individuals. Due to small sample size in this study, there was no strong correlation observed between cognitive impairment and viral reservoir in the CSF compartment. Cognition score in this pilot study indicated that both intact and defective reservoir size are associated with poor attention/working memory.

Conclusions: These data highlight that the CSF is a sanctuary site for the intact HIV-1 reservoir, which persists at significantly higher levels versus the periphery in our cohort.

investigations with a larger sample size are warranted to elucidate potential impact of intact and defective viral sequences on neurocognitive functions in various brain regions.

Group-based trajectory modelling to identify patterns and predictors of myocardial strain in people living with HIV: two-year longitudinal follow-up with speckle tracking echocardiography

H.S. Toh¹, C.-T. Liao², W.-T. Chang², Z.-C. Chen², H.-J. Tang³, H.-C. Ku⁴, W.-P. Chen⁴, C. Strong⁵

¹Chi Mei Medical Center, Department of Intensive Care Medicine, Tainan City, Taiwan, Republic of China, ²Chi Mei Medical Center, Division of Cardiology, Department of Internal Medicine, Tainan City, Taiwan, Republic of China, ³Chi Mei Medical Center, Department of Internal Medicine, Tainan City, Taiwan, Republic of China, ⁴Chi Mei Medical Center, Infection Control Center, Tainan City, Taiwan, Republic of China, ⁵National Cheng Kung University, Department of Public Health, College of Medicine, Tainan, Taiwan, Republic of China

Background: Subclinical myocardial dysfunction has been noticed in people living with HIV (PLHIV) and might contribute to the development of cardiovascular disease (CVD). This study aimed to assess the trend of myocardial strain change over time in PLHIV by using speckle tracking echocardiogram (STE) and investigate the predictors of subclinical myocardial dysfunction.

Methods: A prospective longitudinal cohort study was conducted in an HIV-designated medical center in southern Taiwan. CVD-free asymptomatic PLHIV were followed-up for two years, and data including traditional CVD risk factors and echocardiographic parameters were collected. The trend of myocardial strain change was analysed using a group-based trajectory model, and multinomial logistic regression was performed to identify the predictors among the groups.

Results: A total of 181 PLHIV (173 males, mean age 36.4 ± 11.4) were recruited and categorised into three distinct myocardial strain trajectories: best with slight decline (Group 1: 37.5%), intermedium with gradual decline (Group 2: 49.9%) and worst with slight decline (Group 3: 12.6%). The baseline left ventricular global longitudinal strain (LVGLS) of the groups were -20.5 ± 2.1%, -17.5 ± 2.4% and -15.2 ± 3.2% (p < 0.001), respectively.

Significant predictors associated with the group with gradual strain decline (Group 2) included age ≥ 40 years, antiretroviral therapy (ART) duration ≥ 12 months, and left ventricular ejection fraction (LVEF) < 70%.

The group of the worst strain (Group 3) was associated with current smoking, ART duration ≥ 12 months, LVEF < 60% and ART regimen with non-integrase strand transfer inhibitor.

Conclusions: This is the first longitudinal cohort study using STE to monitor subclinical myocardial dysfunction in PLHIV. Our analyses suggest that age, baseline LVEF, smoking status, ART duration and regimen are crucial factors associated with the different trajectories of myocardial strain.

These findings help to understand the causes of subclinical myocardial dysfunction in PLHIV under ART and guide individualised preventative strategies and early intervention efforts.

Depressive symptoms and metabolic syndrome among people living with and without HIV in urban Zambia and Zimbabwe

A. Mandiriri¹, B.V. Chihota^{2,3}, G. Muula³, T. Shamu^{1,2,4}, F. Mureithi³, H. Nyamutowa¹, S. Bosomprah^{3,5}, C. Bolton-Moore^{3,6}, A. Haas², M. Egger^{2,7}, G. Wandeler^{2,8}, C. Chimbetete¹

¹Newlands Clinic, Research, Harare, Zimbabwe,

²University of Bern, Institute of Social and Preventive Medicine (ISPM), Bern, Switzerland, ³Centre for Infectious Disease Research in Zambia (CIDRZ), Lusaka, Zambia,

⁴University of Bern, Graduate School of Health Sciences, Bern, Switzerland, ⁵University of Ghana, Department of Biostatistics, Accra, Ghana, ⁶University of Alabama, Alabama, United States, ⁷University of Cape Town, Centre for Infectious Disease Research, Capetown, South Africa,

⁸University of Bern, Department of Infectious Diseases, Bern, Switzerland

Background: Depressive symptoms have been shown to exacerbate the risk of metabolic syndrome (MetS) and vice-versa. Independently, MetS and depressive symptoms are known risk factors for cardiovascular diseases (CVDs), which are established leading causes of global mortality.

We sought to understand the prevalence of depression and MetS and their intersection among newly diagnosed people living with (PLWH) and without HIV (PLWOH) in urban Zambia and Zimbabwe.

Methods: We cross sectionally analysed characteristics at enrolment, of participants (≥30 years old) enrolled between August 2019 and January 2023 into a cohort study on non-communicable diseases in urban Zambia and Zimbabwe. Depressive symptoms were assessed using the patient health questionnaire (PHQ-9), with cut-off of 5 indicating at-least mild depressive symptoms.

MetS was defined using the International Diabetes Federation criteria, as presence of central obesity plus any two of: raised blood pressure, impaired fasting glucose, reduced high-density lipoprotein cholesterol and raised triglycerides.

We fitted a logistic regression model to assess the relationship between depressive symptoms and MetS, controlling for age, sex, HIV status, education level, socioeconomic status, drinking and smoking.

Results: Of the 972 participants, median age was 39 years (IQR; 34-46) and 556 (57%) were female. Among PLWH (471/972), median CD4 count was 225 cells/mm³ (IQR; 104-411) and median HIV viral load 27 970 copies/ml (IQR; 325-212 904). The prevalence of depressive symptoms was 35% (342/972, 95%CI; 32-38%), with significant differences by HIV status (31% (95%CI; 27-36) among PLWH and 39% (95%CI; 25-43) among PLWOH, p=0.01). MetS was diagnosed in 17% (95%CI; 13-20) of PLWH and 19% (95%CI; 16-23) of PLWOH, p=0.33. The co-occurrence of MetS and depressive symptoms was 6% (64/972, 95%CI; 5-8%), with no significant difference by HIV status (PLWH, 6% (95%CI; 4-8) vs PLWOH, 7% (95%CI; 5-10 p=0.30)).

After adjustments for potential confounders, we found no evidence of association between MetS and depressive symptoms (aOR 1.17, 95%CI; 0.8-1.7, p=0.79).

Conclusions: We show a high prevalence of depressive symptoms, MetS and their co-occurrence in both adult PLWH and PLWOH. Depressive symptoms were not associated with MetS. Screening for depressive symptoms and MetS as independent risk factors for CVDs in and outside the context of HIV is important.

EPB0180

Characteristics and management of ocular involvement in a large cohort of individuals with Mpox disease

J.L. Blanco¹, M. Pazos¹, J. Riera¹, A. Moll-Udina¹, A. Catala¹, S. Narvaez¹, I. Fuertes¹, M. Dotti-Boada¹, G. Petiti¹, J. Izquierdo-Serra¹, E. Maldonado¹, M. Chang-Sotomayor¹, D. Garcia¹, A. Camos-Carreras¹, V. Gilera¹, N. De Loreda¹, J. Peraza¹, N. Ventura¹, J.F. Spencer¹, G.F. Del Carlo¹, J. Torras¹, A. Adan¹, A. Vilella¹, J.M. Nicolas¹, S. Puig¹, E. Martinez¹, M. Martinez¹, B. Sanchez-Dalmau¹

¹Hospital Clinic Barcelona, Barcelona, Spain

Background: Only sparse and poorly described monkeypox disease cases with ocular involvement have been reported and ophthalmological management remains unclear.

To describe the clinical spectrum of ocular involvement in a large unicentric cohort of patients with monkeypox disease and the preliminary results of a multidisciplinary unicentric therapeutic approach.

Methods: Patients with suspected monkeypox and ophthalmic manifestations attending the Hospital Clínic of Barcelona were prospectively followed. Standardized ophthalmological examination and monkeypox PCR testing of ocular swab samples were performed. A multidisciplinary (ophthalmologist, infectologist and pharmacologists) protocolized strategy for ocular treatment was designed.

Results: Nine (1%) of 880 patients had ocular manifestations including conjunctivitis (n=9), eyelid papules (n=5), corneal ulcers (n=4), conjunctival focal lesions (n=3), corneal stromal edema (n=2), endothelial edema (1/9), anterior uveitis (1/9) and preseptal cellulitis (n=1).

Real-time polymerase-chain reaction for monkeypox virus in ocular swab samples was positive in all patients. Five cases were considered ophthalmologically severe (55.5%) due to risk of potential loss of vision and were treated with tecovirimat. The treatment protocol was stratified according to potential complications of the affected ocular structures (eyelids, conjunctiva, cornea), prioritizing the indication for corticosteroids and/or tecovirimat in the severe cases. Favorable ophthalmologic and general outcomes were observed in all patients.

Conclusions: Monkeypox ocular involvement was uncommon but potentially severe. Virus was always detected in ocular samples. A protocolized treatment strategy including topical and systemic medications depending on the severity of eye involvement showed favorable responses without significant visual sequelae.

EPB0181

Self collected HPV samples can reliably be used in women living with HIV (WLHIV)

H. Sebitloane-Habile¹, T. Ginindza², M. Almonte³, M. Forestier³, A. Baena³, CESTA

¹Univ of KwaZulu Natal, OBs and Gynae, Durban, South Africa, ²UKZN, Oublic Health, Durban, South Africa, ³IARC, France, France

Background: WLHIV have a higher risk of HPV and persistence that may lead to cervical cancer. Treatment of women with HAART has been shown to reduce the incidence of HPV among WLHIV.

The Cervical cancer Screening and Treatment algorithms study using HPV testing in Africa (CESTA) study sought to determine the proportion of HPV in WLHIV with HGSIL could be identified using VIA as triage.

Methods: We enrolled 400 women living with HIV (WLHIV), aged 25-54years of age, who were attending for HIV care at Wentworth hospital, Durban, between October 2019 until July 2020. Women had a self and clinician collected samples and were reviewed after 2 weeks for determination of need for treatment.

Those who had HPV, were further randomized into a 2 arms, in a 4:1 ratio.

Arm 1 was the triage arm, using VIA to determine those in need and are suitable for ablative treatment.

In Arm 2 all women who had HPV were subjected to treatment without VIA as a triage, provided they were eligible. In both arms, women who were deemed suitable for treatment were further randomised in a 1:1 ratio between cryotherapy and thermal ablative therapy. Biopsies were taken from all women in Arm 1.

Results:

- 247/399 (62%) had HPV, more picked up on self than clinician collected samples (48% versus 61%, $p < 0.05$).
- HPV 18/45 (11 – 14%) and with HPV 16 (9-13%) as singular or in combination were the predominant subtypes, however, the majority of women had a combination of other HR-HPV (28-34%).

- HAART duration (less than versus more than 2 yrs), was significantly associated with having HPV, with more women (72%) having HPV among those who used HAART for less than 2 yrs. Similarly, more women who had HPV were likely to have detectable viral load.
- 105 women were evaluable for VIA, (VIA positivity 83%),
- lesions of CIN2 + were more likely to have "ineligible" lesions on VIA ($p = 0.007$), and VIA had an overtreatment rate of 57%.

Conclusions: This study confirms that self-collected samples have a high sensitivity in picking up presence of HPV in the lower genital tract.

EPB0182

Anatomic distribution of HIV-infected cells in tissues after long term antiretroviral therapy

A. Glassey¹, R. Gorelick², T. Nguyen¹, L. Adams¹, M.-E. Zipparo¹, S. Hewitt³, S. Rajan³, K. Lurian³, C.-Y. Lau¹, R. Ramiswami³, S. Hill¹, M. Adan¹, F. Maldarelli¹

¹National Cancer Institute, HIV Dynamics and Replication Program, Frederick, United States, ²HIV Monitoring Core, Frederick, United States, ³National Cancer Institute, Center for Cancer Research, Bethesda, United States

Background: HIV persistence during combination antiretroviral therapy (cART) is the principal obstacle to cure in persons living with HIV (PLWH). Mechanisms contributing to persistence include clonal expansion of infected cells or poor ART penetration in various anatomical compartments are not well understood. Little is known regarding the distribution and the characteristics of intact and deleted proviruses in tissues.

We characterized the persistence of HIV-infected cells from autopsy donations of people undergoing autopsy after long term ART.

Methods: PLWH enrolled in HIV protocols at the NIH Clinical Center with suppressed HIV RNA on long term ART consented to research autopsy underwent post-mortem examination after expiration. Levels of HIV provirus in tissues obtained at autopsy were quantified using a single copy DNA PCR, Intact Proviral DNA Analysis (IPDA), and multiplexed HIV-LTR/*gag* digital droplet PCR assays. *Gag* proviral populations (1.1 kb) were obtained by single genome sequencing (SGS) and analyzed by average pairwise distance (APD) as a measure of genetic diversity and phylogenetics.

Results: Five PLWH (median age = 59.8) on > 4years of suppressive ART expired from comorbid illnesses (3 neoplasms, 1 cardiac disease, 1 infection) underwent autopsy within 3-48 hours. HIV-infected cells were widely distributed in tissues with the highest HIV-DNA levels in lymph node (240-410 copies/million cells), and lowest in brain (1-9 copies/million cells). Multiplexed LTR/*gag* quantification revealed diverse proviral populations structure with LTR:*gag* ratio ranging from 2.09-8.27 across tissues. IPDA noted extensive DNA shearing, exceeding 60-70% of total

DNA, precluding the quantification of intact proviruses. Analyses of *gag* sequences suggested variable levels of hypermutated (6.2-44.4%) and identical proviruses (5.8-44.0%) across tissues. Analyses of unique sequences without hypermutations showed a low level of genetic diversity (APD=0.19%-0.9%) and intermingled proviral populations across tissues.

Conclusions: HIV proviruses are widely distributed in anatomic compartments with significant differential levels of identical, defective and hypermutated proviruses, suggesting the role of local immune responses in shaping the proviral landscape. IPDA analysis revealed human DNA is highly sheared within hours after expiration, complicating quantification of intact proviruses. Multiplexed LTR/*gag* quantification is a useful approach to characterize the proviral populations in this context.

EPB0183

Provider's perception, perceived needs, preferences, benefits, and challenges on the integration of NCDs services delivery with HIV services Rwanda

V. Dushimiyimana^{1,2}, L. Nshimiyimana², G. Van Hove¹, B.A. Kateera³, V.N. Umuhire², Y.D. Nsaba Uwera⁴, M. Twagirumukiza¹, N. Ntusi⁵, S. Nsanzimana⁶, S. Callens¹
¹University of Ghent, Medicine and Health Sciences, Ghent, Belgium, ²Rwanda Biomedical Centre, Research Innovation and Data Science, Kigali, Rwanda, ³Clinton Health Access Initiative, Kigali, Rwanda, ⁴University of Rwanda, Kigali, Rwanda, ⁵University of Cape Town, Cape Town, South Africa, ⁶Rwanda Biomedical Centre, Kigali, Rwanda

Background: Expanded global access to antiretroviral therapy (ART) has turned Human Immunodeficiency virus infection and acquired immune deficiency syndrome (HIV/AIDS) into a manageable chronic disease. Gradually increasing in age poses an increased risk for NCDs to people living with HIV (PLWH). Intervention for the management of non-communicable diseases (NCDs) is needed to improve their quality of life. This study identified the provider's and stakeholders' perceptions on benefits, perceived challenges, and needs on the integration of NCDs services delivery with HIV services in Rwanda and explored the provider's and stakeholders' preferences and needs on the integration of NCDs services delivery with HIV services in Rwanda health facilities.

Methods: The study conducted for the period of 8 months from August 2021. A qualitative approach using Interpretive description and purposive sampling. Data collection was done using an interview guide to conduct in-depth interviews among healthcare providers, HIV and NCDs program implementors from central level, program partners, and civil society. Interviews were conducted in Kinyarwanda, transcribed, translated in English, and analyzed using Dedoose software. Thematic analysis was used. Ethical approval was sought and obtained and participants provided consent.

Results: A total number of 48 in-depth interviews were conducted. Four themes were identified including perception and preference for NCDs-service integration with HIV care services; benefits on the integration of NCDs-service with HIV care services; perceived challenges with NCDs services integration in HIV care and Perceived needs/plan for the integration of NCDs care in HIV services delivery. "We still have the problem of human resource, staff where you find staff which are trained on HIV are not the ones who are trained for NCDs implies that healthcare providers who are providing HIV service have a little knowledge on NCDs and those providing NCDs service have little knowledge on HIV." A civil society respondent

Conclusions: NCDs are a global burden and especially among PLWH the integration of NCDs management in HIV care is a vital need. Thus, the global community and health system should increase awareness of NCDs awareness and invest in healthcare providers' capacity building, infrastructure, and care which will facilitate the smooth provision of NCDs prevention and care to PLWH.

EPB0184

Obstructive sleep apnoea is associated with higher cardiometabolic risk among people living with HIV: a case for screening in Africa

N. Chandiwana¹, G. Akpomiemie¹, J. Marais², A. Lubbe², K. Scheuermaier², W.D.F. Venter¹
¹Ezintsha, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, ²Wits Sleep Laboratory, Brain Function Research Group, School of Physiology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

Background: Obstructive sleep apnea (OSA) is associated with an increased risk for cardiometabolic disease. HIV is an additional risk factor for OSA, even in younger people living with HIV (PLWH) and those without obesity. Despite the potential impact of OSA on quality of life and cardiometabolic health, there are limited data among PLWH in southern Africa where both HIV and obesity are at epidemic levels and cardiometabolic disease common. Understanding the extent of the problem is a critical first step towards developing appropriate interventions for less-resourced high HIV burden settings.

Methods: This is a cross-sectional, observational study of a well-characterised cohort of PLWH enrolled in the ADVANCE trial in South Africa. Between September 2021-November 2022, OSA risk was evaluated using the Berlin questionnaire, a screening tool with high specificity to detect OSA and comprised of 10 questions in three categories. Category one, high-risk was defined as persistent symptoms related to snoring; category two, high-risk was defined as persistent daytime sleepiness, drowsy driving, or both and category three, high-risk was defined as a history of hypertension or a body mass index (BMI) ≥ 30 kg/m². Overall OSA risk was defined as high-risk in at least two out of three categories. Demographic and known

cardiometabolic risk (CMR) markers were compared between participants at low-risk versus high-risk for OSA and a CMR risk score was calculated using BMI, waist circumference (WC), fasting glucose, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, triglycerides, and mean arterial blood pressure.

Results: Of the 170 individuals included in this analysis, mean age was 39.2 years, 61.8% were female, 31% had hypertension and 18.8% were high-risk for OSA. High-risk vs low-risk OSA participants had a higher BMI ($P<0.0001$), higher WC ($p=0.007$), higher hip circumference ($p=0.033$), and higher triglycerides ($p=0.011$). A higher CMR score was seen in those at high-risk OSA vs those at low risk of OSA ($p=0.026$) when adjusting for sex and age.

Conclusions: In a relatively young cohort of PLWH, obesity, and hypertension were common and risk for OSA was high. OSA is a modifiable risk factor for cardiometabolic disease, yet not currently screened for in routine HIV care.

EPB0185

Malnutrition in children living with HIV

I.I. Nkaanah Fomefret¹, R. Ajeh²

¹Ministry of Public Health, Cameroon, Yaounde, Cameroon,

²National AIDS Control Committee, Cameroon, Yaounde, Cameroon

Background: WHO recommends that health care for children living with HIV should be accompanied by systematic assessment and management of their nutritional status. Pediatric HIV infection and malnutrition are major public health issues in sub-Saharan Africa, including Cameroon. This study was carried out to determine the prevalence of malnutrition in terms of stunting, wasting and underweight, assess biochemical indicators (haemoglobin) and immunological status amongst children living with HIV under 15 years of age followed up at the Bamenda Regional Hospital, Cameroon. Malnourished children are likely more immunodepressed compared to their non-malnourished counterpart was our hypothesis.

Methods: A cross-sectional study was conducted on 107 randomly selected children less than 15 years living with HIV and attending the AIDS clinic of the Bamenda Regional Hospital from February to April 2018. Socio-demographic data was obtained using a questionnaire. anthropometric measurements using stadiometer, scale balance, MUAC tape. Hemoglobin and CD4 levels using the hospital's laboratory. We used standard Z-scores and WHO guidelines. SPSS software version 24 for analysis. Statistical significance put at a P-value <0.05 .

Results: 107 children participated, 61.7% were females. 47.7% were aged 6 – 10 years., one of four children (25.2%) were immune-depressed (CD4 count <499 cells/UL), with 12.1% severely (CD4 count <250 cells/UL) and 13.1 moderately immune-depressed (250 – 499 cells/UL). Malnutrition depicted by underweight, stunting or wasting had a prevalence rate of 15%, 27% and 17% respectively. 40.3% were

anemic. A comparison of "normal" versus malnourished children revealed a relative drop in the immunological status (CD4 count) of the latter as follows; wasting-31%, stunting-13% and underweight-10%. This same pattern was also observed but to a lesser extent with respect to hemoglobin levels (wasting -14.7%, underweight-10.4% and stunting-5%).

Conclusions: From these results, one on three children were stunted. Four in ten children were anaemic. Also malnourished children have relatively lower immunologic status. One on three children that were wasted were immunodepressed. These results underscore the need for interventions that address malnutrition in children living with HIV such as; routine assessment for evidence of malnutrition, nutritional education and appropriate nutrient supplementation. It also indicates the need for further research to inform these interventions.

EPB0186

Prevalence and risk factors for renal insufficiency among adults living with HIV in Tanzania: results from a cross-sectional study

T. Ottaru¹, G. Kwezigabo¹, Z. Butt^{2,3}, P. Chillo⁴, H. Siril⁵, L. Hirschhorn⁶, C. Hawkins⁶

¹Muhimbili University of Health and Allied Sciences, Epidemiology and Biostatistics, Dar es Salaam, Tanzania, United Republic of, ²Phreesia Inc., North Carolina, United States, ³Northwestern University, Department of Psychiatry and Behavioral Sciences, Chicago, United States, ⁴Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of, ⁵Muhimbili University of Health and Allied Sciences, Department of Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of, ⁶Robert J Havey Institute of Global Health, Chicago, United States

Background: With improved survival, adults living with HIV (ALHIV) are increasingly likely to experience age- and HIV-related comorbidities such as kidney disease. Other risk factors for kidney disease including high blood pressure (BP), obesity, diabetes, and dyslipidemia are common among ALHIV. The objective of this study was to determine the prevalence of renal insufficiency and its associated risk factors among ALHIV.

Methods: We conducted a cross-sectional study among ALHIV ≥ 18 years on ART at six HIV clinics in Dar-es-Salaam, Tanzania between November 2020 and January 2021. We calculated the prevalence of renal insufficiency (defined as estimated glomerular filtration rate (eGFR) of <60 ml/min/ 1.73m^2) and applied multivariable (MV) logistic regression models to identify independent risk factors of renal insufficiency. Covariates significant at $p<0.2$ in the univariate analysis were included in MV models. We further examined the impact of age and its interaction with other important risk factors for renal insufficiency.

Results: 450 ALHIV on ART were included in the analysis [males 26%; median age 43 (IQR 18-72) years; on tenofovir

containing ART 89%; HIV VL ≤ 50 copies/mL 88%], of these 34 (7.6%) had renal insufficiency. There was a higher prevalence of renal insufficiency among males (12%) vs. females (6%), $p=0.03$; ALHIV ≥ 50 (27%) vs <50 years (4%), $p<0.01$; and those with elevated [120-129/ <80 mmHg (6%)] and high [$\geq 130/80$ mmHg (15%)] vs. normal ($<120/80$ mmHg) blood pressure (BP) (4%), $p<0.01$. In MV analyses adjusting for age (≥ 50 / <50 years), male sex, BP (high/elevated/normal), health insurance coverage (yes/no), dyslipidemia (total cholesterol ≤ 5 / >5 mmol/L) HIV VL (≤ 50 / >50 copies/mL), only older age (aOR 6.53, 95%CI:4.2-10.2, $p<0.01$), and high but not elevated BP (aOR 2.38, 95%CI:1.2-5.0, $p=0.02$) were independently associated with renal insufficiency. The interaction term between age and BP was not significant ($p=0.95$).

Conclusions: The risk of renal insufficiency among ALHIV increased independently with both age and BP. Interventions targeting better BP control and screening for renal insufficiency among older ALHIV are critical to reduce morbidity and mortality related to kidney disease. Further research is needed to determine the synergy between known renal insufficiency risk factors among ALHIV on ART, over time.

Clinical complications of HIV and antiretroviral therapy

EPB0187

Hypertension among people living with HIV after starting or switching to DTG, EFV, or ATV/r-based ART at Newlands Clinic, Zimbabwe

T. Shamu^{1,2,3}, M. Egger^{2,4,5}, T. Mudzviti^{1,6}, C. Chimbetete¹, J. Manasa⁷, N. Anderegg^{4,2}

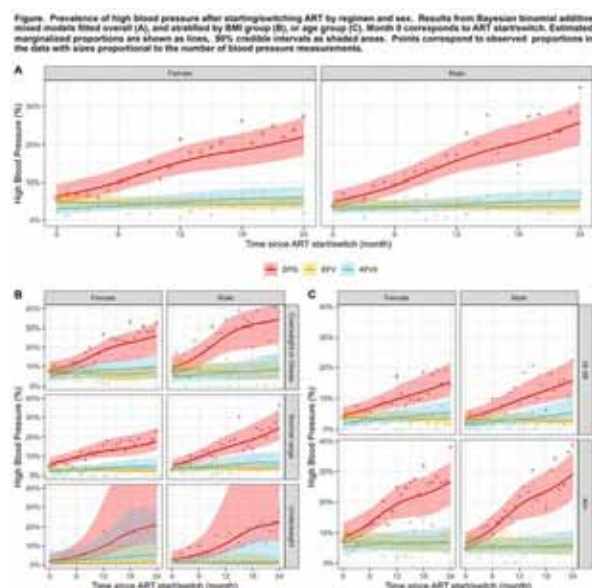

¹Newlands Clinic, Harare, Zimbabwe, ²University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, ³Graduate School of Health Sciences, University of Bern, Bern, Switzerland, ⁴University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, ⁵University of Bristol, Bristol Medical School, Population Health Sciences, Bristol, United Kingdom, ⁶University of Zimbabwe, Department of Pharmacy and Pharmaceutical Sciences, Harare, Zimbabwe, ⁷University of Zimbabwe, Innovation Hub, Harare, Zimbabwe

Background: Dolutegravir (DTG)-based ART has been shown to be associated with weight gain. We previously confirmed this for people living with HIV (PLWH) attending Newlands Clinic in Harare, Zimbabwe. Since overweight and obesity are risk factors for hypertension, we aimed to compare blood pressure (bp) trends of PLWH on DTG-, efavirenz-(EFV), and ritonavir-boosted atazanavir-(ATV/r) based ART.

Methods: We included adult PLWH who started or switched to DTG-, EFV-, or ATV/r-based ART at Newlands Clinic 2008-2022 and extracted bp measurements for two

years after start/switch. We fitted Bayesian binomial additive mixed models to estimate prevalence trends for high bp (systolic pressure >140 mmHg or diastolic pressure >90 mmHg) and hypertension (two consecutive high bp measurements) after start/switch. We included ART regimen, sex and their interaction as fixed effects, a random intercept by person, and smoothed monthly trends by sex and regimen. We fitted models (A) overall and stratified by (B) BMI and (C) age.

Results: We analysed 35449 bp records from 4348 PLWH of whom 3181, 787 and 380 were starting/switching to DTG, EFV- and ATV/r, respectively. We found a substantial increase in the prevalence of high bp over 24 months for DTG, from 6.4% (90%-credible interval 4.4-9.6%) to 22.1% (17.1-27.0%) in females, and from 4.9% (3.3-7.6%) to 25.7% (20.0-31.2%) in males (Figure). This increase was observed in all BMI and age groups, but more pronounced in the elderly (≥ 40 years) and overweight or obese PLWH (BMI ≥ 25 kg/mm²). Prevalence of hypertension was generally lower than of high bp (approximately 15% after 2 years for DTG), but trends were similar. For EFV and ATV/r there was no evidence for an increase in high bp or hypertension after start/switch.

Conclusions: Contrary to EFV and ATV/r, DTG was associated with an increase in prevalence of high bp and hypertension. Routine monitoring of bp in PLWH on DTG is recommended.

**EPB0188****Epicardial adipose tissue thickness for cardiovascular risk prediction in PLWH. Bridging the gap?**

M.G. Castro¹, L.I. Ubiergo¹, E. Butarelli¹, H. Miño¹, F. Cogliano¹, E.A. Rottoli¹, G. Cravero¹, V. Gabrieli², F.R. Galluccio¹, R. Savarino², L.M. Rodeles³, A. Crespo^{1,2}

¹Dr. JB Iturraspe Hospital, Internal Medicine, Santa Fe, Argentina, ²Centro de Especialidades Médicas Ambulatorias de Santa Fe (CEMAFE), Santa Fe, Argentina, ³Universidad Nacional del Litoral, Centro de Estudios en Salud Global (CeSaG), Facultad de Ciencias Médicas, Santa Fe, Argentina

Background: Metabolic dysregulation, inflammation and lipid disorders have been described in PLWH, which could be linked to higher cardiovascular risk. Epicardial adipose tissue is metabolically active and has been associated to inflammation, insulin resistance and coronary disease in the general population.

We aimed to assess whether epicardial adipose tissue thickness (EATT) correlates to clinical and biochemical markers of cardiovascular risk in PLWH.

Methods: Cross-sectional study that included PLWH >18-years-old and HIV-negative controls. BMI ≥ 30 and people with significant comorbidities were excluded. EATT was measured by doppler echocardiography on the right ventricle free wall from both parasternal long and short-axis views. Complete clinical examination and metabolic laboratory tests were performed. The research was conducted in Santa Fe (Argentina) between 2021-2022. A binary logistic regression was performed for multivariate analysis in order to identify variables that significantly predict insulin resistance, defined as a cut-off value of $>1,67$ for HOMA2-IR. For this analysis, HIV-status, age, sex and variables that were associated ($p < 0.05$) to insulin resistance in the bivariate analysis were included.

Results: 118 subjects (81 PLWH). 56,8% male sex. Median age 39,5 (IQR 21,0). The majority (99,2%) of Hispanic ethnicity. Median BMI 24,9 (IQR 21,0). 10-year cardiovascular risk (Framingham) was 2,81% (IQR 7,52). In PLWH, median CD4+ was 527 (IQR 360), 79,1% were undetectable, 100% were on HAART and 50% received Efavirenz.

No between-groups differences were found in BMI, total cholesterol, LDL-c, HDL-c, atherogenic index, fasting glucose or HOMA-IR. PLWH showed higher C-reactive protein (1,00 IQR 3,50 vs 0,590 IQR 3,70, $p=0,013$), D-dimer (0,190 IQR 0,090 vs 0,120 IQR 0,190, $p=0,005$) and EATT (4,10 \pm 0,971 vs 3,49 \pm 0,917, $p=0,007$). EATT significantly correlated to age ($p=0,004$, $Rho=0,333$) and waist-to-hip ratio ($p=0,047$, $r=0,277$), and in PLWH in particular, to HOMA2-IR ($p=0,023$, $Rho=0,420$) and D-dimer ($p=0,008$, $Rho 0,492$). In multivariate analysis, only EATT significantly predicted insulin resistance.

Conclusions: PLWH showed higher EATT as well as low-grade inflammatory markers compared to matched HIV-negative controls. In these people, EATT was associated

with insulin resistance and -potentially- a prothrombotic state. EATT could be a useful tool to bridge the gap in cardiovascular risk assessment in PLWH.

EPB0189**Reversibility of neuropsychiatric adverse events after switching to Darunavir/cobicistat or Doravirine in men on INSTI based regimen**

M.S. Rodríguez Evaristo¹, J.A. Mata Marín², O.C. Martínez Carrizales³, A. Chaparro Sánchez², E. Pérez Barragán², M. Núñez Armendariz², L. Barragán Huerta⁴, J.E. Gaytán Martínez²

¹Hospital de Especialidades Centro Médico Nacional La Raza, Internal Medicine, Mexico City, Mexico,

²Hospital de Infectología Centro Medico Nacional La Raza, Infectious Disease, Mexico City, Mexico, ³Hospital de Infectología Centro Medico Nacional La Raza, Psychiatry, Mexico City, Mexico, ⁴Universidad Autonoma Metropolitana, Biological Science and Health, Mexico City, Mexico

Background: Integrase strand transfer inhibitors (INSTI) are associated with neuropsychiatric adverse events (NPAEs). Switching patients to other regimen could improve NPAEs symptoms.

The aim of this study was to evaluate improvements in NPAEs after switching INSTI based regimen to Darunavir/cobicistat (DRV/c) or Doravirine (DOR) based regimen.

Methods: We designed a single arm trial, at the Hospital de Infectología, "La Raza" National Medical Center since March 2021 to January 2023 in order to evaluate the reversibility of NPAEs detected with Patient Health Questionnaire (PHQ-9), sleep disturbances with Insomnia Severity Index (ISI) and Pittsburgh Sleep Quality Index (PSQI) and anxiety or depression with Hospital Anxiety and Depression Scale (HADS-A and HADS-D) in patients who started INSTI based regimen with Dolutegravir (DTG) or Bictegravir (BIC). NPAEs leading to INSTI discontinuation were considered when PHQ-9 ≥ 15 points, ISI ≥ 15 points, PSQI ≥ 8 and HADS-A or D ≥ 11 .

These patients were switched to DRV/c or DOR based regimen. Then we compared scales at the moment of switch 12 weeks later using the Wilcoxon signed-rank test.

Results: We included 890 treatment-naïve male patients who started antiretroviral therapy with INSTI based regimen, 542 (60.9%) with BIC and 348 (39.1%) with DTG. A total of 32 (3.6%) experienced NPAEs that lead to discontinuation, 20 (62.5%) from BIC and 12 (37.5%) from DTG.

Insomnia by ISI were 20 (62.5%), ISI median 19 (IQR 17-21); depression by PHQ-9 was found in 21 (65.6%) with 19 points (IQR 15-22) and anxiety by HADS-A was found in 12 (37.5%) with 12 points (IQR 11-14). Some patients had more than one NPAE that led to discontinuation; 20 (62.5%) and 12 (37.5%) were switched to DRV/c and DOR respectively.

After 12 weeks we observed significant improvements in PHQ-9, with a median of 5 points (IQR 2-12), $p=0.004$, ISI 7 points (IQR 4-12), $p=0.001$, HADS-A 7 points (IQR 6-9) $p=0.017$.

Conclusions: NPAEs seem to be associated in patients on INSTI based regimen; these NPAEs improve after switching to DRV/c or DOR based regimen since the first 4 and 12 weeks. ISI, HADS, PSQI and PHQ-9 are quick, easy, and self-reported questionnaires to test on each visit.

EPB0190

eGFR change after transitioning to DTG-based ART at Newlands Clinic in Zimbabwe: a cohort study

T. Shamu^{1,2,3}, M. Egger^{2,4,5}, T. Mudzviti^{1,6}, C. Chimbetete¹, J. Manasa⁷, N. Anderegg^{2,4}

¹Newlands Clinic, Harare, Zimbabwe, ²University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, ³University of Bern, Graduate School of Health Sciences, Bern, Switzerland, ⁴University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health, Cape Town, South Africa, ⁵University of Bristol, Population Health Sciences, Bristol, United Kingdom, ⁶University of Zimbabwe, Department of Pharmacy and Pharmaceutical Sciences, Harare, Zimbabwe, ⁷University of Zimbabwe, Innovation Hub, Harare, Zimbabwe

Background: Dolutegravir (DTG) has become the preferred antiretroviral therapy (ART) third drug for integrase strand transfer inhibitor naive clients initiating/switching ART in lower-middle-income countries. DTG causes benign serum creatinine (sCr) elevation without affecting glomerular filtration rate (GFR). sCr based estimated GFR (eGFR) equations consequently show a false decline. The magnitude of this decline remains unevaluated in African settings.

Methods: We analysed routine data from Newlands Clinic, Zimbabwe.

We abstracted sex, age and monthly eGFR (calculated using the CKD-EPI equation) for participants aged ≥18 years who transitioned from tenofovir+lamivudine+efavirenz to tenofovir+lamivudine+DTG (TLD) between 2019 and 2022.

For each participant we calculated eGFR changes compared to their baseline (date of transitioning) eGFR for all measurements available within 12 months prior- and 36 months post-baseline.

We aggregated data by A) month, and B) month, sex, and age group and calculated median changes in eGFR. We fitted weighted additive models to the aggregated data to estimate trends in median changes in eGFR A) overall, and B) by sex and age group.

Results: We included data for 3443 participants (66.2% female) with a median age of 44 years (IQR 35-50). The median baseline eGFR was 108 ml/min (IQR 96-121).

Overall, the predicted trend showed a decline in median eGFR plateauing approximately one-year post-switch (Figure).

Then, the estimated overall median decrease in eGFR was 18.1 ml/min (95% CI 17.1-19.1). Changes in eGFR did not differ substantially by age or sex, ranging from a median

decrease at one-year post-switch of 16.0 ml/min (95% CI 14.5-17.5) in females <30 years old to 20.1 (95% CI 19.0-21.2) in females aged 40-49 years.

Figure. Overall observed (points) and estimated (curve) trend of median change in eGFR before and after transitioning from efavirenz to dolutegravir in combination with tenofovir and lamivudine among adults in Zimbabwe. B. Estimated trends of change in median eGFR before and after transitioning by age group (years) and sex.

Conclusions: In this cohort, median eGFR declined substantially after transitioning to TLD, plateauing after about 1 year. Clinicians with similar clients should be aware of this likely benign decline in eGFR when evaluating the renal function of clients on DTG.

EPB0191

Blood pressure among people living with HIV transitioning from efavirenz- to dolutegravir-based ART: a cohort study from Zimbabwe

T. Shamu^{1,2,3}, M. Egger^{2,4,5}, T. Mudzviti^{1,6}, C. Chimbetete¹, J. Manasa⁷, N. Anderegg^{2,4}

¹Newlands Clinic, Harare, Zimbabwe, ²University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, ³University of Bern, Graduate School of Health Sciences, Bern, Switzerland, ⁴University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health, Cape Town, South Africa, ⁵University of Bristol, Population Health Sciences, Bristol, United Kingdom, ⁶University of Zimbabwe, Department of Pharmacy and Pharmaceutical Sciences, Harare, Zimbabwe, ⁷University of Zimbabwe, Innovation Hub, Harare, Zimbabwe

Background: Following the WHO recommendations in 2019, dolutegravir (DTG) replaced efavirenz as the preferred first-line third drug co-administered with tenofovir and lamivudine/emtricitabine. DTG has been associated with hypertension (HTN).

Methods: We abstracted blood pressure (BP), age, sex, and HTN diagnoses records from routinely collected data at Newlands Clinic, Harare, Zimbabwe. We included adult participants who routinely transitioned from tenofovir+lamivudine+efavirenz (TLE) to tenofovir+lamivudine+DTG (TLD). We aggregated data by month (from 12 months prior to 35 months after transitioning), HTN status and sex. For each aggregated data cell, we calculated median systolic and diastolic pressure

(SBP, DBP) among participants contributing BP measurements to the data cell. We then fitted separate additive models to describe trends in median SBP and DBP by sex and baseline HTN diagnosis.

Results: We analysed 57,970 BP records from 5,487 participants (3,648 [66.5%] female), and 1,023 (18.6%) had a diagnosis of HTN at baseline. Among the non-hypertensive at baseline, there was strong evidence for an increase in median SBP, which was more pronounced in males compared to females and some evidence for a slight increase in DBP as well (Figure).

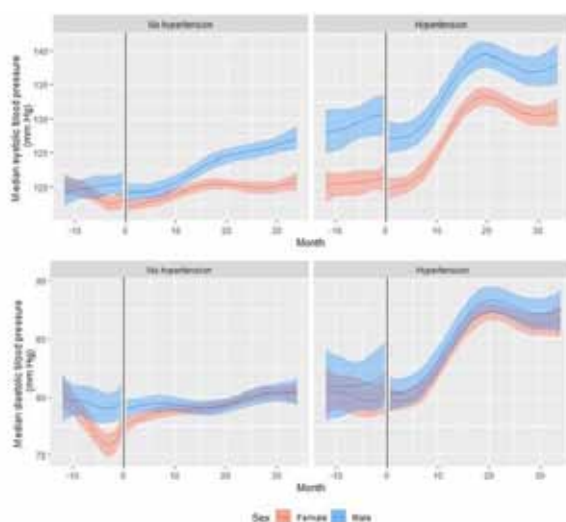

Figure: Estimated trends in the median systolic (top) and diastolic (bottom) blood pressure from 12 months prior to– until 35 months post-transitioning from tenofovir + lamivudine + efavirenz to tenofovir + lamivudine + dolutegravir among patients with and without hypertension at time of transitioning (Month 0).

Figure. Estimated trends in the median systolic (top) and diastolic (bottom) blood pressure from 12 months prior to– until 35 months post-transitioning from tenofovir + lamivudine + efavirenz to tenofovir + lamivudine + dolutegravir among patients with and without hypertension at time of transitioning (Month 0).

Among hypertensive participants, there was evidence for both increasing SBP and DBP, with similar estimated median DBP for both sexes, but higher SBP among males both before and after baseline. The increase in BP among hypertensive participants peaked at 18 months post baseline with an estimated median of 133 (95% CI 131–134) mmHg SBP and 87 (86–89) mm DBP in females and 139 (95% CI 137–141) mmHg SBP and 88 (87–89) mm DBP in males and plateaued thereafter.

Conclusions: Among non-hypertensive participants we observed smaller increase in SBP after transitioning from TLE to TLD and a larger increase in both SBP and DBP all hypertensive participants. Males and those with HTN on TLD could benefit from vigilant BP monitoring.

EPB0192

96-week update: change in weight and BMI associated with switching to bictegravir/emtricitabine/tenofovir alafenamide vs. a dolutegravir-based regimen among virologically suppressed adults living with HIV

C.-P. Rolle^{1,2}, J. Garrett¹, V. Nguyen¹, K. Patel³, F. Hinestrosa^{1,4}, E. DeJesus^{1,4}

¹Orlando Immunology Center, Orlando, United States,

²Emory University, Rollins School of Public Health, Atlanta, United States, ³Gilead Sciences, Foster City, United States,

⁴University of Central Florida College of Medicine, Orlando, United States

Background: Previously, we demonstrated that switching to a bictegravir (BIC) vs. DTG-based regimen (DBR) was associated with lower annualized weight gain of a similar magnitude post-switch at Week 48. Here, we report updated changes in weight and BMI through 96 weeks compared to 2 years prior to switch.

Methods: Data on demographics, clinical characteristics, weight, and BMI are collected from virologically suppressed adults switched to BIC/emtricitabine(F)/tenofovir alafenamide (TAF), DTG+ F/TAF, DTG/abacavir (ABC)/lamivudine (3TC), DTG/rilpivirine (RPV) and DTG/3TC 2 years prior to switch through 144 weeks post-switch. Linear spline models were fit to estimate and compare the trajectories of weight and BMI changes observed pre-and-post-switch.

Adjusted piecewise linear mixed-effects models were fit to examine factors associated with weight and BMI change pre-and-post-switch.

Results: Baseline demographic and clinical characteristics have been previously reported. 673 switched to BIC/F/TAF, 148 switched to DTG + F/TAF, 51 switched to DTG/ABC/3TC, 48 switched to DTG/RPV and 36 switched to DTG/3TC. At Week 96, switching to BIC/F/TAF vs. a DBR (grouped) was associated with lower annualized weight gain post-switch (-0.75 kg/year vs. -0.37 kg/year respectively, $p=0.336$). DTG/3TC switches continued to have the highest annualized weight gain (0.66 kg/year, 95% confidence interval [CI]: -0.6, 1.92), whereas DTG/RPV switches had the lowest annualized weight gain (-2.68 kg/year, 95% CI: -4.61, -0.73) post-switch at Week 96. DTG/RPV and BIC/F/TAF switches were the only groups with significantly lower annualized weight gain post-switch compared to pre-switch trajectories at Week 96.

Similar trends were observed for BMI changes. Baseline BMI<18.5 kg/m² was the only evaluated factor associated with significantly higher annualized weight gain post-switch, whereas multiple factors were associated with significantly lower annualized weight gain, but among them referral to the internal wellness clinic and baseline CD4⁺ T-cell count<200 cells/mm³ were associated with the lowest annualized weight gain post-switch.

Conclusions: At Week 96, switching to a BIC vs. DBR continued to be associated with lower annualized weight gain of a similar magnitude post-switch. Weight and BMI

changes stabilized for many groups at Week 96; however, switching to BIC/F/TAF and DTG/RPV was associated with significantly lower annualized weight gain post-switch.

CD4+ T lymphocyte recovery and cognitive function in women living with HIV

A. Spence¹, X. Geng², K. Makambi², L. Rubin³, F. Palella⁴, A. Levine⁵, C. Rinaldo⁶, P. Wheeler⁷, M. Alcaide⁸, I. Oforokun⁹, A. Adimora¹⁰, G. D'Souza¹¹, K. Weber¹², J. Price¹³, D. Gustafson¹⁴, A. Sharma¹⁵, R.S. Turner¹⁶, S. Kassaye¹
¹Georgetown University Medical Center, Medicine, Washington, United States, ²Georgetown University Medical Center, Biostatistics, Bioinformatics and Biomathematics, Washington, United States, ³John Hopkins, Neurology, Epidemiology, and Psychiatry, Baltimore, United States, ⁴Northwestern University, Medicine, Chicago, United States, ⁵University of California Los Angeles, Medicine, Neurology, Los Angeles, United States, ⁶University Pittsburgh, Medicine, Pittsburgh, United States, ⁷University of Alabama, School of Nursing, Birmingham, United States, ⁸University Miami, Miller School of Medicine, Department of Medicine, Miami, United States, ⁹Emory University, Medicine, Atlanta, United States, ¹⁰University of North Carolina, Medicine and Epidemiology, Chapel Hill, United States, ¹¹John Hopkins, Epidemiology and International Health, Baltimore, United States, ¹²Hektoen Institute of Medicine, Chicago, United States, ¹³University of California San Francisco, Medicine, San Francisco, United States, ¹⁴State University of New York Downstate Health Sciences University, Neurology, Brooklyn, United States, ¹⁵Albert Einstein College of Medicine, Medicine, Bronx, United States, ¹⁶Georgetown University Medical Center, Neurology, Washington, United States

Background: The rate of CD4+ T lymphocyte (CD4) recovery after antiretroviral therapy (ART) initiation can predict death and other morbidity; however, the effects on cognition in women living with HIV (WWH) are unknown.

Methods: WWH who initiated ART during Women's Inter-agency HIV Study enrollment were included. CD4 recovery slope was calculated using data obtained at semi-annual follow-up visits. Global cognitive function was determined using results from a 7 domain neuropsychological test battery.

Demographically adjusted T-scores were used to create domain scores and transformed into a clinical rating score which was used to determine global cognition at the last study visit. Multivariate logistic regression was used to examine the association of cognitive impairment with CD4 slope 2-years after ART initiation.

Results: Among 1,106 women with a median age of 50 [42.25, 55.00] at last cognitive assessment, the median baseline CD4 at ART initiation was 309.5 [176.50, 447.50]. Median CD4 recovery slope 2-years after ART initiation was 62.61 cells/ μ L/year [39.39, 90.34]. Global impairment

was identified in 30% (n=333) of WWH with a median of 11 follow-up visits [IQR 7, 25]. In adjusted analyses, CD4 slope 2 years after ART initiation was not associated with odds of later cognitive impairment in WWH aOR = 1.00 (95% CI 0.998, 1.005).

However, post-menopausal status aOR=1.54 (95% CI 1.13, 2.09), diabetes aOR= 1.79 (95% CI 1.30, 2.47), and baseline hepatitis c virus (HCV) aOR=3.15 (95% CI 1.91, 5.18) were associated with the development of later cognitive impairment. HIV suppression after ART initiation aOR 0.55=(95% CI 0.32, 0.92) and history of drug use were associated with decreased odds of cognitive impairment aOR=0.50 (95% CI 0.34, 0.75).

Conclusions: In this US cohort of WWH, CD4 recovery early after ART initiation was not associated with cognitive impairment. Initiation of ART remains critical to prevent cognitive decline.

Future studies may explore the effect of drug use and management of certain health conditions and the interaction with CD4 recovery on cognition.

EPB0194

Improving the safety of clients on antiretroviral therapy through Drug Use Evaluations (DUE) to manage adverse drug events at six ART sites in the Oromia region of Ethiopia

Y. Wakwoya¹, W. Necho Mulatu¹

¹USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) Project, Oromia, Ethiopia

Background: Antiretroviral therapy (ART) treatment guidelines in Ethiopia endorsed the phasing in of dolutegravir (DTG)-based regimens as the preferred first-line antiretroviral (ARV) drugs in February 2019. WHO (World Health Organization) recommends enhanced monitoring of toxicity during the transition to new ARVs.

However, the USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project identified limitations in the management of adverse drug events (ADEs).

Description: GHSC-PSM supported four hospitals and two health centers to conduct baseline drug use evaluation (DUE) through a review of 525 client charts in 2020 for clients on DTG-based regimens. This review was complemented by an exit interview conducted with 420 clients. A DTG ADE screening tool helped to proactively take history and screen ADEs from all clients on DTG. In 2022, post-intervention DUEs were conducted through a review of 215 charts in two health facilities out of the six ART sites with the baseline to measure progress.

Lessons learned: The baseline DUEs (n=525) on the review of the healthcare client charts indicated that ADEs were not detected and documented. However, the exit interviews (N=420) confirmed that a significant number had experienced ADEs, including 17 percent experienced headaches, 11 percent had insomnia, eight (8) percent faced

nausea, eight (8) percent had tiredness, six (6) percent had allergic reactions, and two (2) percent had diarrhea. After multiple interventions by the project, ADEs were documented in the charts.

The post-intervention DUE conducted through a review of 215 charts indicated that the six ART sites detected 76 ADEs and reported just 29 of them to the national pharmacovigilance center.

Conclusions/Next steps: ADEs were missed by clinicians during visits for refills of ARVs. However, the study showed that conducting DUEs enabled healthcare professionals to be more vigilant in prescribing DTG and enabled ART sites to identify limitations in ADE detection and reporting.

EPB0195

Impact of GLP-1 receptor agonists on body weight in patients with type 2 diabetes and HIV

A. Lloyd¹, M. Brizzi¹, M. Lyons¹, L. Rotert², C. Fichtenbaum²

¹UC Health, Department of Pharmacy, Cincinnati, United States, ²University of Cincinnati College of Medicine, Division of Infectious Diseases, Department of Clinical Medicine, Cincinnati, United States

Background: Integrase strand transfer inhibitor- (INSTI-) based regimens have been associated with clinically significant weight gain in patients with HIV (PWH). The mechanism of which is poorly understood but has been associated with INSTIs interference with estrogen-mediated metabolic pathways, impact on hormones regulating glucose and lipid metabolism, suppression of the melanocortin stimulating system, and reduction in insulin sensitivity.

Additionally, glucagon-like peptide-1 (GLP-1) may be depleted during HIV infection and may play a role in weight gain, however the impact of GLP-1 receptor agonists (GLP-1 RAs) on weight in PWH is unknown.

We evaluated the impact of GLP-1 RA on metabolic outcomes in patients with type-2 diabetes (T2DM) and HIV (DM+HIV) compared to T2DM without HIV (DM).

Methods: Retrospective cohort analysis of metabolic outcomes in DM+HIV compared to DM receiving GLP-1 RAs and receiving care at UC Health outpatient clinics from 08.31.2017 to 08.31.2022. Metabolic outcomes were assessed by matching patients 2:1 by gender, race/ethnicity, GLP-1 RA, and dose.

Results: In this analysis, 15 persons were included in the DM+HIV group compared to 30 persons in the DM group. The mean age was 57 years (± 8.5 years), 13% identified female, 52% were Black, 48% were White, and 46% had GLP-1 RA dose titrated up during the study period. The mean change in weight was -10.4 (± 12.47) kg in the DM+HIV group compared to -1.73 (± 8.45) kg in the DM group ($P = 0.0085$). The mean percentage difference in weight was -8% ($\pm 9.96\%$) in the DM+HIV group compared to -1.47% ($\pm 6.8\%$) in the DM group ($P = 0.013$). The rate of patients achiev-

ing $\geq 5\%$ weight loss was 60% (9/15) in the DM+HIV group compared to 33% (10/30) in the DM group ($P = 0.1158$). The mean percentage difference in hemoglobin A1c was -1.3% ($\pm 2.39\%$) in the DM+HIV group compared to -0.49% ($\pm 2\%$) in the DM group ($P = 0.2415$).

Conclusions: In this cohort, PWH and T2DM had significantly greater weight loss compared to people with T2DM alone. A larger study comparing metabolic outcomes in DM+HIV compared to DM receiving GLP-1 RAs is underway to confirm these results.

Thymosin $\alpha 1$ in restoring immune response in immunological nonresponders

C. Chen¹, J. Wang¹, J. Xun¹, X. Zhang¹, L. Liu¹, Z. Song¹, R. Zhang¹, J. Chen¹, H. Lu^{1,2}

¹Fudan University, Shanghai, China, ²Southern University of Science and Technology, Shenzhen, China

Background: The prognosis of immunological nonresponders (INRs) with HIV is inferior to that of immunological responders. However, no effective strategy is available to restore CD4+ T cell immune response in these individuals. We aimed to explore the safety and efficacy of thymosin $\alpha 1$ in reconstitution of immune response in INRs.

Methods: INRs with CD4+ T cell counts between 100 and 350 cells/ μ L were enrolled and received two-staged 1.6mg thymosin $\alpha 1$ subcutaneous injections for 24 weeks (Qd in the first 2 weeks and Biw in the subsequent 22 weeks) while continuing antiretroviral therapy (NCT04963712). CD4+, CD8+ T cell counts and CD4/CD8 T cell ratio in whole blood, the proportions of CD4+ T, CD8+ T cell subsets, the expression of PD-1 and Tim-3 on T cells and signal joint T cell receptor excision circles (sjTREC) were measured by flow cytometry and real-time PCR, respectively. The primary endpoint is CD4+ T cell counts at week 24.

Results: A total of 20 participants were enrolled. They were mainly male (19/20), aged 48.1 (interquartile range: 40.5-57.0) years old, who had received antiretroviral therapy for 5.6 ± 2.8 years. No significant increase was observed in CD4+ T cell count after thymosin $\alpha 1$ treatment, while CD4/CD8 ratio increased significantly (Fig A).

Importantly, CD4+ T cell proportion, naive CD4+ T, naive CD8+ T cell proportion and sjTREC levels were markedly elevated at week 24 compared to that at baseline (Fig B/C). In contrast, the proportions of CD4+PD1+ T cells, CD4+TIM3+ T cells, CD8+PD1+ T cells and CD8+TIM3+ T cells decreased significantly (Fig D). HIV viral loads were stable during the study and no severe drug-associated adverse events were observed.

Conclusions: Thymosin $\alpha 1$ does not restore CD4+ T cell count. However, it increases thymus output, restores immune exhaustion and improves immunosenescence, which warrants larger clinical trials.

EPB0197

Metabolic syndrome among persons living with HIV on DTG based antiretroviral regimen: outcomes from a longitudinal cohort study in Ghana

V. Ganu^{1,2}, S. Ayisi Addo³, E. Kenu², K. Torpey², M. Lartey^{4,1}

¹Korle Bu Teaching Hospital, Medicine, Accra, Ghana,

²University of Ghana, School of Public Health, Accra,

Ghana, ³Ghana Health Service, National AIDS & STI Control

Programme, Accra, Ghana, ⁴University of Ghana Medical

School, Medicine and Therapeutics, Accra, Ghana

Background: Dolutegravir (DTG) based antiretroviral therapy has become the first line ART for most PLHIV in sub-Saharan Africa. Following increasing reports of DTG associated weight gain and hyperglycemia, these clients are likely to be at risk of metabolic syndrome (MetS).

This study sought to determine the risk of MetS among PLHIV.

Methods: Prospective multi-center observational cohort study among PLHIV in Ghana was conducted from September 2020 to August 2022. Clients with normal fasting blood glucose, HDL cholesterol, triglycerides, waist/hip ratio, BMI and blood pressure were followed for 18 months. MetS was defined as per WHO definition. Person-time and cumulative incidence rates were estimated using "stp-time" function in STATA. Cox proportional hazard model was employed.

Results: A total of 3195 PLHIV were recruited with 73% (2334/3195) being female. Mean age was 45.4 ± 11.8 years. Ten percent of clients were ART naïve before DTG initiation. Total person-months of DTG exposure was 52,113 with overall MetS incidence rate of 10.9 (95% CI: 10.0-11.8) per 1000 person-months. The MetS incidence rates at 3, 6 & 12 months were 331.4 (95% CI: 285.7-384.5), 228.0 (95% CI: 204.1 - 254.7) and 137.5 (95% CI: 125.7 - 150.4) per 1000 person-months respectively. MetS incidence was highest among >60 years (17.9 (95% CI: 14.9-21.7) per 1000 person-months).

MetS incidence rate among females (11.5 (95% CI: 10.5-12.6) per 1000 person-months) was higher than that among males (9.2 (95% CI: 7.8-10.9) per 1000 person-months) but not statistically significant.

Females had 1.4 (95% CI: 1.1 - 1.6) times higher risk of MetS compared to males. PLHIV already on ART before switch to DTG had 1.2 (95% CI: 0.9-1.5) times higher risk of MetS compared to ART naïve. Having a comorbidity at the time of DTG initiation was associated with 2.2 (95% CI: 1.9 - 2.4) times higher risk of MetS. PLHIV aged >60 years had 8.7 (95% CI: 1.9 - 2.4) times higher risk of MetS compared to those <25 years.

Conclusions: The cumulative incidence of MetS was 10.9 (95% CI: 10.0-11.8) per 1000 person-months. PLHIV who were female, had a comorbidity, aged >60 years and with a previous history of ARTs were at higher risk of MetS.

EPB0198

A patient with undiagnosed HIV presenting with hemophagocytic lymphohistiocytosis - the importance of routine HIV testing in hospitalized patients

M. Gao¹, A. Wong¹, C. Vo¹, S. Alkoutami², A. Astua², M. Polcar²

¹Mount Sinai Hospital, New York, United States, ²Elmhurst

Hospital, Infectious Disease, New York, United States

Background: Hemophagocytic lymphohistiocytosis (HLH) is a clinical syndrome marked by dysregulated macrophage-mediated cytokine secretion and a subsequent severe hyperinflammatory response; it can frequently mimic other systemic pro-inflammatory conditions, such as autoimmune conditions, hematological malignancies, and chronic infections. HIV infection is a known but rare cause for secondary HLH, a variant of HLH triggered by extrinsic sources.

Methods: Here, we present a case of a patient who was evaluated by the Infectious Disease Department at Elmhurst Hospital, Queens, New York in September 2022. The patient was a 79 year old Chinese immigrant with no significant past medical history who presented initially with significant altered mental status, SIRS criteria, and other symptoms consistent with bacterial sepsis of abdominal origin.

However, the patient had persistently negative infectious workup, including negative blood, urine, and CSF studies and unremarkable imaging studies. As his hospitalization progressed, his symptoms became refractory to broad-spectrum antibiotic therapy, and he became increasingly hypotensive and acidotic and required intubation.

Results: After HIV testing was recommended by the Infectious Disease Consultant, the patient was discovered to have AIDS with CD4 count 25 cells/mL (9%), with the time and method of initial HIV transmission unknown.

He was then found to meet criteria for HLH with the following five clinical criteria: fever, simultaneous thrombocytopenia and anemia, hypertriglyceridemia, hypofibrinogenemia, and elevated CD25 activity on assay, leading

to a diagnosis of secondary HLH triggered by AIDS. Despite prompt initiation of immunosuppressive therapy, the patient's condition continued to rapidly decline and he passed away within 2 days of diagnosis.

Conclusions: To our knowledge, this is the first documented case of secondary HLH triggered by AIDS presenting initially as sepsis. This case serves as a demonstration of the protean presentation of HIV/AIDS and how AIDS-triggered HLH can easily resemble sepsis.

It also serves as a reminder of the importance of routine HIV screening in patients receiving medical care, even in the absence of known risk factors. An earlier diagnosis of HIV may have changed the outcome for this patient.

EPB0199

Weight gain and lipid changes with switching from boosted protease inhibitor-based regimens to bicittegravir/tenofovir alafenamide/emtricitabine

P. Severe¹, S. Pierre¹, C.F. Duchatellier¹, V.R. Rivera¹, M.F. Pierre¹, N. Dorvil¹, J.B. Marc¹, D. Andre¹, F. Homeus¹, M.L. Aristhomene¹, J.W. Pape^{1,2}, S. Koenig³

¹Les Centres GHESKIO, Port-au-Prince, Haiti, ²Weill Cornell Medical College, New York, United States, ³Brigham and Women's Hospital, Boston, United States

Background: Weight gain is reported with switches from boosted protease inhibitors (bPI) and tenofovir disoproxil fumarate (TDF) to integrase strand transfer inhibitors and tenofovir alafenamide (TAF). Data on metabolic consequences of this weight gain are limited from low and middle-income countries.

Methods: We analyzed changes in weight and lipids from enrollment to Week 48 among a cohort of virally-suppressed adult PLWH who were randomized to continue a second-line bPI-based regimen vs. switch to bicittegravir/TAF/emtricitabine (B/F/TAF) at GHESKIO in Haiti.

Results: 193 clients were randomized (bPI group: 96; B/F/TAF group: 97). At enrollment, 45% received ritonavir-boosted lopinavir and 55% received ritonavir-boosted atazanavir; 78% received TDF (remainder received abacavir or zidovudine), and all received lamivudine.

Median age was 49 (IQR: 42, 57), and 104 (54%) were female. Median weight at enrollment was 65.9 kg in bPI and 62.3 kg in B/F/TAF group ($p=0.1115$); median change in weight at 48 weeks was -1.0 kg (IQR: -2.9, 1.0) and 1.2 kg (IQR: -0.9, 3.5), respectively ($p<0.001$). Weight gain of $\geq 5\%$ at week 48 occurred in 13 (13.5%) in bPI and 29 (29.9%) in B/F/TAF group ($p=0.006$).

Changes from enrollment to week 48 in total, LDL, and HDL cholesterol were similar between the two groups (Table 1).

Within each group, there was no difference in change in LDL from enrollment to week 48 in those with $\geq 5\%$ vs. $<5\%$ weight gain (bPI: -11 [IQR: -33, 17] vs. -6 [IQR: -20, 7]; p -value=0.989; B/F/TAF: -5 [IQR: -25, 13] vs. -2 [IQR: -13, 17]; p -value=0.169).

	Boosted PI Group (n=96)	B/F/TAF Group (n=97)	p-value**
Total Cholesterol (mg/dl)			
Enrollment*	180 (155, 208)	182 (154, 209)	0.877
Change at Week 48*	-12 (-27, 7)	-8 (-29, 11)	0.985
LDL (mg/dl)			
Enrollment*	101 (75, 126)	102 (84, 132)	0.444
Change at Week 48*	-6 (-21, 9)	-2 (-16, 16)	0.123
HDL (mg/dl)			
Enrollment*	49 (42, 61)	48 (43, 60)	0.969
Change at Week 48*	-3 (-11, 5)	-2 (-10, 5)	0.942

*Median values with IQR; ** p-values were from the 2-sided Wilcoxon rank sum test to compare the two treatment groups

Table 1. Change in Lipids from Enrollment to Week 48 by Treatment Group.

Conclusions: Switching from a bPI regimen (largely with TDF) to B/F/TAF is associated with weight gain in Haiti. However, this weight gain does not appear to be associated with an increase in LDL. We will explore changes in CVD risk scores and additional measures of cardiometabolic dysfunction associated with weight gain in this population.

HIV and ageing

EPB0200

Lower prevalence of potential drug-drug interactions among people living with HIV in the era of integrase inhibitor-based antiretroviral therapy

A.-T. Peng¹, S.-H. Huang¹, X.-Y. Li¹, P.-Y. Wu², H.-Y. Kuo¹, C.-C. Hung³

¹National Taiwan University Hospital Hsinchu Branch, Hsinchu, Taiwan, Republic of China, ²National Taiwan University Hospital, Taipei, Taiwan, Republic of China,

³National Taiwan University Hospital Yunlin Branch, Yunlin, Taiwan, Republic of China

Background: Aging people living with HIV (PLWH) are at a higher risk for potential drug-drug interactions (PDDIs) due to an increased burden of co-morbidities and co-medications. Studies on the prevalence of PDDIs among PLWH in the era of integrase strand-transfer inhibitor (INSTI)-based antiretroviral therapy (ART) are limited.

Methods: This cross-sectional study included consecutive PLWH who had been on ART for at least 3 months at two designated hospitals for HIV care in Taiwan. Patients' demographics, HIV treatment history, and the presence of co-morbidities were recorded with REDCap electronic data capture tools.

All prescriptions, including ART and non-ART prescriptions, in the three months prior to the date of review were collected from the NHI-MediCloud System, and screened for red-label and amber-label PDDIs using the University of Liverpool HIV drug interactions database. Prevalence of PDDIs was compared with that in the literature review. Associated factors with DDIs were sought in multivariable analyses.

Results: From June 2021 to August 2022, 1007 PLWH were included. Their median age was 40 years (interquartile range [IQR], 33-49) and 96.2% were taking INSTI-based

ART (16.9% boosted INSTI and 79.3% unboosted INSTI). The proportions of PLWH with ≥ 1 and ≥ 5 co-medications were 65.3% and 18.7%, respectively. Seven (0.7%) PLWH had red-label PDDIs and 163 (16.2%) had amber-label PDDIs, both of which were lower than those observed in historical control (1.4-7.0% with red-label PDDIs and 18.0-52.0% with amber-label PDDIs).

In multivariable analysis, the prevalence of PDDIs was higher in PLWH with an older age (aOR, per 1-year increase, 1.022, 95% confidence interval [CI] 1.004-1.040), increasing number of co-medications (aOR 1.097, 95% CI 1.002-1.201), use of boosted-INSTI-based ART (aOR 8.653, 95% CI 5.003-14.496), and concomitant medications in the alimentary tract and metabolism categories (aOR 11.058, 95% CI 6.648-18.394) and in the categories of antineoplastic and immunomodulating agents (aOR 14.733, 95% CI 1.274-174.016).

docs.google.com/document/d/10fe1J-0jLSG05HSUicWbg_DEo1rIMVqh/edit

Conclusions: In the INSTI era, prevalence of PDDIs declined but remained substantial. HIV care providers should be vigilant on screening and managing the PDDIs, especially in older PLWH, those with polypharmacy, those who are taking booster-containing ART, and those who are taking medications in specific categories.

EPB0201

Aging of brain network connectivity corresponds to cognitive impairment in persons with HIV

K. Petersen¹, P. Millar¹, S. Cooley¹, B. Ances¹

¹Washington University in St. Louis, Neurology, St. Louis, United States

Background: Magnetic resonance imaging can detect brain pathology in persons with HIV (PWH), which can be quantified using the brain-age gap (BAG), the difference between chronological and phenotypic 'biological age.' However, it is unknown whether PWH undergo accelerated age-like changes in the functional connectivity of brain networks, assayed using resting-state functional MRI (rs-fMRI). Machine learning can generate normative connectivity-vs.-age models in persons without HIV (PWoH), which are then applied to PWH to test for serostatus effects.

We hypothesized that connectivity patterns in PWH resemble those of older PWoH (increased BAG) and that aging of brain connectivity correlates with neurocognitive function.

Methods: 419 PWH (age=45.1±15.4 yr.; 75% male; 69% undetectable viral load) and 213 PWoH (age=37.9±17.1 yr.; 50% male) were imaged between 2008 and 2022. rs-fMRI was performed on 3.0-Tesla Siemens scanners (repetition time/echo time=2200/27ms, voxels=3-4mm³). Functional connectivity matrices were calculated by correlating brain activity in 300 regions. A Gaussian process regression model was trained on a separate cohort of PWoH

(N=1001) to estimate BAG from connectivity matrices (Millar, 2022), then applied to the study cohort. Participants completed a 15-test neurocognitive battery, producing a global cognitive Z-score. Hypotheses were tested using mixed-effects linear regression models, with age and biological sex as covariates.

Results: The machine learning model estimated age with mean absolute error (MAE)=12.0 years (Pearson's $R=0.73$). PWH had a mean BAG 2.6 years greater than PWoH, with consistent elevation across the age range ($p=0.001$; *Panel A*). In both groups, greater BAG was associated with worse cognitive performance ($p<0.001$; *Panel B*).

Conclusions: In parallel with HIV-associated brain structural changes, brain network connectivity patterns in PWH resemble those in older PWoH, suggesting increased biological aging and highlighting a potentially useful imaging biomarker of neurocognitive function.

Measuring intrinsic capacity: a screening tool for integrated care in ageing people living with HIV

S.F. Hisham¹, J.S. Lim¹, J.Y. Cheong¹, W.Y. Ho¹, X.W. Tan¹, G.H.-Y. Lui², M. Neelamegam³, S.F. Syed Omar^{1,4}, M.L. Chong^{4,1}, P.L. Wong^{4,1}, R. Rajasuriar^{4,1}

¹Centre of Excellence for Research in AIDS, Universiti Malaya, Kuala Lumpur, Malaysia, ²Chinese University of Hong Kong, Hong Kong, Hong Kong, SAR of China, ³The University of North Texas Health Science Centre, School of Public Health, Fort Worth, United States, ⁴Universiti Malaya, Medicine, Kuala Lumpur, Malaysia

Background: The World Health Organisation (WHO) Healthy Ageing model proposes measuring the construct of intrinsic capacity (IC) to monitor an individual's functional ability. Here, we explored the utility of this measure as a screening tool to assess age-associated functional decline in PLWH.

Methods: 155 PLWH under out-patient care in Universiti Malaya Medical Centre, Malaysia and 89 HIV-uninfected community controls aged 35 years and above were recruited. WHO's Integrated Care for Older People (ICOPE) framework was adapted to derive composite IC scores

(ranging 0-6) for each participant. One point was assigned for each deficit encompassing the five domains of cognition, sensory (hearing and vision), mobility, mood and vitality with higher scores denoting greater IC deficit. IC scores in PLWH (adjusted for age) were then correlated with assessments of disability, quality of life, loneliness, social isolation, self-rated health, mortality risks, polypathology and polypharmacy. Area under the receiver-operator-characteristic (AU-ROC) was calculated to predict frailty in PLWH.

Results: Median (interquartile range, IQR) age among PLWH and controls were 50 (42-56) and 50 (39-59) years, respectively. Majority were males (PLWH=83%, controls=56%) and all PLWH received antiretroviral therapy (ART). Overall, 21% of PLWH reported deficits in two or more domains compared to 10% among controls, $p=0.035$. IC scores correlated with chronological age in controls ($p=0.007$) but not in PLWH ($p=0.194$). Age-adjusted IC was significantly correlated with multiple patient-reported outcomes and clinical markers of aging in PLWH (Figure 1). IC scores demonstrated good ability to characterise frailty in PLWH (frailty phenotype AUC-ROC=0.871; frail scale, AUC-ROC=0.792).

Figure 1. Age-adjusted correlations of intrinsic capacity score with health outcomes in PLWH.

Conclusions: Intrinsic capacity provided a good composite measure of the physical, mental and social functioning of PLWH on ART in Malaysia. It represents an opportunity to incorporate functional assessments into routine HIV care to complement chronic disease-based monitoring. The tool should be validated in larger cohorts of PLWH from diverse settings.

EPB0203

Frailty transition among older adults living with HIV in Thailand: a five-year prospective cohort study

T. Apornpong¹, W.M. Han^{1,2,3}, A. Hiransuthikul^{1,4}, H.M. Lwin¹, S. Gatechompol^{1,2}, S. Ubolyam^{1,2}, S. Kerr^{1,5,3}, A. Avihingsanon^{1,2}, HIV-NAT 006 and 207 study team
¹HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, ²Chulalongkorn University, Center of Excellence in Tuberculosis, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, ³UNSW Sydney, Kirby Institute, Sydney, Australia, ⁴Chulalongkorn University, Department of Preventive and Social Medicine, Bangkok, Thailand, ⁵Chulalongkorn University, Biostatistics Excellence Centre, Faculty of Medicine, Bangkok, Thailand

Background: We investigated frailty transition among well-suppressed people living with HIV (PWH) in a five-year follow-up Thai aging cohort.

Methods: A prospective cohort study was conducted among virologically suppressed PWH aged ≥ 50 years from an aging cohort in Bangkok, Thailand. Frailty phenotypes were assessed at baseline and at five years of follow-up. The frailty status was grouped as robust, pre-frail and frail using 5 criteria: weight loss, low physical activity, exhaustion, weak grip strength and slow gait speed. PWH who died before the end of five-year follow-up were classified as frail. A generalized estimating equation (GEE) model was performed to investigate risk factors associated with transition to more severe frailty stages.

Results: Overall, 181 PWH (62% male; median age of 54 (IQR, 52-59) years) completed baseline and follow-up frailty evaluations. 11 PWH died during 5 years; 4 were in robust stage at baseline. Frailty transition from baseline to year5 is shown in figure 1A. Among 14 PWH who were frail at baseline, 12 (85%) had reverse transitions to pre-frail or robust stage at year 5. Forty-five 45 (25%) had worsening frailty stage. Weak grip strength was the predominant frailty phenotype characteristic at year 5, while low physical activity was predominant at baseline (figure 1B).

Figure 1A. Frailty transition from baseline to year 5.

Figure 1B. Frailty phenotype compared between baseline and year 5.

In multivariable analysis, excessive alcohol consumption (adjusted odds ratio [OR]: 3.00, 95% confident Interval (CI): 1.37-6.55, $p=0.006$), longer duration of ART (OR 1.10, 95%CI:

1.02-1.18, $p=0.011$) and NNRTI regimen at baseline (OR 2.71, 95%CI: 1.35-5.44, $p=0.005$; compared to PI or INSTI) were associated with worsening of frailty stage.

Conclusions: Nearly a quarter of PWH had transitioned to a more severe frailty stage within 5 years. However, the majority of frail PLH at baseline showed improvements in severity, suggesting frailty can be reversible. More research is needed to investigate the mechanisms of frailty transition, including those which are potentially modifiable.

Antiretroviral therapies and clinical issues in adults

EPB0204

Incidence of infections across Islatravir clinical development programs

K. Squires¹, T.A. Correll¹, M.N. Robertson¹, S.O. Klopfer¹, P.M.T. Hwang¹, Y.-P. Zhou¹, E. Martin¹, E. Rhee¹
¹Merck & Co., Inc., Rahway, United States

Background: Islatravir (ISL) is a nucleoside reverse transcriptase translocation inhibitor (NRTTI) being studied for HIV-1 treatment and prevention. Decreases in total lymphocyte (TL) and CD4+ T-cell counts were observed in several ISL clinical trials.

We conducted an analysis to assess infections in all participants, and participants experiencing TL count reductions, across phase 3 ISL clinical trials.

Methods: Infection data from phase 3 clinical trials in the following treatment and prevention development programs were reviewed: doravirine (DOR)/ISL 100mg/0.75mg orally once daily for treatment of virologically suppressed adults with HIV-1 (P017 Group 1 and P018 [switch studies]); ISL 60mg orally once monthly for pre-exposure prophylaxis (PrEP) in adults at high risk for HIV-1 infection (P022 [cisgender women] and P024 [cisgender men and transgender women who have sex with men]).

The incidence of infections (based on adverse events of infections and infestations by system organ class $\geq 5\%$ in any study) in participants who received ISL vs comparator, and in participants with $\geq 30\%$ reductions in TL counts, were compared.

Results: In the 4 phase 3 clinical trials, the incidence rates for overall infections were similar in participants who received ISL vs comparator. COVID-19 was the most common infection in P017, P018, and P024; bacterial vaginosis was the most common infection in P022. Other common infections were chlamydial infections, gonococcal infections, nasopharyngitis, syphilis, vulvovaginal candidiasis, and upper respiratory tract infections (Table).

Infection rates in participants with a $\geq 30\%$ decrease in TL counts were generally comparable in ISL vs comparator groups in P017 and P018 (63/140 [45%] and 64/128 [50%], respectively, vs 25/47 [53.2%]), P022 (90/127 [70.9%] vs 52/78 [66.7%]), and P024 (48/79 [60.8%] vs 20/27 [74.1%]).

	Treatment P017 GP DOR/ISL 100mg/0.75mg QD	P018 DOR/ISL 100mg/0.75mg QD	P022 ISL 60mg QM	P024 ISL 60mg QM	P024 FTC/FTC 100mg/100mg QD

UTI	25 (18.0)	25 (19.5)	25 (18.0)	25 (18.0)	25 (18.0)
Vaginitis	25 (18.0)	25 (19.5)	25 (18.0)	25 (18.0)	25 (18.0)

Table. Most common infections ($\geq 5\%$ in any study) reported in islatravir phase 3 treatment and prevention studies.

Conclusions: There was no observed increase in the incidence of infection in participants receiving ISL versus comparator for treatment or prevention of HIV-1.

EPB0205

The relationship between gender-affirming hormone therapy and tenofovir dried blood spot concentrations among transgender adults switching from tenofovir disoproxil fumarate/emtricitabine to tenofovir alafenamide/emtricitabine for pre-exposure prophylaxis

N. Patel¹, S. Morris², L. Burke², K. Chow², D. Pacheco², P. Anderson³, J. Blumenthal²

¹University of California San Diego, Skaggs School of Pharmacy & Pharmaceutical Sciences, La Jolla, United States, ²University of California San Diego, School of Medicine, La Jolla, United States, ³University of Colorado, Denver, United States

Background: Previous data have demonstrated a lack of an effect of tenofovir-based pre-exposure prophylaxis (PrEP) on hormone concentrations among transgender (TG) individuals taking gender-affirming hormone therapies (GAHT). It is less clear if there is an effect of GAHT on tenofovir-diphosphate (TFV-DP) in dried blood spot (DBS) drug concentrations, especially when switching from tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) to tenofovir alafenamide (TAF)/FTC for PrEP.

The objective of this study was to compare TFV-DP DBS concentrations between users and non-users of GAHT when switching from TDF/FTC to TAF/FTC for PrEP.

Methods: An observational cohort study was performed among a subset of TG individuals enrolled in a clinical trial evaluating switching from TDF/FTC to TAF/FTC for PrEP. Inclusion criteria were age ≥ 18 years old, TG identity, HIV-negative (4th generation), use of both TDF/FTC and TAF/FTC for ≥ 12 weeks, and availability of stored DBS samples for TFV-DP measurement while on both PrEP products. TFV-DP DBS concentrations were evaluated twice: once while on ≥ 12 weeks of TDF/FTC and after switching to TAF/FTC for ≥ 12 weeks. TFV-DP concentrations were compared between users and non-users of GAHT using the Mann-Whitney U test at each assessment.

Results: Among the 40 individuals included, median (interquartile range, IQR) age was 33.0 (28.3 – 39.5) years. Most (70%) were assigned male at birth. There were 29 (72.5%) individuals on GAHT. Median (IQR) TFV-DP concentrations while on TDF/FTC between users and non-users

of GAHT were 1623 (1317 – 2227) and 1839 (1188 – 2098) fmol/punch, respectively ($p=0.79$). Similarly, there was no difference in TFV-DP concentrations between users and non-users of GAHT while on TAF/FTC: 2700 (2208 – 3617) vs 2638 (2159 – 3213) fmol/punches, $p=0.57$, respectively. The relationship between GAHT use and TFV DBS concentrations was not significantly modified by sex assigned at birth (see Table).

	Assigned Male at Birth			Assigned Female at Birth		
	GAHT (n=19)	No GAHT (n=9)	P-value	GAHT (n=10)	No GAHT (n=2)	P-value
Median (IQR) TFV-DP DBS concentration while on TDF/FTC, fmol/punch	1653 (1320 – 2245)	1839 (1131 – 2014)	0.66	1607 (796 – 2174)	1643 (1188 – 2098*)	1.00
*range due to sample size						
Median (IQR) TFV-DP DBS concentration while on TAF/FTC, fmol/punch	3223 (2349 – 4190)	2842 (2375 – 3474)	0.56	2528 (1202 – 2836)	1246 (266 – 2226*)	0.27
*range due to sample size						

Conclusions: In this sample of TG individuals switching from TDF/FTC to TAF/FTC for PrEP, there were no significant differences in TFV-DP DBS concentrations observed between users and non-users of GAHT.

EPB0206

HIV treatment outcomes after 10 years on ART in the TREAT Asia Observational Database (TAHOD) and Australian HIV Observational Database (AHOD)

A. Jiamsakul¹, D. Rupasinghe¹, I. Woolley², J.Y. Choi³, D.J. Templeton^{1,4}, A. Widhani⁵, K. Petoumenos¹, J. Tanuma⁶, TREAT Asia HIV Observational Database (TAHOD) and the Australian HIV Observational Database (AHOD) of IeDEA Asia-Pacific

¹The Kirby Institute, UNSW Sydney, New South Wales, Australia, ²Monash Infectious Diseases, Monash Health, and Monash University, Clayton, Australia, ³Division of Infectious Diseases, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of, ⁴The University of Sydney, Department of Sexual Health Medicine, Sydney Local Health District, and Discipline of Medicine, Central Clinical School, Faculty of Medicine and Health, Sydney, Australia, ⁵Faculty of Medicine Universitas Indonesia – Dr. Cipto Mangunkusumo General Hospital, Jakarta, Indonesia, ⁶National Center for Global Health and Medicine, Tokyo, Japan

Background: An increasing number of people living with HIV (PLHIV) have been receiving antiretroviral therapy (ART) for many years. This study aimed to assess immunological and survival outcomes among PLHIV from Asia and Australia who have been on ART for at least a decade. **Methods:** PLHIV enrolled in TAHOD and AHOD, and on ART for at least 10 years, were included. Factors associated with CD4 cell counts during years 11 to 15 post ART

initiation were analysed using repeated measure linear regression. Survival after 10 years on ART was analysed using Fine and Gray competing risk regression.

Results: We included 4867 PLHIV from TAHOD and 2272 from AHOD. There were 3345 males (69%) in TAHOD, and 2110 (93%) in AHOD. The median lowest post-ART CD4 counts in the first decade was 178 cells/ μ L (IQR 92-287) for TAHOD and 250 cells/ μ L (IQR 140-374) for AHOD. Higher CD4 counts after 10 years were observed when the lowest CD4 levels were higher (101-200 cells/ μ L: difference= 35, 95%CI 18, 51; and >200 cells/ μ L: difference=125, 95%CI 107, 142) compared to CD4 \leq 50 cells/ μ L, and in those who had achieved CD4 \geq 500 cells/ μ L (achieved \geq 500 cells/ μ L then decreased to <500 cells/ μ L: difference=225, 95%CI 213, 236; and always \geq 500 cells/ μ L: difference=402, 95%CI 384, 420) compared to CD4 counts always <500 cells/ μ L in the previous decade. Prior PI-based regimen (difference=-17, 95%CI -33, -1) compared to no PI, and previous treatment interruptions (TI) of 14 days to 3 months and >6 months were associated with lower CD4 counts after 10 years (difference = -38, 95%CI -62, -15; and difference=-44, 95%CI -61, -27, respectively) compared to no TI.

Other factors associated with low CD4 counts were older age, higher viral load, hepatitis B/C co-infection, differing ART regimens, World Bank country income grouping and follow-up time. There was a total of 405 deaths (6%) after 10 years, with a mortality rate of 1.04 per 100 person-years. Controlling for confounders, females had better survival compared to males (sub-hazard ratio=0.65, 95%CI 0.46, 0.91).

Conclusions: Sustaining high CD4 levels and minimising TI have far-reaching benefits well beyond the first decade of ART.

Background: Dolutegravir (DTG) at conception was initially associated with neural tube defects (NTD) in the Botswana Tsepamo study; the association became nonsignificant with increased exposures. We conducted similar surveillance in Eswatini and describe overall birth outcomes in delivering women by HIV and antiretroviral therapy (ART) status.

Methods: We surveilled deliveries across five government hospitals serving urban and rural populations in September 2021-September 2022. Routine data on HIV/ART status and pregnancy outcomes were collected from clinic records. Women delivering live/stillborn infants with birth defects were consented for interviews capturing detailed information and birth defect photographs; a medical geneticist conducted blinded review. We used Chi-square tests for comparison of infant outcome by maternal HIV/ART status.

Results: Among 24,830 deliveries, 82.3% (6,218/7,554) of HIV-positive women received DTG-based ART: 4,832 DTG preconception, 1,025 newly initiated on DTG during pregnancy, and 361 unknown regimen at conception but on DTG at delivery; 1,328 women were on non-DTG-based ART preconception (94.0% efavirenz). Major surface birth defects were identified in 0.4% of live/stillbirths with similar rates by HIV and ART status; 19 (17.9%) major birth defects were NTDs, with no difference between HIV-negative and HIV-positive women.

Compared to HIV-negative women, HIV-positive women were more likely to have a stillbirth (2.0% vs. 2.7%, respectively, $p<0.001$) and had slightly higher rates of low birth-weight (LBW) (11.8% vs. 13.2%, $p=0.004$) and preterm delivery (PTD) (10.3% vs. 11.7%, $p=0.001$).

There were no significant differences between HIV-positive women on DTG and non-DTG at conception for NTD ($p=0.62$), stillbirth ($p=0.19$), LBW ($p=0.35$), or PTD ($p=0.65$).

Women's HIV status and conception regimen	All deliveries (live/stillbirth)	Live births	All major birth defects (all deliveries)	NTD (all deliveries)	Stillbirths (among deliveries and miscarriages*)	LBW (<2500g among live births)	PTD (<37 weeks gestation among live births)
Total	24,830	24,263	106 (0.4)	19 (0.08)	593 (2.2)	2,966 (12.2)	2606 (10.7)
HIV-negative	17,270	16,915	74 (0.4)	13 (0.08)	369 (2.0)	2,000 (11.8)	1744 (10.3)
HIV-positive	7,554	7,348	32 (0.4)	6 (0.08)	223 (2.7)	966 (13.2)	862 (11.7)
DTG-based ART at conception	4,832	4,708	20 (0.4)	4 (0.08)	132 (2.6)	599 (12.7)	536 (11.4)
Non-DTG-based ART at conception	1,328	1,283	8 (0.6)	2 (0.16)	45 (3.2)	176 (13.7)	152 (11.8)
Unknown ART at conception	367	362	0	0	5 (0.8)	49 (13.5)	38 (10.5)
New on ART during pregnancy	1,027	988	4 (0.4)	0	39 (3.8)	142 (14.4)	136 (13.8)
Unknown HIV status	6	5	0	0	1 (2.0)	0	0

*Data available for 2,109 (82.4%) of 2,559 miscarriages. Of 2,109 miscarriages, 566 mothers were HIV-positive (7.0% miscarriages in 8,121 deliveries and miscarriages) and 1,500 HIV-negative (8.0% in 18,771 deliveries and miscarriages).

Table. Rate of birth outcomes by HIV and ART status, N (%).

Conclusions: With 80% of HIV-positive women receiving DTG-based ART (most at conception), HIV-positive women had slightly higher adverse pregnancy outcomes than HIV-negative women. There was no evidence that DTG preconception had an increased rate of any adverse outcome compared to non-DTG at conception.

EPB0208

Effect on weight changes upon discontinuation of dolutegravir from antiretroviral regimens among persons with HIV who experienced weight gain

J. Yin¹, L. Hill¹, N. Patel¹, M. Horberg², C. Lahiri³, K. Althoff⁴, J. Colasanti³, J. Lake⁵, J.R. Koethe⁶, P. Rebeiro⁶, J. Gill⁷, M. Karris¹, C. Rentsch⁸, T. Brown⁴, S. Napravnik⁹, North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD) of IeDEA

¹University of California San Diego, San Diego, United States, ²Kaiser Permanente Mid-Atlantic States, Rockville, United States, ³Emory University School of Medicine, Atlanta, United States, ⁴Johns Hopkins University, Baltimore, United States, ⁵University of Texas Health Houston, Houston, United States, ⁶Vanderbilt University Medical Center, Nashville, United States, ⁷University of Calgary, Calgary, Canada, ⁸London School of Hygiene and Tropical Medicine, London, United Kingdom, ⁹University of North Carolina School of Medicine, Chapel Hill, United States

Background: Weight gain associated with dolutegravir (DTG) has been documented extensively. Among those experiencing weight gain, it is unclear if discontinuation of DTG results in weight loss.

The study objective was to describe the changes in weight while on DTG to changes in weight after discontinuing DTG.

Methods: A retrospective cohort study was performed among PWH (persons with HIV) in the North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD) between 1/2010 - 12/2020. Inclusion criteria were: age ≥ 18 years, receipt of a DTG-containing regimen for ≥ 12 months followed by removing DTG from HIV regimen for ≥ 12 months, non-missing weight measurements, and any weight gain while on DTG.

The mean weights during the pre-(-12 to -6 months)/peri-(-3 to +3 months)/post-(+6 to +12 months) discontinuation periods were used for analysis. Wilcoxon signed rank test was used to compare median weight changes in PWH between pre-/peri- DTG removal and peri-/post- DTG removal. Comparisons of weight change by concomitant agents were performed using the Mann Whitney U test.

Results: Among the 176 PWH, mean (SD) age was 48.1 (12.1) years and 70% were male. Median (IQR) weight at time of DTG discontinuation was 85.4kg (74.2 - 99.9). Change in median (IQR) weight starting 12 months before discontinuing DTG to time of discontinuation was +2.7 (+1.3 - +4.8) kilograms compared to weight change after discontinuation +0.7 (-1.1 - +3), $p<0.001$.

There were no significant differences in weight change after discontinuing DTG between recipients of elvitegravir ($p=0.26$), protease inhibitors ($p=0.80$) and non-nucleoside reverse transcriptase inhibitors ($p=0.99$) in subsequent regimen. Median (IQR) change in weight after discontinuing DTG was not different between those with/without tenofovir alafenamide in the subsequent regimen (+0.7 [-1.0 -

+3.0] vs +0.8 [-2.3 – +3.5] kilograms, $p=0.88$). Similarly, no difference in median (IQR) weight change was observed in those with/without tenofovir disoproxil fumarate in subsequent regimen (+0.6 (-2.4 – +2.9) vs +0.7 (-1.1 – +3.1), $p=0.44$).

Conclusions: Rate of weight change was significantly different before/after discontinuation of DTG. Future studies needed to elucidate the effect of contributory factors such as CD4 restoration, underlying body size, optimal time and amount of weight resolution possible.

Italy, ⁷ViiV Healthcare, London, United Kingdom, ⁸Research

Organization (KC) Ltd, London, United Kingdom

Background: COMBINE-2, a multi-centre observational study, assessed effectiveness and safety of two-drug regimens (2-DR) of an integrase inhibitor (INI) and reverse transcriptase inhibitor in real-world clinical practice in UK, Spain, France, Belgium, Italy and Portugal.

Methods: Adult people with HIV (PWH) on 2-DR from 2014 onwards, were enrolled retrospectively or prospectively after appropriate consent. Viral suppression data after 96 weeks is reported here for stable-switch population. Viral failure is defined as two consecutive HIV RNA ≥ 50 copies/mL. Kaplan-Meier (KM) method was used to estimate the maintenance of viral suppression.

Results: 735 PWH were included (75.7% male, 66.9% white); 186 (25.3%) were on dolutegravir+rilpivirine [DTG+RPV] and 534 (72.7%) on dolutegravir+lamivudine [DTG+3TC]), 15 (2.0%) other 2-DR. At week 96, 696 (94.7%) remained on 2-DR.

Among the 186 PWH on DTG+RPV, 182 (KM estimate: 97.8%) maintained viral suppression Among the 534 PWH on DTG+3TC, 527 (97.7%) were maintained suppression after 96 weeks.

Among the 454 with resistance information, 446 (98.2%) maintained suppression after 96 weeks.

39 (5.3%) individuals had 47 drug-related AEs (Incidence rate per 100 patient-years [IR:3.4 [CI:2.5 – 4.5]), weight gain was most common (8 events). There were two drug-related SAEs (anxiety & depression; low mood), no deaths.

Baseline Characteristics at 2DR initiation	Stable-switch; Suppressed on previous treatment as defined by local guidelines N=735
Age, years, median (IQR)	54 (47-59)
Gender, n (%): Male; Female; Transgender	556 (75.7); 176 (24); 2 (0.3)
Ethnicity, n (%): White; Black; Other; Unknown	492 (66.9); 140 (19); 8 (1.1); 95 (12.9)
Duration of antiretroviral treatment (years): median (IQR)	10.2 (4.7-18.8)
Plasma VL log ₁₀ (cp/ml): median (IQR)	N=725, 1.3 (1.3-1.6)
CD4 count nadir and baseline count (cells/mm ³): N, median (IQR)	N=722, 250.5 (134-365)
Resistance mutations prior to switch – n (%) [NRTI; NNTRI; PI; INI]	N=509, 684 (534-920)
	227/454 (50.0)
	[105/454 (23.1); 91/454 (20.0); 147/454 (32.4); 9/454 (2.0)]

Table 1. Baseline characteristics of 2-DR stable-switch population.

Conclusions: This analysis demonstrated low discontinuation rate and high levels of virologic control over long term, demonstrating that DTG+RPV and DTG+3TC are effective and persistent regimen among virologically suppressed individuals in real world. Virological control among those with resistance mutations continued to be high.

EPB0210

Effectiveness and safety of bictegravir/emtricitabine/tenofovir alafenamide fixed-dose combination for the treatment of people living with HIV in Argentina: first interim report of the BICTARG cohort

D.M. Cecchini¹, E. Bottaro¹, M. Brizuela¹, G. Copertari¹, B. Bacelar¹, G. Castro¹, S. Diana Menendez¹, R. Mauas¹, I. Cassetti¹

¹Helios Salud, Buenos Aires, Argentina

Background: Bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) fixed-dose combination (FDC) showed high rates of efficacy and good safety profile in clinical trials for people living with HIV (PLWH) as initial regimen (treatment naïve, TN) or switch strategy (treatment experienced, TE).

Real-world data for this FDC emerge from cohorts from high-income settings with no reports from resource-constrained settings, such as Latin America. Despite being recommended in Argentina, B/F/TAF is only available in the private health system.

Our institution is the main private HIV healthcare provider in the country with a population of almost 14000 active PLWH. We aim to describe the clinical use, effectiveness, and safety of B/F/TAF in a real-life clinical setting in Argentina.

Methods: The study design was an observational, retrospective open cohort study that examined TN and TE PLWH with a prescription of B/F/TAF from 10/2019 to 12/2021. Twenty-four and 48-week follow-up data were analyzed. Virological suppression at plasma HIV-1 RNA <200 and <50 copies/mL thresholds was assessed.

Oral
abstractsPoster
exhibition

E-posters

Late-breaker
abstractsAuthor
Index

Results: The study included 2671 PLWH: 315 TN (11.7%) and 2356 TE (88.2%). Baseline characteristics: median age (IQR) was 45 (37-53) years; 72.2% were male; 99.6% of Hispanic/Latin ethnicity. In TN group, median baseline viral load (VL, c/mL) and CD4 T-cell count (cells/mL) were: 39750 (7920-202000) and 329 (171-505); 34.9% had at least one comorbidity. For TE group, 89% had a baseline VL <50 and median CD4 T-cell count was 621 (436-843); 63.9% had comorbidities.

Predominant reasons for switch were simplification (54.8%) and toxicity prevention (24.1%). At 24-weeks, 99% and 99.7% of TN and TE continued on B/F/TAF, respectively. At 48-weeks, 99.3% and 99.5% of TN and TE were still on this therapy, respectively. Virological suppression rates (<200/<50 thresholds) for 24 and 48 weeks were 97.4/88% and 100/92% for TN; and 98.9/97% and 98.8/97% for TE, respectively.

Overall, prevalence of adverse events was <1% at 48 weeks, being the predominant weight gain. No virological failures were detected.

Conclusions: In PLWH on B/F/TAF FDC in Latin America, high levels of persistence and virological suppression were observed within one-year of follow-up. Adverse events were extremely infrequent and no cases of virological failure were documented.

EPB0211

Under-representation of women in HIV clinical trials: how can this still be happening?

M. Chirwa¹, Y. Gilleece²

¹Bedfordshire Hospitals NHS Foundation Trust, Luton and Dunstable University Hospital, Luton, United Kingdom,

²Brighton & Sussex Medical School and University Hospitals Sussex NHS Foundation Trust, HIV Medicine & Sexual Health, Brighton, United Kingdom

Background: 54% of people with HIV and 49% of new HIV diagnoses globally are women. Historically, women were significantly underrepresented in clinical trials resulting in insufficient safety and efficacy data. Barriers cited include lack of childcare, mistrust of medical systems, poor access to health care, non-compliance, and safety concerns in women of childbearing age.

Despite well evidenced physiological differences between men and women, clinical trials report outcomes as one homogenised group, meaning sex differences may be unreported and only emerge subsequently in real world data.

Here we investigate whether government strategies and third sector campaigns to include women in research have increased women's participation in clinical trials.

Description: We reviewed HIV phase 3 and 4 clinical drug trials registered, completed and with available results on ClinicalTrials.gov from 01/01/2018 to 01/01/2023 recruiting men and women. We collected data on interventions, region, eligibility criteria, participant numbers, ethnicity, and sex-related reporting.

Lessons learned: 25 Clinical trials were identified. Studies excluded were single sex (7), paediatric (1), non-drug (1) and non-HIV drug (3) trials leaving 13 studies: 7 evaluated INSTI regimens, 2 vaccines, 1 injectable ART and 2 DAAs. Studies were predominantly conducted in resource rich countries (11/13, 85%).

There were 3144 participants; 23% (735) cis women; 33% (1025) Black African/American. 12/13 (92%) trials requested exclusion of pregnant women with a requirement not to fall pregnant within the study period; 46% (6/13) further required women not to fall pregnant before and after the trials (range: 30 days prior to 6 weeks post). Median trial duration was two years. Exclusion of breastfeeding women and use of reliable contraception was required in 69% (9) and 61% (8) of trials respectively. Only one trial reported sex-disaggregated data and 4 commented on efficacy of interventions between sexes.

Conclusions/Next steps: Campaigns and policies have raised the profile of gender equality in research but not translated into proportionate representation of women in recent clinical trials. Women's participation in clinical trials remains low with persistent significant recruitment barriers and is not representative of the global HIV population.

More drastic measures including minimum proportion of women and mandatory reporting of sex-disaggregated data are urgently needed.

EPB0212

Implementation of long-acting cabotegravir and rilpivirine in vulnerable populations with complex needs: primary 48-week results of JABS

M. John^{1,2}, L. Williams¹, G. Nolan¹, M. Bonnet¹, A. Allen¹, A. Castley², D. Nolan¹

¹Royal Perth Hospital, Department of Clinical Immunology, Perth, Australia, ²PathWest, Immunology, Murdoch, Australia

Background: Long-acting cabotegravir plus rilpivirine is effective and safe HIV treatment in phase III randomised controlled clinical trials. Individuals in the wider community with risk factors for non-adherence who may benefit from this approach have been under-represented in registrational trials.

The injectable Antiretroviral feasibility Study (JABS) seeks to evaluate the effectiveness of long-acting regimens in a "real world" Australian setting, with inclusion of participants with complex medical needs and social vulnerability, including those with historical non-adherence or non-engagement who receive individualised adherence support through a multidisciplinary program (REACH) embedded within the clinical service.

Methods: JABS is a 48-week, single centre, single arm, open label study of long-acting cabotegravir 600mg plus rilpivirine 900mg maintenance therapy administered 2-monthly to adults with treated HIV-1. The primary endpoint is the proportion of attendances/delivery of injections within a seven-day dosing window over 12

months. Secondary and exploratory endpoints include proportions of missed/rescheduled appointments, use of oral bridging, discontinuations, virological failures, adverse events, multiple participant related outcomes and changes to service delivery.

Results: Sixty participants were enrolled by May 2022. Median age was 40 years (IQR 36–47); 15% (n=9) female at birth; 51% males and 89% females were born overseas. Complexity/vulnerability factors included social isolation (50%), mental health/AOD issues (30%), and financial instability (13%). Sixteen (27%) received enhanced support through REACH. Of 315 injection doses analysed to date, 97.8% injections were within prescribed windows. Seven doses given outside the dosing window were due to planned (n=4, all work-related) and unplanned (n=3) interruptions. Two oral bridging courses were required. There were 6 discontinuations, due to patient decision (n=3), CNS side-effects during oral lead-in (n=1), positive Hepatitis B serology (n=1), and drug interaction (n=1).

There were no virological failures or serious adverse events. Participant experience and service delivery outcomes are presented separately, and updated results will be presented with planned study completion in May 2023.

Conclusions: Adherence to 2 monthly intramuscular cabotegravir plus rilpivirine in an Australian clinic population is very high, including in those who access individualised adherence support. Real world efficacy and safety is comparable to phase III randomised clinical trials.

EPB0213

Effects of Atripla® and ethanol co-administration on rat caput epididymis tissues: a study on morphometry and androgen receptor immunoreactivity

T. Nyirenda^{1,2,3}, A. Abdulkadir^{3,4}, L.R. Sena³, J.V. Feliu², K.H. Erlwanger⁵, E.F. Mbajjorgu³

¹Khalifa University, Department of Anatomy and Cellular Biology, College of Medicine and Health Sciences, Abu Dhabi, United Arab Emirates, ²National University of Science and Technology, Department of Anatomy and Physiology, Bulawayo, Zimbabwe, ³University of the Witwatersrand, Division of Histology and Embryology, School of Anatomical Sciences, Johannesburg, South Africa, ⁴Federal University Birnin Kebbi, Department of Anatomy, College of Health Sciences, Kebbi State, Nigeria, ⁵University of the Witwatersrand, School of Physiology, Johannesburg, South Africa

Background: High compliance antiretroviral drug formulations have often paralleled the uptake of an alcohol drinking lifestyle among male populations of Sub-Saharan African region with limited exploration on the combinational effects to reproductive health.

Therefore, this study investigates the in-vivo effects of the single-pill antiretroviral drug Atripla® and ethanol co-administration on androgen receptor immunoreactivity (AR-ir) of rat caput epididymis tissues.

Methods: Thirty-two adult male Sprague Dawley rats were randomly assigned into four groups of eight rats each. The control group received distilled water only (vehicle), while groups ATp, E and ATpE received Atripla® only, 6% ethanol only, both Atripla® and 6% ethanol respectively.

After ninety days treatment, the rats were euthanised and epididymides were harvested for histology. Atripla® was given at a dose of 27.5 mg/Kg via flavoured gelatine cubes while ethanol and vehicle were given *ad libitum*. Measurement of connective tissue area fraction, epididymal tubular diameter, area and epithelial height were conducted. Blood samples were collected to measure serum testosterone concentrations. Quantitative analysis of principal cell nuclei AR-ir was done using Image J® software.

Results: Inflammatory infiltrates, fibrosis and increased luminal debris were observed in treatment groups sections, with alterations being mild, moderate and severe in ATp, ATpE and E group respectively. Group E had significantly reduced epididymal tubular diameter and epithelial height values ($P<0.001$), while all morphometric values for ATp and ATpE groups were comparable to group C. Weak and significantly reduced AR-ir was observed in the tissues of all treatment groups compared to the study control group ($P<0.05$, ANOVA). Group E had the least AR-ir percentage value followed by EATp and ATp respectively. Changes in testosterone levels among the treatment groups were not significant.

Conclusions: This study shows that tissue alterations caused by Atripla® and ethanol co-administration are detrimental to epididymis function. However, the mild effects of Atripla® only treatment observed signal success of single-pill therapy in the mitigation of adverse effects. The possible ameliorative interaction of Atripla® and ethanol observed warrants further investigation.

Evaluation of prevention of parent to child transmission services available for pregnant women living with HIV in Larkana District, Sindh, Pakistan

F. Mir¹, V. Simms², A.A. Nathwani¹, A. Memon¹, E. Kazmi³, J.A. Jagirani⁴, N. Zaka⁵, A. Hussain⁵, S.K. Asghar⁶, R. Malyuta⁷, D. Mbori-Ngacha⁷, S.F. Mahmood⁸, R.A. Ferrand^{9,1}

¹The Aga Khan University, Pediatrics and Child Health, Karachi, Pakistan, ²London School of Hygiene and Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom, ³Communicable Disease Control Sindh (CDC-Sindh), Department of Health, Karachi, Pakistan, ⁴Peoples Primary Healthcare Initiative (PPHI), Karachi, Pakistan, ⁵UNICEF Pakistan, Islamabad, Pakistan, ⁶UNICEF Pakistan, Karachi, Pakistan, ⁷UNICEF HQ, New York, United States, ⁸The Aga Khan University, Department of Medicine, Karachi, Pakistan, ⁹London School of Hygiene and Tropical Medicine, Clinical Research, London, United Kingdom

Background: The 2019 outbreak in children in Larkana, Pakistan revealed bridging between high risk groups and general population. Since then, there is a steady increase in new adult and paediatric HIV infections. We evaluated Prevention of Parent to Child Transmission (PPTCT) services available in Larkana District, Pakistan.

Description: We assessed 'on-site' capacity at 47 Peoples Primary Healthcare Initiative (PPHI)-run facilities providing maternal newborn and child health (MNCH) services in Larkana District using a questionnaire for facility personnel.

We also observed prospective patient flow and HIV/HBV/HCV testing trends for 1 month at two government-run PPTCT centers.

Lessons learned: Of 47 PPHI-run MNCH facilities, in Larkana district, 23 had Basic Health Unit (BHU) status, 6 BHU+ (24hour BHU services) and 18 were dispensaries[FM1] [VS2]. Most respondents were physicians (38%) or lady health visitor/midwives (40%).

Almost half had been in service for ≥ 5 years. HIV testing was offered at all clinics. PPTCT guidelines were available at 8 of 47 facilities. 31 facilities provided safe delivery and 6/16 correctly referred for safe delivery. 1 facility provided ART and 17/46 correctly referred. Formal training for HIV care and prevention had never been conducted by national or provincial program at 42/47 PPHI facilities. Only 9/31 (29%) centers providing safe delivery and 5/35 centers providing couples HIV testing and counselling (CHTC) had received training in previous two years.

At two government-run PPTCT facilities 2378 women sought antenatal care and 592 women delivered during one month. At one, 94-98% of women were offered testing for HIV, HBV and HCV, but only 7.5% were offered syphilis testing. At other, 46% of women were offered testing for HIV, HBV and HCV, and syphilis testing was similar (43%). Reasons for offering testing varied between both centers;

prior history of blood transfusion and surgery accounted for almost 100% testing decisions in one but for only 50% in other.

Conclusions/Next steps: A robust PPTCT strategy relevant to this concentrated, resource-constrained epidemic setting needs to be developed with validation of testing criteria (risk-assessment based or universal) deploying multiplex testing platforms (HIV/syphilis, HBV/HBC). Regular training and skill-building for providing comprehensive care to PWLHIV is urgently needed.

EPB0215

Evaluation of clinical outcomes of pregnant women living with HIV receiving prevention of parent to child transmission services in Larkana District Pakistan

F. Mir¹, V. Simms², A.A. Nathwani¹, A. Memon¹, P.D. Lalwani³, A. Isran⁴, S. Memon⁵, E. Kazmi⁶, N. Zaka⁷, A. Hussain⁷, S.K. Asghar⁸, R. Malyuta⁹, D. Mbori-Ngacha⁹, S.F. Mahmood¹⁰, R.A. Ferrand^{11,1}

Background: Over the past two decades, Prevention of Parent To Child Transmission (PPTCT) services for pregnant women living with HIV (PWLHIV) in Larkana District Pakistan have concentrated on women with known HIV+ status.

We evaluated clinical outcomes in women who received PPTCT interventions during pregnancy in Larkana district from program inception in 2006 till December 2021.

Methods: We conducted a retrospective review of available medical records of PWLHIV registered for PPTCT during pregnancy between 2006 till December 2021 at 2 public sector hospitals. Files of HIV-exposed infants were also reviewed.

Results: Of a total of 359 PPTCT encounters during study period, medical records were available for 237 pregnant women. Most (87.9%) were illiterate, all were housewives and none reported being a key population member. Testing data of spouses was available for 78% and 60.9% of tested spouses were HIV positive. 75.1% of women had

previous children (178/237) and 72 (40.4%) had at least one child who had died. Out of 117 women who were diagnosed with HIV from 2019 onwards, 45 (58.8%) had at least 1 child who died. Co-infections with HCV (10.7%) and HBV (3.8%) were common. A high proportion (51.5%) had anaemia (Hb<10.0gm/dl). Only 1.8% had viral load ≥ 1000 copies/ microliter at time of registration, but 83.9% had low grade viremia (50-1000 copies) with a not-zero risk of transmission.

94.5% of women registered for care within 14 days of diagnosis and 99.6% initiated ART at the registration visit. Infant prophylaxis was initiated 92.6% of HIV-exposed infants within 1 day of birth.

Of 223 HIV-exposed infant records reviewed, 43% had low birthweight (<2500g). HIV prevalence among fathers of HIV-exposed children was 57.5% (N=113 tested). HIV prevalence among siblings of HIV-exposed children was 8.8% (N=181 tested). HIV testing was completed in 67.9% of infants and among them, HIV prevalence was 7.6%.

Conclusions: A high proportion of PWLHIV with previous children had at least one child death. Maternal anaemia and co-infections (HBV and HCV) were common.

There was considerable lapse in follow-up testing of HIV-exposed infants. The HIV Care Program needs to address identified gaps in service delivery for PWLHIV urgently.

EPB0216

Participant-reported outcomes with long-acting lenacapavir-based regimens among heavily treatment-experienced people living with HIV in the CAPELLA clinical trial

M. Ramgopal¹, D. Mezzio², K. Dunn², S.-Y. Liu², X. Chen², A. Castagna³, M.S. Rhee²

¹Florida State University, Fort Pierce, United States, ²Gilead Sciences, Inc., Foster City, United States, ³Università Vita-Salute San Raffaele, Milan, Italy

Background: Heavily treatment-experienced (HTE) people living with HIV (PLWH) and multidrug resistance have limited treatment options and often experience symptoms that negatively impact their health-related quality of life (HRQoL). Novel therapeutic options that have activity against resistant HIV, are more convenient, and require less frequent administration are needed for HTE PLWH. Lenacapavir is a first-in-class capsid inhibitor that can be administered subcutaneously (SC) twice a year.

In an ongoing Phase 2/3 study (CAPELLA; NCT04150068) of HTE PLWH with failing antiretroviral regimens, lenacapavir SC added to an optimized background regimen (OBR) led to high rates of virologic suppression and was generally well tolerated.

In this analysis, we describe participant-reported outcomes (PROs) from CAPELLA through week 52 (W52).

Methods: Scores from 5 validated instruments were collected at baseline and through W52: EuroQol-5 Dimensions-5 Levels (EQ-5D-5L) index, EQ-5D-5L visual analogue scale (VAS), Short Form-36 (SF-36), HIV Symptom Index

(HIV-SI), and Numeric Pain Rating Scale (NPRS). The safety analysis set, including all participants who received ≥ 1 dose of study drug, was used for all analyses.

Results: Up to 64 of 72 enrolled participants had data available through W52. Mean EQ-5D-5L index, EQ-5D-5L VAS, SF-36 physical component, and SF-36 mental component scores were 0.87, 81, 48.5, and 48.4, respectively, at baseline and 0.83, 86, 49.9, and 48.0 at W52. Scores remained relatively consistent over time (<7% change), with values near US population norms (0.851 for EQ-5D-5L index, 80.4 for EQ-ED-5L VAS, 50.0 for SF-36). For 15 of 20 HIV-related symptoms assessed via HIV-SI, fewer participants reported bothersome symptoms at W52 than at baseline. NPRS scores at the time of injection varied by individual, with mean scores of 3.9, 5.1, and 4.4 at first (W0), second (W26), and third injection (W52).

Conclusions: These PRO results demonstrate high, stable HRQoL over time, supporting the tolerability of SC lenacapavir plus OBR. The PRO results align with the favorable safety profile and low discontinuation rates of lenacapavir previously reported from the CAPELLA trial. These data, reflecting the perspectives of people treated, highlight the potential for lenacapavir plus OBR to decrease most HIV symptoms, without compromising HRQoL, for HTE PLWH.

EPB0217

The relationship between tenofovir urine and tenofovir diphosphate dried blood spot concentrations among transgender adults switching from tenofovir disoproxil fumarate/emtricitabine to tenofovir alafenamide/emtricitabine for HIV pre-exposure prophylaxis

N. Patel¹, S. Morris², L. Burke², C. Conyngham³, K. Chow², D. Pacheco², S. Hebel³, P. Anderson⁴, J. Blumenthal²

¹University of California San Diego, Skaggs School of Pharmacy & Pharmaceutical Sciences, La Jolla, United States, ²University of California San Diego, School of Medicine, La Jolla, United States, ³UrSure Inc, Boston, United States, ⁴University of Colorado, Denver, United States

Background: Traditional methods of performing therapeutic drug monitoring (TDM) are invasive and not timely. A real-time, urine-based tenofovir (TFV) assay may overcome TDM issues and be a useful tool to measure adherence in individuals taking tenofovir-based PrEP. Among transgender (TG) persons, it is unclear if use of gender affirming hormone therapy (GAHT) among TG individuals alters the relationship between urine (u)TFV and TFV diphosphate (DP) dried blood spot (DBS) concentrations. Study objectives were to:

- Assess the correlation between uTFV and TFV-DP concentrations while taking tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) and tenofovir alafenamide (TAF)/FTC and
- Determine if use of GAHT impacts this relationship among TG persons taking PrEP.

Methods: A cohort study was performed among TG individuals enrolled in a clinical trial evaluating switching from TDF/FTC to TAF/FTC for PrEP. Inclusion criteria for this study were age ≥ 18 years old, TG identity, HIV negative (antigen/antibody test), use of both TDF/FTC and TAF/FTC for ≥ 12 weeks, and availability of stored urine and DBS samples for TFV-DP measurement while on both PrEP products. uTFV (UrSure) and TFV-DP (University of Colorado) concentrations were evaluated twice: once while on ≥ 12 weeks of TDF/FTC and once after switching to TAF/FTC for ≥ 12 weeks. The relationship between uTFV and TFV-DP concentrations was assessed using Pearson correlation coefficient.

Results: 37 individuals who met inclusion criteria. The median (interquartile range, IQR) age was 33.0 (28.5 – 39.0) years and two thirds were assigned male at birth. Seventy-three percent used GAHT. There was no significant correlation between uTFV and TFV-DP concentrations while taking TDF/FTC ($r^2=0.17$, 95% confidence interval, CI: -0.16 – 0.47, $p=0.31$). Conversely, uTFV and TFV-DP concentrations were significantly correlated when participants were taking TAF/FTC ($r^2=0.66$, 95% CI: 0.44 – 0.81, $p<0.001$). Significant correlations were observed for users and non-users of GAHT while taking TAF/FTC but not TDF/FTC (Table).

		Correlation coefficient (r^2)	95% Confidence Interval	P-value
On TDF/FTC	GAHT use	0.22	-0.17 – 0.56	0.27
	No GAHT use	-0.08	-0.67 – 0.58	0.83
On TAF/FTC	GAHT use	0.47	0.13 – 0.72	0.01
	No GAHT use	0.94	0.77 – 0.98	<0.001

Table.

Conclusions: Among TG individuals taking PrEP, uTFV measurement could be a useful adherence tool while taking TAF/FTC but not TDF/FTC, regardless of use of GAHT. This may be due, in part, to differences in saturation of renal elimination pathways.

EPB0218

Switching to dolutegravir/lamivudine (DTG/3TC) is non-inferior to continuing tenofovir alafenamide (TAF)-based regimens at Week 196: TANGO subgroup analyses

D.E. Smith¹, J.-P. Routy², S. Scholten³, J.O. Sierra⁴, M. Ait-Khaled⁵, R. Wang⁶, P. Saggu⁷, R. Moodley⁵, B. Jones⁵
¹Albion Centre, Sydney, Australia, ²McGill University Health Centre, Montreal, Canada, ³Praxis Hohenstaufenring, Cologne, Germany, ⁴Hospital Costa del Sol, Marbella, Spain, ⁵ViiV Healthcare, Brentford, United Kingdom, ⁶ViiV Healthcare, Durham, United States, ⁷GSK, Brentford, United Kingdom

Background: Switching to DTG/3TC from 3- or 4-drug TAF-based regimens showed durable high efficacy in virologically suppressed adults with HIV-1 through Week (W) 196 in the TANGO study. To further investigate DTG/3TC efficacy

in TANGO participants who switched to DTG/3TC on Day 1 and those who switched at W148, we present Snapshot virologic response by subgroup based on demographic and baseline disease characteristics and baseline third agent class.

Methods: TANGO is an open-label, multi-center, randomized, phase 3 study assessing efficacy and safety of switching to DTG/3TC vs continuing TAF-based regimens. Adults with HIV-1 RNA <50 c/mL on TAF-based regimens for >6 months without prior virologic failure or documented NRTI or INSTI resistance were eligible. Participants were stratified by baseline third agent class and randomized 1:1 to switch to DTG/3TC on Day 1 (early-switch [ES] group) or continue TAF-based regimens for 144 weeks. Participants who continued TAF-based regimens and maintained virologic suppression at W144 switched to DTG/3TC at W148 (late-switch [LS] group).

Results: At W196, TANGO included 369 ES group and 298 LS group participants treated with DTG/3TC for 196 and 48 weeks, respectively. Few ES participants (3/369 [$<1\%$]; 95% CI, 0.0%-1.7%) and 0/298 (95% CI, 0.0%-0.0%) LS participants had HIV-1 RNA ≥ 50 c/mL at W196 by Snapshot analysis (ITT-E). Overall ES group and LS group Snapshot virologic response rates were consistent with rates across their respective subgroups related to demographic characteristics, baseline disease characteristics, and baseline third agent class at W196 (Figure). Safety was consistent across subgroups within ES and LS groups. Confirmed virologic withdrawal criteria were met by 1/369 ($<1\%$) ES and no LS participants through W196, with no resistance observed.

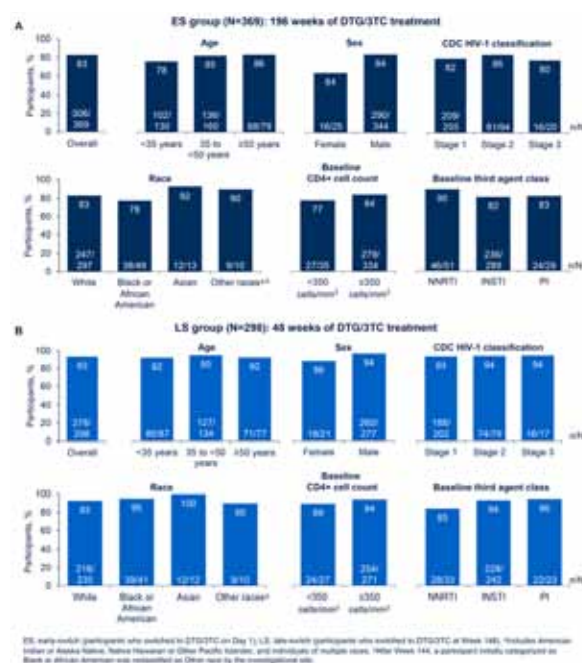

Figure. Proportion of participants in the (A) ES and (B) LS DTG/3TC groups with HIV-1 RNA <50 c/mL at week 196 overall and by subgroup (Snapshot, ITT-E).

Conclusions: These results support that switching to DTG/3TC from TAF-based regimens effectively maintains virologic suppression across different demographic and baseline characteristic subgroups at 48 and 196 weeks.

EPB0219

Islatravir (MK-8591) has no meaningful effect on the pharmacokinetics of atorvastatin and metformin following coadministration

J. McCrea¹, M. Patel¹, Y. Liu¹, A. Litovsky¹, R. Witter¹, R. Vargo¹, S.A. Stoch¹, M. Iwamoto¹, R.P. Matthews¹

¹Merck & Co., Inc., Rahway, United States

Background: Islatravir (ISL) is a deoxyadenosine analog reverse transcriptase inhibitor being studied for HIV-1 treatment. Because people living with HIV often have comorbidities such as dyslipidemia and/or type 2 diabetes mellitus, we investigated the effects of ISL coadministration on atorvastatin (ATV) and metformin (MET) pharmacokinetics (PK). Based on preclinical drug interaction data, no interaction was expected.

Methods: MK-8591-040 was a 2-period fixed-sequence, open-label, drug-drug interaction study of ISL on ATV and MET PK in healthy adult participants. In Period 1, participants were coadministered a single dose of ATV (20 mg) + MET (1000 mg). Following a 5-day minimum washout period, participants received ATV (20 mg) + MET (1000 mg) coadministered with a single oral dose of ISL (60 mg) in Period 2. Blood samples were collected up to 72 hours postdose in each period to characterize the plasma PK of ATV and MET. PK parameters assessed included area under the concentration-time curve from 0 hours to infinite time ($AUC_{0-\infty}$), maximal concentration (C_{max}), and trough concentration at 24 hours (C_{24}). Safety and tolerability were monitored throughout the study.

Results: Fourteen participants (n = 10 male, n = 4 female) aged 22-55 years were enrolled and completed the study. Atorvastatin and MET plasma PK profiles were generally similar after administration of ATV + MET with or without ISL. The geometric least-squares mean ratios (GMRs; 90% confidence interval [CI]; ATV + MET + ISL / ATV + MET) for ATV and MET PK parameters are summarized in the *Table*. Co-administration of a single oral dose of ISL with ATV + MET was generally well tolerated.

PK Parameter	ATV	MET
	ATV + MET + ISL / ATV + MET GMR (90% CI)	ATV + MET + ISL / ATV + MET GMR (90% CI)
$AUC_{0-\infty}$	1.04 (1.00, 1.10)	0.87 (0.79, 0.96)
C_{max}	0.86 (0.72, 1.04)	0.80 (0.70, 0.91)
C_{24}	1.01 (0.93, 1.10)	1.13 (1.00, 1.26)

Table. Summary Statistics of ATV and MET Plasma PK Parameters (n = 14)

Conclusions: Coadministration of ATV + MET with a single oral dose of ISL did not have a clinically meaningful effect on the PK profiles of either ATV or MET.

EPB0220

Probability of single tablet regimens BIC/FTC/TAF, E/C/F/TAF, RPV/FTC/TAF, DTG/RPV or DTG/ABC/3TC discontinuation at 18 months in real life settings in the ANRS-CO3 - AQUIVH-NA cohort

O. Leleux¹, A. Peyrouny- Mazeau¹, A. Perrier¹, M. Hessamfar², G. Le Moal³, D. Neau⁴, H. Wille⁵, C. Cazanave⁴, E. Lazaro⁶, P. Duffau², B. Castan⁷, V. Gaborieau⁸, L. Wittkop¹⁹, F. Bonnet¹²

Background: Single tablet regimens (STRs) have been associated with improved adherence to treatment for people living with HIV (PLWH) and now account for the vast majority of treatments in France. However, the probability of STRs discontinuation and virological failure (VF) in suppressed HIV RNA persons who start STRs in real life settings is unknown.

Methods: PLWH included in the French regional prospective cohort ANRS-CO3-AQUIVH-NA were included if they had a suppressed HIV RNA and CD4 count available when switching to one of the following regimens BIC/FTC/TAF, E/C/F/TAF, DTG/RPV, RPV/FTC/TAF or DTG/ABC/3TC at least once during their follow-up between 2018/01/01 and 2021/12/31.

Results: During the period, 2934 PLWH have received at least once STRs, which represent 3243 STRs different lines (299 PLWH add two or more STRs), 1182 BIC/FTC/TAF, 307 E/C/F/TAF, 413 DTG/RPV, 1147 RPV/FTC/TAF, 194 DTG/ABC/3TC regimens. Women represented 29% of PLWHA, ranging from 26% on BIC/FTC/TAF to 33.0% on DTG/ABC/3TC. Median age was 52.5 years ranging from 50.5 years on E/C/F/TAF and DTG/RPV to 55.9 years DTG/RPV; 17.9% were AIDS stage, ranging from 14.7% on RPV/FTC/TAF to 22.2% on DTG/ABC/3TC; 13.5% were sub-saharian African origin ranging from 8% on DTG/RPV to 16.2% on RPV/FTC/TAF. The median CD4 count was 702 cells/mm3 [IQR: 510-922].

At 18 months of follow-up, the cumulative probability (Aalen Johansen method) of STRs discontinuation was 19.5% overall [IQR: 18.1-21.0%], 16.9% [IQR: 13.0-21.1%] for DTG/

RPV, 17.0% [IQR: 14.8–19.3%] for RPV/FTC/TAF, 17.8% [IQR: 15.4–20.2%] for BIC/FTC/TAF, 26.3% [IQR: 21.3–31.6%] for E/C/F/TAF, and 37.9% [IQR: 30.7–45.0%] for DTG/ABC/3TC.

The main reported causes of discontinuation were side-effects (33%), physician choice (21%) non-optimal treatment (18%) and person's choice (12%).

At 18 months, 3.3% [IQR: 2.6–4.0%] of PLWH had a cumulative probability of VF on STRs (two consecutive HIV RNA >50 cp/ml or one >1000 cp/ml), ranging from 2.3% [IQR: 1.5–3.4%] on RPV/FTC/TAF and 7.7% [IQR: 3.9–13.2%] on DTG/ABC/3TC.

Conclusions: The highest risk of discontinuation at M18 was observed on the E/C/F/TAF and DTG/ABC/3TC strategies. Virus-suppressed PLWH who switched to one of the STRs maintained virologic suppression with a low risk of VF observed in 3.3% of PLWH.

Cabotegravir + rilpivirine long-acting outcomes by sex at birth, age, race, and body mass index: a subgroup analysis of the Phase 3b SOLAR study

B. Eu¹, S. Oka², J. Sims³, V. Estrada⁴, M. McKellar⁵, J. Flores⁶, A. Potthoff^{7,8}, L.A. Gordon⁹, D. Sutherland-Phillips⁹, K. Sutton⁹, C.L. Latham⁹, A. Berni¹⁰, R. Urbaityte¹⁰, R. Van Solingen-Ristea¹¹, R. D'Amico⁹, H.P. Garges⁹, K. Smith⁹, J. van Wyk¹²

¹Prahran Market Clinic, Melbourne, Australia, ²AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, Japan, ³St. Hope Foundation, Houston, United States, ⁴Hospital Clínico de San Carlos, Madrid, Spain, ⁵Duke University School of Medicine, Durham, United States, ⁶Hospital Arnau de Vilanova, Valencia, Spain, ⁷Walk In Ruhr, Center for Sexual Health and Medicine, Bochum, Germany, ⁸Ruhr-Universität Bochum, Bochum, Germany, ⁹ViiV Healthcare, Durham, United States, ¹⁰GSK, London, United Kingdom, ¹¹Janssen Research and Development, Beerse, Belgium, ¹²ViiV Healthcare, Brentford, United Kingdom

Background: Cabotegravir + rilpivirine (CAB+RPV) is a complete long-acting (LA) every 2 months (Q2M) regimen for maintaining HIV-1 virologic suppression. The Phase 3b SOLAR study demonstrated noninferior efficacy of CAB+RPV LA Q2M vs. continuing daily oral bictegravir/emtricitabine/tenofovir alafenamide (BIC/FTC/TAF) at Month (M) 12, with 90% of switch participants preferring LA therapy.

We present outcomes within key subgroups who received CAB+RPV LA.

Methods: SOLAR is a Phase 3b, randomized (2:1), open-label, multicenter, noninferiority study assessing switching virologically suppressed adults to CAB+RPV LA Q2M vs. continuing daily BIC/FTC/TAF.

Data from participants receiving CAB+RPV LA were analyzed by sex at birth, age, race, and body mass index (BMI). Endpoints assessed at M12 included the proportion with plasma HIV-1 RNA ≥50 copies/mL and <50 copies/mL

(FDA Snapshot algorithm), incidence of confirmed virologic failure (CVF; two consecutive HIV-1 RNA ≥200 copies/mL), change from baseline in CD4⁺ cell counts, and three single-item questions exploring an individual's fear of disclosure, anxiety relating to adherence requirements, and daily reminder of their HIV status (FAD questions).

Results: Overall, 447 participants received CAB+RPV LA (modified intention-to-treat exposed population); 17% were female sex at birth, 19% were aged ≥50 years, 69% were White, 21% had a BMI ≥30 kg/m². At M12, rates of virologic non-response (HIV-1 RNA ≥50 copies/mL) and suppression (HIV-1 RNA <50 copies/mL) with CAB+RPV LA ranged 0–2% and 89–92%, respectively, across subgroups. Overall, 2/447 (<1%) participants had CVF (Table).

Changes from baseline in CD4⁺ cell counts were similar between subgroups. After 12 months on CAB+RPV LA, the proportion of participants reporting "never"/"rarely" for the three single-item FAD questions increased from baseline across all subgroups.

	Overall		Sex at birth				Age (years)							
	CAB+RPV LA (n=447)	BIC/FTC/TAF (n=337)	CAB+RPV LA		BIC/FTC/TAF		CAB+RPV LA		BIC/FTC/TAF		CAB+RPV LA		BIC/FTC/TAF

A Bayesian update on discontinuation of cabotegravir and rilpivirine using cohort data

S. Noe¹, K. Morbach¹, F. Schabaz¹, A. von Krosigk¹, C. Wiese¹, K. Rücker¹, B. Mück¹, A. Huber¹, E. Wolf², C. Jonsson-Oldenbüttel¹, ArchHIV Study Group

¹MVZ München am Goetheplatz, Munich, Germany, ²MUC Research, Munich, Germany

Background: Long-actig (LA) antiretroviral therapy with cabotegravir (CAB) and rilpivirine (RPV) has become available as a routine treatment option for many people with HIV (PWH). There is ongoing concern about discontinuation of CAB/RPV LA, e.g. due to injection site reactions, and virologic failure. Available data mainly derives from the two-monthly (Q8W) arm of the ATLAS-2M trial (n=522), where many participants had been carried over from ATLAS (n=195), possibly biasing results.

We aimed to perform a Bayesian update of the available information, using cohort data from a large single HIV center.

Methods: Posterior distributions of the probability of discontinuation and virologic failure were estimated using prior information from ATLAS-2M (Q8W only) and the likelihood for both events from data of PWH initiating two-monthly CAB/RPV LA between January and December 2021 at a single large HIV outpatient clinic, MVZ München am Goetheplatz, Germany.

Results: 94 virologically suppressed treatment experienced PWH with at least one injection of CAB/RPV were included for analysis, of which 17 (18.1 %) discontinued treatment before 48 weeks. In 1 (1.1 %) discontinuation was due to virologic failure with emerging resistance. The updated probability of discontinuation within 48 weeks after initiation of CAB/RPV resulted in an estimate of 8.7% (CI95 8.0; 9.5), while it was 1.6% (CI95 1.3; 1.9) for virologic failure.

Figure 1: Density of the probability of discontinuation (left) and virologic failure (right), using a Bayesian update of clinical trial data. Red lines indicating the prior distribution of each of the two events, assuming an underlying beta-distribution, while blue lines indicating the likelihood function derived from the cohort data used for analysis. Histograms are illustrating the posterior distribution of the two events. Probabilities were re-scaled (factor 100) for better visualization.

Conclusions: The estimated probability of discontinuation of CAB/RPV LA (Q8W) was found to be about 8.7% (CI95 8.0; 9.5) when combining prior information from ATLAS-2M (6.9 % Q8W) with findings from real-life data (18.1 %). As the prior dominated the likelihood due to the higher number of participants, this estimate might be biased downwards. The updated probability of virologic failure was found to be about 1.6% (CI95 1.3; 1.9). More real-life data and tools for person selection are needed to establish the role of CAB/RPV LA.

EPB0223

Real-world utilization and effectiveness of long-acting cabotegravir+rilpivirine in the United States: Trio Cohort study

R. Elion¹, S. Sarkar², J. Radtchenko¹, A. Frick¹, G. Sridhar², J.J. Eron³, J.C. Gathe Jr.⁴, S. Santiago⁵, J. Van Wyk², V. Vannappagari²

¹Trio Health, Louisville, United States, ²ViiV Healthcare, Research Triangle Park, United States, ³University of North Carolina at Chapel Hill, Chapel Hill, United States, ⁴Dr. Joseph C. Gathe Jr., Houston, United States, ⁵Care Resource, Miami, United States

Background: Cabotegravir+Rilpivirine (CAB+RPV) is the first FDA-approved long-acting (LA) injectable antiretroviral therapy (ART) indicated for the maintenance of virologic suppression (HIV-1 RNA <50 copies/mL) among ART-experienced people with HIV (PWH). CAB+RPV LA can be administered every month or every two months. This study assessed utilization and effectiveness of CAB+RPV LA in real world settings in the US.

Methods: Adult PWH who received ≥1 documented dose of CAB+RPV injections through September 2022 were identified using electronic medical records from Trio Health HIV Network. Results were stratified by baseline viral load (VL), defined as the most recently recorded VL prior to CAB+RPV injections (VL <50 or ≥50 copies/mL).

Results: 190 PWH who received ≥1 dose of CAB+RPV are included in this analysis. Of them, 189 (99.5%) were treatment-experienced (1 with unknown treatment history); 170 (89.5%) had VL <50 copies/mL at baseline (BL-suppressed), 15 (8%) VL ≥50 copies/mL (BL-viremic), and 5 (3%) unknown VL at baseline. Median follow-up between first dose of injections to analysis date was 5.5 months (IQR: 3.1, 8.2).

BL-suppressed individuals received median 2 injections and 162 (95%) remained on CAB+RPV at time of analysis. Of 49 BL-suppressed with ≥1 VL recorded after initial injections (follow-up VL), 47 (96%) had VL <200 copies/mL and 41 (84%) had VL <50 copies/mL. Of 166 BL-suppressed with baseline BMI, 60 (36%) had BMI ≥30; 17 (28%) individuals with high BMIs had follow-up VL with 15 (88%) having follow-up VL <200 copies/mL.

Among 15 BL-viremic individuals, 7 had follow-up VL (all <200 copies/mL, 3 (43%) <50 copies/mL). Of 14 BL-viremic with baseline BMI, 6 (43%) had BMI ≥30, of them 3 (50%) had follow-up VLs, all had <200 copies/mL.

n (%) unless specified	BL-suppressed <50 copies/mL n=170	BL-viremic (≥50 copies/mL) n=15
Male Gender	116 (68)	8 (53)
White Race	76 (45)	5 (33)
Median Age (IQR)	46 (36, 55)	38 (32, 44)
Median BMI kg/m ² (IQR)	28 (25, 32)	28 (26, 32)
Recorded VL post initial dose of CAB+RPV injection	49 (29)	7 (47)
Follow-up VL <50 copies/mL	41/49 (84)	3/7 (43)
Follow-up VL <200 copies/mL	47/49 (96)	7/7 (100)

Conclusions: These early data demonstrated high levels of virologic control suggesting that CAB+RPV was effective among virologically suppressed individuals. Future analyses with longer observation intervals will allow for understanding outcomes among viremic individuals and with different dosing schedules.

EPB0224

Association of oral lead-in and persistence on cabotegravir and rilpivirine long-acting in 'real-life'

S. Noe¹, K. Morbach¹, F. Schabaz¹, C. Wiese¹, K. Rücker¹,

A. von Krosigk¹, A. Huber¹, B. Mück¹, E. Wolf²,

C. Jonsson-Oldenbüttel¹, ArchHIV Study Group

¹MVZ München am Goetheplatz, Munich, Germany, ²MUC Research, Munich, Germany

Background: Before the initiation of long-acting (LA) cabotegravir and rilpivirine (CAB/RPV), oral lead in (OLI) is an option, intending to rule out potential (systemic) side effects. The desire of people with HIV (PWH) to skip this phase is often in contrast to the wish of health care professionals to 'test' the drug in a short acting form before administering the first LA dose. This study aimed to add to the understanding of the relevance of OLI with regards to persistence on CAB/RPV.

Methods: Retrospective cohort study in PWH exposed to at least one dose of CAB/RPV orally (as OLI) and/or intramuscularly from January 2021 onwards. Persistence on CAB/RPV LA was compared between PWH, receiving at least one dose of CAB/RPV LA with or without OLI. Analysis was repeated after stratification for previous antiretroviral regimen (dolutegravir containing yes/no). Standard and modified log-rank tests (using Peto-Peto-Prentice weighing), were used to compare event-times in the overall and the early time on treatment, respectively.

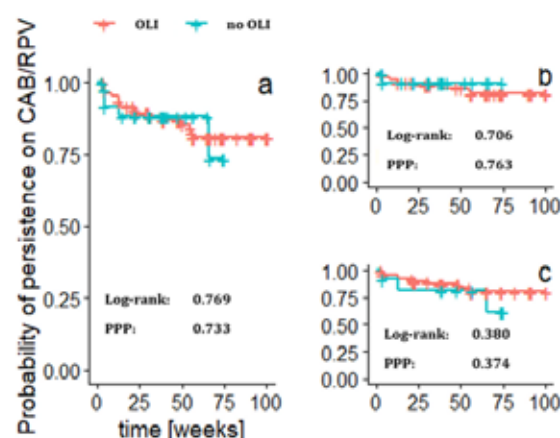

Figure 1. Survival curves for the entire study sample with exposure to at least one dose of long acting cabotegravir/rilpivirine (a), as well as for the strata of a previous dolutegravir containing (b) versus non-dolutegravir containing (c) antiretroviral therapy regimen. p-values are based on standard log-rank tests as well as using Peto-Peto-Prentice (PPP) weighing.

Results: 161 PWH were included into the analysis; 122 (75.8%) received OLI. While 8 (6.6 %) did not proceed to LA after OLI, in only one (0.8 %) a potential side effect was the reason. Times of persistence on CAB/RPV LA was not significantly different for PWH with and without OLI ($p=0.769$). Stratifying for ART prior to CAB/RPV yielded in similar results, whether the previous ART was dolutegravir containing ($p=0.706$, fig 1b) or not ($p=0.380$, fig 1c).

Conclusions: Rates of discontinuation during OLI was low and time of persistence on CAB/RPV LA was not significantly different between PWH with and without OLI. Therefore, if clinically necessary, its omission seems to be safe in general. Particularly in the subgroup of PWH without prior DTG-containing ART, the validity of our findings might be limited by low sample size.

²Baylor College of Medicine Children's Foundation Malawi, Lilongwe, Malawi

Background: Universal ART has dramatically reduced mortality for people living with HIV (PLHIV), but advanced HIV disease (AHD) amongst those newly diagnosed continues to cause unacceptably high mortality. Malawi Ministry of Health (MoH) HIV care and treatment guidance emphasizes routine advanced HIV disease screening of all newly diagnosed PLHIV to help reduce mortality. Implementation of AHD screening in Malawi has been suboptimal with low rates of screening coverage. We conducted a brief, continuous quality improvement (CQI) intervention to improve AHD screening.

Methods: Fourteen high-volume health facilities were selected for site-led targeted CQI interventions with supervision by program leadership. The CQI was implemented at targeted sites (N=7) in February 2022 with others serving as controls (N=7). Introductory lectures reviewing AHD best practices were followed by site-level planning to identify and address implementation gaps. Exemplary interventions included optimizing clinic flow, clarifying provider roles, and addressing AHD testing commodity supply chain gaps. Impact on the number of newly diagnosed PLHIV screened for AHD was assessed using deidentified program data and the difference-in-differences (DD) method implemented via Tobit regressions incorporating district random-effects and year fixed-effects.

Results: Before CQI implementation, the proportion of people newly diagnosed with HIV completing AHD screening was significantly lower in intervention versus control sites (68 vs. 92%) ($p<0.001$) (Figure 1). After CQI implementa-

tion, AHD screening coverage improved at all sites, with a greater increase at target sites with the new proportions now similar (98% vs 99%). The DD estimate or the effect attributable to the CQI was +24 percentage points (95% CI=3.06, 45.2) ($p=0.025$).

Figure 1. Effect of a quality improvement initiative on AHD screening coverage.

Conclusions: A site-led CQI intervention to address gaps in AHD screening resulted in a significant increase in coverage to near universal screening. Followup of outcomes for clients screened is ongoing. Continuous attention to CQI cycles is critical to ensure sustained AHD screening and that gaps are quickly identified and addressed.

Background: While limited, evidence of the effects of dolutegravir (DTG)-based antiretroviral therapy (ART) regimens suggests that they are associated with weight gain. This study aimed to compare weight gain and body mass

index (BMI) among patients on DTG- and non-DTG ART regimens in the Central Africa International epidemiology Databases to Evaluate AIDS cohort.

Methods: All ART-naïve adults (≥ 19 years) initiating ART between 2018 and 2020 at 21 HIV clinics in Burundi, Cameroon, Democratic Republic of Congo, Congo and Rwanda with a weight measure within 3 months of ART initiation and at 12 months (± 3 months) after ART initiation. Mean weight and BMI changes at 12 months after ART initiation, were computed. Linear regression models were used to estimate unadjusted and adjusted differences in weight and BMI associated with DTG use. Among patients with normal baseline BMI (18.5-24 kg/m²), predictors of >10% weight gain were determined using modified Poisson regression.

Results: Of 3,418 adults initiating ART, 1,116 initiated DTG regimens and 2,032 non-DTG regimens. Women comprised 61.5% of patients overall but only 49.6% of those on DTG. Mean age was 39 years among men (95%CI:38.3-39.4) and 35 years among women (95%CI: 34.9-35.9, $p<0.0001$). Mean weight at baseline was 59.1kg (95%CI: 58.3-59.8) and 60.1kg (95%CI: 59.6-60.7) among patients on DTG- and non-DTG regimens, respectively ($p=0.023$). Baseline BMI (22.5 kg/m²) did not differ by DTG use. Absolute changes in mean weight at 12 (± 3) months were +2.62kg (95%CI: 2.14-3.10) in DTG patients and +1.99kg (95%CI: 1.64-2.35) in non-DTG patients ($p=0.04$). BMI changes were +0.73kg/m² (95%CI: 0.62-0.84) and +0.97kg/m² (95%CI: 0.78-1.16), respectively ($p=0.03$). Among patients with normal baseline BMI, 18.8% had >10% increase in weight, with no difference by regimen type (α RR: 1.08; 95%CI: 0.81-1.44). Being female (α RR: 1.33 95%CI: 1.08-1.66), having advanced HIV disease (α RR: 1.82; 95%CI: 1.45-2.29) and ART initiation age ≥ 30 were associated with >10% weight gain.

Conclusions: While DTG regimens were associated with greater weight and BMI increases by 12 months, but was not associated with >10% weight increases among those with normal baseline BMI. Further research is necessary to assess longer-term DTG-associated weight gain and its clinical implications.

EPB0227

Factors associated with viral rebound among PLHIV who achieved viral suppression in Eswatini: a retrospective cohort study

E. Daniel¹, S. Dlamini¹, S. Perry¹

¹Baylor College of Medicine Children's Foundation - Eswatini, Mbabane, Eswatini

Background: In Eswatini, current understanding of the prevalence and variables related to viral rebound (VR) following viral suppression among people living with HIV (PLHIV) is limited by a lack of comprehensive research. VR can increase the risk of virologic failure and drug resistance, leading to long-term health consequences. The purpose of this study is to evaluate the factors associating to VR among PLHIV who achieved viral suppression in Eswatini.

Oral
abstracts

Poster
exhibition

Methods: This retrospective cohort study used electronic medical records from 3 clinic-based cohorts in Eswatini spanning 2005-2022. VR was characterized by a viral load ≥ 1000 copies/mL after 2 consecutive viral load tests < 1000 copies/mL (15%, n=660). Sustained viral suppression (SVS) included PLHIV who achieved viral suppression without rebound while active at the clinic (68%, n=2885).

Participants with less than 2 tests or who did not demonstrate viral suppression (12%, n=513, 5%, n=213) were excluded. Analysis used SAS Chi-square and ANOVA with a significance level of 0.05.

Results: The total cohort (n=3,545) consisted of 1352 males (41.1%) and 2193 females (58.9%) with an average age of 27.0 years. ART adherence (X2 (5) = 82.28, $p < 0.001$), current age group (X2 (7) = 260.69, $p < 0.001$), and gender (X2 (1) = 19.96, $p < 0.001$) showed significant associations with VR.

The largest proportion of VR was observed in the 18-24 yrs age group (36.8%), while the largest group of SVS was observed in those aged 36-50 yrs (31.3%). One-way ANOVA revealed a statistically significant difference in age between PLHIV who experienced VR ($\mu = 22.64$) compared to SVS ($\mu = 31.39$) (F1, 3544 = 168.04, $p < .0001$).

Nearly half (49.2%) of the VR group had 95-105% adherence in their file compared to 64.6% in the SVS group. Females were more likely to demonstrate SVS (63.6%) than males (36.4%).

Conclusions: This study highlights the importance of age, gender, and adherence as significant factors associated with viral rebound among PLHIV in Eswatini.

The results suggest that future interventions should focus on efforts that are specific to improved adherence in younger male PLHIV, to enhance viral suppression and sustain life long ART in resource limited settings such as ours.

EPB0228

Towards colorimetric readout of a rapid enzymatic assay for measuring nucleotide analogs used in ART and PrEP

C. Kwong¹, C. Rodgers¹, M. Walenta¹, S. Akerkar¹, C. Craig², A. Olanrewaju^{1,2}

¹University of Washington, Bioengineering Engineering, Seattle, United States, ²University of Washington, Mechanical Engineering, Seattle, United States

Background: Measuring adherence to ART and PrEP can help to improve HIV treatment and prevention outcomes. We developed the REVerSe TRanscriptase Chain Termination (RESTRICKT), an enzymatic assay that semi-quantitatively measures nucleotide reverse transcriptase inhibitors (NRTIs) included in most ART and PrEP regimens. RESTRICKT currently measures DNA synthesis using a fluorescent dye which increases the cost of required instrumentation and may preclude use in low- and middle-income settings. Here we evaluated colorimetric detection with leucocystal violet (LCV) dye as an alternative approach suitable for minimally instrumented readout.

Methods: For RESTRICKT assays, we incubated reverse transcriptase enzyme (RT), nucleotides, DNA templates, and primers at 37°C for 30 minutes. LCV and PicoGreen® dye were added to provide colorimetric and fluorescent output respectively. We excluded RT from negative controls to evaluate baseline signal of ssDNA.

In previous clinical validation experiments, the concentration of single-stranded DNA (ssDNA) template was limited to < 2 nM. Thus, we synthesized dsDNA from 0.56 nM of ϕ X174 bacteriophage (5386 nt long) ssDNA in RESTRICKT assays. To evaluate the LCV colorimetric readout beyond this range, we tested 57 nM of ϕ X174 bacteriophage double-stranded DNA (dsDNA) standard.

Results: Fluorescent outputs of dsDNA products synthesized by RESTRICKT were 2.5-fold greater than "no synthesis" negative controls with significant distinction between the two groups ($p = 0.0002$, Figure 1A). However, there was no absorbance distinction between dsDNA and negative controls (Figure 1B).

The ϕ X174 bacteriophage dsDNA standard – 100X more concentrated than the DNA template used in RESTRICKT – produced significantly higher absorbance levels detectable both by the naked eye and the plate reader (Figure 1B).

Figure 1.

Conclusions: DNA templates used in RESTRICKT are at inadequately low concentrations for detection by LCV. Ongoing work is focused on additional optimization and alternative colorimetric detection methods to provide rapid and minimally-instrumented colorimetric readout for the RESTRICKT assay.

High treatment continuity established among people with HIV devolved to Community Pharmacy Antiretroviral Refill Program (CPARP) in Southern Nigeria

S. Arthur¹, I. Elechi², K.-A. Ukpog², F. Agu³, E. Umana³, A. Achanya³, E. Nwanja¹, U. Akpan¹, A. Idemudia¹, O. Toyo¹, A. Adeoye¹, O. Onyedini¹, D. Ogundehin⁴, E. James⁴, A. Eyo¹

¹Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, ²Achieving Health Nigeria Initiative (AHNI), Abuja, Nigeria, ³Howard University Global Initiative Nigeria (HUGIN), Abuja, Nigeria, ⁴USAID, Abuja, Nigeria

Background: In 2018, PEPFAR through USAID supported the implementation of a community pharmacy ART refill program (CPARP), a sustainable financing initiative, leveraging private pharmacists to serve as satellite pharmacies to public hospitals and provide ARV refills to recipients of care.

Our study aims to assess continuity in treatment outcomes for multi-cohort of people living with HIV (PLHIV) devolved to CPARP in Akwa Ibom state, Nigeria.

Description: Stable clients (at least 12 months on ART, viral load <1000 copies/ml) who presented for refills were introduced to the CPARP model. Those who were willing and able to pay were given a list of community pharmacies to choose from, signed a consent form and were entered into a devolvement register. Clients paid about (N1000 [$< \$3$] per refill visit) towards human resource and administrative costs, while ARVs are provided free.

The clients were on six-monthly refills and the community pharmacies were responsible for client tracking; requesting refill medications and documentation on a monthly basis. We analysed data for clients devolved to CPARP between January 2018 to December 2021 across 20 health facilities in Akwa Ibom State, Nigeria.

We determined the 12-month retention rate - proportion of those devolved and accessing their refills through the CPARP model. We defined optimal retention based on a priori expectation of a 95% PEPFAR threshold for retention. All analyses were conducted using SPSS vs 24, with a significant p-value < 0.05.

Lessons learned: A total of 3,590 PWH [males = 1,304; Females = 2,286] were devolved to the CPARP model (2017=415, 2018=383, 2019=242, 2020=511, 2021=2,039). Median age at devolvement was 38 years (IQR: 32-45 years) and average duration on ART was 4 years (2-7 years). Overall, 12-month retention rate was 95.6% (2017=91.4%, 2018=92.0%, 2019=95.3%, 2020=96.9%, 2021= 98.3%) [Log Rank (Mantel-Cox) test = 6.5; p-value=0.17]. Of the 132 client losses, only 3 voluntarily dropped out of the program (35 died, 34 interrupted treatment, 11 stopped treatment, 52 migrated to other locations).

Conclusions/Next steps: The CPARP model is a self-sustaining model for retaining clients on treatment. ART programs that are heavily reliant on donor funding should consider these models for adoption.

EPB0230

Comparison of long-acting lenacapavir Phase 2/3 regimen vs simplified regimen using population-PK analysis and simulation

N.A. Shaik¹, F. Bellanti², K. Pollireddy², V. Jogiraju¹, C. Comisar², S. Girish¹, M. Rhee¹, R. Palaparthi¹, R. Singh¹
¹Gilead Sciences, Inc., Foster City, United States, ²Certara, Inc., Princeton, United States

Background: Lenacapavir (LEN) is approved for multidrug resistant HIV-1 in combination with other antiretrovirals for heavily treatment-experienced (HTE) individuals. In the ongoing pivotal Phase 2/3 study, participants received oral LEN loading (600mg on Days 1 and 2; 300mg on Day 8) followed by 927mg SC Q6M starting from Day 15 (Phase 2/3 regimen).

This regimen and a more convenient, simplified regimen (927mg SC Q6M and 600mg PO on Days 1 and 2) were recently approved by the USFDA, steady-state pharmacokinetic (PK) data in HTE individuals are currently not available for the simplified regimen.

Our objective was to compare simulated steady-state LEN concentrations following administration of the Phase 2/3 and simplified regimens.

Methods: A previously developed 2-compartment population-PK model with 1st-order process for oral absorption, and parallel 1st-order and transit compartments for subcutaneous absorption and linear elimination was used to simulate LEN concentrations. Simulations were performed with both the Phase 2/3 and simplified regimens, and LEN exposure metrics were compared.

External validation was conducted using observed 6-month data for the simplified regimen in healthy participants (GS-US-200-5709, Cohort 2).

Results: Simulations suggested that the simplified regimen was comparable ($\pm 14\%$) to the Phase 2/3 regimen up to Week-26 (6 months) after first SC dose (Table 1).

Exposure metrics were identical at steady-state for both regimens. Steady-state was achieved by the 2nd SC dose with 1.2-fold accumulation for both regimens. External validation indicated that the model captured the simplified regimen data adequately (Figure 1).

Parameter	Phase 2/3 Regimen			Simplified Regimen	
	Mean (%CV)	Days 1-15	Day 15-End of Month 6	Day 1-End of Month 6	Steady State
C_{max}^1 , ng/mL	69.6 (56.0)	87 (71.8)	97.2 (70.3)	104 (59.7)	97.2 (70.3)
AUC _{0-24h} ¹ , h*ng/mL	15,600 (52.9)	250,000 (66.6)	300,000 (68.5)	257,000 (65.1)	300,000 (68.5)
C_{trough}^1 , ng/mL	35.9 (56.8)	32.7 (88)	36.2 (90.6)	32.7 (88)	36.2 (90.6)

AUC_{0-24h}¹, area under curve over dosing interval; C_{max}^1 , maximal concentration; C_{trough}^1 , trough concentration.

Table 1. Simulated Exposures of LEN in HTE Using Phase 2/3 Regimen and Simplified Regimen

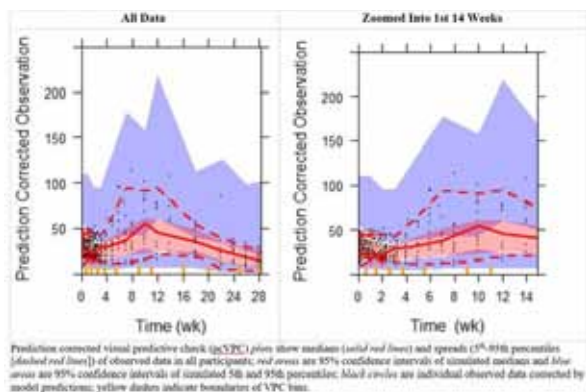

Figure 1. pcVPC of external validation of simplified posology LEN PK data from study GS-US-200-5709

Conclusions: Lenacapavir exposure metrics were comparable between Phase 2/3 and simplified regimens. These data support the use of the simplified regimen for ongoing LEN treatment and prevention studies.

EPB0231

Incidence and types of Adverse Drug Reactions to first-line antiretroviral therapy in Nigeria

A. Oyetola¹, S. Usang², P. Agada², E. Oiwoh¹, A. Blessing¹, B. Asuquo¹, D. Oqua², O. Omeh², K. Agu², U. Akpan¹, J. Umana¹, A. Idemudia³, O. Toyo¹, A. Adeoye¹, O. Onyedini¹, D. Ogundehin⁴, E. James⁴, A. Eyo¹
¹Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, ²Howard University Global Initiative Nigeria (HUGIN), Abuja, Nigeria, ³FHI 360, Abuja, Nigeria, ⁴USAID, Abuja, Nigeria

Background: Individuals react differently to medicines, and adverse drug reactions (ADR) can affect an individual's adherence to treatment.

The study aims to determine the rate, severity, types and timing of ADR among people on fixed-dose Tenofovir/Lamivudine/Dolutegravir antiretroviral regimen in Nigeria.

Description: This retrospective study involved people receiving a fixed dose of Tenofovir / Lamivudine /Dolutegravir (300mg / 300mg / 50mg) in 53 health facilities in Cross River State, Nigeria. Drug prescriptions were done in line with the national treatment guidelines.

Clients were routinely monitored and screened for ADR at every clinic encounter, and all identified ADRs were reported using a national reporting form. Data on the number, type, severity categories, dates of onset of ADR, and drug commencement were abstracted between June 2020 and August 2022.

Outcomes analyzed include ADR rate (proportion of those screened who experienced ADR), ADR severity (graded based on severity into mild, moderate, severe, and life-threatening), type (classified based on organ or system affected), and time to ADR (time between drug commencement and the onset of ADR, in days). Data were analyzed and summarized using frequencies on SPSS version 26.

Lessons learned: A total of 32,304 clients (M:10300, F:22004) were screened for ADR with a median age of 39 years [IQR 31-47] and 97.0% (n=31322) were adults. 233 clients (M:58, F:175) reported experiencing ADR (0.7% ADR rate), and 95.3% of them were adults (>15years).

ADR rate was higher in females (0.8%, 175/22004) than males (0.3%, 58/10300). The median time to ADR was 7 days [IQR 2-92 days]. There were 79 different types of ADRs (n=361) reported with 55.4% affecting the Central and Peripheral Nervous System, 14.1% with dermatologic symptoms, 12.7% with gastroenteric symptoms, 8.9% with systemic symptoms (e.g. body weakness, body pains, oedema, etc) and 8.9% with other organ affectations. 60.9% of ADRs were mild, 32.6% moderate, 6% severe and 0.4% life-threatening.

Conclusions/Next steps: ADRs are rare among clients receiving fixed-dose Tenofovir/Lamivudine/Dolutegravir and are usually life-threatening when it occurs. Active screening and close monitoring, especially within 92 days of commencing treatment are important in ensuring optimal treatment outcomes for clients.

EPB0232

Prevalence and predictors of persistent low-level HIV viraemia among people receiving Dolutegravir-based antiretroviral therapy in Southern Nigeria

O. Onwah¹, E. Nwanja¹, U. Akpan¹, A. Idemudia², O. Toyo¹, A. Adeoye¹, O. Onyedini¹, D. Ogundehin³, E. James³, A. Eyo¹
¹Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, ²FHI 360, Abuja, Nigeria, ³USAID, Abuja, Nigeria

Background: Persistent low-level viraemia (pLLV) is a risk factor for virologic failure among people on antiretroviral therapy (ART). With the scale-up of Dolutegravir (DTG)-based regimen, this paper assesses the prevalence and predictors of persistent low-level viraemia among clients receiving DTG-based regimen in Nigeria.

Methods: This retrospective cohort study used routine program data from electronic medical records for persons receiving DTG-based regimen in 155 health facilities supported by PERFAR through USAID in Akwa Ibom and Cross Rivers States, Nigeria. Persons with low-level viraemia (LLV), i.e. plasma viral load (VL) between 51 and 999 copies/ml, received additional adherence support from trained case managers.

Demographic (age, sex) and clinical (duration on ART, viral suppression status, and service delivery models) data were extracted and reviewed. Clients on ART ≥6 months, with baseline viral load in September 2021, and two subsequent viral load results were included in the study.

The outcome analyzed was pLLV defined as two consecutive LLV results within the 12 months period. Descriptive statistics were used to summarize indices and multivariate logistic regression analysis was used to determine the predictors of pLLV using STATA ver.14 with significance set at .05.

Oral abstracts

Poster exhibition

Author Index

Results: The study included 140,587 PLHIV, 63.6% (n=89,434) being females, a median age of 37 years [31-45 years], and a median ART duration of 2 years [2-4 years]. The majority [n=125,619; 89.4%] were on differentiated service delivery models. The prevalence of LLV at the initial measure was 10.4% (n=14,665/140,587).

However, at repeat measure, the occurrence of persistent LLV was 0.6% (n=844/140,587). The majority of PLHIV with initial LLV [n = 13,002/14,665] attained undetectable VL level (≤ 50 copies/ml), and only 173/14,665 transitioned to Virologic Failure (VL ≥ 1000 copies/ml).

In multivariate analysis, increasing ART duration [coef. = 0.05; 95%CI: 0.03 – 0.07; $p < 0.001$] and being on no differentiated service delivery models [coef. = 0.38; 95%CI: 0.19 – 0.57; $p < 0.001$] had positive association with pLLV. However, there was no association between client age and pLLV occurrence.

Conclusions: pLLV was associated with longer ART duration and non-differentiation of ART services. This finding strengthens recommendations for frequent viral load monitoring and the benefits of intensive adherence support for clients with LLV.

EPB0233

Therapeutic monitoring of long-acting injectable rilpivirine using a rapid enzymatic assay

C. Brainerd¹, C. Craig², L. Tukei¹, M. Vuong¹, A. Olanrewaju^{1,2}

¹University of Washington, Bioengineering, Seattle, United States, ²University of Washington, Mechanical Engineering, Seattle, United States

Background: Long-acting injectable (LAI) antiretroviral (ARV) drugs can alleviate gaps in HIV treatment caused by insufficient daily pill adherence. Despite this advantage, significant inter-individual pharmacokinetic variability in phase 3 trials suggests a need for therapeutic monitoring. Objective ARV measurement typically performed using Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS) is arduous and expensive. Our group recently developed the REVerSe TRanscriptase Chain Termination (RESTRIC) enzymatic assay for rapid and inexpensive measurement of oral ARVs. RESTRIC measures reverse transcriptase (RT) inhibitors based on their inhibition of DNA synthesis.

Here we demonstrate that RESTRIC can measure clinically relevant concentrations of LAI-rilpivirine used in HIV treatment.

Methods: We performed RESTRIC assays by incubating DNA templates, primers, nucleotides, and RT enzyme at 37°C for 30 min. We added PicoGreen® fluorescent dye to detect double-stranded DNA and measured inhibition of DNA synthesis at rilpivirine drug concentrations ranging from 10^{-6} M to 10^{-8} M since the alert threshold from the French Agency for Research on AIDS and Viral Hepatitis is 32 ng/mL (8.73×10^{-8} M). We normalized data using “no enzyme” controls and “no drug” controls.

Results: No DNA synthesis occurred in the “no enzyme” controls while no DNA inhibition occurred in the “no drug” controls. We observed distinguishable inhibition across rilpivirine concentrations (Fig.1) with a $26.0 \pm 4.6\%$ decrease from the “no drug” controls for 10^{-8} M ($p = 0.022$), $53.7 \pm 6.8\%$ decrease for 10^{-7} M ($p = 0.0015$) and an $84.7 \pm 5.8\%$ decrease for 10^{-6} M ($p = 0.0002$).

Therefore, we can distinguish between a “no drug” control and rilpivirine concentrations above and below the clinically relevant alert threshold (8.73×10^{-8} M).

Conclusions: The RESTRIC assay optimized for LAI-rilpivirine can distinguish clinically relevant concentrations in a dose-dependent manner. Rapid and accessible therapeutic monitoring would allow clinicians to evaluate inter-individual pharmacokinetic variability of LAI concentrations to improve HIV treatment outcomes.

Sustained viral load suppression among people living with HIV on Dolutegravir-based regimen in Southern Nigeria

S. Usang¹, A. Babatunde Oyetola², P. Agada¹, M. Ihemeje², B. Asuquo², D. Oqua¹, K. Agu¹, O. Omeh¹, J. Umana², K. Odey², E. Nwanja², U. Akpan², A. Idemudia³, O. Toyo², A. Adeboye², O. Onyedini², D. Ogundehin⁴, E. James⁴, A. Eyo²

¹Howard University Global Initiative Nigeria (HUGIN), Abuja, Nigeria, ²Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, ³FHI 360, Abuja, Nigeria, ⁴USAID, Abuja, Nigeria

Background: Prior to the introduction of newer antiretroviral regimens viral suppression among individuals on antiretroviral therapy was suboptimal. In 2018, the transition to a newer Dolutegravir (DTG)-based regimen commenced for individuals on ART in Nigeria.

This study assesses long-term viral load outcomes of persons living with HIV (PLHIV) who transition to DTG-based regimen.

Description: This retrospective cohort study used routine program data from an electronic database of PLHIV (>15 years) receiving ART across 155 health facilities; with the

support of PEPFAR through USAID in Akwa Ibom and Cross River State, Nigeria. Data for PLHIV who weighed above 30kg, were on first-line regimen, transitioned to DTG-based regimen as of June 2020, and had a viral load test done at transitioning and two (2) subsequent viral load tests at least 12-months apart, were abstracted.

Outcomes analyzed include - Sustained viral suppression (i.e. three consecutive VL result <1000copies/ml), sustained viral unsuppression (i.e. three consecutive VL result ≥1000copies/ml), and viral rebound (i.e. any unsuppressed VL ≥1000copies/ml after an initial viral suppression) as of June 2022. Frequencies were used to summarize indices.

Lessons learned: A total of 40,980 [Female = 28,295; Male = 12,685] persons >15years were transitioned as of June 2020 with median age of 37 years [IQR 30-45years]. Viral suppression was 86.8% at baseline (35,568/40,980), and 98.5% at 24months post-transitioning. 84.2% of persons had sustained viral suppression throughout the monitoring period, while 2.5% experienced viral rebound and 0.3% sustained viral unsuppression (Figure 1).

Figure 1: Long-term viral load outcomes in a large ART cohort in Nigeria, June 2020-June 2022. (n=40,980)

Conclusions/Next steps: Majority of clients transitioned to DTG-based regimen attained sustained viral suppression. However, there is a need to set-up adherence system to support PLHIV on DTG-based regimen because viral rebound and sustained viral unsuppression also occur.

Background: Previous studies in adult and pediatric populations with HIV have indicated that antiretrovirals have different effects on weight and metabolic parameters. Tenofovir alafenamide (TAF) has a neutral effect on weight gain; however, its impact on weight has not been assessed in children aged <6 years. We explored the effect of switching to a TAF-based regimen on weight, height and lipid metabolism in virologically suppressed young children with HIV (aged ≥2 years).

Methods: This analysis included virologically suppressed children aged ≥2 years weighing 14 to <25 kg from two ongoing, open-label studies; participants received bictegravir/emtricitabine/TAF (B/F/TAF; NCT02881320) or elvitegravir/cobicistat/F/TAF (E/C/F/TAF; NCT01854775) for ≥48 weeks.

We evaluated demographics and changes in weight, height, body mass index (BMI) and lipid metabolism parameters.

Parameter, median (IQR)	Baseline [†] (n=49)	Change from baseline at Week 48 (n=49)
Weight Z-score	-0.56 (-1.52, -0.05)	0.26 (0.00, 0.51)
Height Z-score	-0.29 (-1.42, 0.19)	0.06 (-0.26, 0.37)
BMI Z-score	-0.68 (-1.53, 0.07)	0.31 (-0.32, 0.85)
BMI-for-age percentile	24.9 (6.3, 52.9)	4.1 (-4.8, 17.3)

Generated based on the year 2000 growth charts from the US Centers for Disease Control and Prevention website. [†]Includes all participants who received ≥1 dose of study drug; [†]Baseline value was the last available value collected on or prior to first dose of study drug

IQR, interquartile range

Table 2. Lipid metabolism parameters at baseline, change from baseline at Week 48 and lipid metabolism categories by visit (safety analysis set*; total population)

Results: The total population included 49 participants (B/F/TAF: n=22; E/C/F/TAF: n=27). Median (interquartile range) age was 6 (4, 7) years, 42.9% were male and 81.6% were Black. At Week 48, weight, height, and BMI Z-scores along with BMI-for-age percentile increased from baseline (Table 1).

Conclusions: At Week 48, the proportion of participants who were underweight decreased and the proportion who were normal weight increased; the proportion of participants who were overweight or obese remained stable. Overall, lipid metabolism parameters improved during 48 weeks of treatment. These changes are consistent with normal child development during this time-frame and support the use of TAF in this population.

EPB0236

Longitudinal lymphocyte dynamics in virologically suppressed children with HIV initiating single-tablet elvitegravir, cobicistat, emtricitabine and tenofovir alafenamide (E/C/F/TAF)

Background: Lymphocyte counts fluctuate in young children, and several antiretroviral therapies have been associated with hematologic effects. We assessed lymphocyte dynamics in virologically suppressed children with HIV (age 2–<12 years) receiving elvitegravir, cobicistat, emtricitabine and tenofovir alafenamide (E/C/F/TAF) for 48 weeks.

Methods: This analysis included virologically suppressed children with HIV from Cohorts 2 and 3 (C2 and C3) of a Phase 2/3 open-label study (NCT01854775). Children in C2 (age 6–<12 years, weight ≥ 25 kg) and C3 (≥ 2 years, 14–<25 kg) received once-daily E/C/F/TAF for ≥ 48 weeks. Lymphocyte populations were analyzed by flow cytometry of whole blood, using anti-CD3, CD4, CD8, CD16, CD19 and CD56 panel of antibodies.

Results: Overall, 79 participants were enrolled. In C2 (n=52) and C3 (n=27), respectively, median (interquartile range [IQR]) age was 10 (9, 11) and 6 (4, 8) years, 42% and 37% were male, and 71% and 89% were Black. Median (IQR) absolute lymphocyte counts ($\times 10^3/\mu\text{L}$) at baseline in C2 and C3 were 2.31 (1.92, 2.78) and 2.96 (2.39, 3.82), respectively; these decreased during treatment (particularly in C3), with changes of -0.04 (-0.67, 0.29) and -0.52 (-1.16, -0.05) at Week 48. There were also small decreases in median (IQR) absolute CD4 T-cell counts (cells/ μL), with changes of -33 (-194, 80) and -187 (-370, 44) in C2 and C3, respectively, at Week 48. However, the relative proportion of CD4 T cells and the CD4/CD8 ratio remained stable during treatment. Changes in CD8 T-cell, B-cell and natural killer cell counts are shown in the Table.

Conclusions: Minor fluctuations in absolute lymphocyte subpopulation counts were observed over 48 weeks of E/C/F/TAF. The decline in absolute CD4 T-cell counts mirrors known physiological fluctuations in young children, mainly observed in those aged <6 years. No clinically relevant effects of E/C/F/TAF on lymphocytes were identified in this population.

EPB0237

Viral suppression and retention in care of clients on multi-month dispensing

B. Kisunte¹, T. Roche¹, R. Mwanjili¹, J. Gwimile¹, A. Kayabu², E. Ketang'enyi¹, L. Mwita³

¹Baylor College of Medicine Children's Foundation Tanzania, Clinical, Mwanza, Tanzania, United Republic of, ²Baylor College of Medicine Children's Foundation Tanzania, Monitoring and Evaluation, Mwanza, Tanzania, United Republic of, ³Baylor College of Medicine Children's Foundation Tanzania, Executive Director, Mwanza, Tanzania, United Republic of

Background: Multi-month dispensing (MMD) of Antiretroviral (ARV) strategy reduces monthly medication refill visits to either three- or six-months intervals depending on eligibility criteria. It minimizes barriers for clients and health-system levels, simultaneously improving health outcomes for clients. Baylor Mwanza COE adopted 3MMD strategy in August 2018.

This study aims to assess viral suppression and retention for children and adolescents living with HIV registered on 3MMD between August 2018 and June 2021.

Methods: Review of clinical charts of children and adolescents aged 5-19 years old registered on 3MMD was conducted between August 2018 and June 2021. Viral load (VL) results before 3MMD strategy and current VL within 12 months were recorded.

Moreover, data on type of caregiver, ARV regimen, home address, age, continuity in care and reasons for dropping out of 3MMD were recorded.

Results: Out of 210 clients on 3MMD, 116 (55.2 %) were females and 181 (86.2%) aged between 10-19 years old. Most clients, 198 (94%), were on Dolutegravir-based while 12 (6%) on Protease Inhibitors-based regimen. More than half, 129 (61%) of clients are cared for by mothers, 12 (6%) by fathers, and 69 (33%) had other guardians as primary caregivers.

Almost half of clients, 103 (49%), live within 10 kilometres(km) from COE; 89 (42%) within 11-30km, 12(6%) within 31-100km and only 6 (3%) more than 100km. On commencing 3MMD, 207 (99%) clients had VL below 50 copies/mL and 3 (1%) had VL of 55 copies/ml.

On assessment, majority of clients 197 (94%) maintained VL below 50 copies/mL and remained on 3MMD while 13 (6%) clients with an average age of 15 years old and on Dolutegravir-based regimen had VL above 50 copies/mL and exited 3MMD.

Out of 13 clients, 7(54%) were excluded in the first and 6(46%) in second year of 3MMD. Among them, 9 (69%) are cared for by mothers and 11 (85%) lived near COE.

Conclusions: Majority of clients on 3MMD were able to maintain viral suppression and retained in care despite minimal follow-up and living far away; further studies with larger cohort will give better description of pediatric MMD and inform stakeholders on this strategy.

Burden and associated factors of depression and anxiety among young Thai men who have sex with men at risk for and living with HIV

S. Pangprasertkul¹, O. Mueangmo^{1,2}, J. Saheng^{1,2}, W. Wongjak², T. Chaito², A. Oun-arom³, N. Manojai⁴, T. Sudjaritruk^{1,2}

¹Division of Infectious Diseases, Department of Pediatrics, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, ²Clinical and Molecular Epidemiology of Emerging and Re-emerging Infectious Diseases Research Cluster, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, ³Chiang Mai University, Department of Psychiatry, Faculty of Medicine, Chiang Mai, Thailand, ⁴Mplus Foundation, Chiang Mai, Thailand

Background: We aimed to assess prevalence and associated factors of depression and anxiety among Thai young men who have sex with men (YMSM) at risk for and living with HIV.

Methods: A cross-sectional study was conducted among YMSM (18-25 yrs) who were at risk for or living with HIV, and attended HIV clinic at a community clinic or tertiary hospital in Chiang Mai, Thailand. Patient Health Questionnaire 9-item (PHQ-9) and Generalized Anxiety Disorder 7-item scales (GAD-7) were used to screen for depression and anxiety, whereas post-traumatic stress disorder (PTSD) Checklist-Civilian Version (PCL-C) and Multidimensional Scale of Perceived Social Support (MSPSS) were performed to screen for PTSD and social support (low-to-medium support: score 1.0-5.0; high support: score 5.1-7.0), respectively.

Logistic regression analysis was conducted to identify factors associated with significant depressive symptoms (PHQ-9≥10 of 27) and anxiety symptoms (GAD-7≥10 of 21) among these populations.

Results: We enrolled 100 YMSM at risk for HIV (median age: 20 yrs) and 50 YMSM living with HIV (median age: 22 yrs). Among at-risk YMSM, 28% had moderate-to-high self-evaluated risk of HIV infection, and 24% were on pre-exposure prophylaxis.

Of YMSM living with HIV, all were clinically stable on cART, and 78% had viral load <20 copies/mL. The prevalence of significant depressive symptoms were 27% (95%CI: 19-37%) and 32% (95%CI: 20-47%) ($P=0.81$), and significant anxiety symptoms were 15% (95%CI: 9-24%) and 16% (95%CI: 7-29%) ($P=0.97$) for YMSM at risk for and living with HIV, respectively.

In multivariable logistic regressions, having significant anxiety symptoms (adjusted odds ratio[aOR]: 1.6; 95%CI: 1.2-2.2), and low-to-medium social support (aOR: 7.3; 95%CI: 1.1-50.4) were associated with significant depressive symptoms for at-risk YMSM, whereas higher PCL-C scores (aOR: 1.3; 95%CI: 1.1-1.6, per one score increased) was an associated factor for YMSM living with HIV.

Regarding significant anxiety symptoms, having significant depressive symptoms was the only associated factor for at-risk YMSM (aOR: 1.7; 95%CI: 1.2-2.4), and this factor showed a trend toward statistical significance for YMSM living with HIV (aOR: 1.6; 95%CI: 0.9-2.7).

Conclusions: Significant depressive and anxiety symptoms were prevalent among our Thai YMSM, both at risk for and living with HIV. An integrated mental health services are critically needed for these populations.

Outcomes of children living with HIV transitioned to Dolutegravir based antiretroviral therapy regimens in Midlands and Manicaland Provinces of Zimbabwe, 2022

M. Dhodho¹, E. Tachiwenyika¹, T. Samushonga¹, T.P. Sibanda¹, N. Ganje¹, M. Muzondo¹, A. Muchedzi¹, T. Tafuma¹, J. Muguse¹, B. Chindove¹, A. Mushavi², P. Andifasi², T. Apollo², C. Gwanzura², C. Mupanguri², M. Muchekeza², T. Nyagura³, M. Mhangara³, T. Tapera³, T. Nyamundaya¹

¹Zimbabwe Health Interventions, Harare, Zimbabwe,

²Ministry of Health and Child Care, Harare, Zimbabwe,

³USAID-Zimbabwe, Harare, Zimbabwe

Background: Dolutegravir (DTG) is an anti-retroviral medicine proven to significantly reduce viral load (VL) among people living with HIV (PLHIV). Zimbabwe Health Interventions (ZHI) is supporting government to roll out DTG based regimens in children living with HIV (CLHIV) on anti-retroviral therapy (ART). Transition to DTG based regimens for children with weight below 20kgs was started in June 2021. There is paucity of data in Zimbabwe on VL suppression rates and clinical outcomes of CLHIV transitioned to DTG based regimens. We assessed outcomes of CLHIV before and after DTG transition in Manicaland and Midlands provinces between June and July 2022.

Methods: We conducted an analytic cross-sectional study focusing on client outcomes before and after DTG transition across 34 sites with at least 1000 ART clients. The study focused on client status before and after transition to a DTG regimen. All children on ART in these facilities were included. Client clinical charts were reviewed, and data were abstracted and captured into Kobo Toolbox. Data were analyzed using Stata 15 and study was covered by the Medical Research of Zimbabwe approved protocol (MRCZ/E/159).

Results: Data for 1,003 children were collected and 811 (80.9%) were initiated on a non-DTG based ART regimen when they started ART. Of the 811 children, 635 (72.3%)

were transitioned to a DTG based containing regimen. Of the 220 children who had a documented viral load below 1000 before DTG transition, 216 (98.1%) of them had a viral load remaining below 1000 and four had a viral load above 1000. Of the 56 children who had a viral load above 1000, 85% (48) had suppressed after transition to DTG based regimen and 8 remained unsuppressed.

Children who remained on a non-DTG containing regimen were 8 times more likely to have unsuppressed VL compared to those who switched to DTG (RR 7.86, 95% CI 2.4-25.2).

Conclusions: A significant proportion of children were transitioned to a DTG containing regimen and had better VL suppression compared to those on a non DTG regimen. We recommend transitioning all children to a DTG regimen to improve virological outcomes in children.

EPB0240

"I did not want them seeing me": Factors influencing antiretroviral treatment adherence during the adolescent period of young people with perinatal HIV in Thailand: a qualitative study

L. Aurpibul¹, A. Tangmunkongvorakul¹, C. Detsakunathiwachara¹, A. Srita¹, S. Masurin¹, P. Meeart¹, W. Chueakong¹

¹Chiang Mai University, Research Institute for Health Sciences, Chiang Mai, Thailand

Background: The varying rates of antiretroviral treatment adherence between 19-99% in adolescents living with HIV were reported globally. Young people with perinatal HIV (YPHIV) who survived and grew up into adulthood experienced adherence challenges that led to unsustainable but resumable virologic suppression. We explored factors influencing treatment adherence during adolescent years from real-life experiences of YPHIV.

Methods: A qualitative study was conducted from June to November 2022 in Chiang Mai, Thailand. Twenty YPHIV (8 females and 12 males, aged 21-29 years) were invited to share their adolescent experiences through in-depth interviews. Audio transcripts were analyzed using content analysis to identify the barriers and facilitators influencing treatment adherence.

Results: The study divided barriers and facilitators to treatment adherence in their adolescent period into the personal, community, and healthcare system levels. At the personal level, barriers to treatment adherence included hanging out with friends, sticking in the middle of work or entertainment, uncertain working hours, belief in their strength/ invincibility, unfavorable personal life situations, mental health difficulties, pill burden, and unbearable side effects of medications.

The facilitators were perceiving their health deterioration and revisiting opportunistic infections during virologic failure, being afraid of hospitalization and medical procedure-related suffering, and the wish to be healthy and move on.

At the family, friends, and community level, the most common barrier reported was fears of HIV disclosure when taking medications. While the facilitators included perceiving family support, the desire to prevent mother-to-child transmission, perceiving their own responsibility for kids, and determination to complete family without HIV transmission.

At the healthcare system level, extra medical care payment and transportation costs to the clinic were identified as barriers to adherence. The unfavorable service behaviors of healthcare providers were described as a part of their HIV care experiences which could be considered barriers or facilitators in different circumstances.

Conclusions: The main factors influencing adolescents' treatment adherence concentrate on various personal factors and fears of HIV disclosure. Understanding those existing factors would enable mindful health service delivery.

Our study supported the need to allocate more time for tailored individual counseling to maximize their adherence self-efficacy during the transitional period of young people's life.

HIV Rapid testing as a screening test for HIV-Exposed children on the OPPTIM Study in South Africa

L. Fairlie¹, S. Sawry¹, S. Pals², G. Sherman^{3,4}, D. Williamson², J. Le Roux¹, B. Ngeno⁵, L. Berrie⁶, K. Diallo⁶, M. Hurlston Cox², M. Mogashoa⁶, M. Chersich¹, S. Modi²

¹Wits RHI, University of the Witwatersrand, Johannesburg, South Africa, ²Division of Global HIV & Tuberculosis (DGHT), Centers for Disease Control and Prevention (CDC), Atlanta, Georgia, United States, ³Paediatric HIV Surveillance in the Centre for HIV and STI, National Institute for Communicable Diseases, Division of the National Health Laboratory Service, Johannesburg, South Africa, ⁴University of the Witwatersrand, Department of Paediatrics & Child Health, Faculty of Health Sciences, Johannesburg, South Africa, ⁵Merck Pharmaceutical Company, Atlanta, Georgia, United States, ⁶Division of Global HIV and TB (DGHT), CDC, Pretoria, South Africa

Background: HIV rapid testing (HRT) in children <18 months may reduce the number of polymerase chain reaction (PCR) tests required, if limited to children screening HRT positive. Persistence of maternal HIV antibodies in children beyond 18-months limits use of HRT for diagnosis. We describe sero-reversion at various time points in HIV-exposed, uninfected children.

Methods: Mother-child pairs were enrolled in the OPPTIM study at the child's 6, 10, or 14-week clinic visit between July 2018 and April 2019. At enrolment, 6-, 9-, 12-, 18-, 21- and 24 months, children were tested using three HRTs (Trinity Biotech Uni-Gold™, INSTI® and Abbott Determine™) and had a POC EID (Cepheid GeneXpert) test conducted using whole blood, by trained study staff.

Abbott Architect™ HIV ELISA assays were performed at 18-, 21-, and 24-months. HRT seropositivity is presented at each visit per test. Interrater agreement between tests was calculated using the Kappa (κ) statistic.

Results: In the study, 404 children were enrolled, 143 (35.4%), 201 (49.8%) and 60 (14.9%) at 6, 10 and 14 weeks, respectively. 216 (53.5%) male, 234 (57.9%) exclusively breast-feeding, 149 (36.9%) exclusively formula feeding, and the remainder mixed feeding. The Determine test remained positive in 50% of children at 12-months.

For the INSTI and Uni-Gold tests, only 23% and 28% (respectively) remained positive at 6-months and <7% by 9-months. None of the children tested PCR positive at any time point. Agreement between the INSTI and Uni-Gold HRTs was 93.7% (κ=0.84, p<0.001), across all time periods.

At 18-months, 3/24 children who tested positive on any HRT, were HIV ELISA positive; 18/21 HIV ELISA positives were HRT negative (κ=0.04, p<0.247). At 21- and 24-months, all HIV ELISA assays were negative among 8 HRT-positive children while 19 were HIV ELISA positive but HRT negative (κ=-0.04, p<0.681 and κ=-0.03, p<0.683, respectively). Attrition was high, only 59% in study at 18-months, 34% at 21-months, and 56% at 24-months.

Conclusions: Delayed seroreversion for HRT beyond 18 months is minimal using HRT, but HRT and HIV ELISA may result in false positive diagnoses and an HIV PCR should be conducted to confirm the diagnosis and avoid unnecessary treatment.

Adherence to antiretroviral therapy (ART), drug resistance, and their impact on evolving viral suppression among a long-term cohort of youth living with perinatal HIV infection in western Kenya

R. Vreeman¹, W. Nyandiko^{2,3}, A. DeLong⁴, A. Chory¹, M. Scanlon⁵, J. Aluoch³, A. Ngeresa³, V. Novitsky⁴, F. Sang³, C. Ashimosi³, S. Ayaya^{2,3}, E. Jephkemboi³, M. Orido³, J. Hogan⁴, R. Kantor⁴

¹Icahn School of Medicine at Mount Sinai, Arnhold Institute for Global Health, New York, United States, ²Moi University College of Health Sciences, Eldoret, Kenya, ³Academic Model Providing Access to Health Care (AMPATH), Eldoret, Kenya, ⁴Brown University, Providence, United States, ⁵Indiana University Center for Global Health, Indianapolis, United States

Background: In African settings, youth living with HIV (YLWH) rarely have comprehensive antiretroviral therapy (ART) adherence monitoring or drug resistance (DR) testing. We longitudinally assessed ART adherence and its impact on viral outcomes among Kenyan YLWH.

Methods: YLWH ≤15 years on NNRTI-based 1st line ART were enrolled at the Academic Model Providing Access To Healthcare (AMPATH) in western Kenya. Adherence was monitored prospectively by caregiver-reported questionnaires, electronic dose monitors (MEMS) and NNRTI plasma drug levels at months 1 (M1) and 4 (M4), defined as:

1. Number of missed/late doses,
2. % MEMS openings,
3. MEMS interruptions ³48 hours,
4. Duration of maximum interruption, and;
5. Low/therapeutic/high plasma NNRTI levels.

DR was evaluated upon treatment failure (TF; viral load (VL) >1,000 copies/mL). TF was modeled with logistic regression (odds ratio (OR) and 95% confidence interval (CI) for each adherence measure, adjusted for age, CD4%, ART duration and sex). DR mutations (DRMs) were modeled with Poisson regression (rate ratio (RR) and CI). Interaction terms were examined if adherence effect on M4 TF differed by M1 TF status.

Results: At enrollment, 692 participants (51% female; median age 8.4 years) had median 2.6 years on ART. All were on nevirapine/efavirenz-based regimens, most combined with abacavir/lamivudine. Of 464 with M1 VLs, 143 (31%) had TF. Among those with M1 TF, 43% had TF at M4. Lower percent MEMS adherence was associated with TF (OR=0.69 per 1 unit z-score higher MEMS adherence, 95% CI=0.50-0.95), as was more enrollment non-adherence (OR=1.25 per 1 higher non-adherence, 95% CI=1.05-1.48). DRMs were detected in 93% of the 120/143 available M1 genotypes. The M1 DRM number was greater for those with shorter maximum treatment interruptions (log-10 transformed (RR)=0.63, CI=0.42-0.94), more ART years (Log-10 transformed RR=1.47, CI=1.15-1.89), and higher M1 log-10 VL (RR=1.21, CI=1.06-1.37).

Percent adherence by MEMS[®] had a significant, U-shaped relationship, with most DRMs at lower (<50%) adherence. Having therapeutic (RR=2.11, CI=1.45-3.08) or supra-therapeutic (RR=1.58, CI=1.11-2.27) vs. sub-therapeutic drug levels was associated with more DRMs.

Conclusions: Extensive non-adherence, associated with high TF and DR were seen in Kenyan youth with HIV, outcomes assumed - but seldom documented in this setting.

EPB0243

Underlying causes of death in children living with HIV in Tanzania

T.J. Masenge¹, F. Haraka², B. Benedicto³, F. Bigirwamungu⁴, L.A. Faux During⁵, M. Maro⁶, M.P. Mungo⁷, J. Mkumbo⁸, R. Van de Ven⁹, S.J. Kimambo¹⁰

Background: Children living with HIV account for 4% of the global HIV burden but 15% of AIDS-related deaths. The Elizabeth Glaser Pediatric AIDS Foundation (EGPAF) established routine Pediatric mortality reviews to understand the underlying causes of deaths among children receiving antiretroviral therapy (ART) in Tanzania; a facility-level expert team reviews each death case and determines underlying causes of death. For home deaths a verbal autopsy is conducted. The aim of this study is to determine the commonest underlying causes of death in children on ART.

Methods: A longitudinal analysis of secondary data was conducted, using the national HIV database from 437 health care facilities across five EGPAF-supported regions in Tanzania. We included children aged 0-14 years who were in care by September 2021 and were followed through September 2022.

We defined underlying causes of death as recorded diagnoses in the database. More than one cause of death could be present for a child.

Results: A total of 6,019 children were in care by September 2021, and 845 were newly diagnosed during the study period, making a study population of 6,864 children. Overall, 3,501(51%) were female, and the majority 3,295 (48%) were 10-14 years of age. There were 102 deaths (1.5%) in children during this period among them 54 (53%) were female. A total of 53 (52%) occurred among those newly diagnosed. Most deaths (68%) were among children age <5 years. The most common underlying causes of death were severe acute malnutrition (43%), tuberculosis (27%)

and pneumonia (11%). Severe acute malnutrition was the most common cause of death in both children who were on antiretroviral therapy (ART) for >12 months (53%) and <12 months (34%). Other causes of death were Septicaemia (10%), Diarrhoea (9%) accidents (7%), meningitis (2%) and unknown (8%).

Conclusions: Severe acute malnutrition was the most common underlying cause of death among children on ART. Pediatric HIV programs should consider nutritional intervention packages to prevent and treat malnutrition in children living with HIV.

EPB0244

Viral suppression in the era of transition to Dolutegravir-based therapy in Cameroon: children at high risk of virological failure

A.D. Nka¹, J. Fokam², F.Y. Mamgue Dzukam³, J. Gabisa Efakika⁴, Y. Bouba⁵, M.C. Tommo Tchouaket², A.C. Ka'e², E. Ngoufack Jagni Semengue², S. Moudourou², N. Fainguem², S.C. Billong⁶, A.-C. Zoung-Kanyi Bissek⁷, V. Colizzi², C.-F. Perno⁸, S.M. Sosso², A. Ndjolo²

¹Chantal Biya International Reference Centre for Research on HIV/AIDS Prevention and Management (CIRCB), Virology, Yaounde, Cameroon, ²Chantal Biya International Reference Centre for Research on HIV/AIDS Prevention and Management (CIRCB), Yaounde, Cameroon, ³University of Buea, Yaounde, Cameroon, ⁴Centre Pasteur Cameroun, Yaounde, Cameroon, ⁵Central Technical Group, National AIDS Control Committee, Yaounde, Cameroon, ⁶National HIV Drug Resistance Working Group, Yaounde, Cameroon, ⁷Division of Health Operational Research, Ministry of Public Health, Yaounde, Cameroon, ⁸Bambino Gesù Pediatric Hospital, Rome, Italy

Background: Transition to Dolutegravir (DTG)-based antiretroviral therapy (ART) may improve virological response (VR) in sub-Saharan Africa. Because VR may vary by age, understanding ART response across age-range may inform interventions on ART program.

Our objective was to compare VR between children, adolescents and adults in the Cameroonian context.

Methods: A comparative study was conducted from January 2021 to May 2022 amongst ART-experienced patients received at the Chantal BIYA International Reference Centre for HIV/AIDS prevention and management in Yaounde-Cameroon for plasma viral load (PVL) monitoring. PVL was measured on Abbott m2000RT-PCR as per manufacturer's instructions.

VR was defined as viral suppression (VL< 1000 copies/mL) and viral undetectability (VL< 50 copies/mL). Data were analyzed by SPSS v.20.0, with p< 0.05 considered as significant.

Results: A total of 9034 patients, 72.8% female, were enrolled (8565 adults, 227 adolescents, 222 children); 1618 were on NNRTI-based, 299 on PI-based, and 7118 on DTG based ART (82 children, 198 adolescents, 6824 adults). Median (IQR) duration on ART was 24 (12-72) months.

Overall, VS was 89.9% (95% CI: 89.2-90.5) and viral undetectability was 75.8% (95% CI 74.8-76.7). Following ART-regimen, VS on NNRTI-based, PI/r-based, and DTG-based therapy was respectively 86.5%, 60.2% and 91.8%, p<0.0001. Following ART-duration, VS was respectively 90.4% (M12), 87.8% (M24), 89.1% (M36), and 90.0% (≥ M48), p<0.0001. Following gender, VS was 91.0% (females) versus 87.1% (males), p<0.0001. Following age, VS was 65.2% (children), 74.4% (adolescents), and 90.9% (adults), p<0.0001.

Following multivariate analysis, predictors of VS were adults, females, TLD regimens, and cART duration >24 months (p<0.05).

Conclusions: In Cameroon, ART response indicates encouraging rates of VS (about 9/10) and viral undetectability (about 3/4), driven essentially by access to TLD-based regimens in the adult populations. However, ART response was very poor in children, underscoring the need for scaling-up pediatric DTG-based regimens.

EPB0245

A decade of care: long term outcomes of a paediatric HIV cohort

B. Kasimonje¹, T. Shamu^{1,2,3}, T. Mudzviti^{1,4}, L. Chirumuta¹, C. Chimbetete¹, M. Pascoe¹, R. Luethy¹

¹Newlands Clinic, Harare, Zimbabwe, ²University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, ³University of Bern, Graduate School of Health Sciences, Bern, Switzerland, ⁴University of Zimbabwe, Department of Pharmacy and Pharmaceutical Sciences, Harare, Zimbabwe

Background: Data on long-term outcomes of children receiving antiretroviral therapy (ART) in sub-Saharan Africa are sparse. We describe 10-year outcomes of children commenced on ART.

Methods: We conducted a retrospective cohort study at Newlands Clinic, Zimbabwe. All children living with HIV aged <18 years at ART commencement until 31 December 2010 were included.

Sociodemographic and clinical data were abstracted from the clinic's electronic database. Descriptive statistics were used to explain study variables.

Results: We analysed records for 1028 young people, 534 (52%) females with a median age of nine years (IQR 5 – 13) at ART initiation. The median time to ART initiation was 74 days (IQR 37-177).

At baseline, 519 (50.5%) were either single or double orphans, 563 (55.4%) were diagnosed with WHO clinical stage 3 or 4, and 638 (62.1%) had anaemia. The majority were initiated on stavudine, or zidovudine combined with lamivudine and nevirapine (907, 88.3%).

At the time of analysis, 673 (65.5%) were still in care, 142 (13.8%) had died, 69 (6.7%) were lost to follow up, and 144 (14.0%) had transferred out. The median duration on ART was 12 years (IQR 8.8-13.7). Amongst those in care, 585 (86.9%) had HIV virologic suppression (<50 copies/mL) while 42 (6.2%) had a viral load >1000 copies/mL. During

follow up, 321 (31.2%) had at least one diagnosis of tuberculosis, the second most common opportunistic infection (OI) was recurrent pneumonia (198, 19%). Virologic suppression rates increased over time, see Figure 1.

Figure. Proportion of patients with virologic suppression over time.

Conclusions: We show high rates of retention and virological suppression. Comprehensive care in a sub-Saharan African cohort of young people with advanced HIV disease and a high prevalence of OIs can result in good long-term outcomes. Further research is needed in evaluating HIV service delivery and differentiated care for YPLHIV.

Spanish cohort of HIV mother-infant pairs: current epidemiology and perinatal transmission (2020-2022)

A. Berzosa^{1,2}, M. Illán^{1,2}, S. Jimenez^{3,2}, A. Diaz^{4,2}, I. Jarrin⁴, M.D. Sanchez⁵, I. Romero⁶, M.J. Fernandez⁷, A. Gonzalez⁸, A. Maruenda⁹, A. Abdelkader¹⁰, A. Tagarro¹¹, E. Marquez¹², E. Garrote¹³, B. Carazo¹⁴, R. Polo¹⁵, M.L. Navarro^{3,2}, J.T. Ramos^{1,2}, Spanish Cohort of HIV Mother-infant Pairs
¹Hospital Clínico San Carlos, Madrid, Spain, ²CIBERINFEC, Madrid, Spain, ³Hospital Gregorio Marañón, Madrid, Spain, ⁴Centro Nacional de Epidemiología, Instituto de Salud Carlos III, Madrid, Spain, ⁵Hospital Virgen de la Salud, Toledo, Spain, ⁶Hospitales HM, Madrid, Spain, ⁷Hospital Clínico, Santiago de Compostela, Spain, ⁸Hospital del Henares, Coslada, Spain, ⁹Hospital Comarcal, Vinaros, Spain, ¹⁰Hospital Comarcal, Melilla, Spain, ¹¹Hospital Infanta Sofía, San Sebastian de Los Reyes, Spain, ¹²Hospital San Pedro de Alcantara, Cáceres, Spain, ¹³Hospital Basurto, Bilbao, Spain, ¹⁴Hospital Regional, Málaga, Spain, ¹⁵Ministerio de Sanidad, Madrid, Spain

Background: HIV perinatal transmission rate has decreased in our setting to around 1%. Aims: to describe the current situation of pregnant women living with HIV (WLHIV) and their newborns and to assess HIV perinatal transmission in Spain.

Methods: WLHIV deliveries included in the Spanish Cohort of pregnant WLHIV and their children during 2020-2022 were analyzed.

Results: There were 344 WLHIV pregnancies registered in 61 public-hospitals in Spain: median age 32.8 years (IQR:28.7-37.5), 32.5% Spanish, 27.5% African, 22.8% Latin-America.

Overall, 73.7% women acquired HIV by sexual transmission and 20% by perinatal transmission. Most women (79.3%) were HIV-diagnosed before current pregnancy, 19.5% during pregnancy, 0.3% at delivery. The rates of WLHIV living with HBV and HCV were 7.8% and 4.9%. Gestational control was appropriate in 89.7% of pregnancies.

Overall, 98.3% WLHIV received ART during pregnancy, 89% achieved undetectable viral load (VL) at delivery. Delivery route was vaginal in 60.3%, 26.3% were elective Caesarean-sections and 13.1% urgent Caesarian-sections.

There were 354 newborns (10 twin pregnancies) identified: 53.2% male, 11% preterm-newborn (2.8% < 32 weeks of pregnancy) and 8.5% with low-birth-weight. 85.6% of the newborns received monotherapy prophylaxis with zidovudine and 9.8% triple therapy.

Only one child did not receive ART prophylaxis, and two received breastfeeding few days after birth, without perinatal HIV transmission. There were no HBV or HCV transmission. Three cases of intrauterine transmission were detected (0.85%; 95% CI 0.3-2%), with positive PCR at 48 hours of life.

Two mothers (from Spain and Guinea) were diagnosed at 35 and 36 weeks of gestation and received TDF/FTC/RAL, with detectable VL (18849 and 273 cp/ml) at delivery (elective Caesarean-section at week 38). The third woman was HIV-diagnosed at week 26, starting treatment with TDF/FTC/EFV but with poor adherence.

Despite elective Caesarean-section at week 38, with a VL of 95000 cp/ml at delivery, and triple ART postexposure prophylaxis the child acquired HIV.

Conclusions: Most WLHIV are immigrants, diagnosed before pregnancy and have good control of HIV during pregnancy in Spain. Even with the low current rate of HIV perinatal transmission (0.85%), there is a need to ensure that WLHIV have access to effective preventive measures to completely eliminate neonatal transmission.

Uptake and outcomes of tenofovir alafenamide fumarate (TAF) –based therapy in children and young people living with HIV (CLWHIV) in the European Pregnancy and Paediatric Infections Cohort Collaboration (EPPICC)

S. Crichton¹, E. Chappell¹, K. Doerholt², M. Navarro³, A. Noguera-Julian⁴, V. Spoulou⁵, C. Teixeira⁶, A. Judd¹, I.J. Collins¹, European Pregnancy and Paediatric Infections Cohort Collaboration

¹University College London, MRC Clinical Trials Unit, London, United Kingdom, ²St George's University Hospitals, London, United Kingdom, ³Hospital General Universitario „Gregorio Marañón“, CIBERINFEC ISCIII, Madrid, Spain, ⁴Sant Joan de Déu Hospital Research Foundation, Barcelona, Spain, ⁵“Agia Sofia” Children's Hospital, 1st Dept of Paediatrics, Athens, Greece, ⁶Centro Hospitalar e Universitário do Porto, Porto, Portugal

Background: TAF was originally approved in Europe for CLWHIV aged ≥6 years in 2016, initially as part of fixed-dose combinations (some approvals were extended to age ≥2 years in 2022). Data are limited on TAF uptake and outcomes in this population.

Methods: CLWHIV aged <18 years at HIV diagnosis and followed in 11 cohorts across Europe were included. Uptake of TAF, characteristics at TAF start and viral suppression (VS) (viral load (VL)<50c/ml) at 6, 12 and 18-months on TAF were described by treatment and VL status at TAF start.

Results: Of 3318 in follow-up since 2016, 670 (20%) ever received TAF; 56% were female; 95% perinatally acquired HIV or were aged <10 years at entry to HIV care; 36% from the UK, 26% Spain, 24% Italy, 15% elsewhere in Europe; median age at ART initiation was 3.5[IQR 0.6,8.8] years. At TAF start 11% were aged 5-11, 24% 12-17, 27% 18-23 and 20% ≥24 years. Half (48%) were on an INSTI-based regimen, 31% PI, 13% NNRTI, 7% other/multiple classes; 66% previously used TDF. Twenty-one (3%) were treatment naïve and 649 (97%) treatment-experienced, of whom 51% had VL<50, 24% were viremic (VL≥50) and 25% had unknown VL at TAF start. Those treatment-experienced and viremic, and those naïve, had the lowest CD4 counts (Table). Median duration on TAF was 1.2[0.6,2.0] years. At 6, 12 and 18-months on TAF, overall VS was >80% but was lower in those treatment-experienced and viremic at TAF start.

(Median [IQR])	Naïve, n=21	Treatment experienced, VL<50, n=330	Treatment experienced, VL≥50, n=157	Treatment experienced, VL unknown, n=162
Age (years)	14.8 [14.2,16.4]	17.1 [13.8,22.1]	17.7 [15.0,22.0]	20.1 [14.6,22.8]
CD4 count (n=19,273,147,47)	373 [211,660]	720 [575,951]	482 [299,670]	644 [468,898]
Log viral load (n=18,157)	4.2 [3.5,5.1]		3.4 [2.5,4.3]	

Table: Characteristics at start of TAF by treatment status and viral load

Figure. Viral suppression <50c/mL at 6, 12 and 18m on TAF by treatment status and viral load at TAF start.

Conclusions: CLWHIV who were virally suppressed at TAF start maintained good levels of suppression over follow-up, and two-thirds of those who were treatment-experienced and viremic at TAF start achieved viral suppression. Longer-term follow-up data are needed, particularly in younger children.

EPB0248

Young adults who acquired HIV perinatally have poorer viral suppression than those who acquired HIV later in life: a population survey in Zimbabwe

V. Simms^{1,2}, C. Dziva Chikwari^{1,2}, E. Dauya², T. Bandason², K. Kranzer^{3,2}, R.A. Ferrand^{3,2}, CHIEDZA trial team

¹London School of Hygiene & Tropical Medicine, MRC International Statistics and Epidemiology Group, London, United Kingdom, ²The Health Research Unit Zimbabwe (THRU ZIM), Harare, Zimbabwe, ³London School of Hygiene & Tropical Medicine, Clinical Research Department, London, United Kingdom

Background: Young adults (aged 18-24 years) in Zimbabwe may have acquired HIV perinatally or horizontally. Perinatally acquired HIV is often diagnosed late and may lead to worse health outcomes compared to later acquisition.

We aimed to compare the demographic and clinical characteristics of young people who were diagnosed with HIV in childhood and adulthood, as a proxy for route of HIV acquisition (perinatal vs horizontal).

Methods: A cross-sectional representative population-based survey of young people aged 18-24 years was conducted in 3 provinces in Zimbabwe. Participants were asked their HIV status, the date of their HIV diagnosis if positive, and whether they had been diagnosed as a child. A dried blood spot was taken to measure HIV viral load. Multilevel mixed-effects generalized linear modelling was used to estimate the association between HIV acquisition time and viral non-suppression, defined as ≥1000 copies/ml.

Results: 17,682 participants (60.8% female) were enrolled of whom 12,003 (67.9%) knew their HIV status; 435 (3.6%) reported being HIV positive and 90.0% were taking ART. All but 6 reported their age at diagnosis: 196/429 (45.7%)

were diagnosed as children (median age of diagnosis 7 years (IQR 1-12)) and median diagnosis age in the remaining 233 participants was 21 years (IQR 19-24). 54/429 (12.6%) of those with HIV were underweight (BMI z-score <-2) with no difference by acquisition route.

A higher proportion of adult-diagnosed than child-diagnosed participants were female (91.4% vs 76.5%), had ever had sex (93.6% vs 61.5%), ever been married (60.1% vs 19.4%) and ever been pregnant (77.5% of women vs 39.3%). Over half (53.9%) of participants diagnosed in childhood had viral non-suppression compared to 39.2% of those diagnosed as adults. After adjusting for sex, age, marital status and education, those diagnosed as children had higher odds of viral non-suppression (adjusted odds ratio=1.85, 95%CI 1.13-3.02, p=0.014).

Conclusions: Young adults who acquired HIV perinatally are at greater risk of viral non-suppression compared to their peers who acquired HIV in adulthood. Extending into adulthood, those with perinatally acquired HIV continue to have additional needs and worse outcomes.

EPB0249

Early ART and mental health outcomes by school-age and adolescent years of life: a longitudinal comparative study of HIV-exposed and community control adolescents from Uganda

A. Coventry¹, A. Sikorskii², S. Zalwango³, I. Familiar-Lopez², V. Cardino⁴, B. Giordani⁵, A. Ezeamama²

¹University of Washington, Seattle, United States, ²Michigan State University, Psychiatry, Okemos, United States,

³Kampala Capital City Authority, Kampala, Uganda,

⁴Michigan State University, Food Science & Nutrition, East Lansing, United States, ⁵University of Michigan, Ann Arbor, United States

Background: The relevance of anti-retroviral therapy (ART) exposures in the gestational period and early childhood for mental health outcomes in late childhood and adolescence is unclear. Hence, we examine the hypothesis that *In-utero*/peripartum antiretroviral (IPA) exposure type is associated with mental health symptoms at 8 – 18 years old among 577 children perinatally HIV-infected (CPHIV), HIV exposed uninfected (CHEU) and HIV unexposed and uninfected (CHUU).

Methods: Per medical records, IPA exposure was categorized separately for CHEU and CPHIV as no IPA, single-dose nevirapine with/without zidovudine (sdNVP±AZT), sdNVP+AZT+Lamivudine (3TC), or combination ART (cART). Self-reported anxiety and depressive symptoms were evaluated at intake, 6- and 12- months follow-up with Behavioral Assessment System for Children .

Multivariable linear regression models estimated differences (b) with 95% confidence intervals (95% CI) for various IPA exposure-types vs. CHEU without IPA exposure.

Results: Depressive and anxiety symptoms were lower in CHUU relative to CHEU/CPHIV whereas both symptoms were similar for CPHIV vs. CHEU. Relative to CHEU with-

out IPA exposure, CHEU with sdNVP±AZT exposure had elevated anxiety (b =0.51, 95%CI:[0.06, 0.96]) and depressive symptoms (b =0.48, 95%CI:[0.07, 0.89]).

Likewise, CHEU with sdNVP+AZT+3TC exposure had higher anxiety (b=0.45, 95%CI: [0.03, 0.86]) and depressive symptoms (b =0.72, 95% CI: [0.27, 1.17]) vs. CHEU without IPA exposure. Depressive/anxiety symptoms were similar for CHEU/CPHIV exposed to peripartum cART (b =0.12 to 0.60, 95% CI: [-0.41, 1.30]) and for CHUU (b =-0.04 to 0.08, 95% CI: [-0.24, 0.29]) vs. CHEU without IPA exposure.

Conclusions: Among CHEU, peripartum sdNVP±AZT and sdNVP+AZT+3TC exposure predicted clinically important elevations in anxiety and depressive symptoms at 8 – 18 years old. We found no evidence that cART exposure was associated with mental health symptoms at 8 – 18 years old.

These results underscore the importance of monitoring mental health trajectory of HIV-affected children to identify vulnerable children and inform mental health interventions, if warranted.

EPB0250

Efficacy and safety of dolutegravir/lamivudine (DTG/3TC) in antiretroviral therapy (ART)-naïve adolescents living with HIV-1: DANCE study Week 96 results

T. Puthanakit¹, L. Aupibul², M. Lopez³, C. Vavro³, G. Bontempo⁴, K. Morarji⁵, M. Ciuffa⁵, T. Chakraborty⁶, A. Buchanan³, L. Tan⁷

Durham, United States, ⁴ViiV Healthcare, Branford, United

States, ⁵GSK, Brentford, United Kingdom, ⁶GSK, Bangalore,

India, ⁷ViiV Healthcare, Brentford, United Kingdom

Background: DTG/3TC is an effective, well-tolerated initial ART regimen globally recommended for adults with HIV-1, but data are scarce for equivalent use in adolescents. We present efficacy and safety of DTG/3TC in ART-naïve adolescents with HIV-1 through Week (W) 96.

Methods: DANCE is an ongoing phase 3b, single-arm, multi-center, open-label study evaluating once-daily, fixed-dose combination DTG/3TC (50 mg/300 mg) as initial ART for adolescents aged ≥12 to <18 years and weighing ≥25 kg, with HIV-1 RNA 1000 to ≤500,000 c/mL. The previously reported primary endpoint assessed proportions achieving HIV-1 RNA <50 c/mL (Snapshot, ITT-E) at W48. Secondary endpoints assessed proportions with HIV-1 RNA <50 c/mL (Snapshot, ITT-E), safety, and tolerability at W96. Participants meeting confirmed virologic withdrawal (CVW) criteria (consecutive HIV-1 RNA measurements ≥200 c/mL) underwent viral resistance testing.

Results: Of 32 enrolled participants, 66% were male, 59% were Asian, and 41% were Black; median age was 17 years. At W96, 22/32 (69%; 95% CI, 50%-84%) participants had HIV-1 RNA <50 c/mL (Snapshot, ITT-E). W96 virology data

were absent for 7 participants due to GCP-related site closure and imputed as treatment failures (Snapshot, ITT-E). In W96 sensitivity analyses excluding data from these 7 participants, 22/25 (88%; 95% CI, 69%-97%) achieved HIV-1 RNA <50 c/mL. Median (Q1-Q3) CD4+ cell count increased from baseline (371.5 [270.0-507.5] cells/mm³) to W96 (682.0 [499.0-863.0] cells/mm³). One participant had CVW at W72; no findings of treatment-emergent mutations were observed through W96.

Overall, 29/32 (91%) participants experienced AEs through W96, with 27/32 (84%) participants having a maximum grade 1 or 2 AE. AEs leading to withdrawal were grade 2 depression and suicidal ideation (n=1) and grade 3 glomerular filtration rate decrease (the only drug-related AE; n=1). Four SAEs were reported in 3/32 (9%) participants (anal abscess, orchitis, and post-operative complication after vulvovaginal wart removal in participant with vulvovaginal warts SAE); none were drug-related.

Conclusions: DTG/3TC was well-tolerated, demonstrated high efficacy, and had a high barrier to resistance in ART-naïve adolescents with HIV-1 through W96.

These results and well-established data in adults support DTG/3TC as a first-line ART treatment option in adolescents to achieve and maintain virologic suppression.

EPB0251

Improved viral load suppression with transition to pediatric dolutegravir among ART-experienced children in Kenya and Cote d'Ivoire

R. Masaba¹, J. Kose^{2,3}, M. Kouadio⁴, S. Siamba¹, M. Ouma¹, J. Akuno², M. Mukaminega⁵, M. Gill⁶, A. Tiam⁵

¹Elizabeth Glaser Pediatric AIDS Foundation, Research, Nairobi, Kenya, ²Elizabeth Glaser Pediatric AIDS Foundation, Program, Nairobi, Kenya, ³ErasmusMC, Department of Viroscience, Rotterdam University, Rotterdam, Netherlands, ⁴Elizabeth Glaser Pediatric AIDS Foundation, Research, Abidjan, Cote D'Ivoire, ⁵Elizabeth Glaser Pediatric AIDS Foundation, Program, Washington D.C., United States, ⁶Elizabeth Glaser Pediatric AIDS Foundation, Research, Washington D.C., United States

Background: Access to safer and more efficacious and tolerable antiretroviral therapy (ART) is recommended for children and adolescents living with HIV (CALHIV). We evaluated viral load (VL) suppression at baseline and subsequent VL outcomes in a cohort of ART-experienced children who transitioned to dolutegravir (DTG)-based ART in Kenya and Cote d'Ivoire (CDI).

Methods: This was an observational prospective cohort study of ART-experienced CALHIV who transitioned to DTG-based regimens. CALHIV 0-14 years, weighing 3-20 kilograms, were enrolled in 12 randomly selected facilities in CDI and Kenya, November 2021-May 2022 and followed for 12 months. Study facilities were randomly selected using probability proportional to size. Demographic data were collected, and VL testing were completed at baseline, 6 and 12 months.

The national guidelines on use of antiretroviral drugs for treating and preventing HIV recommend VL monitoring at baseline, 6 and 12 months for CALHIV who are optimized on DTG-based regimen. Data were summarized using frequencies and proportions, as well as median and interquartile ranges.

Results: Overall, 676 CALHIV initiated pediatric DTG with a median age of 9 (IQR: 6-12) years were enrolled into the study. A total of 355 (52.5%) were female, and 639 (83.3%) were living with biological parents. About three quarters (73.2%, 494/676) of the CALHIV were on a protease inhibitor-based regimen prior to DTG initiation. Median duration on ART regimen prior to DTG transition was 59 (IQR: 32, 84) months. Baseline VL uptake was 494/676 (83.3%). The uptake dropped to, 50% at 6 months and 74% at 12 months.

Compared to a VL suppression of 80.6% [95% Confidence Interval (CI): 77.4%, 83.9%] at baseline, overall suppression was 87.7% [95% CI: 83.6%, 91.7%] at 6 months (p=0.013), and 89.6% [95% CI: 85.8%, 93.5%] at 12 months (p=0.002) post-DTG transition. There was no statistically significant difference in the viral load suppression at 6 and 12 months post-DTG transition (p=0.486).

Conclusions: While there remain challenges with viral load uptake and testing at time of transition to optimized regimen and follow up for CALHIV, there is improved VL suppression with DTG transition.

EPB0252

Improved virologic suppression in children living with HIV under the age of 5 in Tanzania after the initiation of a viremia clinic and pediatric dolutegravir

K.P. McKenzie^{1,2,3}, M. Mnkondya¹, B. Mayalla¹, L. Kombi¹

¹Baylor College of Medicine Children's Foundation - Tanzania, Mbeya, Tanzania, United Republic of, ²Baylor College of Medicine, Houston, United States, ³Baylor International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Houston, United States

Background: Children living with HIV (CLHIV) below the age of 5 years (<5) often have worse treatment outcomes and lower rates of virologic suppression (VS) than older children. Some pediatric centers have utilized resources to address possible barriers to VS including socioeconomic factors, stigma, poor peer or parental support, medication tolerability, etc.

Methods: Data was extracted from December 2021 to November 2022 to investigate the outcomes of an interdepartmental Viremia Clinic started in February 2022 to improve clinic VS. The study included active clients at the Baylor College of Medicine Children's Foundation - Tanzania clinic in Mbeya who had their viral load (VL) measured within the previous 12 months and had been on antiretroviral therapy (ART) for ≥6 months. Per national guidelines, the first-line ART regimen for children <20kg was abacavir-lamivudine-lopinavir/ritonavir (ABC-3TC-

LPV/r) and dolutegravir (DTG) 50mg could be used if ≥ 20 kg. Due to drug stock-outs, only LPV/r granules were available for most of the study period. Widespread use of pediatric DTG (dispersible tabs) began around August 2022.

Results: VS in <5 was 80.9%(18/94) in December 2021 while the overall clinic suppression rate was 92.4%(1296/1402). Compared to ages ≥ 5 years, <5 VS was significantly lower ($p<0.0001$). <5 VS reached a nadir of 76.8%(76/99) before rising to 92.2%(94/102) by November 2022, surpassing the overall clinic VS of 91.7%(1239/1351) (see figure).

In April 2022, the percentage of those failing who were <5 reached a maximum of 20.8%(21/101) but then fell to 7.1%(8/112) by November 2022.

Figure. Virologic suppression rates by age group.

Conclusions: Despite historical challenges in <5 , we saw sustained improvements in VS rates that improved after the initiation of a Viremia Clinic and pediatric DTG. Moreover, clinic-wide rates of VS have begun to improve, though less dramatically than in <5 .

Integrase inhibitor use in children living with HIV in Europe & Thailand over the last decade (2010-2020): uptake and virological response

K. Scott¹, S. Crichton¹, A. Judd¹, C. Carreras-Abad², S. Guillén Martín^{3,4}, L. Marques⁵, L. Naver⁶, V. Spoulou⁷, A. van Rossum⁸, I.J. Collins¹, on behalf of the European Paediatric and Pregnancy Infections Cohort Collaboration (EPPICC)

¹University College London, Institute of Clinical Trials & Methodology, London, United Kingdom, ²Hospital Universitari Germans Trias i Pujol, Department of Pediatrics, Barcelona, Spain, ³Instituto de Salud Carlos III, CIBER en Enfermedades Infecciosas (CIBERINFEC), Madrid, Spain, ⁴Hospital Universitario de Getafe, Department of Pediatrics, Madrid, Spain, ⁵Centro Hospitalar e Universitário do Porto, Department of Pediatrics, Centro Materno Infantil do Norte, Porto, Portugal, ⁶Karolinska University Hospital, Department of Pediatrics, Stockholm, Sweden, ⁷"Agia Sofia" Children's Hospital, First Department of Pediatrics, Athens, Greece, ⁸Erasmus MC University Medical Center-Sophia Children's Hospital, Department of Pediatrics, Rotterdam, Netherlands

Background: Integrase inhibitors (INSTIs) were approved for paediatric use from 2013 and are preferred anchor drugs for children living with HIV (CLWHIV). We assessed INSTI uptake and virological response in CLWHIV in real-world settings across Europe and Thailand between 2010-2020.

Methods: CLWHIV aged <18 years in the European Pregnancy and Paediatric Infections Cohort Collaboration at start of each calendar year were included in repeated cross-sectional analyses to describe trends in anchor drug class over time.

Characteristics at INSTI start, and proportion virally suppressed (VS) <50 copies/mL at 12 and 24-months after drug start, were described by treatment and viral load status at INSTI start.

Results: Of 7,835 CLWHIV included, the proportion taking INSTI increased from 0% in 2010 to 1% in 2015 and 22% in 2020. Uptake was highest in Western Europe, with 50% on INSTI by 2020 compared to $\leq 11\%$ in other regions (Eastern & Central Europe, Russia).

Among 1,674 CLWHIV ever taking INSTI, 65%(1,085) took dolutegravir, 32%(532) raltegravir, 11%(176) elvitegravir and 1%(18) bictegravir. 53% were female, median age at INSTI start was 13 years [IQR 10,15]. 23% on raltegravir were <6 years compared to $\leq 2\%$ on other INSTIs.

At drug start, the proportion naïve, treatment-experienced and VS, treatment-experienced and viremic (≥ 50 copies/mL) were: 9%, 46% and 26% for dolutegravir, 8%, 22%, 43% for raltegravir, 3%, 58% and 22% for elvitegravir and 11%, 33% and 28% for bictegravir, respectively; the remainder were treatment-experienced with missing viral load. At 12 and 24-months after INSTI start, the proportion VS was highest among those treatment-expe-

rienced and VS at drug start (>85%) and lowest among those treatment-experienced and viremic (<60%), across INSTI drugs (Figure).

Figure. Viral suppression at 12 and 24 months after INSTI start, by drug (dolutegravir, elvitegravir and raltegravir) and viral load (VL) status at drug start (insufficient numbers on bictegravir).

Conclusions: Even by 2020 INSTI access in children living in Eastern/Central Europe and Russia, was poor. Among children with comparable treatment history at INSTI start, VL suppression was similar across the INSTI drugs.

EPB0254

Effectiveness of caregiver mentor directly observed treatment and support model on viral load suppression among children and adolescents living with HIV in Uganda

K. Edward Kiranda¹, D. Kalibbala², E. Magongo Namusoke², M. Nakanwagi², I. Dumba³

¹Ministry of Health Uganda, AIDS Control Program, Kampala, Uganda, ²Ministry of Health, AIDS Control Program, Kampala, Uganda, ³USAID Uganda, Health, Kampala, Uganda

Background: Viral load non-suppression remains a challenge among children and adolescents. Those with detectable viral load receive intensive adherence counseling (IAC) but with non-compliance and a low re-suppression rate (23%). Caregivers sometimes fail to attend these sessions due to environmental, personal, psychological, financial, and child-related challenges. Directly observed therapy (DOT) has shown great improvement in treatment outcomes through improving literacy and supporting drug administration challenges using a peer-to-peer approach. We assessed the effectiveness of the caregiver DOTs model on viral load suppression in Uganda.

Methods: We conducted a mixed methods implementation effectiveness Type 2 study among caregivers at Kasaala HCIII, Kiganda HCIV, Kiboga, Mityana, and Mubende Hospital in Central Uganda from June to December 2022. We identified caregivers of unsuppressed children and adolescents (2-15years) and paired them with caregivers of those suppressed from the same area within a radius of 2 kilometers on a ratio of 1:5-7. We trained those with suppressed children and adolescents

as mentors in providing treatment literacy, and directly observing daily treatment. They conducted Dots for a period of 60-90 days and provided linkage to livelihood support. We analyzed the viral load results after the third IAC and those who were still unsuppressed were checked for Drug resistance.

Results: A total of 30 caregivers of 49 unsuppressed children were enrolled on the study. The average age of the children was 8.8(±3.8) Years 20 males and 29 females. Of which 77.1% were on 1st Line, 20.8% were on 2nd Line, and 77.6% were on DTG-based regimen. The mentors identified lack of information, negligence, low treatment literacy, and lack of a supportive environment at home as the major factors for non-suppression.

After the DOTs intervention, 28 (57.1%) had non-detectable viral load, 18 (36.7%) suppressed with viral load < 200 copies, 1 lost to follow-up, and 2 had unsuppressed viral load and confirmed having Drug-resistant.

Conclusions: Caregiver DOTs can effectively support caregivers of non-suppressing children and adolescents to improve treatment outcomes through improving literacy and supporting drug administration. Therefore, there is a need to support caregiver mentors to provide peer-to-peer support at the household which reduces the burden on the overloaded health facilities.

EPB0255

High Prevalence of low level viremia among infants initiated on antiretroviral drugs following Mother to Child Transmission of HIV

I.L. Nankya¹, C. Matama², D. Rutebarika², R. Basiima², I. Namyalo², P. Arikod², F. Muwabe¹, C. Kityo³

¹Joint Clinical Research Center, Molecular Biology, Kampala, Uganda, ²Joint Clinical Research Center, Pediatrics, Kampala, Uganda, ³Joint Clinical Research Center, Kampala, Uganda

Background: With the elimination of mother to child transmission of HIV campaigns, the number of transmissions among new born babies has greatly reduced. However, it is imperative that those who sero-convert achieve complete and sustained viral suppression.

We assessed the prevalence of low level viremia among infants initiated on antiretroviral therapy (ART) over a period of two years in a Ugandan cohort.

Methods: The Drug Resistance Testing among Infants at Baseline study (DRIBS) is currently ongoing at Joint Clinical Research Centre in Uganda. We enrolled infants who started treatment following a confirmed positive Early Infant Diagnosis (EID) Test. Infants were followed for two years. Baseline CD4 and viral load (VL) were done. Response to therapy monitoring using viral load was done. Intensified Adherence Counseling (IAC) and HIV drug resistance testing was done.

Results: Between June 2018 and October 2021, 100 infants were enrolled. 71% of the babies have completed. Non-HIV related deaths accounted for 4%. Median age at di-

Oral abstracts

Author Index

agnosis was 79 (IQR, 57.75;140.75) days with 4% diagnosed within 6 weeks after delivery. Median age at initiation of therapy was 110.5 (IQR, 87.0;162.0) days. Median baseline %CD4 was 26 (IQR, 18.75;32) with 9% of babies being severely immunosuppressed. Median baseline log viral load was 4.44 (IQR, 3.19;5.58). At six months, 35% and 60% had VL <50 and <1000copies/ml respectively.

At 12 months, 40% and 70% had VL <50 and <1000copies/ml respectively. At month 18, 45% and 66% had VL <50 and <1000copies/ml respectively.

The proportion of babies with low level viremia (50-999copies/ml) at months 6, 12, 18 was 25%, 30%, and 21% respectively. Post IAC VL revealed that of the 58% babies with VL <1000copies/ml, only 23% had <50copies/ml. Of note, was the high proportion of LLV (35%) following IAC. When compared with the mothers' post IAC VL, 42% mothers had <50copies/ml with only 11.5% LLV.

Conclusions: Viral suppression and complete viral suppression are achieved much slower in the pediatrics implying it might take longer in babies to achieve the third 95.

Furthermore, the higher prevalence of LLV in pediatrics compared to the mothers in the same cohort has important implications on response to therapy.

EPB0256

Dolutegravir in our youngest cohort: follow-up of genotype led antiretroviral optimization in unsuppressed children

S. Perry¹, M. Abadie¹, J. Petrus¹, L. Mpango², C.M. Nyapokoto³, M. Beneus⁴, N. Dube⁵, S. Dlamini⁵, N. Mthethwa⁶

¹Baylor College of Medicine, Pediatrics, Mbabane, Eswatini, ²Elizabeth Glaser Pediatric AIDS Foundation, ASPIRE Project (USAID), Mbabane, Eswatini, ³Eswatini National AIDS Program, HIV Care and Treatment, Mbabane, Eswatini, ⁴Georgetown University, Centre for Global Health Practice and Impact (CGHPI), Mbabane, Eswatini, ⁵Baylor College of Medicine Children's Foundation-Eswatini, Mbabane, Eswatini, ⁶Eswatini National AIDS Program, Paediatric HIV, Mbabane, Eswatini

Background: In 2021, pediatric Dolutegravir 10 mg tablets (pDTG) became available to children living with HIV in Eswatini. Selection of nucleoside reverse transcriptase inhibitor (NRTI) backbone was genotype guided in clients with a detectable viral load (DVL) on a first-line Protease Inhibitor (PI) regimen.

Methods: This is a retrospective review of routine data for pediatric clients with VL >1,000 copies/mL on first-line, PI-based antiretroviral therapy (ART) that accessed genotypes before optimization. The National Reference Laboratory performed genotypes in Johannesburg and the Stanford HIVdb Program was used to calculate predicted activity of NRTIs. This abstract will share the most recent VL during the 18 months after optimization.

Results: Thirty clients on first line ABC-3TC-LPV/r (abacavir, lamivudine, lopinavir/ritonavir) with viral loads > 1,000 copies/mL were genotyped. Average age was 2.6 years (50% male, 50% female). Half (50%; 15/30) demonstrated drug pressure (through the presence of M184V(14) or T215S(1) alone) with no or low-level ABC resistance and were optimized to ABC-3TC-DTG.

Follow-up VL≤400 copies/mL in this cohort was 85% (11/13; 2 LTFU). Wild-type virus was observed in 37% (11/30). These clients were optimized to ABC-3TC-DTG, and subsequent VL ≤400 copies/mL was observed in 67% (6/9; 1 remains on PI).

The final 4 clients (13%; 4/30) had high level ABC resistance on genotype and were optimized to AZT-3TC-DTG. VL ≤400 copies/mL was observed in 75% (3/4), with the remaining 1 viral load <1000 copies/mL.

Overall VL suppression (≤400 copies/mL) was 77% (20/26) at an average of 5 months after pDTG initiation (1-13 months). No PI mutations were present in this cohort.

Conclusions: Our cohort demonstrates high re-suppression rates with the introduction of pDTG despite still struggling to reach national suppression targets. However, high level ABC resistance does exist in this young cohort, confirming that in resource limited settings without genotype guidance, some children are being placed on regimens that are not fully active.

It is unknown if this is a safe and durable strategy. Protease inhibitor mutations were not routinely identified, suggesting this class of drugs may still be useful in the future should they fail a DTG based regimen.

EPB0257

Viral load suppression in children living with HIV after pediatric dolutegravir optimization in Eswatini

M. Abadie^{1,2}, S. Dlamini¹, J. Petrus^{1,2}, N. Dube¹, N. Mthethwa³, S. Perry^{1,2}

¹Baylor College of Medicine Children's Foundation Eswatini, Mbabane, Eswatini, ²Baylor College of Medicine, Pediatrics, Houston, United States, ³Eswatini National AIDS Program, National Paediatric HIV Care and Treatment Coordinator, Mbabane, Eswatini

Background: In September 2021, Eswatini began optimizing children under 20kg to pediatric dolutegravir (pDTG)-based Antiretroviral Treatment (ART). All children on first line ART optimized either to ABC/3TC/DTG if viral load (VL) ≤400copies/mL; or if VL ≥1000copies/mL, genotype results were used to inform an optimized NRTI backbone with pDTG. All children with VL 401-999 went through adherence counseling. This is a description of early viral load outcomes for these children.

Methods: This is a retrospective review of routinely collected data from all children on first line ART optimized to pDTG based ART from August 2021 until January 2023 at Baylor College of Medicine Children's Foundation-Eswatini. Data were extracted from electronic medical records

and imported into STATA 17 for analysis. McNemar's Test using 95% confidence intervals ($p < 0.05$) was used to determine significance in viral suppression (≤ 400 copies/mL) before and after optimization.

Results: Since optimization, 369 children have accessed pDTG; 57 as new initiations and 312 through optimizations. Of the 57 newly initiated, 46% were (26/57) male and 54% (31/57) female with an average age of 17 months (0-83 months). The suppression rate for this group was 78% (21/27) at an average of 7 months post pDTG initiation (4-14 months).

Of the 312 children optimized to pDTG, 224 had VL results both before and after optimization. These children were 42% male (95/224) and 58% female (129/224) with an average age of 55 months (7-206 months). Before optimization, 95% were on ABC/3TC/LPV/r (212/224); after optimization, 97% were on ABC/3TC/DTG (219/224).

There was a significant increase in the VL suppression rate (89% pre-optimization to 95% post-optimization; $p < 0.05$) at an average of 7.6 months post pDTG optimization (0.03-16 months). Stratified by age in 12-month increments, suppression rates for all groups increased to $>90\%$ after optimization except for with children between 12-23 months who increased to only 77% (10/13).

Conclusions: Children have benefited from introduction of pDTG. All children have seen improved viral suppression, but the 12-23 months age group and new initiations still struggle to meet national targets. Pending viral load data will continue to be tracked and evidence generated will be shared over the coming years.

EPB0258

High acceptability and preference for pediatric dolutegravir 10mg among children living with HIV in Nigeria at 1- and 6-month follow up, an observational study

Background: Nigeria is an early adopter country of the generic formulation of pediatric dolutegravir 10mg (pDTG) that became accessible in December 2020. This study aims to assess the acceptability and preference of pDTG among children living with HIV newly initiated or transitioned to the drug. Findings from the study was used to guide national scale-up.

Methods: Pediatric clients weighing $>3\text{kg}$ and $<20\text{kg}$ were enrolled between September and December 2021 in 7 sites across 7 state (Akwa-Ibom, Benue, Cross river, Lagos, Plateau, Rivers and Sokoto). Acceptability and experiences were assessed through surveys conducted with clients and their caregivers as respondents at 1 and 6 months following pDTG initiation using a structured questionnaire. Participants were asked about side effects, ease of administration, and regimen preferences. Data from 1- and 6-month follow-ups were analyzed for frequencies and trends.

Results: The study enrolled 180 clients and the mean age was 4.7 years, with 98% being treatment experienced. At month 1, 99% of the treatment experienced respondents prefer the pDTG-based regimen to their previous regimen, this increased to 100% at month 6. On ease of administration, at month 6, 99% and 100% of respondents respectively reported that pDTG tastes better and was easier to administer than previous regimen, compared to 99% and 96% respectively at month 1. 99% of respondents at both months 1 and 6 were satisfied or very satisfied with their pDTG regimen.

The most common side-effect reported at months 1 and 6 was increased appetite (25% and 43% respectively). 97% and 94% of respondents at months 1 and 6 respectively

abstracts

Poster
exhibition

E-posters

Late-breaker
abstracts

Author
Index

reported that the client either gained weight appropriately or had no change in weight. Hyperactivity was reported by 29% of participants at month 6.

Conclusions: There is a high acceptability and preference for pDTG compared to legacy regimens such as LPV/r, with improved taste and ease of administration.

Increased appetite was the most common side-effect reported.

With the favourable findings from the study to date, national HIV program has commenced scale-up of pDTG with emphasis on pharmacovigilance.

Further follow-up at 12 months will provide more evidence of pDTG's impact.

Uganda

Background: Following the successful global rollout of dolutegravir for antiretroviral treatment of adults and children over 20kg, a pediatric dolutegravir formulation (pDTG) became available in late 2021. This dispersible tablet is administered once daily, and with better taste and potency is expected to improve pediatric outcomes.

To inform the introduction of this optimal treatment for children living with HIV (CLWH), we systematically monitored health care workers' (HCWs) experiences prescribing pDTG as well as health outcomes of pDTG initiates.

Methods: TORPEDO is a mixed-methods, prospective cohort study of CLWH initiating pDTG at 19 pediatric HIV treatment sites in 3 countries with early access to pDTG: Benin (6 sites), Nigeria (7 sites), and Uganda (6 sites). 510 CLWH were enrolled from October 2021–June 2022. Six-months following introduction, individually administered surveys were collected from study facility HCWs. Surveys included questions on HCWs' experiences prescribing

pDTG. Viral load (VL) test results at baseline and 6 months following pDTG initiation were analyzed; undetectable VL was defined as <50 copies/mL and viremia was defined as greater than 1,000 copies/mL.

Results: 89 HCWs [54% physicians, 17% nurses, 11% clinical officers] were surveyed between April 2022–November 2022. Over 90% had more than 5 years health care experience, and almost 80% had more than 5 years of experience treating HIV. All respondents (100%) believed that clients preferred pDTG over previous drugs. Nearly all HCWs (n=86, 97%) observed better client adherence; 72 (81%) observed fewer side effects compared to lopinavir/ritonavir. 87 respondents (98%) reported increased confidence in prescribing pDTG; reasons for this included "better tolerated" as the most frequent response and "improved side effects or outcomes" as the second most frequent.

When asked to share observations on prescribing pDTG, almost three-quarters said "appropriate or better weight gain." At baseline, 69% of VL tests were "undetectable", and 16% had viremia (n=357); at 6-months, 85% were undetectable and 6% had viremia (n=310).

Conclusions: Improved tolerability and adherence as reported by prescribers of pDTG was supported by improved viral suppression amongst study participants. Further analysis of long-term client VL results, as well as weight and body-mass index trends, will provide more evidence of pDTG's impact.

EPB0260

HIV drug resistance trends among 251 treatment experienced children and young adults (0-24 years)

S. Perry¹, M. Abadie¹, L. Mpango², C.M. Nyapokoto³, N. Mthethwa⁴

¹Baylor College of Medicine, Pediatrics, Mbabane, Eswatini,

²Elizabeth Glaser Pediatric AIDS Foundation, ASPIRE Project (USAID), Mbabane, Eswatini, ³Eswatini National AIDS

Program, HIV Care and Treatment, Mbabane, Eswatini,

⁴Eswatini National AIDS Program, Paediatric HIV, Mbabane, Eswatini

Background: Treatment-experienced clients are failing antiretroviral therapy (ART) throughout Sub-Saharan Africa. The resulting HIV Drug resistance mutations (DRMs) present an urgent need for genotyping, and access to robust treatment options, to provide successful individualized lifelong treatment in our most vulnerable pediatric clients living with HIV.

This abstract looks at early resistance trends in our treatment experienced pediatric and young adult clients in Eswatini (0-24 years).

Methods: This is a retrospective review of electronic medical records and genotype results from Baylor Children's Foundation-Eswatini and referrals from other facilities in Eswatini. All genotypes are from treatment-experienced clients, 0-24 years old, with at least two detectable viral loads on Protease Inhibitor (PI) or Dolutegravir (DTG)-

based ART. Genotypes were done through the National Reference Laboratory in South Africa using dried blood spot (DBS) specimens in alignment with National Treatment Guidelines. Stanford HIVdb Program was used to calculate predicted activity of ART.

Results: Genotypes were performed in 251 clients between January 2014 and January 2023 (39% (99/251) female; 61% (152/251) male). Sixteen percent (40/251) showed intermediate level or higher resistance to LPV/r; 43% (17/40) of those also showed intermediate or higher resistance to DRV/r. Most common PI mutations were M46I (34), V82A (33), I74V (33). INSTI resistance testing was performed on 13 samples. Fifteen percent (2/13) had intermediate or high level DTG resistance due to the following mutations: E138AK(1), G140A(1), Q148R(1), R263K(1).

Intermediate or high resistance to Rilpivirine (RPV) was observed in 29% of genotypes (74/251) despite no clients being on non-nucleotide reverse transcriptase inhibitors (NNRTI) at the time of sample collection. Most common nucleotide reverse transcriptase inhibitor (NRTI) mutations were M184V (127), M41L (28), D67N (25), T215Y (25).

Conclusions: Trends in DRMs in Eswatini give insight into future effective ART for treatment-experienced clients and may inform national policies regarding sequencing of ART moving forward. Pediatric surveillance resistance testing is needed in Eswatini and the region to inform national ART optimization guidelines and advocacy for access to novel treatment options for our most vulnerable clients.

EPB0261

Implementation of a Quality Improvement collaborative of HIV status disclosure of Young People Living with HIV in Zimbabwe

A. Sellberg¹, B. Tapesana¹, B.B. Khabo¹, V. Chitiyo¹, N. Willis¹, F. Mavhunga¹, T. Magadza¹, T. Takundwa¹, K. Thomson², S. Wiktor², Z. Bangani³, T. Maphosa³, T. Apollo⁴, E. Govha⁴, B. Makunike-Chikwinya⁵, G. Gonesse⁵
¹Zvandiri, Harare, Zimbabwe, ²University of Washington, International Training and Education Center for Health, Washington, United States, ³CDC, Harare, Zimbabwe, ⁴Ministry of Health and Child Care, Harare, Zimbabwe, ⁵Zimbabwe Technical Assistance, Training, and Teaching Centre for Health, Harare, Zimbabwe

Background: Despite the progress made in HIV services, treatment and mental health outcomes of Adolescents and Young People Living with HIV (AYPLHIV) remain sub-optimal, of which non-disclosure to the AYPLHIV of their HIV status is a key factor.

To address this challenge, the Ministry of Health and Child Care (MoHCC) of Zimbabwe recommends that full disclosure be done before 10 years of age, yet Zvandiri programmatic data (May 2022) showed that 1,443/6,666 (22%) of AYPLHIV aged 10-14, and 389/9,149 (4%) of AYPLHIV aged 15-19 were not disclosed to. Zvandiri connects AYPLHIV with trained, mentored, peer counsellors. We utilised a Quality Improvement (QI) collaborative from April

to September 2022 to improve disclosure status among AYPLHIV across three selected districts (Hurungwe, Nkayi, and Goromonzi).

Description: As part of the QI collaborative, the Zvandiri District Team (ZDT) engaged Health Care Workers (HCW) and peer counsellors to elucidate the disclosure status of supported AYPLHIV. AYPLHIV who were not fully disclosed to were identified and followed up for disclosure support. The QI package included documentation of disclosure status in health care files, monthly caregiver support meetings and individual additional counselling, and HCW Initiated Opt-out Disclosure Sessions (HIODS).

Lessons learned: The disclosure rate increased from 959/1319 (73%) to 1266/1319 (96%) over six months as all AYPLHIV without full disclosure and their caregivers received the QI package of disclosure support. Of the 53 (Female:36, Male:17) AYPLHIV who did not receive full disclosure, 45/53 (85%; Female:30, Male:15) were aged 10-14 and 8/53 (15%; Female:6, Male:2) were aged 15 and above. Reasons for non-disclosure:

- 12/53 (23%) absent primary caregiver
- 26/53 (49%) caregiver unwilling to disclose
- 4/53 (8%) AYPLHIV with cognitive impairment
- 11/53 (21%) disclosure process ongoing

Conclusions/Next steps: The QI collaborative was successful in improving disclosure status among AYPLHIV, which is expected to improve retention in care, mental health status and overall treatment outcomes for the AYPLHIV. This initiative has demonstrated the importance of active follow up and documentation of disclosure status among AYPLHIV, in addition to caregiver counselling and HIODS. Primary caregivers working abroad posed a special challenge, as the secondary caregivers were hesitant to disclose in their absence.

EPB0262

Impact of a teen club model on improving HIV outcomes among adolescents in rural Neno district, Malawi: a retrospective cohort study

C. Trapence¹, C. Kachimanga¹, D. Suffrin¹, C. Kanyenda¹, E. Ndarama², F. Muyila², E. Connolly¹, A. Kulinkina³
¹Partners in Health, Neno, Malawi, ²Neno District Hospital, Neno, Malawi, ³Swiss Tropical and Public Health Institute, Basel, Switzerland

Background: HIV which affects over one million people in Malawi, is a significant public health concern. The rate of improvement is slower among adolescents and young adults, despite significant progress toward attaining the 95-95-95 UNAIDS targets throughout the whole population of HIV-positive persons. For instance, retention and viral load suppression rates in adolescents aged is below 76%, while same rates reach 90% in adults.

As a result, differentiated teen club models were introduced in Malawi's in 2006 as part of the national strategy to build a strong national HIV program. In Neno district, teen club was introduced in 2013 with an aim of improv-

ing the clinical outcomes for this subpopulation. Our goal therefore is to compare the impact of the teen club model to the standard care on HIV treatment outcomes among ALHIV in Neno District.

Methods: Retrospective cohort study using routine patient data extracted from the electronic medical record system in Neno District. We enrolled 532 adolescents living with HIV (ALHIV), with 235 in teen clubs and 297 in the standard care, matched on age, sex and ART initiation year. Our primary outcome was attrition defined as a combination of treatment outcomes 'died', 'defaulted' and 'transferred out'. Multivariate Cox regression was used estimate the hazard ratios of the risk factors of attrition in care.

Results: Over a four-year follow-up period, ALHIV who participated in the teen club had a significantly higher likelihood of remaining in care than those who did not (HR=2.80; 95% CI: 1.46, 5.34). Teen clubs also increased the probability of measuring viral load and body mass index (BMI) but did not change the probability of viral load suppression. Age at ART initiation < 15 years (aHR=0.37; 95% CI: 0.17, 0.82) reduced the risk of attrition from HIV while underweight status (aHR=3.18; 95% CI: 1.71, 5.92) increased the risk of attrition after controlling for sex, WHO HIV staging, and teen club participation.

Conclusions: The teen club model has the potential to improve treatment outcomes among ALHIV. In addition to retaining adolescents in HIV care, greater attention is needed to treatment adherence and viral suppression in this special population.

Clinical issues specific to key populations

Single cell rna-seq analysis of persons with HIV and opioid use

K.M. Roskin^{1,2}, H.L. Meeds³, J.M. Krishnan³, C. Freiermuth^{4,5}, J.L. Brown^{6,7}, M.S. Lyons⁸, M. Juhascik⁹, K.E. Sherman^{3,5}, J.T. Blackard^{3,5}

¹Cincinnati Children's Hospital Medical Center, Cincinnati, United States, ²University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States, ³University of Cincinnati College of Medicine, Internal Medicine, Cincinnati, United States, ⁴University of Cincinnati College of Medicine, Emergency Medicine, Cincinnati, United States, ⁵University of Cincinnati College of Medicine, Center for Addiction Research, Cincinnati, United States, ⁶Purdue University, Psychological Sciences, West Lafayette, United States, ⁷University of Cincinnati, Department of Psychology, Cincinnati, United States, ⁸Ohio State University, Emergency Medicine, Columbus, United States, ⁹Miami Valley Regional Crime Laboratory, Montgomery County Coroner's Office, Dayton, United States

Background: The US is experiencing a major drug epidemic largely attributed to synthetic opioids including fentanyl. We previously reported that fentanyl enhanced replication of HBV, HCV, and HIV *in vitro*.

Here, we considered how illicit fentanyl use in persons with HIV impacted gene expression in peripheral blood mononuclear cells (PBMCs).

Methods: Whole blood was collected from adults with opioid use, as well as non-opioid using controls. Plasma samples were screened by Liquid Chromatography Mass Spectrometry for commonly abused drugs. Single cell barcoding and complementary DNA were performed using Chromium Next GEM Single Cell 5' Reagent Kits. Data were integrated and cell clusters identified using Seurat. Cell types were assigned by label transferred from an annotated reference dataset. Differentially expressed genes were identified using 1) log₂ fold-change ≥ 0.25, 2) at least 10% of cells expressing the gene in both compared groups of cells, and 3) Wilcoxon rank sum test Bonferroni-adjusted p value < 0.01.

Results: Single cell RNAseq data were obtained from 7 HIV positive / HCV negative, 8 HIV negative / HCV positive, and 12 HIV positive / HCV positive individuals, and one HIV negative / HCV negative individual, including 23 males and 5 females. Fentanyl was detected in 13 individuals. Other drugs of abuse also detected included cocaine (4), marijuana metabolite (10), and methamphetamine (3). An average of 13,745 cells were sequenced per individual. Cell frequencies were not different by opioid status for most cell types except NK cells (lower for opioid use; p = 0.027). Among HIV/HCV co-infected persons, differentially expressed genes during opioid use included:

1. MTRNR2L8 in CD4⁺ T cells,
2. MTRNR2L8, hemoglobin subunit B (HBB), and RPS4Y1 in CD8⁺ T cells,
3. MTRNR2L8, HBB, multiple interferon-stimulated genes, LY6E, LGALS2, XAF1, and APOBEC3A in monocytes, and;
4. MTRNR2L8, HBB, XAF1, and RPS4Y1 in B cells.

Conclusions: These findings suggest multiple pathways by which opioid use contributes to HIV pathogenesis. Rigorous characterization of the interactions among HIV, opioids, and host cells will improve clinical management paradigms for difficult-to-treat populations, facilitate public health policies given severely strained resources, and reveal additional pathways for novel target-specific therapeutic interventions.

EPB0264

Oropharyngeal presentation of mpox: a neglected entity?

D. Salusso¹, L. Spadaccini¹, J.L. García¹, M.V. Iannantuono¹, H. Ludvik¹, F. Bilbao¹, C. Petriglieri¹, M. Sandoval¹, J.R. García¹, C. César¹, C. Pérez¹, M.I. Figueroa¹, P. Cahn¹

¹Fundación Huésped, Research Department, Buenos Aires, Argentina

Background: Oropharyngeal manifestations were not initially reported in the case-definition of mpox. Pharynx involvement may mimic other diseases and lead to underdiagnosis. The aim of this study was to evaluate the prevalence of oropharyngeal mpox among clients from a single center in Buenos Aires, Argentina.

Methods: We analyzed medical records of clients diagnosed with mpox evaluated at a Buenos Aires clinical center focused on STIs from June 28 to December 22, 2022. We collected data on demographics, clinical presentation, concomitant STIs, and hospital admission. PCR in clinical samples was used to diagnose mpox. Data analysis was made with RStudio V2022.12.0+353.

Results: Forty-five clients (41 MSM, 4 TGW) with a median age of 33 years (IQR 28-40) were included. 8/45 (17%) were people living with HIV, 7 of them on antiretroviral therapy (ART) and virally suppressed; of those HIV-negative, 86% (32/37) were on PrEP. The most commonly reported symptoms were lymphadenopathy (84%), cutaneous lesions (84%), fever (57%), myalgias (48%), headache (45%), and arthralgias (13%). Anal lesions were observed in 37% of clients, oral lesions (ulcers, vesicles, and mucosal inflammation) in 31%, and pharyngitis in 22%. Syphilis was observed in 27% (10/37). Those with pharyngitis were more likely to have concomitant oral involvement ($p < 0.05$, Fisher test). Three clients presented oropharyngeal manifestation without rash or rectal involvement. In consequence, two of them had a delay in mpox diagnosis due to misdiagnosis of bacterial pharyngitis. One client with dysphagia required hospital admission.

Conclusions: The clinical occurrence of pharyngitis, especially when presenting as an isolated symptom, can lead to misinterpretation of the disease and delays in diag-

nosis. Although pharyngitis is a less frequent symptom of mpox, it should be considered for diagnosis in high-risk populations.

EPB0265

Evaluating the perceptions of PWID about long-acting MOUD, PrEP, and ART

P. Thepmankorn¹, R. Flumo¹, A. Nyaku¹

¹Rutgers New Jersey Medical School, Department of Medicine, Newark, United States

Background: To successfully achieve the Ending the HIV Epidemic goals, the United States must address HIV treatment and prevention in the context of the co-occurring opioid crisis. Long-acting, injectable forms of pre-exposure prophylaxis (LAI-PrEP) and antiretroviral therapy (LAI-ART) and extended-release medications for opioid use disorder (XR-MOUD) may potentially reduce treatment attrition. However, few studies have evaluated community receptiveness regarding LAI-PrEP, LAI-ART, and XR-MOUD among PWID.

Methods: We conducted a cross-sectional survey of adults with OUD and a history of injection drug use attending a NJ syringe exchange program (SEP) to assess their prior experiences with HIV treatment and prevention, OUD care, and knowledge, attitudes, and preferences regarding LAI.

Results: 178 participants were included in the analysis. 15 participants were persons living with HIV (PWH), 72 were high risk for HIV (HRH), and 91 were low risk for HIV (LRH). Though nearly 60% of participants had previously taken MOUD, knowledge of XR-MOUD formulations was low (40% PWH, 45.8% HRH, and 41.6% LRH, $p = \text{NS}$) and interest in XR-naltrexone (33.3% PWH, 27.8% HRH, 26.7% LRH, $p = \text{NS}$) and XR-buprenorphine (33.3% PWH, 18.3% HRH, 20.9% LRH, $p = \text{NS}$) was low.

General PrEP knowledge was high (59.1% HRH and 63.9% LRH, $p = \text{NS}$), but prior usage was low (11.1% HRH and 6.7% LRH, $p = \text{NS}$) and interest in LAI-PrEP was low (18.1% HRH and 21.1% $p = \text{NS}$). PWH had high awareness of LAI-ART (66.7%) and high interest in receiving either monthly or bimonthly LAI-ART (66.7%). There was a statistically significant difference in interest in receiving a form of LAI-antiviral ($p = 0.02$). Interest in integrated care was greater for PWH (69.2%), compared to the HRH (29.8%) or LRH (33.9%) ($p = 0.03$) groups. Preferred treatment locations varied; PWH preferred care in an HIV clinic (46.7%) or mobile clinic (26.7%) while both HRH (31%) and LRH (27.3%) preferred a SEP.

Conclusions: Our findings indicate increased education and outreach efforts tailored towards PWID are needed, especially ones focused on XR-MOUD and LAI-PrEP. Given the difference in treatment location preferences and interest in integrated treatment, a differentiated care model may be useful in reaching PWID with OUD and at-risk for HIV as compared to PWID with OUD and HIV.

**EPB0266****Mpox knowledge, concern, willingness to change behaviour, and seek vaccination in Australia: results of a national cross-sectional survey**

J. MacGibbon¹, V.J. Cornelisse^{2,3}, A.K.J. Smith³, T.R. Broady¹, M.A. Hammoud², B.R. Bavinton², H. Paynter⁴, M. Vaughan⁵, E.J. Wright^{6,7,8}, M. Holt¹

¹UNSW Sydney, Centre for Social Research in Health, Kensington, Australia, ²UNSW Sydney, Kirby Institute, Kensington, Australia, ³New South Wales Health, Sydney, Australia, ⁴Australian Federation of AIDS Organisations, Sydney, Australia, ⁵ACON, Sydney, Australia, ⁶Monash University, Department of Infectious Diseases, Alfred Hospital and Central Clinical School, Melbourne, Australia, ⁷Burnet Institute, Melbourne, Australia, ⁸The Peter Doherty Institute of Infection and Immunity, Melbourne, Australia

Background: Mid-2022 saw a global mpox outbreak affecting predominantly gay and bisexual men in non-endemic countries. Australia had never previously recorded mpox cases and there was no prior research on knowledge or attitudes to mpox. We therefore assessed knowledge and concern about mpox, acceptability of behavioural changes to reduce transmission risk, and willingness to be vaccinated.

Methods: A national, online survey was conducted August–September 2022 among gay, bisexual and queer-identifying men and non-binary people. We report descriptive statistics for survey measures. We used multivariate logistic regression to identify factors associated with vaccine willingness.

Results: Of 2287 participants, 95.7% identified as male and 82.8% were gay. 98.6% had heard about mpox and 64.4% were concerned about acquiring it. Most of the 2268 undiagnosed participants identified skin lesions (92.0%), skin rash (87.2%), and fever (72.6%) as potential symptoms, and prolonged and brief skin-to-skin contact as potential ways to acquire monkeypox virus (93.7% and 82.0%, respectively).

The most acceptable behavioural changes (prior to vaccination) were reducing or avoiding attendance at sex parties (65.9%) and sex-on-premises venues (66.4%), and having fewer sexual partners (64.6%). 14.2% of the sample had already received ≥1 dose of Modified Vaccinia Ankara vaccine.

Most unvaccinated and undiagnosed participants were willing to be vaccinated (1457/1733; 84.1%). Bisexual participants were less willing to be vaccinated than gay participants (aOR=0.63, 95%CI=0.41–0.96, $p=0.032$). Participants who were concerned/very concerned about acquiring mpox were much more willing to be vaccinated than unconcerned participants (aOR=5.18, 95%CI=3.36–7.99, $p<0.001$). Participants with greater numbers of recent male sexual partners (between 11–20) were also more willing to be vaccinated compared to those with fewer than 10 partners (aOR=1.85, 95%CI=1.02–3.37, $p=0.044$).

Other factors were not independently associated with vaccine willingness (e.g., residential location, education, HIV status/PrEP use, perceived likelihood of acquiring monkeypox virus, any recent condomless casual sex).

Conclusions: Most participants had heard of mpox and were familiar with the most common clinical symptoms and transmission routes. We found very high willingness to be vaccinated against mpox, however bisexual participants appeared less willing to be vaccinated, and this group might benefit from targeted education on the importance of vaccination.

EPB0267**Factors associated with viral load suppression amongst transgender people in South Africa**

R. Bothma¹, A. Bangalee¹, N. Mogashoa¹, N. Hill¹, J. Imrie¹, J. Lawrence²

¹Wits RHI, University of the Witwatersrand, Johannesburg, South Africa, Hillbrow, South Africa, ²United States Agency for International Development (USAID)/ South Africa, Pretoria, South Africa

Background: Sustained viral load suppression (VLS) can improve quality of life amongst transgender people living with HIV (TPLHIV). However, transgender people continue to experience disparities along the HIV care continuum due to a myriad of psychosocial and socio-economic factors. Insights into factors that influence VLS are critical to determine targeted interventions for transgender health programmes. This analysis presents characteristics of TPLHIV accessing health services from USAID-funded dedicated transgender clinics in four South African districts and characterizes factors associated with VLS in this group.

Methods: We used routine programme data that were manually collected and recorded in REDCap between October 2021 and September 2022. We summarised client characteristics using descriptive statistics and conducted a multivariable logistic regression in Stata v16 to identify factors associated with VLS (<50 copies/mL) among TPLHIV ($p<0.05$).

Results: Among 889 TPLHIV who were eligible for a viral load test during the period of review, 773 (87%) underwent a viral load test. Amongst these, 90.4% were transgender women, 7.3% were gender non-conforming, and 2.3% were transgender men. The median age was 29 years, 72% were unemployed, and 8% reported experiencing physical and/or sexual violence in the last 12 months. At least 20% (153/773) had completed tertiary education and 86% (664/773) were treatment naïve at baseline. VLS was 59% (459/773) amongst those who had a viral load test done. The odds of VLS were higher amongst TPLHIV who were ART experienced (vs. those who were ART naïve; aOR =4.80, 95% CI: 1.80,12.79). Transgender people on a protease inhibitor-based regimen (vs. those on a dolutegravir-based regimen aOR=0.068, 95% CI: 0.008,0.57) and those who had experienced violence in the last 12 months (vs.

those who had not; aOR=0.46, 95% CI: 0.23,0.86) were less likely to be suppressed. Although level of education was not statistically associated with VLS, our analysis demonstrated improved VLS with increasing education levels.

Conclusions: VLS remains a challenge amongst TPLHIV. Integrating HIV health services with programmes that address gender-based violence, offer educational opportunities, and provide enhanced adherence support could improve VLS in this vulnerable group. Moreover, the continued roll-out of dolutegravir in South Africa may provide benefits in achieving or maintaining VLS.

EPB0268

The role of substance use in structural heart disease among unsheltered and unstably housed women living with HIV

E. Riley¹, E. Vittinghoff², A. Ravi², P. Coffin³, K. Lynch², A. Wu², C. Martinez⁴, P. Hsue²

¹University of California, San Francisco, Medicine, San Francisco, United States, ²University of California, San Francisco, San Francisco, United States, ³San Francisco Department of Public Health, San Francisco, United States, ⁴University of Miami, Miami, United States

Background: People living with HIV have increased risk of cardiovascular disease, but few studies focus on women. A recent report showed that, among women living with HIV (WLH), those with CD4+ counts<200 cells/mm³ had a higher prevalence of left ventricular hypertrophy. However, the impact of substance use on structural heart disease among WLH is less well established.

Methods: We recruited WLH from San Francisco shelters, meal programs and street encampments. Between 2016 and 2019, participants completed six monthly interviews, specimen collection, and one transthoracic echocardiogram. Electronic health records were reviewed to assess the most recent CD4+ count prior to the echocardiogram. We used multinomial logistic regression to assess associations between echocardiographic indices of cardiac hypertrophy (concentric hypertrophy, concentric remodeling and eccentric hypertrophy, each compared to "normal cardiovascular indices") and study factors, including cardiovascular risk factors, substance use, and HIV-specific factors (CD4+ count, viral load, HIV medication).

Results: Among 59 participants, the average age was 53 years and 70% were ethnic minority women. Just over 70% had elevated blood pressure (BP), 10% had diabetes and 10% reported a prior myocardial infarction. Toxicology-confirmed substance use included tobacco (63%), cannabis (52%), cocaine (51%), methamphetamine (29%), and alcohol (26%).

Adjusting for systolic BP and viral load, *concentric hypertrophy* was detected in 26% of participants. It was more prevalent in those who used cocaine (adjusted Relative Risk [aRR]=62.0, 95% CI: 5.07-759, p<0.01) and less prevalent in those who used cannabis (aRR=0.10, 95% CI: 0.01-0.81, p=0.03).

Concentric remodeling was detected in 40% of participants. It was also more prevalent in those who used cocaine (aRR=15.6, 95% CI: 1.76-138, p<0.01) and less prevalent in those who used cannabis (aRR=0.15, 95% CI: 0.02-0.97, p=0.04).

Eccentric hypertrophy was detected in 7% of participants. It was not significantly associated with factors studied here. CD4+ count was not significantly associated with these outcomes.

Conclusions: Among polysubstance-using WLH, cocaine use had a strong association with structural heart disease by echocardiography, while this finding was not demonstrated for other toxicology confirmed substance use or HIV-specific factors.

Whether cannabis use mitigates the impact of cocaine on structural heart disease among WLH merits further investigation.

EPB0269

Review of antiretroviral therapy coverage among prisoners living with HIV in 10 African countries

P. Agboola¹

¹Federal Medical Centre, Ebute-Metta, Nigeria

Background: Achieving UNAIDS' vision of zero new HIV acquisition, zero discrimination, and zero AIDS-related deaths requires that everyone needing Antiretroviral therapy has timely access to life-saving medication and is aware of HIV prevention services. HIV prevalence in African correctional facilities is significantly higher than that of the general population. The HIV risk in these population increases through needle sharing, sexual violence, unprotected, unplanned sexual intercourse, and other risky behaviors.

This study assesses antiretroviral therapy coverage among prisoners in selected African countries.

Methods: We extracted data on antiretroviral therapy (ART) coverage among prisoners living with HIV in Africa from the UNAIDS database. The study covered the following African countries with available data: Burkina Faso, Cote D'Ivoire, Chad, Ghana, Togo, South Africa, Uganda, Zambia, Malawi, and Zimbabwe.

Data reported in this review were also obtained from different e-bibliographic, including PubMed PubMed Central, Google Scholar, Science Direct, and Research Gate. About 37 papers published from 2017 to 2021 met the inclusion criteria.

Key terms used in the search were "Antiretroviral therapy," "Prisons," "HIV treatment," "Correctional facilities," "HIV/AIDS medication," and "Key population."

Results: All ten countries have experienced an increase in ART coverage among prisoners living with HIV from 2017 to 2021, except for Cote D'Ivoire, having an 11.1% decrease. Ghana, Malawi, and Zambia have the highest ART coverage of 100% for their prisoners living with HIV, while Burkina Faso and Togo have the lowest ART coverage of 21.8% and 34.1%, respectively.

Countries selected in Southern Africa slightly have a higher coverage of ART among their prisoners living with HIV than other African regions.

Conclusions: There are glimpses of progress regarding ART coverage among prisoners living with HIV in the selected countries; however, we still have a long way to go in enhancing ART coverage among key populations to achieve UNAIDS 95-95-95 goal by 2030.

There is a need to design additional interventions and strategies to address the gaps and scale ART coverage among key populations in Africa.

Other strategies and therapies

EPB0270

Effects of oral cannabinoids on systemic inflammation and viral reservoirs in people with HIV on antiretroviral therapy: results of the CTNPT 028 clinical trial

R.-S. Mboumba Bouassa^{1,2}, E. Comeau¹, A. Pagliuzza³, Y. Alexandrova^{1,2}, S. Samarani², J. Needham⁴, J. Singer⁴, T. Lee⁴, F. Bobeuf², C. Vertzagias², G. Sebastiani^{2,4}, S. Margoese⁴, E. Mandarin⁴, M. Klein^{2,4}, B. Lebouché^{2,4}, J.-P. Routy^{2,4}, N. Chomont³, M.-A. Jenabian^{1,4}, C. Costiniuk^{2,4}

¹Université du Québec à Montréal (UQAM), Department of Biological Sciences, Montreal, Canada, ²Research Institute of the McGill University Health Centre, Montreal, Canada, ³Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CR-CHUM), Montreal, Canada, ⁴CIHR Canadian HIV Trials Network, Vancouver, Canada

Background: Chronic HIV infection is characterized by persistent chronic inflammation despite antiretroviral therapy (ART). Cannabinoids are reported with anti-inflammatory properties and may represent a potential strategy to reduce systemic inflammation in people with HIV (PWH).

Methods: Ten PWH (median age: 57.5 years, 8 males) on ART were randomized ($n=5$ /group) to increasing doses of oral Δ^9 -tetrahydrocannabinol (THC): cannabidiol (CBD) combination (THC/CBD: 2.5/2.5 to 15/15mg daily) capsules or CBD-only (200 to 800mg daily) capsules, for 12 weeks. Blood specimens were prospectively analyzed before cannabinoid initiation and after the completion of cannabinoids treatment.

Hematology and biochemistry profiles were used to assess the safety of cannabinoids. Plasma levels of inflammatory markers IFN- γ , TNF- α , IL-1 β , IL-6, IL-8, and IP-10, and anti-inflammatory IL-10 were determined using a Luminox assay, and LPS, sCD14, sCD27, gut damage markers REG-3 α and I-FABP were quantified by ELISA.

Multi-color flow cytometry was used to immunophenotype T-cells. HIV DNA and cell-associated RNA (LTR-gag) were measured in blood CD4 T-cells and in cell pellets from semen by ultra-sensitive qPCR, and cell-free viral RNA was measured in semen supernatant.

Results: Eight individuals completed the study. Cannabinoids did not alter participants' hematology/biochemistry profiles. CD4 count and CD4/CD8 ratio were stable and viral load remained suppressed throughout the study. Cannabinoids significantly reduced plasma levels of the following inflammatory markers from initiation *versus* the end of the intervention: IFN- γ ($p=0.03$), TNF- α ($p=0.02$), IL-1 β ($p=0.02$), and REG-3 α ($p=0.04$).

In addition, cannabinoids also significantly reduced the frequency of PD1+ memory CD4 T-cells ($p=0.02$), CD28-CD57+ senescent CD4 and CD8 T-cells ($p=0.05$ and $p=0.04$, respectively) and CD39+ regulatory T-cells ($p=0.01$). There was no significant change in HIV DNA and RNA levels in blood or semen nor in other plasma inflammatory markers.

Conclusions: Cannabinoids reduced markers of systemic and gut inflammation, as well as senescence and exhaustion markers in T-cells in PWH, providing rationale for a larger clinical trial.

ART resistance

EPB0271

Assessment of transmitted drug resistance mutations to doravirine (MK-1439) in Argentina

D.M. Cecchini¹, I. Cassetti^{1,2}, F. Scarnato¹, A. Fiori², J. Nuevo¹, C. Villaverde², A. Sucari³, M.C. Torroja⁴, G. Bugarín⁴, G. Lopardo²

¹Helios Salud, Buenos Aires, Argentina, ²FUNCEI, Buenos Aires, Argentina, ³Laboratorio Dr. Stambouljan, Buenos Aires, Argentina, ⁴MSD Argentina, Vicente Lopez, Argentina

Background: Latin America (LATAM) has reported moderate to high levels of transmitted drug resistance in people living with HIV, mostly to NNRTIs. Doravirine (DOR) is a novel NNRTI that has shown non-inferior efficacy to DRV/r and EFV-based regimens in phase 3 trials and has a favorable safety and tolerability profile. DOR has a unique NNRTI resistance profile with antiviral potency against the most prevalent NNRTI-associated resistant viruses. To date, no data exist regarding the prevalence of DOR RAMS (Resistance Associated Mutations) in LATAM.

We describe the prevalence of DOR RAMS in genotypes from antiretroviral treatment (ART) naïve adults in two reference HIV clinics in Buenos Aires, Argentina.

Methods: Retrospective cross-sectional, non-interventional study, period 01/2017-09/2021. Baseline genotype samples requested as routine clinical practice from ART naïve people living with HIV were retrospectively analyzed for RAMS associated with resistance to DOR according to the ANRS algorithm.

Results: 1667 samples were analyzed: 81.2% corresponded to male sex persons, the median (IQR) of age was 34 (28-43) years; 9.9% had evidence of recent infection. Predominant route of infection was sexual (99.83 %); 52.6% were men who have sex with men. Median (IQR) HIV-1 viral load

and CD4-T cell count were 50550 c/mL (15300-183500) and 363 cells/mL (212-532). Thirty-seven (2.2%) patients harbored mutations or a combination of mutations that, in accordance with the algorithm, would confer resistance to DOR (table 1). DOR was classified as "susceptible" and predicted to be efficacious in 98% of the samples.

	N (%)

*Mutations are listed individually, but a combination of two is required to confer possible resistance to doravirine.

Table 1.

Conclusions: In a sample of ART naïve population from Argentina, the prevalence of DOR RAMS was low (2.2%) which provides reassurance about the use of doravirine in the treatment of this population in Argentina.

EPB0272

Prevalence and dynamics of drug resistance during dolutegravir-containing treatment in a pediatric population living with HIV-1 (IMPAACT P1093)

C. Boyce¹, M. Bishop¹, S. Styrchak¹, K. Knowles², C. Vavro³, R. Hazra⁴, E. Townley⁵, R. Nixon⁶, R. Smith⁶, G. Gottlieb^{6,7}, T. Ruel⁸, A. Wiznia⁹, L. Frenkel^{7,10}, IMPAACT P1093 Study Team

Background: A secondary objective of IMPAACT P1093, a phase I/II study of dolutegravir (DTG) and optimized background therapy (OBT) in children (4 weeks to <18 years) living with HIV-1 in nine countries in Africa, Americas, and Asia, is to assess changes in HIV-1 genotypes and phenotypes to DTG and OBT in children with/without intermittent viremia or treatment failure.

Methods: Plasma RNA from participants at enrollment and longitudinal specimens from intermittent viremias or protocol-defined virologic failures were genotyped for resistance, including minority variants, using a laboratory-developed PacBio assay. The prevalence and dynamics of DTG and OBT resistance were assessed using Stanford HIV Database with resistance to PIs, NRTIs, and NNRTIs defined by genotypic susceptibility scores (GSS) ≥ 30 and to DTG by GSS ≥ 10 . Phenotyping of participant-derived recombinant viruses was performed using our single-cycle reporter assay to determine the DTG 50%-effective concentration (EC₅₀) and EC₅₀ fold-change between baseline and later, on-treatment timepoints.

Results: Genotyping at enrollment was successful for 153/169 (90.5%) participants (12/181 specimens unavailable) with resistance detected to PIs (n=22; 14.4%), NRTIs (n=69; 45.1%), NNRTIs (n=73; 47.7%), but not to INSTIs (n=0), including M184V (n=59), L74V (n=16), and K70R (n=13). Intermittent viremia or confirmed failure occurred in 48/169 (28.4%) participants (median viral load: 5,055 copies/mL [IQR: 1,468-36,193 copies/mL]), with DTG-associated mutations detected in 11/48 (22.9% [12.0-37.3%]) (Table 1). Phenotypic analyses of four participants' genotypes confirmed reduced DTG susceptibility (Table 2). Resistance at enrollment was not associated with viremia or selection of DTG resistance.

Virologic Outcome During DTG-based ART	N=	Pre-DTG Genotype			History of Prior ARV Exposure at Entry	
		Wild-type	Drug Resistant	No Genotype	Naïve	Experienced
Viremia	49	12 (24.5%)	33 (67.3%) PI: 7 NRTI: 22 NNRTI: 22	4 (8.2%)	4 (8.2%)	45 (91.8%)
DTG Resistance G118R (n=6) Q148K (n=1) N155H (n=3) R263K (n=4)	11/49 (22.4%)	3 (27.3%)	8 (72.7%) PI: 1 NRTI: 6 NNRTI: 3	0	0	11 (100%)
No DTG Resistance	30/49 (61.2%)	8 (26.7%)	19 (63.3%) PI: 6 NRTI: 14 NNRTI: 14	3 (10%)	2 (6.7%)	29 (93.3%)
No Genotype	7/49 (16.3%)	1 (12.5%)	6 (75.0%) PI: 0 NRTI: 2 NNRTI: 5	1 (12.5%)	2 (25.0%)	6 (75.0%)
Suppressed	132	44 (33.3%)	66 (50.0%) PI: 16 NRTI: 46 NNRTI: 51	22 (16.7%)	13 (9.9%)	119 (90.1%)
Total	181	56	99	26*	17	164

*12 participants specimens unavailable; 14 participants' specimens did not amplify

Table 1: Summary of genotypic drug resistance detected by virologic outcome

Case	HIV-1 Subtype	Weeks of DTG Treatment	Major Integrase Mutations	Minor Integrase Mutations	Replication Capacity ^a	DTG EC ₅₀ (nM) ^b	Fold-Change ^c
1	C	0 32	None G118R	None L74I	80 35	1.7±0.29 19±6.1^d	11
2	CRF01_AE	0 20	None G118R	L74I T66I, L74I	95 29	1.8±0.03 38±3.1^d	21
3	B	162	S147G, R263K	E138T	55	12±3.9^e	5.0 ^f
4	B	51	G118R	E138K, V151I	71	19±2.4	8.4 ^f

^a Replication capacity expressed as the % of HIV-1NL4-3 titer

^b Mean 50% effective concentration ± standard deviation

^c Fold change in EC₅₀ value relative to the corresponding week-0 clone, unless otherwise indicated

^d Bold type indicates a significant difference compared to the EC₅₀ for the corresponding week-0 clone (p < 0.05, ANOVA with Tukey's multiple comparisons test)

^e Bold type indicates a significant difference compared to the EC₅₀ for HIV-1NL4-3 (p < 0.05, ANOVA with Tukey's multiple comparisons test)

^f Fold change relative to HIV-1NL4-3 (EC₅₀ for dolutegravir, 2.3 ± 0.70 nM)

Table 2: Preliminary findings of phenotypic analyses of DTG-resistant genotypes

Conclusions: Selected resistance to DTG was prevalent among participants with viremia, including as minority variants either alone or in addition to majority variants, but was not associated with resistance at enrollment.

EPB0273

Assessment of prevalence, patterns, and risk factors of HIV drug resistance among pregnant women living with HIV in Tanzania

M. Tsere¹, B. Jullu², H. Siril¹, E. Aris¹, G. Lyatuu³, D. Sando⁴, N. Ullenga⁵, P. Njau⁶, P. Rwehumbiza⁷, E. Mmari⁷, G. Mgomella⁷, M. Jalloh⁸, M. Amuri⁸

¹Management and Development for Health, Clinical Services, Dar es Salaam, Tanzania, United Republic of, ²Management and Development for Health, Surveillance, Dar es Salaam, Tanzania, United Republic of, ³Management and Development for Health, Programs, Dar es Salaam, Tanzania, United Republic of, ⁴Management and Development for Health, Management, Dar es Salaam, Tanzania, United Republic of, ⁵Management and Development for Health, Laboratory Services, Dar es Salaam, Tanzania, United Republic of, ⁶Ministry of Health, National AIDS Control Program, HIV Care and Treatment, Dodoma, Tanzania, United Republic of, ⁷Tanzania Country Office, U.S. Centers for Disease Control and Prevention, Clinical Services, Dar es Salaam, Tanzania, United Republic of, ⁸Tanzania Country Office, U.S. Centers for Disease Control and Prevention, Surveillance, Dar es Salaam, Tanzania, United Republic of

Background: By 2013, Tanzania adopted life-long antiretroviral (ART) policy for all pregnant and lactating women (LLAPLa/Option B+). The country scaled-up option B+ coverage to reach 93% of pregnant women by 2018. Despite this success, the emergence of HIV drug resistance (HIVDR) mutations may threaten the intervention.

Methods: We conducted a cross-sectional multistage cluster sampling assessment through health facilities on randomly selected ART naïve and experienced pregnant women with unsuppressed HIV viral load (≥1000 copies/ml) of all ages from April to September 2019.

Plasma samples were collected for HIV viral load and genotypic testing. Poisson regression models were used to determine risk factors. A two-sided p-value of <0.05 was considered statistically significant.

Results: A total of 1,002 pregnant women were genotyped and the HIVDR prevalence of all drug classes was 56%. HIVDR mutations affected 55% of Non -Nucleoside/ Nucleotide Reverse Transcriptase Inhibitors (NNRTI), 33% of Nucleoside Reverse Transcriptase Inhibitors (NRTI), and 2% of Protease Inhibitors (PI) class drugs.

Prevalence of HIV pretreatment drug resistance (PDR) was 27% and acquired drug resistance (ADR) was 79%. Factors significantly associated with increased risk of overall HIVDR were excessive drinking of alcohol [aRR=1.62, 95% CI: 1.02-2.59, p=0.0430]; having >1 sexual partner [aRR=2.82, 95% CI: 1.17-6.77, p=0.0204]; ever used tobacco [aRR=6.46, 95% CI: 1.42-29.38, p=0.0157]; HIV subtype URF_A1D [aRR=1.55, 95% CI: 1.15-2.1, p=0.0043]; vaginal discharge [aRR=1.18, 95% CI: 1.02-1.37, p=0.0302]; and prior ARV exposure [aRR=1.18, 95% CI: 1.04-1.33, p=0.0089].

Factors significantly associated with decreased risk were last condom use [aRR=0.35, 95% CI: 0.13-0.95, p=0.0385], being on second line regimen (LPV/r+TDF+FTC) [aRR=0.43, 95% CI: 0.22-0.86, p=0.0168]; and HIV subtype A [aRR=0.82, 95% CI: 0.69-0.97, p=0.0188].

Conclusions: HIVDR prevalence was high in our tested populations, and the mutations mostly affected the efficacy of NNRTI and NRTI class drugs. The ART-experienced pregnant women harbored a greater level of viral drug resistance mutations than ART naïve pregnant women. All ART experienced women who become pregnant with high HVL test result should be immediately tested for HIV-DR to avoid mother to child transmission.

EPB0274

Subtype A1, D, and recombinant HIV-1 natural polymorphisms associated with lenacapavir drug resistance in Mbarara, Uganda

D. Omoding¹, N. Musinguzi¹, Y. Boum II², C. Muzooru¹, S. Kigozi¹, P.W. Hunt³, J.N. Martin³, D.R. Bangsberg⁴, J.E. Haberer^{5,6}, M.J. Siedner^{1,5,6}, S. McCluskey^{1,5,6}, G.Q. Lee⁷
¹Mbarara University of Science and Technology, Mbarara, Uganda, ²Institut Pasteur de Bangui, Bangui, Central African Republic, ³University of California, San Francisco, San Francisco, United States, ⁴Oregon Health Sciences University, Portland, United States, ⁵Massachusetts General Hospital, Boston, United States, ⁶Harvard Medical School, Boston, United States, ⁷Weill Cornell Medicine, Department of Medicine, New York, United States

Background: Lenacapavir (LEN) belongs to a new class of HIV drugs called capsid inhibitors, which target viral Gag p24. LEN is effective in combination with other antiretrovirals (ART) for subtype B HIV-1 infections. However, less data is available for its activity in non-subtype-B HIV-1, which could harbor natural polymorphisms that may reduce LEN susceptibility.

Methods: The Uganda AIDS Rural Treatment Outcomes (UARTO) cohort enrolled ART-naïve adults in Mbarara, Uganda between 2002-2010 just prior to their initiation of ART. Participants were followed longitudinally until 2015. Archived plasma samples collected at any viremic time points pre- and post-ART-initiation were subjected to HIV-1 *gag* p24 Sanger sequencing, subtyped by RIP 3.0 and aligned using MUSCLE against reference sequence HXB2. Lenacapavir-associated resistance mutations were defined according to the 2022 IAS-USA drug resistance mutations list including L56I, M66I, Q67H, K70N/S/R, N74D/S, A105T and T107N. We also examined mutations reported in other studies including Q67K/N, K70H, N74H, A105S, and T107A/C.

Results: We obtained 741 HIV-1 *gag* sequences from 546 participants; 73% were from pre-treatment specimens. The median age was 34 (IQR 29-39), and 69% of participants were female. Median pre-treatment viral load and CD4 count were 5.2 log₁₀ copies/mL (IQR 3.7-5.7) and 127 cells/μL (IQR 64-196), respectively.

All went on to initiate ART with an NNRTI-containing regimen. Cohort viral subtype distribution was 51% A1, 4% C, 30% D, 1% G and 14% intersubtype-recombinants. HIV-1 natural polymorphisms associated with LEN resistance were observed in 6/546 participants (1%; 95% CI 0.4-2.4%): One of these individuals (infected with C/D recombinant HIV-1) had K70R at 6-month post-therapy, and five individuals (three infected with A1 and two D HIV-1), had T107A pre-ART. In one individual, T107A persisted up to 3 years during post-therapy-initiation follow-up. Phylogenetic analysis revealed that p24 sequences containing T107A did not cluster into unique monophyletic groups, suggesting independent mutation events as opposed to transmission clusters.

Conclusions: Among individuals in western Uganda living with subtype A1, D, and intersubtype recombinant HIV-1, we observed a 1% prevalence of natural viral polymorphisms associated with lenacapavir resistance. Our findings provide preliminary evidence that LEN is likely to be active against circulating HIV-1 viruses in this region.

Interpretation of doravirine resistance by algorithm in antiretroviral-naïve people with HIV in Haiti

S. Pierre¹, J. Wu², R. Campo³, E. Asante-Appiah⁴, D. Andre¹, C.F. Duchatellier¹, J.B. Marc¹, D. Lespinasse¹, S. Ávila-Ríos⁵, C. Garcia Morales⁵, J.R. Pierre¹, M.F. Pierre¹, P. Severe¹, B. Liautaud¹, J.W. Pape^{6,1}, S. Koenig⁷
¹GHEKIO Centers, Clinical Trial Unit, Port-au-Prince, Haiti, ²Analysis Group, Inc, Boston, United States, ³Merck & Co., Inc., Upper Gwynedd, United States, ⁴Merck & Co., Inc., Rahway, United States, ⁵Centro de Investigación en Enfermedades Infecciosas, Instituto Nacional de Enfermedades Respiratorias Ismael Cosío Villegas, Ciudad de México, Mexico, ⁶Weill Cornell Medical College, New York, United States, ⁷Brigham and Women's Hospital, Boston, United States

Background: We report the prevalence of resistance-associated mutations in reverse-transcriptase sequences among a sample of antiretroviral therapy (ART)-naïve persons at GHEKIO, in Port-au-Prince, Haiti, and the differences in susceptibility to doravirine (DOR) by algorithm. Pre-treatment non-nucleoside reverse transcriptase inhibitor (NNRTI) resistance mutations are common in Haiti due to high utilization of efavirenz (EFV)-containing regimens.

Methods: From September 2018 to July 2019, we conducted HIV genotypes for 365 ART-naïve people ≥15 years of age. DOR resistance was defined as low or intermediate (predicted ≥ 15 or ≥30-fold change in susceptibility, respectively) by Stanford algorithm version 9.1, or detection of DOR-specific major mutations as defined by the MSD*, French National Agency for AIDS Research version 32 (ANRS), and International AIDS Society-USA October 2019 (IAS-USA) algorithms (2, 3).

According to the MSD algorithm, primary mutations confer resistance to DOR by themselves; secondary mutations confer only a modest reduction (≤ 5 -fold) in isolation, but can confer a substantial reduction in combination with other substitutions; low-impact mutations have no impact in isolation but combinations of ≥ 5 can reduce DOR susceptibility. The only primary mutations that were included in all algorithms were V106A, Y188L, F227C, and M230L.

Results: The interpretations of the clinical significance of DOR resistance-associated mutations varied by algorithm (see Table 1). The prevalence of DOR resistance was Stanford: 6.6% (low-level) and 5.8% (intermediate-level); MSD: 1.9%; ANRS: 4.7%; IAS-USA: 1.1%. With MSD algorithm, 1.1% had ≥ 1 primary mutation (V106A: 0.3%; Y188L: 0.5%; M230L: 0.3%), 1.1% had ≥ 2 secondary mutations (V108I: 1.6%; H221Y: 2.2%; P225H: 1.4%), and 0.3% had ≥ 5 low-impact mutations.

L100I + K103N + P225H	X (score: -10)			

Table 1. Clinically significant doravirine mutations, by Algorithm.

Conclusions: Despite some variability across algorithms, the predicted clinical impact of NNRTI mutations on DOR in a setting with high resistance to EFV among ART-naïve individuals is low. Further phenotypic and clinical data are needed to determine the clinical impact of single and combination mutations.

EPB0276

Pretreatment drug resistance and molecular epidemiology of HIV-1 across the Philippines

A.M. Villanueva^{1,2,3}, F. Di Giallonardo², M.A. Otiang¹, I. Haron¹, M. Ribo¹, E.F. Telan¹

¹San Lazaro Hospital, National Reference Laboratory for HIV/AIDS, Hepatitis, and Other Sexually-Transmitted Infections, Manila, Philippines, ²University of New South Wales, Kirby Institute, Kensington, Australia, ³Nagasaki University, School of Tropical Medicine and Global Health, Nagasaki, Japan

Background: HIV/AIDS epidemic in the Philippines is the fastest growing in Asia with a 237% increase in new cases from 2010-2020. The Philippines is far from the 95-95-95 target set by UNAIDS. Treatment failure is a hindrance to this goal. One factor causing poor treatment response is HIV drug resistance (HIVDR). The WHO emphasized the role of nationally-representative surveillance data on pretreatment HIVDR to guide policies on first-line ART, PrEP, and PEP regimens.

This is the first study that aims to generate such data from various regions in Philippines. We estimated the frequencies of pretreatment HIVDR and described the molecular epidemiology of HIV-1 in the country.

Methods: A total of 252 plasma samples were collected from pretreatment individuals across nine geographical areas. We extracted HIV-RNA using QIAasympy DSP Virus/Pathogen Kit and measured viral load using *artus*[®] HI Virus-1 RT-PCR Kit. We amplified *Pol* region through PCR and sequenced amplicons using Illumina DNA Prep preparation on MiSeq and iSeq.

We generated consensus sequences using Geneious. Then, analyzed sequences using Stanford HIVdb for subtyping and HIVDR data.

Results: Twenty-seven percent were $<100,000$ copies/mL, 50% were 100,000-1,000,000, and 23% were $>1,000,000$ copies/mL.

Out of 250 with subtype data, 221 (88%) were CRF01_AE, 8% (21) B, and the remaining were other subtypes and CRFs.

Out of 249 with HIVDR data, one had intermediate resistance to Tenofovir and one had high-level resistance to Lamivudine. Five (2%) had high-level and three (5%) had intermediate resistance to Efavirenz. Four (2%) had high-level and one had intermediate resistance to Rilpivirine. Six (2%) had high-level and 14 (6%) intermediate, resistance to Nevirapine.

Phylogenetic analysis reveals likely transmission clusters within the island of Iloilo, and potential transmissions across land-accessible provinces surrounding Metro Manila.

Conclusions: High frequencies of resistance to NVP supports the recent change in first-line ART regimen to TDF + 3TC + DTG. However, increasing frequencies of EFV resistance should be a concern for the HIV-TB, pregnant, and women of childbearing age populations. The same applies for second-line drug RPV.

Lastly, we recommend implementation of interventions for the local transmission of HIV in Iloilo, and in Metro Manila and its nearby provinces.

SARS-CoV-2, COVID-19 and HIV

EPB0277

Impact of COVID-19 pandemic on HIV viral load testing in paediatric HIV clinics in the European Pregnancy and Paediatric Infections Cohort Collaboration (EPPICC)

S. Crichton¹, C. Epalza², T. Goetghebuer³, C. Jackson¹, A. Judd¹, M. Le Prevost¹, L. Marques⁴, V. Spoulou⁵, I.J. Collins¹, European Pregnancy and Paediatric Infections Cohort Collaboration

¹University College London, MRC Clinical Trials Unit, London, United Kingdom, ²Hospital Universitario 12 de Octubre, Pediatric Infectious Diseases Unit, Department of Pediatrics, Pediatric Research and Clinical Trials Unit (UPIC), Translational Research Network in Pediatric Infectious Diseases (RITIP), Madrid, Spain, ³Hopital St Pierre, Brussels, Belgium, ⁴Centro Hospitalar e Universitário do Porto, Serviço de Pediatria, Departamento da Infância e da Adolescência, Centro Materno Infantil do Norte, Porto, Portugal, ⁵"Agia Sofia" Children's Hospital, 1st Dept of Paediatrics, Athens, Greece

Background: The COVID-19 pandemic impacted HIV services globally, with clinics limiting in-person visits and prioritising those seen in person. In children and young people living with HIV (CLHIV) we explored trends in viral load (VL) testing and associated factors from 2015 to Sept 2020.

Methods: Data from 12 paediatric HIV cohorts in Europe were included. First, generalised estimating equations (GEE) were used to estimate VL testing rates and the proportion of results unsuppressed (VL \geq 200c/ml). Models assessed trends by calendar year for 2015–2020, and by month for 2019–2020. Second, using logistic regression we explored factors associated with having \geq 1 VL test in the first quarter of the pandemic (April–June 2020).

Results: Between 2015–2020, 4,659 CLHIV were in follow-up; 35% in Ukraine, 24% United Kingdom, 25% Russia, 16% elsewhere in Europe. Overall, VL test rates were stable from 2015–2019 ($p=0.250$) before declining in 2020 (Fig.A) with lowest rates in April (Fig.B). The proportion of unsuppressed VL tests decreased over time (Fig.C).

Among 1,784 CLHIV in care during April–June 2020, 54% were female, median age was 12.3[IQR 8.1,15.5] years. CLHIV who may be considered priority included those treatment naïve (0.8%) or who started ART within previous 12-months (6.9%), interrupted treatment (2.5%), had recent viremia (\geq 1 VL \geq 200c/ml in previous 12-months) (25.6%) or CD4 $<$ 200 at last visit (1.4%).

Overall, 22.3% had \geq 1 VL test between April–June 2020. In multivariable models, adjusting for cohort, age and sex, recent viremia (OR=2.1(1.5,2.8)), and starting ART in previous

12-months or ART naïve (OR=2.1(1.3,3.4), vs. on ART \geq 3 years) were associated with increased odds of having a VL; treatment interruptions had lower odds (OR=0.3(0.1,1.0)).

Figure. Estimated VL test rates averaged over calendar years (A) and by month (B) and proportion with VL $>$ 200c/ml by year (C) and month (D) (95% confidence intervals).

Conclusions: The pandemic had considerable impact on VL testing and there was evidence of prioritisation of tests for some groups. The proportion unsuppressed was declining pre-pandemic, further data are needed to assess if trends continue post-pandemic.

Background: PLWH are underrepresented in SARS-CoV-2 vaccine trials. We studied a primary scheme based on Ad5-nCoV vaccine (CanSino Biologics Inc./The Beijing Institute of Biotechnology).

The primary endpoint was to evaluate safety and immunogenicity of two doses of Ad5-nCoV in PLWH. ClinicalTrials.gov:NCT05005156

Methods: Phase 2b trial. Participants received two doses of Ad5-nCoV vaccine (intramuscular, dosage 5×10^{10} vp) at days 0 and 56, were assessed for safety and immunogenicity through 52 weeks.

Safety analysis: solicited adverse events (SolAEs) within 7, unsolicited AEs within 28 days, serious adverse events (SAE), medically attended adverse events (MAAE) within 52 weeks. HIV viral load (HIV-VL), CD4, CD4/CD8 ratio were measured day 0, week 24, and week 52.

Immunogenicity analysis: geometric mean concentration (GMC) S-RBD IgG antibody, geometric mean titer (GMT) pseudo-virus neutralizing antibody (nAbs) at day 0, weeks 4, 12, 24 and 52.

Overall 52 weeks' safety analysis and 24-weeks result of humoral response, HIV-VL and CD4/CD8 ratio are presented.

Results: Between June 2021 -January 2022, 140 PLWH were vaccinated. Baseline: median age: 41, 79% male, 94% (<40 copies/mL), median CD4 cell count: 728 cells/ul; CD4/CD8 ratio:0.80. SolAEs incidence: 79.5 %, mostly grade 1 (drowsiness and site injection pain). Sixteen (11.3%) unsolicited AEs were reported, mainly asthenia. Seven SAEs occurred; none related to the vaccine. Two MAAEs possibly related to vaccination: fever and acute unilateral hearing loss. No new AIDS-defining illness. Confirmed COVID-19 cases :47 (incidence33.6%, 98% Grade 1-2).

At week 24, no changes at CD4 cells (median):686 cells/ul, CD4/CD8 ratio:0.85 were seen while 3 participants showed HIV-VL >200 copies/mL. Immunogenicity: RBD and nAbs increases were significant until week 12 with a reduction between week 12-24 ($p=0.52$) (see table 1- 2).

Table 1	Day 0 n=140	Week 4 n=136	Week 12 n=128	Week 24 n=100	p-value
Anti-RBD antibodies geometric mean concentration (GMC) (CI 95%) **	7.09 (5.85 - 8.60)	104.62 (77.13 - 141.92)	261.10 (210.14 - 324.43)	173.28 (119.27 - 251.74)	<0.01*
Anti-RBD antibodies Geometric mean increase (GMI) (CI 95%) ***	NA	14.63 (11.43- 18.71)	35.31 (27.99- 44.55)	22.31 (15.05- 33.09)	
Table 2	Day 0 n=140	Week 4 n=136	Week 12 n=128	Week 24 n=100	p-value
SARS-CoV-2 neutralizing antibodies, Geometric mean titers (GMT) (CI 95%) **	5.60 (4.91- 6.34)	15.98 (11.90- 21.45)	46.47 (36.22- 59.62)	36.20 (25.08- 52.24)	<0.01*
SARS-CoV-2 neutralizing antibodies, Geometric mean increase (GMI) (CI 95%)***	NA	2.85 (2.28- 3.56)	8.14 (6.65- 9.97)	6.20 (4.44-8.65)	

** GMCs/GMTs and CI 95% are presented. Comparison between visits were performed by Friedman test for paired data on a logarithmic scale. Post-hoc analysis (pairwise comparisons) was performed by Wilcoxon signed rank test with continuity correction, and Bonferroni's method for multiple comparison correction was applied.

***GMI (the geometric mean increase) was calculated as the geometric mean of the ratios of the titer of the visit to the baseline titer.

Conclusions: Ad5-nCoV vaccine was well tolerated in PLWH, without new HIV-related events reported. Ad5-nCoV vaccine showed a good safety and immunogenicity profile and a neutral effect on HIV surrogate markers.

EPB0279

Recombinant Novel Coronavirus Vaccine (Adenovirus Type 5 Vector) (Ad5-nCoV) in persons living with HIV (PLWH): Immunogenicity comparative analysis between one dose and two doses of Ad5-nCoV vaccine

P. Cahn¹, L. Barrreto², M.I. Figueroa¹, V. Fink¹, M.J. Rolon³, G. Lopardo⁴, I. Cassetti⁵, M. Ceschel¹, P. Patterson¹, G. Miernes¹, A. Nava¹, J. Geffner⁶, J. Gou⁷, T. Zhu⁷, S. Halperin⁸

¹Fundacion Huesped, Research Department, Ciudad Autónoma de Buenos Aires, Argentina, ²CanSino Biologics Inc, Toronto, Canada, ³Hospital Juan A. Fernández, Ciudad Autónoma de Buenos Aires, Argentina, ⁴FUNCEI, Ciudad de Buenos Aires, Argentina, ⁵Helios Salud, Ciudad de Buenos Aires, Argentina, ⁶University of Buenos Aires, INBIRS-Biomedical Research Institute on Retrovirus and AIDS, Ciudad de Buenos Aires, Argentina, ⁷CanSino Biologics Inc, Tianjin, China, ⁸Dalhousie University, Canadian Center for Vaccinology, Halifax, Canada

Background: PLWH are underrepresented in many SARS-CoV-2 vaccine trials. We conducted a study in this population based on Ad5-nCoV vaccine (CanSino Biologics Inc./ The Beijing Institute of Biotechnology).

The study was planned to compare one or two doses, aiming was to evaluate the immunogenicity response at each study arm. ClinicalTrials.gov: NCT05005156.

Methods: Phase 2b trial. Between June 2021- January 2022, participants were enrolled in Argentina. Groups were defined according to the randomized study design: group 1: placebo day 0/ Ad5-nCoV vaccine day 56 and; group 2: Ad5-nCoV days 0 and 56.

Analysis includes receptor-binding domain (RBD) and neutralizing antibodies (nAbs) results at day 0 (D0) and 84 (D84) after vaccination. Geometric mean concentration(GMC), geometric mean titers (GMT), geometric mean increase (GMI), seroconversion rate (proportion of participants with GMI ≥ 4 from baseline) were calculated. To compare groups and time, a mixed effects linear regression model was fit.

Figure 1. GMCs, percentage of positive subjects at baseline and seroconversion rate for RBD antibodies concentration per period.

Figure 2. GMTs, percentage of positive subjects at baseline and seroconversion rate for SARS-CoV-2 neutralizing antibodies per period (nAbs).

Results: A total of 140 participants were included. Median age: 41 (IQR:31-48), 79% male, 94% virologically suppressed (<40 copies/mL), median CD4 cell count: 728 cells/ul (IQR:528-938). GMC-RBD antibodies at D0 and D84 6.63/73.5 group 1, and 7.1/282.4 group 2. (figure 1) GMI D84: 10.9 group 1 and 37.9 group 2. RBD seroconversion:74% and 93% group 1 and 2 respectively. GMT-nAbs at D0 and D84:5.3/10.4 group 1 and 5.6 / 54.1 group 2. (figure2) GMI D84: 1.9 group 1 and 9.4 group 2. The nAbs seroconversion at D84:26% (group 1) and 82.2% (group 2) Increase in RBD antibodies and nAbs was observed for both groups ($p < 0.01$). being higher for group 2 ($p < 0.01$).

Conclusions: The results of the first study with Ad-5 platform in PLWH suggest that a second dose administered 56 days apart improves humoral immunity against SARS-CoV-2 and could be immunologically beneficial for this population.

Background: The COVID-19 pandemic has had an important impact on healthcare services globally and in Mozambique. In June 2021, a cohort study ("COVID19-hIV") was initiated in three provinces in Mozambique, evaluating the COVID-19 pandemic's impact on people living with HIV, healthcare workers and on the healthcare system. It included assessments of health facility (HF) fidelity to the national infection prevention and control (IPC) program and preparedness for future COVID-19 outbreaks.

Methods: Between August 2021-November 2022, trained study staff performed serial assessments (with intervals of 2 to 8 months) of the preparedness and fidelity to IPC/COVID-19 guidelines at three selected urban HF in three provinces (Maputo City, Inhambane, Zambézia). The assessment tool, adapted from a Ministry of Health-approved checklist, included 12 sections from 4 key areas (general aspects, aspects per service, COVID prevention measures, material/waste management). Items of each area were graded according to the proportion of standards met (minimum recommended 80%). Descriptive analysis was done using Microsoft Excel.

Results: Eleven assessment rounds were completed. Adherence to IPC/COVID-19 standards ranged between 62.0% to 86.4%, with the highest score in the HF in Inhambane and the lowest in the Zambézia HF. All sites, except Zambezia, showed improvement over time (see Table). Improvement between the first and last rounds was primarily seen in the following assessment components: compliance with prevention measures among healthcare staff and management measures such as making available protective personal equipment, hygiene material and consumables, sterilization of used materials, infectious waste management and preparedness to manage persons with COVID-19.

Material processing and sterilization (7 items)	100.0%	71.4%	100.0%	100.0%	57.1%	100.0%
Waste management (7 items)	85.7%	71.4%	71.4%	85.7%	57.1%	85.7%
Average	72.3%	80.3%	61.7%	62.0%	65.0%	86.4%

Table: IPC assessment results per site.

Conclusions: The improvement in adherence to national IPC/COVID-19 guidelines observed in two of the three facilities participating in the COVIV study, reaching the minimal recommended standard over the evaluation period, suggesting an effort by the healthcare system to more successfully implement IPC guidelines including pandemic-related preparedness.

However, the varying levels of improvement observed indicates a need for site-specific monitoring and support for IPC implementing guidelines.

Thailand, ³U.S. Military HIV Research Program, Silver Spring,

Maryland, United States, ⁴Henry M. Jackson Foundation

for the Advancement of Military Medicine, Inc., Bethesda,

Maryland, United States, ⁵Institute of HIV Research and

Innovation, Bangkok, Thailand

Background: The Thai government's response to the COVID-19 pandemic included the implementation of social distancing such as limiting interprovincial travel and closure of entertainment venues.

We analyzed the effect of the COVID-19 pandemic on sexual practices and incidence rates (cases/1000 participants, IR) of gonorrhea, chlamydia in an acute HIV cohort in Bangkok, Thailand.

Methods: Participants of the RV254 Acute HIV cohort underwent regular assessments, including self-reported sexual practices and nucleic acid amplification assay for

gonorrhea and chlamydia annually. Self-reported number of insertive and receptive sexual partners were compared using t-test. Yearly incidence rates (IR) of gonorrhea and chlamydia during the COVID-19 pandemic (2020-2021) were compared with the yearly IR pre-pandemic (2019) using chi-square tests.

Results: Overall, 622 male participants (95% MSM), median age of 30 years, completed 2,795 visits between 2019 and 2021. The mean number of receptive partners in the past 6 months decreased from 1.69 in 2019 to 1.11 in 2020 ($P=0.0074$) and 0.99 in 2021 ($P=0.0024$). The mean number of insertive partners in past 6 months decreased from 1.27 in 2019 to 0.86 in 2020 ($P=0.12$) and 0.73 in 2021 ($P=0.0386$). The incidence of chlamydia decreased from 126.93 in 2019 to 83.33 in 2021, a 34% ($P=0.036$) decline. There was no significant change in the incidence of gonorrhea (34% and 40%, $P=0.111$ and 0.094 in 2020 and 2021).

Figure 1a. Mean number of insertive and receptive partners.

Symbol Meaning

ns	$P > 0.05$
*	$P \leq 0.05$
**	$P \leq 0.01$
***	$P \leq 0.001$
****	$P \leq 0.0001$

Figure 1b. Gonorrhea and chlamydia incidence rate per 1000

Conclusions: Number of sexual partners significantly decreased among acute HIV cohort participants in Bangkok during the pandemic. However, not every STD showed decreasing incidence rate within the same period. HIV and sexual health programs must take into account other sexual/risk behaviors, beyond number of sexual partners, in order to deliver services tailored to various sexual life contexts of their clients.

City, Mexico

Background: People with HIV (PWH) have a higher risk for severe disease due to SARS-CoV-2 infection. There are few studies on the frequency of PASC in PWH, the associated factors, and its impact on quality of life.

We aim to analyze the frequency of PASC in PWH and its impact on quality of life among PWH in care at the HIV Clinic of a tertiary teaching Hospital (INCMNSZ).

Methods: All individuals seen at the HIV Clinic from November to December of 2022, with a history of acute COVID-19 from January 1, 2021, to August 31, 2022, were included. Data were collected from the electronic chart.

A validated questionnaire was conducted to collect data related to the episode of acute COVID-19 and PASC defined as the presence of persistent/new symptomatology or laboratory/radiological abnormalities 12 weeks after acute COVID-19 with no other cause in addition to an assessment of health-related quality of life using EuroQol-5D-5L (EQ-5D-5L) with values set for Mexican adult general population.

Results: 399 individuals were seen at the HIV clinic during the study period, 103 had acute COVID-19 and 80 agreed to participate. All 80 participants were on ART during the study period, and 29(36%) had PASC according to the definition. Fatigue was the most frequent symptom (72%), followed by anxiety (52%), insomnia (52%) and headache (48%). The percentage of individuals with CD4 cell counts <200cel/mm³ was similar between participants with PASC vs without PASC (17% vs 10%, p=0.48), and also the percentage of participants with three doses of SARS-CoV-2 vaccination (90% vs 92%, p=0.69, respectively).

Female (p=0.023), overweight/obesity (p=0.03) and the presence of ≥3 comorbidities (p=0.0049) were more likely to be present in the PASC group. Individuals with PASC had a negative impact on quality of life (p=0.0007) and lower overall health status (p=0.01). Absence of PASC was associated significantly with greater perception of maximum health status (p=0.0003).

Conclusions: In a highly vaccinated population of PWH, PASC was a common finding (36%). Associated factors were being female, having overweight/obesity, and the presence of 3 or more comorbidities. Lower quality of life was observed in those with PASC. Comparative studies with non-HIV population are needed.

Background: The SARS-CoV-2 pandemic has exacerbated the challenges already faced by people living with HIV (PLWH). However, the mid-term impact of SARS-CoV-2 on the course of HIV infection remains uncertain.

Our aim was to assess the effect of SARS-CoV-2 infection in PLWH on plasma biomarkers related to coagulation pathways and cardiovascular disease.

Methods: Cross-sectional study of 95 PLWH under ART stratified by SARS-CoV-2 infection: a) 47 individuals sampled ≥ 1 month after the recovery (PLWH/SARSCoV2) and all of them reported symptoms; b) 48 pre-pandemic individuals without previous infection (PLWH). 12 weeks (median) elapsed between symptoms onset and sample collection. None of the individuals had been vaccinated against SARS-CoV-2.

We analysed 21 biomarkers related to inflammation, 9 biomarkers linked to coagulation pathways, 2 biomarkers associated with cardiovascular disease and the biomarkers Ferritin and D-Dimer on plasma by Procartaplex Multiplex Immunoassays. Differences between groups were analysed using a generalized linear model, adjusted by sex and etnia, and corrected by false discovery rate (FDR). Significant values were defined as aAMR≥1.2 and FDR<0.1.

Results: PLWH had a median age of 45 years, 81.9% were Caucasians, 80% were man with 9 years of HIV acquisition.

PLWH/SARSCoV2 group showed significantly higher values in the C-reactive protein, prothrombin, antithrombin and factors IX, XI, XII, XIII, protein S, and D-dimer levels, biomarkers related to coagulation pathways, and in natriuretic peptides and ferritin levels, biomarkers associated with cardiovascular disease (Figure).

In addition, the inflammatory biomarkers IL-4, IL8, IL12p70, IL13, IL17A MIP-1α, MIP-1β, IP-10 and TNF-β showed a significantly increased in the PLWH/SARSCoV2 group. However, PLWH/SARSCoV2 group showed lower levels of MCP-1 compared to PLWH (Figure).

Figure.

Conclusions: Infection with SARS-CoV-2 in PLWH leads to significant alterations in biomarkers involved in coagulation pathways and cardiovascular disease at mid-term, which could accelerate premature dysfunction and associated complications at long-term.

Low CD4 T-cell count further attenuates immunogenicity of COVID-19 vaccines in people with HIV: a systematic review and meta-analysis

D.W.J. Griffin^{1,2}, R. Pai Mangalore^{1,2}, J.F. Hoy^{1,2}, J.H. McMahon^{1,2}

¹Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia, ²Monash University, Central Clinical School, Melbourne, Australia

Background: People with HIV (PWHIV) are at greater risk of morbidity and mortality following COVID-19 than the general population.

This systematic review and meta-analysis aims to explore the immunogenicity of COVID-19 vaccines in PWHIV compared to controls.

Methods: A systematic search of EMBASE, Medline and relevant conference databases until June 16th 2022, identified studies comparing immunogenicity (SARS-CoV-2 spike-IgG seroconversion, SARS-CoV-2 neutralising antibody responses, and SARS-CoV-2-specific T-cell responses) in PWHIV versus controls, and compared responses in PWHIV with low (<350 cells/ μ L) and high (>350 cells/ μ L) CD4 counts.

Meta-analysis of seroconversion and neutralisation responses was conducted.

Results: Twenty-seven studies were eligible, including 4,451 PWHIV and 5,984 controls. PWHIV were less likely to seroconvert following a primary vaccine schedule (RR 0.97, 95% CI 0.95-0.99), and less likely to elicit neutralising antibodies (RR 0.95, 95% CI 0.91-0.99). Participants with CD4 <350 were less likely to seroconvert when compared with PWHIV with CD4 >350 (RR 0.91, 95% CI 0.83-0.99). In PWHIV receipt of non-mRNA vaccines were associated with 14% reduction in seroconversion (RR 0.86, 95% CI 0.77-0.96) compared to receiving mRNA vaccines. Seven studies reported on T-cell responses.

Although measured outcomes were heterogeneous, four studies reported lower responses in PWHIV than controls.

Figure 1. Forest plot comparing seroconversion response in a) PWHIV versus controls, and b) PWHIV with CD4 < 350 versus >350 cells/ μ L following dose two of any COVID-19 vaccine.

Conclusions: PWHIV experience reduced seroconversion and neutralization responses following a primary COVID-19 vaccination than controls. Non-mRNA vaccines and low CD4-count are associated with poorer responses. PWHIV should be prioritized for mRNA COVID-19 vaccines, especially with CD4 count <350 cells/ μ L.

Further studies are warranted to investigate vaccine boosting strategies in different CD4 T-cell count strata among PWHIV, and the role of contemporary bivalent vaccines.

EPB0285

Adaptation of HIV care, support and treatment (CST) services during COVID-19 pandemic in Indonesia

P. Gemilang¹, L. Sagoro¹, M. Sebayang¹, S. Nita¹, T. Hadi¹

¹Jaringan Indonesia Positif, Central Jakarta, Indonesia

Background: The COVID-19 pandemic has impacted healthcare systems in lower to middle income countries, including Indonesia. The simultaneous occurrence of COVID-19 and existing health problems, such as HIV, has strained healthcare systems and led to reduced access to care for non-COVID-19 related diseases.

Therefore, a study describing the capacity of healthcare workers and facilities in maintaining HIV services as well as perspective from PLHIV towards the readiness of HIV services implementation during the COVID-19 pandemic in Indonesia is needed.

Methods: A triangulation mixed method approach was employed in this study. Data was collected for five months from September 2022 to January 2023 and both quantitative and qualitative methods were utilized.

The study collected data from 32 health facilities across Jakarta, Banten, and West Java through an online cross-sectional survey, in-depth interviews with 41 health workers in charge of HIV services, and focus-group discussion with 104 PLHIV.

Oral
abstracts

Results: There are several primary challenges faced by PLHIV in accessing adequate HIV services during the pandemic, including their high risk to co-infection and socio-economic vulnerability. The shift in public health priorities from HIV CST services to COVID-19 response also led to overworked healthcare workers, reduced access to care due to closure of some facilities, and changes in operating hours. The education program (-25%), mobile voluntary counseling test (VCT) (-31%), and tracing for lost to follow up (-20%) all decreased significantly.

As such, new innovations are needed to address these challenges, such as: multi-month dispensing (88.79%), ART home-based delivery (53%), and technological-based innovations such as online tracing or web seminars as information and education media.

Conclusions: To mitigate these challenges, the study recommends strategies aimed at improving the delivery of essential services to PLHIV during the pandemic. This includes promoting and investing in telemedicine services, and adopting technologies to facilitate HIV service delivery and improve access to care.

It is also vital to foster partnerships between health facilities, communities, and other stakeholders to enhance comprehensive HIV services during and after the pandemic.

Lastly, the study advocates for increased funding and resources for the strengthening of health systems to ensure continuity of essential services during and after the pandemic.

Serological responses to primary course and booster SARS-CoV2 vaccination in people with HIV: the SCAPE-HIV study

T.J. Barber^{1,2}, C. Smith³, S. Bhagani¹, S. Madge¹, M. Lipman¹, M. Lucey⁴, K. Spears¹, J. Hart⁴, F. Burns^{1,2}, M. Johnson¹, D. Peppas^{1,5}

¹Royal Free London NHS Foundation Trust, HIV Medicine, London, United Kingdom, ²University College London, Institute for Global Health, London, United Kingdom, ³University College London, London, United Kingdom, ⁴Royal Free London NHS Foundation Trust, Virology, London, United Kingdom, ⁵University College London, Institute of Immunity & Transplantation, London, United Kingdom

Background: Some people with HIV (PWH) display blunted serological responses to SARS-CoV-2 vaccination. Given the evolving pandemic/emergence of variants of concern (VOCs) it is important to address what factors/comorbidities influence these responses to develop optimal vaccination schedules to protect against disease.

Methods: SCAPE is a cross-sectional study of PWH attending our site between Apr 21-Nov 22. Analysis restricted to those who received two vaccine doses ≥ 15 days prior to study visit (median 93, max 480). Participants provided a blood sample for serology and completed a question-

naire (demographics, comorbidities, HIV history, COVID symptoms, confirmed SARS COV-2, vaccinations). Subset of 55 individuals were re-sampled >15 days after their third vaccine dose.

Results: 520 met eligibility/had data in window. 433(83.6%) male, 502(96.5%) virally suppressed on ART with median CD4 619 cells/mm³ (IQR 450-795). 296 (56.9%) received Astra-Zeneca and 207 (39.8%) Pfizer primary course. 516 (99.2%) had positive anti-spike (S) and 135 (26.0%) positive anti-nucleocapsid (N) antibody. 4/520 (0.8%) did not seroconvert (1 seroconverted after 3rd dose, 1 renal transplant, 1 immunodeficiency, 1 lymphoma). Of 481/520 with quantitative results available, median (IQR) anti-S titre was 1734 (IQR:488,>2500); 372 (77.3%) and 204 (42.4%) had titres >400 and >2500 respectively. Factors associated with anti-S titres shown in Table 1:

		Spike titre ≤ 400 (n=109)	Spike titre >400 (n=372)	P-value
Age	>60 years	48 (44.0%)	94 (25.3%)	<0.0001
White	Yes	84 (77.1%)	272 (73.1%)	0.41
Enough money to meet basic needs (vs. rarely/never)	Always/sometimes	103 (94.5%)	352 (94.6%)	0.96
Current CD4:CD8 ratio	Median (IQR)	0.93 (0.65, 1.21)	1.17 (0.79, 1.38)	0.57
Dual antiretroviral regimen	Yes	22 (20.2%)	93 (25.0%)	0.30
Reports prior COVID disease	Yes	5	27	0.33
Key worker during pandemic	Yes	18 (16.5%)	44 (11.2%)	0.31
Worked from home during pandemic	Yes	44 (40.4%)	165 (44.4%)	0.46
Household size	≥ 3 people	20 (20.8%)	43 (14.1%)	0.11

Among 55 individuals re-sampled after third mRNA vaccine, all (100%) had positive anti-S and 19/23(82.6%) had titre >2500 . 33/55(60%) had positive anti-N; 23/33 previously had a negative anti-N after two vaccine doses.

These results are in line with emergence of circulating VOCs (eg omicron/delta) with increased ability to evade immune responses after vaccination.

Conclusions: We observe high levels of seroconversion following primary vaccination course in context of well suppressed HIV. Suboptimal serological responses could be reflective of older age and/or comorbidities.

Further analysis is underway to define additional clinical parameters associated with attenuated responses and risk of breakthrough infection. By refining stratification we can identify vulnerable groups for monitoring, or tailored intervention strategies.

**EPB0287****COVID-19 breakthroughs among people with HIV in South Carolina**

X. Yang¹, J. Zhang², S. Chen², Z. Liu², B. Olatosi³, S. Weissman⁴, X. Li¹

¹University of South Carolina, Department of Health Promotion, Education and Behavior, Arnold School of Public Health, Columbia, United States, ²University of South Carolina, Department of Epidemiology and Biostatistics, Arnold School of Public Health, Columbia, United States, ³University of South Carolina, Department of Health Services Policy and Management, Arnold School of Public Health, Columbia, United States, ⁴University of South Carolina, Department of Internal Medicine, School of Medicine, Columbia, United States

Background: The risk of breakthroughs in people with HIV (PWH) merits continued monitoring as the pandemic persists, immunity to the primary vaccine series wanes, boosters are widely recommended, and new variants emerge. This study aims to estimate the evolving rate and risk of breakthroughs among fully vaccinated PWH in South Carolina (SC).

Methods: This retrospective population-based cohort study used data from an integrated electronic health record (EHR) database in SC. Adult PWH who were fully vaccinated prior to March 30, 2022 were included. The breakthrough case was defined as a COVID-19 acquisition 14 days after an individual was fully vaccinated.

We analyzed the risk and associated factors of the outcome using Cox proportional hazard models in the overall population and also stratified by different variants of concern circulating in SC. Different COVID-19 vaccine types, prior history of COVID-19 acquisition, and HIV markers were assessed as risk factors for the outcome.

Results: Among 7,596 vaccinated PWH, the rate of breakthroughs was 119.0 cases per 1,000 person-years. In the overall population, taking the Moderna vaccine (Moderna vs Pfizer: adjusted Hazards Ratio [aHR]: 0.79; 95%CI: 0.66, 0.93) and receiving booster dose (aHR: 0.19; 95%CI: 0.15, 0.24) were associated with fewer breakthrough cases. Individuals who were vaccinated during Delta (aHR: 1.50; 95%CI: 1.25, 1.80) and Omicron (aHR: 2.86; 95%CI: 1.73, 4.73) dominant period were more likely to have breakthroughs than Alpha dominant period. When stratified the analysis by three periods, a dramatically increased trend of breakthrough rates was observed.

Across the three sequential subgroups, the protective effect of booster dose and prior history of COVID-19 acquisition were all diminished during the Omicron period. There was no association of breakthrough with viral suppression, but a higher CD4 count (>500 vs <200: aHR: 0.69; 95%CI: 0.50, 0.95) was associated with fewer breakthroughs among PWH.

Conclusions: As the pandemic evolved, the rate of breakthrough cases was much higher (during the Omicron period) than observations in previous studies.

Receipt of booster dose conferred further protection against breakthrough among PWH, but only restricted to before Omicron dominant period. PWH with pronounced immunodeficiency still has a higher risk for COVID-19 breakthroughs.

EPB0288**Influence of the COVID-19 pandemic in the rate of viral suppression of people living with HIV in Mexico under antiretroviral therapy**

E. Loreda-Martínez¹, R. Rodríguez-Díaz¹, E. Vidal-Laurencio¹, A. Ramos¹, A.P. Valdez¹, L.E. Soto-Ramírez¹

¹Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Infectious Diseases, Mexico, Mexico

Background: COVID-19 pandemic has imposed several negative effects on public health including HIV diagnosis and treatment. In Mexico, most of the clinical care centers were closed, limiting the follow-up of people living with HIV (PLWH) on antiretroviral therapy (ART). Our objective was to determine the rate changes in HIV viral suppression during the pandemic lockdown.

Methods: Our laboratory performs viral load (VL) determinations for our institution (INCMNSZ) and nineteen states of the Mexican Republic (Externals), using the Abbott RealTime HIV-1 m2000 VL testing. We included all cases that have at least two VL determinations during the Pre-pandemic period (all year 2019 and the first quarter of 2020) and also during the Pandemic period (the last two quarters of 2020 and all 2021).

For analysis, individuals were divided between institutional and Externals; and between undetectable (all VL below the level of detection), and detectable (at least one determination over threshold).

Results: We analyzed a total of 19,020 cases, 1,812 INCMNSZ and 17,208 Externals; the global rate of undetectability increased during the Pandemic period in each population, from 80 to 86%, and 70 to 79%, respectively. At INCMNSZ, 1,565/1,812 (86%) were undetectable during the Pandemic period with the majority of these (86%) also undetectable in the Pre-pandemic; on the other hand, those that were detectable during the Pandemic were commonly detectable in the Pre-pandemic (56%). For the External cases, 13,638/17,208 (80%) were undetectable during the Pandemic, the majority already being undetectable during the Pre-pandemic (77%). Similarly to INCMNSZ, most of the External cases detectable during the Pandemic were already detectable before (60%).

Conclusions: Virological suppression in PLWH was not affected during the COVID-19 pandemic in Mexico, despite the different centers analyzed around the country. These results, related to several factors of the healthcare system and the people themselves (adherence), emphasize the capability of an adequate ART follow-up even in difficult scenarios.

Epidemiology of HIV

EPC0289

Perception and vaccine readiness towards monkeypox among men who have sex with men living with HIV in China: a cross-sectional study

L. Fu¹, Y. Sun¹, Y. Li¹, B. Wang¹, L. Yang¹, T. Tian¹, X. Wu¹, X. Peng¹, Q. Liu¹, Y. Chen¹, Y.-F. Lin¹, H. Li², X. Meng³, H. Zou¹
¹Sun Yat-Sen University, Shenzhen, China, ²Center for Disease Control and Prevention, Shizhong District, Jinan, China, ³Wuxi Municipal Center for Disease Control and Prevention, Wuxi, China

Background: Men who have sex with men (MSM) make up the majority of cases in the current monkeypox outbreak. We aimed to investigate the perception and vaccine readiness towards monkeypox among MSM living with HIV in China.

Methods: This cross-sectional online study was conducted August 10 to September 9, 2022. Participants responded to survey questions about their socio-demographic information, HIV status, sexual behaviors, monkeypox knowledge, and attitudes towards monkeypox vaccines.

Results: A total of 577 MSM living with HIV participated in the study. 37.6% expressed concerns about the monkeypox epidemic in China, 56.8% were willing to adopt monkeypox vaccination, and 20.8% followed information about monkeypox.

Men who had >4 sexual partners in the past 3 months (aOR=1.9 95% CI: 1.2-2.8), had close contact with >4 individuals in a day (3.1, 1.5-6.5), were worried about the monkeypox epidemic in China (1.6, 1.1-2.3), and believed that monkeypox vaccines are safe (6.6, 2.7-16.4) and effective (1.9, 1.1-3.3) for individuals living with HIV were more likely to be willing to adopt monkeypox vaccination.

Men with high school education or below (0.5, 0.3-0.9), sometimes (0.5, 0.3-0.8) and seldom or never (0.5, 0.3-0.9) followed information about monkeypox were less likely to be willing to adopt monkeypox vaccination.

Figure 1. Reasons for unwillingness to vaccinate against monkeypox.

Conclusions: The ongoing monkeypox pandemic has not attracted widespread concerns among MSM living with HIV in China. Over half of MSM living with HIV were willing to adopt monkeypox vaccination. Efforts should be made

to raise awareness of the potential risk of monkeypox in this high-risk population. Public health strategies should fully address predictors of vaccination willingness.

EPC0290

Beyond the usual suspects: what really impacts quality of life among older people with HIV?

M. Stooze¹, J. Dawe², D. Cassano¹, R. Keane³, S. Ruth⁴, A. Wilkinson¹, I. Elsum¹, J. Gunn¹, G. Brown⁵, M. West⁶, J. Hoy⁷, J. Power⁸
¹Burnet Institute, Melbourne, Australia, ²University of Bristol, Bristol Medical School, Bristol, United Kingdom, ³Living Positive Victoria, Melbourne, Australia, ⁴Thorne Harbour Health, Melbourne, Australia, ⁵University of New South Wales, Sydney, Australia, ⁶Victorian Department of Health, Melbourne, Australia, ⁷Alfred Hospital, Melbourne, Australia, ⁸La Trobe University, Melbourne, Australia

Background: Improved life expectancy has led to an aging population of people living with HIV (PLHIV). Research on aging among PLHIV has focused on physical health and early onset morbidity, with less attention paid to psychosocial factors affecting quality of life (QoL). To inform programs to support healthy aging among PLHIV in Australia, we determined the association of QoL with a-priori identified experiences of older PLHIV considered modifiable through targeted interventions.

Methods: In an established national survey of the health and wellbeing of Australian PLHIV, participants aged 50+ years completed additional questions relevant to aging. QoL was measured using PozQoL, a validated multidimensional (health, psychological, social, functional) QoL tool (score range=1-5, higher score indicates better QoL). Using covariates selected by directed acyclic graphs, including self-reported comorbidities, general linear regression models indicated change in PozQoL score (reported as β) with past 12-month experience of:

1. Food insecurity;
2. Stigma;
3. Isolation from the HIV community; and;
4. Difficulties accessing non-HIV health services (compared to not having these experiences).

Results: Among 319 participants, median age was 59 years (IQR=54-65), most were male (90%), and identified as gay or bisexual (92%). Mean PozQoL scores were higher among PLHIV who were: older, more educated, lived in rural areas, in a relationship, employed, had higher income, and first diagnosed with HIV pre-cART availability in Australia. Experiences of food insecurity (21%), isolation from the HIV community (36%), stigma (48%) and difficulties accessing non-HIV health services (46%) were common. Overall PozQoL scores were lower among PLHIV who reported experiencing food insecurity ($\beta=0.49$; 95%CI=0.74-0.24), stigma ($\beta=0.53$; 95%CI=0.73-0.33), isolation from HIV community ($\beta=0.49$; 95%CI=0.70-0.29), and difficulty accessing non-HIV health services ($\beta=0.50$; 95%CI=0.71-0.30).

Late-breaker abstracts

Author Index

Most participants (82%) reported at least one co-morbidity and 27% reported >3 co-morbidities; specific co-morbidities and cumulative number of co-morbidities were not associated with overall or domain-specific PozQol scores.

Conclusions: Findings suggest that HIV clinical and other support services should adopt person-centred approaches to supporting the wellbeing of older PLHIV, including integrating programs to support economic security and foster connections with community and broad health service networks.

EPC0291

Time to antiretroviral therapy initiation and its associated factors among people living with HIV: results from the Tanzania HIV Impact Survey 2016-2017

A. Ismail^{1,2}, A. Kailembo², C. Mahende², M. Amuri², P. Njau³, R. Laws⁴, H. Maruyama⁵, D. Hoos⁵, G.S. Mgomella², M. Swaminathan², M.F. Jalloh²

¹Integral Global Consulting, Tucker, United States, ²US Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, ³Ministry of Health, National AIDS Control Programme, Dodoma, Tanzania, United Republic of, ⁴U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, ⁵ICAP at Columbia University, New York, United States

Background: The universal test-and-treat (UTT) strategy for HIV was recommended by World Health Organization in 2015 and was adopted by Tanzania in October 2016. Baseline information on the length of time between HIV diagnosis and initiation on antiretroviral therapy (ART) is lacking, which is useful in the evaluation of UTT strategy progress.

To understand time to ART initiation before UTT implementation, we analyzed data from the Tanzania HIV Impact Survey (THIS) 2016-2017.

Methods: Our evaluation comprises 985 participants living with HIV (PLHIV) aged 15 years and older (figure 1). Participants self-reported HIV status and ART use during interview. In addition, confirmation of HIV status and detection of ART in blood was done in the laboratory.

A cox proportional hazard model was used to estimate demographics and sexual behaviors covariate effects on 'time to ART initiation' before UTT. Sampling weights and Jackknife variance estimation were included during the analysis. We estimated adjusted hazard ratios (aHR) with 95% confidence intervals (95%CI).

Results: Out of 1,070 confirmed PLHIV, 985 were included in the evaluation, whereby 88 PLHIV were diagnosed after UTT adoption and 897 before UTT adoption. Before UTT, the median time to ART initiation was 4 months (inter-quartile range [IQR] 3-7 months) compared to 1 month [IQR: 1-2] after. Prior to UTT, shorter time to ART initiation was associated with being an older adult (50+ years) [aHR

1.39, 95%CI 1.15-1.69] compared to adults 25-49 years and having primary education or higher [aHR 1.29, 95%CI 1.02-1.61] compared to having no formal education.

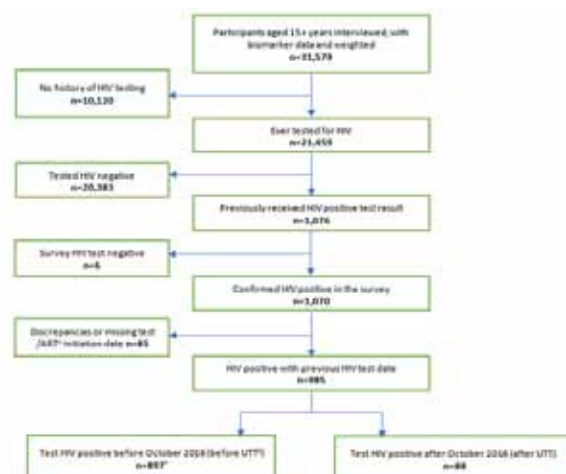

Figure 1. Flowchart of sample size for time to ART initiation analysis: Tanzania HIV Impact Survey 2016-2017.

ART = Antiretroviral Therapy

UTT = Universal Test and Treat

*Initiated in ART = 676 (75.4%) and not initiated on ART = 221 (24.6%) by survey interview date.

Conclusions: Prior to UTT strategy adoption, PLHIV experienced differential time to ART initiation, with those aged 25-49 years and never attended to school notably taking longer time. These findings provide a baseline for measuring the progress towards UTT in Tanzania once results from the ongoing THIS 2022-2023 becomes available.

compared to viral suppression by antiretroviral therapy (ART). We hypothesized that immune activation associated with LLV may promote the development of NCDs.

Methods: At enrollment into the ongoing African Cohort Study, participants who were on ART for at least six months with a viral load <1,000 copies/mL were categorized as either undetectable or LLV (any detectable VL<1000 copies/mL). The interaction between viral load category and 13 biomarkers from a Luminex panel (R&D systems, Minneapolis, MN) were examined for any NCD and separately for hypercholesterolemia, hyperglycemia, elevated blood pressure, and renal insufficiency using modified Poisson regression with robust standard errors.

Results:

Figure 1. Coefficients and 95% confidence intervals for interaction between LLV and biomarker in the association with any NCD.

red box = $p < 0.05$

A total of 1,384 participants were included with 53% ($n=736$) having an undetectable viral load and 47% ($n=648$) LLV. Forty-two percent ($n=586$) had at least one NCD, which did not vary significantly by viral load category (42% undetectable vs 43% LLV, $p=0.77$). Biomarker concentrations were higher among participants with LLV and undetectable viral load for CD163 ($p=0.01$), TNF- α ($p<0.001$), IL-6 ($p=0.04$), CD25/IL-2R α ($p<0.001$), IL-1 β ($p=0.03$), CXCL9 ($p=0.002$), and lower concentration among LLV for CXCL10/IP-10 ($p<0.001$). Examining any NCD, there was a statistically significant interaction between LLV and TNF- α , CCL2/MCP-1, and TNF-RII (Figure 1).

Examining each NCD individually, there was a significant interaction between LLV and CCL2/MCP-1 for elevated blood pressure and hyperglycemia while the LLV and CD163 interaction was statistically significant in the association with hypercholesterolemia.

Conclusions: These findings elucidate a potential mechanism for the development of NCDs among individuals with LLV, primarily interacting with the TNF pathway which has well-established associations with the development cardiovascular disease. Therefore, aggressive management of LLV may positively impact NCDs in PLWH.

Very high HIV incidence among men who have sex with men (MSM) and transgender women (TGW) in Indonesia: a retrospective observational cohort study

B. Dhyah Kunthi Wardhani¹, A.E. Grulich², N.H. Kawi^{3,4}, M.Y.O. Prasetya⁵, H. Luis⁶, G.B.S. Wirawan⁷, P.E. Pradnyani^{8,1}, J. Kaldor², M. Law², S. Ronoatmodjo⁴, E.P. Sihotang³, B.R. Bavinton², P. Januraga^{1,9,10}

¹Udayana University, Center for Public Health Innovation (CPHI), Denpasar, Indonesia, ²The Kirby Institute, University of New South Wales, Sydney, Australia, ³Klinik Utama Globalindo, Jakarta Selatan, Indonesia, ⁴University of Indonesia, Epidemiology Department, Faculty of Public Health, Depok, Indonesia, ⁵Klinik Bali Medika, Badung, Indonesia, ⁶Yayasan Bali Peduli, Denpasar, Indonesia, ⁷University of New South Wales, Sydney, Australia, ⁸Politeknik Kesehatan Kartini Bali, Denpasar, Indonesia, ⁹Udayana University, Department of Public Health and Preventive Medicine, Denpasar, Indonesia, ¹⁰WM Medika Clinic, Yayasan Kerti Praja, Denpasar, Indonesia

Background: There are no longitudinal HIV incidence data among men who have sex with men (MSM) and transgender women (TGW) in Indonesia. Pre-exposure prophylaxis (PrEP) use is very low and HIV treatment cascade outcomes are poor.

Methods: We conducted a retrospective cohort study using medical record data from five private/non-government clinics in Indonesia (Jakarta=1, Bali=4). We reviewed all HIV tests among self-reported MSM/TGW aged ≥ 18 years between 1-Jan-2018 to 31-Dec-2020 in Jakarta and 1-Jan-2017 to 31-Dec-2019 in Bali.

Those with an HIV-negative baseline test and ≥ 1 follow-up tests were included in the person-years (PY) at risk to determine HIV incidence and 95% confidence intervals (CI). Person-years at risk calculation started at first negative test until last recorded negative test or seroconversion. Multivariate Cox-regression was used to determine factors associated with HIV acquisition; we report adjusted Hazard Ratios (aHR) and 95%CI for these associations.

Results: Of 5,203 and 2,815 individuals in Jakarta and Bali, respectively, 3,998 and 2,119 were HIV-negative at baseline (HIV prevalence=23.2% and 21.9%). The longitudinal sample included 1,418 and 873 individuals with repeat tests (min-max=2-13 mean=3.71 SD=2.06 median=3 IQR=2-4).

About one-quarter were aged <25 years, 94% were MSM, and >60% had been tested for HIV previously. In Jakarta, there were 127 HIV incidences in 1354.5 PY, 9.39/100 PY (95%CI=7.89-11.17). In Bali, 71 incidences in 981.2 PY, 7.24/100 PY (95%CI=5.73-9.13).

Compared to those 18-24 years, incidence was lower in older patients (Jakarta - 30-39 years: aHR=0.58, 95%CI=0.35-0.96; 40+ years: aHR=0.34, 95%CI=0.14-0.80; Bali - 25-29 years: aHR=0.51, 95%CI=0.29-0.89; 30-39 years: aHR=0.35, 95%CI=0.19-0.65; 40+ years: aHR=0.11, 95%CI=0.03-0.48). In Jakarta, those with university education had lower incidence than those without (aHR=0.62,

95%CI=0.43-0.91). In Bali, those who were referred by outreach workers had higher incidence than those who self-presented (α HR=1.70, 95%CI=1.04-2.78).

Conclusions: In the first multi-provinces HIV incidence study in Indonesia among MSM/TGW, we observed very high incidence rates. In this setting of very low PrEP use, measures to encourage regular HIV testing and effective use of HIV prevention methods, including rapid PrEP scale-up and demand creation, are urgently needed. Greater local and international investment in HIV prevention and treatment in these populations must be prioritised to meet global AIDS elimination goals.

³University of Bordeaux, National Institute for Health and Medical Research (INSERM) UMR 1219, Research Institute for Sustainable Development (IRD) EMR 271, Bordeaux Population Health Centre, Bordeaux, France, ⁴Espoir Vie-Togo Clinic, Lomé, Togo, ⁵Université de Lomé, Centre de Formation et de Recherche en Santé Publique, Centre Africain de Recherche en Epidémiologie et Santé Publique, Lomé, Togo

Background: Studies to evaluate the associations between food insecurity and mental health among people living with HIV (PLHIV) in West Africa are limited. This study was conducted to determine whether food insecurity is associated with depressive and/or anxiety symptoms among PLHIV in Togo, West Africa.

Methods: PLHIV ≥ 40 years old on ART ≥ 6 months were enrolled at the EVT Clinic, Lomé, Togo. The Household Food Insecurity Access Scale was used to measure food insecurity. Mild to severe depressive and anxiety symptoms were assessed using the Patient Health Questionnaire-9 (score ≥ 5) and Generalized Anxiety Disorder-7 (score ≥ 5) instruments, respectively. Logistic regression was used to identify factors associated with depressive and/or anxiety symptoms.

Results: Among the 300 participants enrolled, 222 (74.0%) were female. The median age was 51 years (IQR 47-57). More than half (54.5%) did not receive an education beyond primary school, and the majority (70.3%) earned $< 50,000$ FCFA (~ 83 USD) per month. The median CD4 count was 509 cells/mm³ (IQR 352-687) and 97.7% were virologically suppressed (< 1000 copies/mL).

The majority (73.0%) were food insecure (11% were mildly food insecure, 41% were moderately food insecure, and 21% were severely food insecure). Nearly half (48.5%) had depressive symptoms (35.0% suffered from mild depression, 10.7% from moderate depression, and 2.7% from

moderately severe depression), and 26.0% suffered from anxiety symptoms (20.7% from mild anxiety and 5.3% from moderate anxiety). The majority (52.8%) suffered from depressive and/or anxiety symptoms.

Moderate and severe food insecurity were associated with depressive symptoms (OR=1.79, 95%CI 1.001-3.20; OR=3.87, 95%CI 1.93-7.78, respectively) and anxiety symptoms (OR=2.41, 95%CI 1.13-5.11; OR=4.90, 95%CI 2.18-10.92, respectively).

Education beyond primary school was protective against both depressive symptoms (OR=0.54, 95%CI 0.34-0.85) and anxiety symptoms (OR=0.34, 95%CI 0.20-0.60). Sex, age, and income were not associated with depressive and/or anxiety symptoms.

In multivariable analysis, severe food insecurity was the strongest predictor of depressive symptoms (OR=3.74, 95%CI 1.85-7.56) and anxiety symptoms (OR=4.76, 95%CI 2.09-10.83).

Conclusions: Food insecurity is strongly associated with poor mental health among PLHIV in Togo. Future prospective studies to understand and address the causal links between food insecurity and mental health are warranted.

Melbourne, Melbourne School of Population and Global Health, Melbourne, Australia

Background: HIV-diagnosed gay and other men who have sex with men (MSM) are a key risk group for hepatitis C acquisition (HCV), with injecting drug use (IDU) a known risk of transmission. Little is known about trends in IDU among MSM in countries with ongoing HCV transmission

among this group. Among MSM who are HIV/HCV-diagnosed, we aim to calculate annual proportions of recent IDU in six high-income countries.

Methods: Data were from the International Collaboration on Hepatitis C Elimination in HIV Cohorts, including data from Australia, Canada, France, Spain, the Netherlands, and Switzerland. Eligibility for this study required individuals to identify as MSM.

The proportion of IDU was the number of MSM reporting recent IDU (i.e., past 1-6 months) divided by the number of MSM with a study visit in a calendar year (2010-2019), stratified by HCV exposure and country.

HCV exposure was an HCV positive antibody or RNA test calculated at baseline (i.e., study enrolment or Jan 1, 2010, whichever was later) and each calendar year.

Results: Of 18,959 participants, 13,709 identified as MSM, of which 718 (5.2%) reported recent IDU between 2010-2019. Among participants HCV exposed (n=1817 at baseline), recent IDU was stable for Australia (n=333) at ~40%, Canada (n=415) at ~20%, France (n=197) at <5%, Spain (n=139) at ~4%, and Switzerland (n=560) at <10%. There was some evidence of a potential decrease in IDU in the Netherlands (n=173; 15% to 9%) but 95%CI were overlapping. Among participants HCV unexposed (n=11,892 at baseline), annual proportions were low, with some evidence of slight increases in France (n=1601), Spain (n=4514), and Switzerland (n=5604), from 0% to 1%, and the Netherlands (n=173) from 0% to 6%, although 95%CI were overlapping for most countries.

Conclusions: Annual proportions of recent IDU were stable among MSM who were HCV exposed, varying between countries, potentially due to differences in cohort design. Among those HCV unexposed, annual proportions of IDU were lower but may have increased, 2010-2019.

Findings indicate IDU remains a risk for potential HCV transmission in these cohorts, highlighting the importance of accessible harm reduction services and HCV testing, treatment, and prevention measures for MSM.

EPC0296

Correlates of HIV infection among Tanzanian young adults aged 15-24 years: evidence from the Tanzania HIV Impact Survey 2016-2017

J. Hawk¹, A. Ismail^{1,2}, A. Kailembo¹, M. Amuri¹, C. Mahende¹, P. Njau³, W. Maokola³, H. Maruyama⁴, K. Brown⁵, G.S. Mgomella¹, M. Swaminathan¹, N. Schaad¹, M.F. Jalloh¹

¹Tanzania Country Office, Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, Tanzania, United Republic of, ²Integral Global Consulting, Tucker, United States, ³National AIDS Control Programme, Dodoma, Tanzania, United Republic of, ⁴Tanzania Country Office, ICAP at Columbia University, Dar es Salaam, Tanzania, United Republic of, ⁵U.S. Centers for Disease Control and Prevention, Atlanta, United States

Background: Despite targeted prevention interventions, young adults aged 15-24 years in Tanzania experience disproportionate risk for HIV infection. While most prevention programs target adolescent girls and young women (AGYW), less is known about factors affecting young adults as the HIV epidemic continues to shift over time. This analysis examines correlates of HIV infection among young people in Tanzania.

Methods: This assessment used nationally representative data from 10,364 participants aged 15-24 years in the Tanzania HIV Impact Survey 2016-2017. HIV status is the primary outcome of interest in this assessment.

Firstly, HIV infection is described in the sample of young people. Secondly, log-binomial regression models were used to assess social, demographic, and sexual behavior correlates of HIV positive status among young adults.

Sampling weights to account for study design and non-response, and Jackknife variance estimation were included during the analysis. We estimated prevalence ratios (PR) with their corresponding 95% confidence intervals (95%CI).

Results: Among 10,364 participants aged 15-24 who were tested for HIV, HIV prevalence was 1.38% (CI: 1.14-1.66) with females (2.12%CI: 1.75-2.58) and males (0.63%CI: 0.40-0.99). From multivariable analysis, young adults aged 20-24 years were three times more likely to have HIV infection than those aged 15-19 years (aPR:3.03 95%CI 1.78-5.16).

Those with no education had increased likelihood of HIV infection compared to those who had secondary or higher education (aPR: 2.41 95%CI: 1.39-4.19).

Furthermore, respondents who reported engaging in sex for money were three times more likely to have HIV infection than their peers who did not engage in transaction sex (aPR: 3.06 95%CI: 1.65-5.66).

Conclusions: Our findings showed varied vulnerability of young people to HIV infection. HIV risk was markedly increased among the older age group, those with no education, and those engaging in transactional sex.

While some global efforts are on-going to reduce infection among adolescents and young adults including UNAIDS 2025 road map, continuously finding innovative

A cluster of phylogenetically close strains to the highly virulent variant of HIV-1 subtype B circulating in the Netherlands was detected in Japan

M. Otani¹, M. Imahashi², R. Minami³, A. Hachiya², M. Matsuda², M. Nishizawa¹, T. Shiino^{4,1}, T. Matano^{1,5}, Y. Yokomaku², Y. Iwatani¹, T. Kikuchi¹, Japanese Drug Resistance HIV-1 Surveillance Network

¹National Institute of Infectious Diseases, AIDS Research Center, Tokyo, Japan, ²National Hospital Organization Nagoya Medical Center, Clinical Research Center, Nagoya, Japan, ³National Hospital Organization Kyushu Medical Center, Clinical Research Institute, Fukuoka, Japan, ⁴National Center for Global Health and Medicine, Center for Clinical Sciences, Tokyo, Japan, ⁵The University of Tokyo, The Institute of Medical Science, Tokyo, Japan

Background: A highly virulent variant of HIV-1 subtype B (VB variant) considered to induce high set-point viral load (VL) and rapid CD4 decline was reported in the Netherlands. In the present study, we examined whether HIV-1 strains phylogenetically close to the VB variant are circulating in Japan.

Methods: Nucleotide sequences in the protease and reverse transcriptase (PR-RT) coding regions (nt 2,253-3,269 in HXB2) from 9,735 people newly diagnosed with HIV-1 in 2003-2020 in the Japanese Drug Resistance HIV-1 Surveillance Network, and all publicly available 288,324 PR-RT sequences in GenBank as of 2022/08/31, including 15 VB variant sequences, were used for the analyses. Phylogenetic trees were inferred using FastTree 2.1. Genetic distances were calculated by TN93.

Results: Phylogenetic analysis of the VB variant and Japanese sequences revealed that 8 Japanese sequences were in the same cluster with the VB variant strains (local support value: LSV 98%), having a median genetic distance of 3.5% (range 2.6%-4.6%) to a representative VB variant (MT458931).

Then, to assess the phylogenetic relationship of the VB variant and available global sequences, we performed a phylogenetic analysis including the 15 VB variant sequences, the abovementioned 8 Japanese sequences, 14,210 randomly selected global sequences (5% of the entire GenBank), and 396 sequences with genetic distance <4% to MT458931 from the entire Genbank PR-RT. In the global phylogenetic tree, 26 sequences, including 15 VB variant sequences, 3 previously reported sequences from Poland and Belgium, and 8 Japanese sequences, belonged to the same cluster (LSV 99%).

The 8 individuals were all Japanese MSM diagnosed in 2009-2016, with a median VL of 51,000 copies/mL (IQR 33,575-98,250) and CD4 count of 255/ μ L (149-392) at diag-

nosis. Comparing the 8 individuals with other Japanese MSM living with HIV-1 subtype B (n=6,197, median VL: 69,000 [20,000-250,000], median CD4: 239 [78-384]), there were no significant differences in VL or CD4 count at diagnosis (age-adjusted regression).

Conclusions: Phylogenetic analysis of the PR-RT region identified a Japanese cluster that is phylogenetically close to the VB variant. Further analysis of host and viral factors could be the next issue to be addressed to elucidate the mechanism of difference in virulence.

EPC0298

Methods to establish accurate transmission cluster identification for HIV public health use

B. Obeng¹, R. Kouyos², K. Kusejko², A. Kelleher¹, F. Di Giallonardo¹

¹University of New South Wales, Kirby Institute, Sydney, Australia, ²University of Zurich, Zurich, Switzerland, Division of Infectious Diseases and Hospital Epidemiology, Zurich, Switzerland

Background: To achieve the UNAIDS 95/95/95 targets, a better understanding of the drivers of the HIV-1 epidemic with multifaceted approaches including accurate transmission cluster and outbreak identification are needed. However, viral sequences from different laboratories are derived from a variety of regions of the HIV-1 genome, which may affect phylogenetic clustering outputs. We assessed the accuracy of phylogenetics based on different HIV-1 genomic regions.

Methods: We used 190 subtype B and 403 subtype C near full-length genome sequences. The two sequence sets were divided into sub-genomic data sets covering *gag*, *pol*, and *env*, and *pol* was further sub-divided into *pr-rt*, *rt-int*, and *pr-rt-int*. Cluster analyses were performed using distance and maximum-likelihood methods by specifying varying node support and distance thresholds of 70-90% and 1.5-4.5% respectively. Tree topologies of full-length genomes were compared with sub-genomic regions using *v_measure* and *variation_info* to assess the goodness and similarity in cluster partitions and visualized via principal component analysis.

Results: Tree topologies differed for different genomic regions of both datasets. The full-length trees had the highest log-likelihoods (-165150.63 for subtype B and -555599.49 for subtype C) when compared to *gag*, *pol*, *env* of subtypes B and C respectively. The *pr-rt-int* trees also had higher log-likelihoods (-166423.16 for subtype B and -562903.76 for subtype C) when compared to *pr-rt* and *rt-int* of subtypes B and C respectively. However, the observed variation in topologies did not statistically affect the homogeneity of clustering (mean *v_measure*= 0.99) but had observed similarity in cluster partitions (mean *variation_info*= 2.3e-4). For both full-length and *pr-rt-int* trees, the approximately-unbiased (AU) test of topology was statistically significant (*p*AU=+1), indicating accep-

tance of those trees as representative of the true evolutionary tree. The clustering pattern was most stable across all sub-genomic regions (except *env*); 15/16 (94%) for subtype B and 20/23 (87%) for subtype C when using a genetic distance of 2.5%.

Conclusions: Using a genetic distance of 2.5% is most suitable for clustering analyses when using sequence data covering different sub-genomic regions. Notably, using the *pr-rt-int* region is sufficient for determining potential transmission clusters and can be used for near real-time HIV-1 cluster detection.

EPC0299

HIV incidence among key populations accessing free HIV testing under Universal Health Coverage in Thailand from 2008 to 2022

S. Phuthomdee^{1,2}, S. Teeraananchai^{1,3}, C. Lertpiriyasuwat⁴, R. Triamwichanon⁵, P. Wareechai⁵, P. Benjarattanaporn⁶, D. C. Boettiger⁷, N. Phanuphak⁸

¹Kasetsart University, Faculty of Science, Department of Statistics, Bangkok, Thailand, ²Srinakharinwirot University, Panyanantaphikkhu Chonprathan Medical Center, Nonthaburi, Thailand, ³Kasetsart University, Faculty of Science, Biomedical Data Science Program, Bangkok, Thailand, ⁴Ministry of Public Health, Department of Disease Control, Bureau of AIDS and STIs, Nonthaburi, Thailand, ⁵National Health Security Office, Bangkok, Thailand, ⁶Joint United Nations Programme on HIV/AIDS, Bangkok, Thailand, ⁷University of New South Wales, Kirby Institute, Sydney, Australia, ⁸Institute of HIV Research and Innovation (IHRI), Bangkok, Thailand

Background: New HIV infections in Thailand are concentrated among key populations, mainly men who have sex with men (MSM), transgender women (TGW), sex workers (SW), and people who inject drugs (PWID). We studied HIV incidence among key populations and associated factors using our National Voluntary Counselling and Testing (VCT) Database which records HIV test results of Thai citizens who access free HIV testing twice a year under the country's Universal Health Coverage (UHC) system.

Methods: HIV testing data from the VCT Database were retrieved from key population individuals aged ≥15 years from 2008-2022. Baseline was defined as the date of first HIV test. HIV incidence rate was calculated by dividing the total number of confirmed HIV-positive cases by the total number of person-years of follow-up (PY). Kaplan-Meier graphs were used to estimate overall cumulative probability of HIV incidence. Cox regression analysis was performed to identify factors associated with HIV incidence and calculate the hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: There were 76,393 (55%) MSM, 26,357 (19%) PWID, 31,920 (23%) SW, and 3,014 (2%) TGW. HIV testing increased from 12,655 in 2008-2013 to 42,484 in 2014-2016, and 82,547 in 2017-2022. HIV incidence rate was highest among TGW at 216.9 (95%CI 199.6-235.7), followed by MSM at 151.9 (95%CI

150.0-154.2), PWID at 21.6 (95%CI 20.8-22.4), and SW at 11.65 (95%CI 10.90-12.45) per 100 PY. Median (IQR) CD4 count at diagnosis was highest among MSM at 253 (86-415), followed by TGW at 239 (81-447), SW at 184 (54-401), and lowest in PWID at 113 (32-304) cells/mm³. Recent years of HIV testing decreased chance of HIV incidence; 2008-2010 as reference; aHR 0.41 for 2011-2013 (95%CI 0.38-0.44), 0.21 for 2014-2016 (95%CI 0.19-0.22), and 0.11 for 2017-2022 (95%CI 0.10-0.12).

Conclusions: Overall HIV incidence among key populations decreased over time. MSM and TGW had a higher incidence, although CD4 counts at diagnosis tended to be higher, than PWID and SW. HIV testing among key populations increased over time corresponding to the establishment of the "key population-led health services" in 2015. Thailand must ensure the sustainability of UHC and KPLHS to reach its ending AIDS goal.

EPC0300

Predictors of frailty transitions in persons aging with HIV (PAH) in Uganda: the HASA prospective cohort

G. Banturaki¹, P. Mbabazi¹, S. Naikoba¹, J. Musazizi¹, B. Castelnouvo¹

¹Infectious Diseases Institute, Research, Kampala, Uganda

Background: The scale up of ART in sub-Saharan Africa (SSA) has resulted into increased life expectancy. Frailty is an aging-related syndrome, heightened by acquired HIV, marked by diminished physiologic reserve and vulnerability to stress, predictive of hospitalization or deaths. Elderly persons can easily transition from one state of frailty to another, thus we aimed to describe the frailty transitions and the risk factors of frailty in clients ≥60years in Kampala, Uganda during 1 year follow up.

Methods: We used the Markov multi-state model to estimate frailty transition probabilities in adults ≥ 60 years during 1 year of follow-up, the data that is so far collected. Four states of possible transition were considered: robust, pre-frail, frail, and death. Frailty was assessed using the physical frailty phenotype. Covariates were selected into the model based on their theoretical, clinical, and statistical relevance to a stable parsimonious model. We used the msm in R software to analyze the frailty transition intensities.

Results: We included 451 participants. At baseline, the median age was 64 years (IQR 60-68) 231 (51.2%) were males. The baseline CD4 count was 664(IQR 461-795) cells/mm³. Majority 412(91.8%) had viral load less than 50 copies/ml, and 130(28.8%) had ≥2 non-communicable diseases (NCDs).

Females were associated with a lower risk of transitioning from robust to pre-frail, pre-frail to robust compared to males (HR: 0.93(0.42-2.08), HR: 0.60(0.26-1.40) respectively. Females had an increased risk of transitioning from pre-frail to frail, pre-frail to death compared to males (HR: 1.78(0.66-4.82), (HR: 1.17(0.14-9.99) respectively. PAH with 2 or

more NCDs were more at risk of transitioning from robust to pre-frail, pre-frail to frail (HR: 1.28 CI (0.54-3.01), (HR: 2.74 (1.05-7.15) respectively. Pre-frail PAH with 2 or more NCDs were at a higher risk of death compare to those with 1 NCD (HR: 1.59 (0.22-11.7).

Conclusions: Gender and NCDs are risk factors associated with frailty transitions. Understanding the predictors of frailty transitions will help design of interventions that support transition into better frailty states.

EPC0301

Effectiveness of harm reduction interventions on HIV incidence among people who inject drugs in a conflict affected region of Myanmar, 2008-2020: analysis of a retrospective cohort dataset

A. McNaughton¹, J. Stone², K.T. Oo³, Z.Z. Let⁴, M. Taw⁴, M.T. Aung⁴, A.M. Min⁴, A. Lim², E. Wisse⁵, P. Vickerman²

¹University of Oxford, Pandemic Sciences Institute, Oxford, United Kingdom, ²University of Bristol, Population Health Sciences, Bristol, United Kingdom, ³Community Support Worker, Kachin, Myanmar, ⁴Médecins du Monde, Kachin, Myanmar, ⁵Médecins du Monde, Paris, France

Background: Kachin in Myanmar is heavily affected by conflict. People who inject drugs (PWID) in Kachin have high HIV prevalence (>40%), but there is no data on incidence. We used HIV testing data from three harm reduction drop-in centres (DIC) in Kachin (2008-2020) to determine HIV incidence trends among PWID and associations with intervention uptake.

Methods: Individuals were HIV-tested at first DIC visit and periodically thereafter, during which demographic and risk behaviour data were collected. Two DIC provided opioid agonist therapy (OAT) from 2008. Monthly DIC-level needle/syringe provision (NSP) data was available for 2012-2020. Site-level 6-monthly NSP coverage was denoted low, high, or medium if it was below the lower quartile, above upper quartile, or between these quartiles of provision levels over 2012-2020, respectively. HIV incidence was estimated by linking subsequent test records for those initially HIV-negative. Associations with incidence were examined using Cox regression.

Results: Follow-up HIV testing data was available for 33.6% (2,227) PWID initially testing HIV-negative, with 444 incident HIV infections during 6,266.5 person-years (py) of follow-up. Overall HIV incidence was 7.1 per 100py (95%CI 6.5-7.8), which decreased from 19.3 (13.3-28.2) in 2008-11 to 5.2 per 100py (4.6-5.9) in 2017-20. After adjustment, recent (≤6weeks) injecting (aHR 1.74, 1.35-2.25) and needle sharing (aHR 2.00, 1.48-2.70) were associated with higher incidence. In a reduced dataset including data on OAT access and NSP coverage (2012-2020 for DIC providing OAT), being on OAT during follow-up was associated with reduced HIV incidence (aHR 0.36, 0.27-0.48, compared to never taking OAT) as was high NSP coverage (aHR 0.64, 0.48-0.84, compared to medium coverage). 6-monthly NSP coverage was inversely correlated with HIV incidence (Figure).

Figure. NSP and HIV incidence correlation.

Conclusions: Although HIV incidence is high among PWID in Kachin, findings underscore the substantial impact that OAT and NSP can have in challenging resource-poor conflict-affected settings, highlighting the importance of offering widespread provision.

EPC0302

Investigating the associations between drought, poverty, high-risk sexual behaviours, and HIV incidence in Sub-Saharan Africa: a cross-sectional study

A. Trickey¹, L. Johnson², R. Bonifacio³, A. Kiragga⁴, G. Howard⁵, S. Biraro⁶, T. Wagener⁷, A. Low⁸, P. Vickerman¹

¹University of Bristol, Population Health Sciences, Bristol, United Kingdom, ²University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health and Family Medicine, Cape Town, South Africa, ³World Food Programme, Geospatial Analysis Unit, Rome, Italy, ⁴Makerere University, Research Department, Infectious Diseases Institute, College of Health Sciences, Kampala, Uganda, ⁵University of Bristol, Department of Civil Engineering and Cabot Institute of the Environment, Bristol, United Kingdom, ⁶ICAP at Columbia University, Kampala, Uganda, ⁷University of Potsdam, Institute of Environmental Science and Geography, Potsdam, Germany, ⁸Columbia University, Department of Epidemiology, Mailman School of Public Health, New York, United States

Background: Climate change is increasing the likelihood of drought in sub-Saharan Africa where HIV prevalence is high. It has been hypothesised that drought and other extreme weather events could increase levels of HIV transmission through various mediating mechanisms. We investigated potential mechanisms linking drought to poverty, poverty to increased sexual behaviours, and increased sexual behaviours to recent HIV acquisition in sub-Saharan Africa.

Methods: Nationally-representative Population-Based HIV Impact Assessment (PHIA) surveys were undertaken among people aged 15-59 during 2016 in Eswatini, Lesotho, Tanzania, Uganda, and Zambia. PHIA data were geospatially linked to Climate Hazards Group InfraRed Precipitation with Station (CHIRPS) data for 2014-2016, with

local droughts defined as cumulative rainfall between 2014-2016 being in <15th percentile of all 2-year periods over 1981-2016.

Multivariable logistic regression was used to examine the associations between:

- Drought and poverty 2 lowest wealth quintiles),
- Wealth quintiles and sexual behaviours (transactional sex, intergenerational sex, and high-risk sex [condomless sex with a non-permanent partner]), and;
- Sexual behaviours and recent HIV acquisition (measured using antigen avidity immunoassays).

Analyses a/b were stratified by urban/rural, and analyses b/c were stratified by age and gender. Results for each country were pooled using random-effects meta-analysis.

Results: Data were included on 102,081 people (51.6% female); 31.5% resided in areas affected by drought during 2014-2016. We found positive associations between experiencing drought and poverty in both rural and urban areas, and generally negative associations between wealth and increased sexual behaviours for women, but less so for men.

Transactional sex, in particular, was less common among wealthier than poorer women. Among women in each age group analysed, those reporting each sexual behaviour had higher odds of recent HIV acquisition, except for intergenerational sex among women aged 25-59.

Men of all ages reporting transactional sex had higher odds of recent HIV acquisition, and men aged 15-24 and 40-59 reporting high-risk sex also had increased odds of recent HIV.

Conclusions: Our findings suggest that droughts could potentially increase HIV transmission through increasing poverty and then sexual risk behaviours, possibly more so in women. Future analyses need to better understand this potential causal mechanism.

EPC0303

Past-year transactional sex associated with HIV and STIs among MSM in the U.S.: findings from the American Men's Internet Survey, 2017-2021

K. Atkins¹, J.M. Wiginton², T. Carpino¹, T.H. Sanchez³, O.W. Edwards³, S.M. Murray⁴, S.D. Baral¹

¹Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States,

²University of California-San Diego, Division of Infectious Diseases and Global Public Health, Department of

Medicine, San Diego, United States, ³Emory University Rollins School of Public Health, Department of

Epidemiology, Atlanta, United States, ⁴Johns Hopkins Bloomberg School of Public Health, Department of Mental Health, Baltimore, United States

Background: Cisgender men who have sex with men (MSM) engaged in transactional sex (TS) experience socio-structural vulnerabilities that may shape HIV risk. Few studies have estimated the prevalence or correlates of TS among MSM in the United States (U.S.).

Methods: Using 2017-2021 data from the American Men's Internet Survey, we summarized the prevalence of TS (past-year receipt of money or drugs for sex) and assessed differences in characteristics of MSM who did and did not report TS via chi-square tests. Modified Poisson regression with robust variance estimation was used to calculate prevalence ratios (PRs) associated with reporting TS for past-year sexually transmitted infection (STI), current HIV status and either antiretroviral use (if living with HIV) or pre-exposure prophylaxis (PrEP) use (if not living with HIV), adjusting for age, education, income, survey year, and healthcare engagement.

Results: Across 52,449 observations, TS prevalence was 3.67% (n=1,927). Across survey years, prevalence ranged from 3.01% in 2017 to 4.26% in 2020 overall and 6.41% in 2018 to 31.6% in 2021 among MSM living with HIV. In bivariate analyses (Table), TS was associated with younger age, non-Hispanic white race/ethnicity, urbanicity, lower income, past-year homelessness, being uninsured, condomless anal sex (CAS) and serodiscordant CAS, and illicit and injection drug use. In adjusted analyses, TS was associated with increased HIV (PR 1.50, 95% CI=1.32-1.71) and STI prevalence (PR 2.38, 95% CI=2.18-2.60) and lower antiretroviral use (PR 0.92, 95% CI=0.87-0.96). TS was not associated with PrEP use.

¹ "Yes" responses shown; ² Not shown; other/multiple insurance (7.1% among those with no TS history; 7.0% among those with TS history); ³ Based on the U.S. National Center for Health Statistics (NCHS) 2013 urban-rural classification scheme. Urban: large central metropolitan, large fringe metropolitan, medium metropolitan, small metropolitan. Rural: micropolitan, non-core (nonmetropolitan counties not in micropolitan statistical areas).

Table. Characteristics of cisgender MSM in the US by past-year transactional sex (n = 52,449).

Conclusions: Among 50,000+ cisgender U.S. MSM, structural and behavioral risks converge to reinforce HIV/STI disparities for those reporting TS. While sex work remains criminalized in the U.S., reaching MSM engaged in TS via interventions that not only address substance use and HIV care gaps, but also structural vulnerabilities including housing instability and poverty, is critical for ending the HIV epidemic.

**EPC0304****HIV acquisition among adolescent girls and young women 13-24 years in Wakiso district, Uganda**

A. Daama^{1,2}, S. Mugamba¹, G. Kigozi Nalwoga¹,
E. Kyasanku¹, G. Kigozi¹

¹Africa Medical and Behavioral Sciences Organization, Kampala, Uganda, ²Makerere University, Kampala, Uganda

Background: Despite the HIV prevention strategy such as the Determined Resilient Aids-free Safe girl /woman (DREAMS) that targets AGYW aged 10-24 in Uganda, HIV infections still occur. We described HIV positivity rates among Adolescent girls and young women (AGYW) to inform HIV programming.

Methods: Data from a cross-sectional study was conducted from March 1st to September 30th, 2021, among Adolescent girls and young women (AGYW) of Wakiso district in the Population Health Surveillance cohort implemented by the Africa Medical and Behavioral Sciences Organization. HIV tests were conducted to establish HIV positivity rates. Semi-structured data was collected and variables such as age, marital status, education, occupation were included in the analysis.

At bivariate analysis, variables with $P < 0.20$ were included in the logistic regression model. A multivariable logistic regression was used to determine the predictors HIV acquisition.

Results: Of 433 HIV tests conducted, 3.2%(14/433) were positive. AGYW aged 20-24 had the highest positivity rate of 6%(11/183), followed by 15-19 years with HIV prevalence approximately 2% (3/183) and 13-14 years had zero HIV infection. AGYW whose occupation was agriculture had a higher HIV risk compared to those engaged in business, (AOR=5.6; 95% CI: 1.23, 25.62), $p = 0.026$. Age, education level, marital status and pregnancy were not associated with HIV acquisition.

Conclusions: Overall, HIV positivity rates increased with age and therefore, more efforts should focus on AGYW aged 20-24. However, among AGYW aged 13-14 had zero infections, therefore the Ugandan ministry of health should strengthen HIV prevention and scale-up testing among AGYW whose primary occupation is agriculture.

EPC0305**The MPOX/HIV co-infection data dashboard**

N. Girometti¹, S. Bhagani², C. Brooks³, H. Honour³,
A. Pozniak⁴

¹Chelsea and Westminster Hospital, HIV, London, United Kingdom, ²Royal Free Hospital, London, United Kingdom, ³Research Organisation Kings Cross, London, United Kingdom, ⁴NEAT ID, Brussels, Belgium

Background: People living with HIV (PLHIV) may have been affected disproportionately, 48% of persons reported to WHO were MPOX/HIV coinfectd. There were concerns PLHIV may be more likely to be hospitalised with a higher risk of death and this information was not specifically being documented contemporaneously.

As a rapid response to monitor this, the NEAT ID network set up a web-based dashboard collecting monthly data on MPOX/HIV co-infection, the number hospitalised and deaths from sites in Europe and Latin America. Aggregate data could be accessed on-line.

Methods: The Dashboard was opened in July 2022 to the network of NEAT ID Foundation of 150 sites in 20 countries in collaboration with EACS.. Participating sites were asked to back date entries to April 2022 and then submitted data on cases from July to November 2022. Data were from 31 global submitting sites 26 from 16 European countries and 5 in Latin America.

Data were collected cumulatively over time recording the number of cases of MPOX/HIV infection recorded, hospitalisations and deaths. The data were presented graphically on the NEAT ID website for public view.

Results: There were 907 persons with MPOX/HIV Co-infection reported from the network from April to end November 2022 with 53 (5.8%) Hospitalisations and 1 (1.1%) Death. The majority of persons were reported from Europe with 778 cases and 51 hospitalisations but no deaths. There were 129 persons reported from Latin America including 2 hospitalisations and the only death. There was a substantial increase in cases from June onwards with a flattening off by October.

Conclusions: The dashboard was helpful in that it was reassuring there was no signal during the evolution of the MPOX epidemic that hospitalisations or deaths were disproportionately occurring in the MPOX/HIV co-infected population over the 7 months of data reporting and was consistent with WHO global general population data.

EPC0306

Elevated homocysteine may mediate the association of HIV with subclinical coronary atherosclerosis among middle-aged adults

H. Lai¹, S. Lai¹, G. Gerstenblith²¹University of Maryland School of Medicine / Institute of Human Virology, Epidemiology, Baltimore, United States,²Johns Hopkins School of Medicine, Medicine, Baltimore, United States

Background: Elevated homocysteine may mediate the development of coronary atherosclerotic disease in middle-aged and older adults. It has been shown that people with HIV tend to have higher homocysteine concentrations than those without HIV. However, whether and how elevated homocysteine impacts HIV-associated subclinical coronary artery disease has not been reported. The key objective of this study was to examine whether and how elevated homocysteine influences HIV-associated coronary stenosis among middle-aged and older adults.

Methods: Between June 2004 and November 2019, 922 middle-aged adults, most of whom were black, with/without HIV in Baltimore, Maryland, United States, were enrolled in an observational study of the effects of HIV and other factors on subclinical coronary atherosclerosis. Those with HIV were recruited from the Johns Hopkins Adult HIV clinic. Those without HIV were recruited from the same neighborhoods where the majority of participants with HIV resided. The Committee on Human Research at the Johns Hopkins School of Medicine approved the study protocol.

Subclinical coronary atherosclerosis was confirmed with contrast-enhanced computed tomographic angiography. Of these 922, 707 with measured homocysteine were included in this study. mediation analysis was performed to examine whether and how elevated homocysteine mediated the association between HIV and subclinical coronary stenosis.

Results: Among the 707 study participants, 297 were female, 477 were living with HIV, and 313 had coronary stenosis. The mean age was 54.5 (± 8.9) years. After adjusting for cigarette smoking, glucose, HDL, LDL, depression, cocaine use and race, causal mediation analysis showed that the effect of HIV on coronary stenosis absent elevated homocysteine ($> 14 \mu\text{mol/L}$) was not significant ($p=0.13$), 35% of the HIV effect on coronary stenosis was attributed to the mediation of elevated homocysteine ($p=0.02$), and the proportion of total effect due to the interaction between HIV and elevated homocysteine was 64%.

Conclusions: This study suggested that one possible causal pathway through which HIV was associated with elevated homocysteine (mediator), and the mediator was associated with coronary stenosis. The mediator accounted for a substantial portion of the HIV effect, and the magnitude of the effect of HIV on coronary stenosis depended on the levels of homocysteine.

EPC0307

Trends towards micro-elimination of HIV transmission among gay and bisexual men in New South Wales (NSW)

P. Keen¹, S. Nigro², C. Chan¹, M. Holt³, B.R. Bavinton¹, V. Delpech², C. Selvey², C. Power⁴, R. Guy¹, S. Clackett⁴, A. McNulty^{5,6}, M. Vaughan⁷, C. Treloar⁴, C. Murray⁴, J. Costello⁸, A. Pinto¹, B. Luisi⁹, A.E. Grulich¹, on behalf of the NSW HIV Prevention Research Implementation Science and Monitoring (HIV PRISM) Partnership
¹Kirby Institute, Sydney, Australia, ²Communicable Diseases Branch, Health Protection NSW, NSW Health, Sydney, Australia, ³Centre for Social Research in Health, UNSW, Sydney, Australia, ⁴Centre for Population Health, NSW Ministry of Health, Sydney, Australia, ⁵Sydney Sexual Health Centre, Sydney, Australia, ⁶School of Population Health, UNSW Sydney, Sydney, Australia, ⁷ACON, Sydney, Australia, ⁸Positive Life NSW, Sydney, Australia, ⁹NSW Multicultural HIV and Hepatitis Service, Sydney, Australia

Background: The NSW HIV Strategy 2021-2025 targets 'virtual elimination', which it defines as a 90% reduction in HIV infections relative to a 2008-2012 baseline. It also contains ambitious targets for increased HIV testing and PrEP-use in gay and bisexual men (GBM).

Methods: We examined trends in HIV notifications among GBM, and in "early-stage infections", defined as HIV likely acquired in the previous 12 months. Trends in HIV testing (previous 12 months) and PrEP use (previous six months) among GBM reporting condomless anal intercourse with casual partners (CLAIC) were examined in the Sydney Gay Community Periodic Survey (behavioural surveillance surveys) between 2008-2021.

We examined trends state-wide, and in 3 postcode-defined strata, based on estimated proportions of gay male residents in each postcode: $\geq 20\%$ gay (inner-city Sydney); 5-19% (inner-metropolitan); and $< 5\%$ (outer-metropolitan and remainder of NSW).

We assessed time trends in testing and PrEP within these postcode categories, and differences between postcode categories in 2021 were assessed using logistic regression.

Results: Compared to the baseline, annual notifications among GBM declined 49% overall (from the five-year mean of 267 between 2008-2012 to 136 in 2021), and by 85%, 46%, and 22% in $\geq 20\%$, 5-19% and $< 5\%$ postcodes, respectively. Early-stage HIV infections declined even more (70% overall; 138 to 42) and by 95%, 75% and 39% across postcode categories. During 2008-2021 annual HIV testing increased, both overall ($p<0.001$), and in each postcode category ($p<0.001$ in each).

In 2021, men in the $\geq 20\%$ postcodes had higher HIV testing (95%) than men in the $< 5\%$ postcodes (87%; $p=0.015$). Between 2015-2021 PrEP use also increased overall ($p<0.001$) and in each postcode category ($p<0.001$ in each). In 2021, men in the $\geq 20\%$ postcodes had higher PrEP use (83%) than men in the 5-19% and $< 5\%$ postcodes (71%; $p=0.021$, and 51%; $p<0.001$, respectively).

Author Index

Conclusions: HIV notifications among GBM in NSW have declined, and in inner-Sydney declines in recent infections have exceeded the Strategy target for virtual elimination of HIV transmission. This was reflected in prevention uptake, with higher testing and PrEP use among men in inner-Sydney. Achieving state-wide HIV elimination in GBM will require increased uptake of testing and PrEP among GBM outside inner-Sydney.

EPC0308

Active linkage to care outcomes in the Mozambique Population-based HIV Impact Assessment (INSIDA 2021)

A. Nicolau¹, E. Fazito Rezende², Â. Augusto³, A. Sabonete³, K. Ngale¹, M. Boothe⁴, M. Metz², S. M. Farley², K.C. McCabe⁵, G. Amane⁶, E. Samo Gudo³

¹ICAP at Columbia University, Maputo, Mozambique, ²ICAP at Columbia University, New York, United States, ³National Institute of Health (INS), Marracuene, Mozambique, ⁴Joint United Nations Programme on HIV/AIDS (UNAIDS), Maputo, Mozambique, ⁵MassGenics assigned to Division of Global HIV & TB, US Centers for Disease Control and Prevention, Maputo, Mozambique, ⁶National Program for Control of STIs & HIV/AIDS, Ministry of Health, Maputo, Mozambique

Background: The Mozambique Population-based HIV Impact Assessment was conducted in 2021/2022 to measure the impact of the national response to HIV among adults 15 years and older. Participants who tested HIV-positive during the survey and reported not being on antiretroviral therapy (ART), were offered active linkage to care (ALTC).

Methods: The contact information (phone number and address) of those consenting to ALTC was shared with provincial HIV managers within 7 days of completing data collection in the enumeration area. HIV managers coordinated linkage activities with health counselors from Health Facilities (HF) and community-based organizations (CBOs). Survey staff contacted the HIV managers to confirm the linkage outcome of each participant.

A spreadsheet was used to register the dates participants were tested, contacted and initiated on ART.

Results: Of the 14,488 individuals tested for HIV using the National Rapid Test algorithm, 2,038 positive participants were identified; of these, 744 participants were eligible for ALTC. Among the eligible participants, 709 (95.3%) provided consent to have their contact information shared for ALTC, and 660 (93.1%) were successfully contacted by health counselors. Participants that selected to be contacted only by visits were less likely to be successfully contacted (86.9%) when compared to those that chose to be contacted by either SMS or call (96.3%). Health counselors were unable to contact the remaining 49 (6.9%) participants due to imprecise address or outdated/inaccurate phone number collected during the survey. Of the participants that could be contacted, 618 (93.6%) were successfully initiated on ART and 42 (6.4%) did not visit the HF

after contact. Overall, 618 (83.1%) of participants eligible for ALTC initiated ART. The mean duration from household testing to initiation of treatment was approximately 30 days.

Conclusions: Linking household-based survey participants to HIV care and treatment has always been a challenge. However, INSIDA 2021 demonstrates that ALTC is feasible when conducted in close collaboration with existing health system processes and local (or community) partnerships. Survey ALTC could be improved by ensuring accurate contact information is collected during the survey interview, sensitizing the participant of the importance of providing a phone number, and by reducing the linkage time.

Population size estimation within a biobehavioral survey among people who inject drugs and men who have sex with men in the survey cities of the Kyrgyz Republic, 2021

N. Usmanova¹, B. Kalmyrzaev¹, D. Biihosunova¹, A. Mereke², A. McIntyre², J. Neal², B. Sheratieva³, L. Yanbukhtina³, C. Zhumalieva³, A. Solpueva³, A. Bekbolotov³, M. Tursunbekov⁴, A. Kariyova⁴, G. Esenkeldieva⁴, V. Ivakin⁵, A. Deryabina⁵, P. Nado^{1,11}

¹Centers for Disease Control and Prevention, DGHT, Bishkek, Kyrgyzstan, ²Centers for Disease Control and Prevention, DGHT, Atlanta, United States, ³Republican Center for Control of Blood Born Viral Hepatitis and HIV, Bishkek, Kyrgyzstan, ⁴ICAP at Columbia University, Bishkek, Kyrgyzstan, ⁵ICAP at Columbia University, Central Asia Regional Office, Almaty, Kazakhstan

Background: The Kyrgyz Republic (KR) is a country with an HIV epidemic concentrated among key populations (KP). However, updated, high-quality population size estimates (PSE) for KP are lacking. Accurate KP PSE, particularly at a sub-national level, are necessary to design and evaluate programs and policies to prevent new HIV acquisitions and to monitor the dynamics of the epidemic. Incorporating empirical PSE methods within biobehavioral surveys may offer an efficient opportunity to generate valid PSEs for select populations.

Methods: Using respondent-driven sampling (RDS), a biobehavioral survey (BBS) was conducted among PWID in Bishkek, Karabalta, Karasuu, Osh, Tokmok, and Sokuluk and among MSM in Bishkek and Osh in 2021. The BBS incorporated multiple empirical PSE methods – successive sampling PSE (SS-PSE), unique object multiplier, 3-source capture – recapture (3-SCR) and service multiplier.

A Bayesian-based model was used to synthesize the various estimates to generate point estimates and plausibility bounds by location.

Results: The results of the PSE exercise suggest that Bishkek had 6,100 MSM, constituting 2.0% of the adult male population (plausibility bounds [PB], 1.7%-2.4%); Osh – 860 (1.0%; 0.8%-1.1%). The number of PWID was 4,100 (1.4%; PB,

1.1%-1.6%) in Bishkek; 110 (1.1%; 0.7%-1.4%) in Kara-Balta; 380 (1.4%; 1.2%-1.63%) in Karasu; 1,150 (0.9%; 0.7%-1.2%) in Osh; 710 (1.3%; 1.0%-1.6%) in Sokuluk, and 220 (1.3%; 1.0%-1.6%) in Tokmok.

Conclusions: These updated estimates generally fell within the globally recognized ranges. The triangulation of survey and programmatic data over time along with use of synthesis models could help refine PSE and support the optimal allocation of limited resources and improve target-setting and program monitoring.

EPC0310

Mollicutes in people living with HIV/AIDS at a regional reference center for sexually transmitted infections in Southwest Bahia - Brazil

L. Gusmão¹, A. Oliveira¹, H. Martins¹, H. Brito¹, Á. Silva¹, J. Nunes¹, C. Oliveira¹, A. Amorim¹, D. Medeiros¹, G. Campos¹, L. Marques¹

¹Federal University of Bahia, Multidisciplinary Institute for Health, Vitória da Conquista, Brazil

Background: *Mollicutes* sp. are known to cause various infections in the urogenital tract and to act as HIV cofactors in developing AIDS. Thus, the present study aimed to identify the prevalence of *Mollicutes* sp. in People Living with HIV/AIDS (PLHIV) in a Reference Center for Sexually Transmitted Infections (STIs) in the southwest region of Bahia and correlate with the identified sociodemographic, behavioral, and clinical characteristics.

Methods: Cross-sectional study that included 67 HIV+ men and woman in follow-up. Urethral and cervical samples were collected. *Mollicutes* sp. detection was performed using qPCR. Data collection was obtained by an interview and clinical data by medical records at the health center. Poisson regression with robust variance was used to estimate the prevalence ratio (PR) and its 95% confidence interval. We conducted multivariate analysis by Poisson regression and considered a p-value <0.05 for statistical significance.

Results: A high prevalence of *Mollicutes* sp. infection (76.1%) was found in PLHIV: 11.9% had *Mycoplasma genitalium*, 37.3% *M. hominis*, 44.8% *Ureaplasma parvum* and 7.5% *U. urealyticum*. After the multivariate analysis, being female (PR=1.33, 95%CI= 1.01 - 1.76), non-black race/color (PR=1.29, 95%CI = 1.04 - 1.60) and co-infection with syphilis (PR=1.33, 95%CI= 1.01 - 1.74) were associated with a higher prevalence of *Mollicutes* sp.

Non-black race/color (RP=1.70, 95%CI= 1.08 - 2.70), age of first sexual intercourse up to 14 years (PR=1.87, 95%CI= 1.15 - 3.06), and having had up to 5 sexual partners in their lifetime (PR=1.68, 95%CI= 1.07 - 2.65) were associated with a higher prevalence of *Mycoplasma* spp.. Cytokine analysis revealed increased levels of IL-10 and IL-1 β in those infected with *Ureaplasma* spp.

Conclusions: These results showed a high prevalence of *Mollicutes* sp. in PLHIV. It is necessary to strengthen efforts to expand the screening protocol for STIs in this target

audience for emerging and asymptomatic microorganisms of the *Mollicutes* class and thus promote safer sexual practices.

EPC0311

Alcohol use and advanced HIV disease: population-based data from four sub-Saharan African countries

D.M. Reed¹, S. Gutkind¹, J.M. Juma², R. Nyirenda³, J.E. Justman^{1,4}

¹Columbia University, Mailman School of Public Health, Epidemiology, New York, United States, ²Ministry of Health, National AIDS Control Program, Dodoma, Tanzania, United Republic of, ³Ministry of Health, National HIV, Viral Hepatitis & STI Program, Lilongwe, Malawi, ⁴ICAP at Columbia University, New York, United States

Background: Alcohol use is common among people living with HIV (PLWH) and is associated with poorer medication adherence, drug effectiveness, and overall quality of life. However, alcohol use among people living with advanced HIV disease (i.e., a CD4 count <200 cp/mL) is not well characterized, particularly in sub-Saharan Africa (SSA) where alcohol use is growing. We assessed the association between alcohol use and advanced HIV disease among PLWH in four SSA countries.

Methods: We pooled data from the 2015-2017 Malawi, Tanzania, Zambia, and Zimbabwe Population-based HIV Impact Assessments, nationally representative household surveys. We assessed the prevalence of past month's alcohol use and the average number of drinks per drinking day. We used logistic regression to model associations between any alcohol use and advanced HIV disease, adjusting for age, education, country, urbanicity, wealth index, and antiretroviral treatment (ART) status. We weighted analyses for country-specific sampling designs.

Figure. Prevalence of alcohol use among people living with HIV and advanced HIV disease across four sub-Saharan African countries.

Results: Among 9,907 PLWH, 15% (1,456/9,907) have advanced HIV disease. Most people living with advanced disease were from Tanzania (34%), were male (52%), were 40+ years (50%), completed primary school (50%), from a rural area (59%), had a second highest household wealth quintile (26%), and were not on ART (57%).

Compared to the overall population, prevalence of alcohol use was greater among all PLWH and even greater among people living with advanced HIV disease (Figure), 41% of whom reported 3-4 drinks per drinking day. Compared to PLWH without advanced HIV disease, people living with advanced HIV disease had greater odds of reporting alcohol use (adjusted odds ratio: 1.2; 95% Confidence Interval: 1.1-1.5).

Conclusions: Alcohol use was common among people living with advanced HIV disease in SSA, a similar pattern seen in high-income countries. With increasing consumption rates in SSA, clinical programs linking PLWH to care should integrate culturally-relevant alcohol services to mitigate this public health problem.

EPC0312

Success of key population program on HIV control among female sex workers in Rwanda

C. Kayitesi¹, G. Rwibasira¹, E. Remera¹

¹Rwanda Biomedical Center, HIV Division, Kigali, Rwanda

Background: Globally, female sex workers represent a high-risk group for HIV with more than 40% of new infections. Since 2014 the national HIV program initiated the key population facility and community-based interventions, including the HIV and sexual transmitted infections testing, provision of condom, as well as education to HIV prevention and income generating. We present a 10-year trend in HIV prevalence among FSW.

Methods: Over the last decade, Rwanda Biomedical Centre conducted 3 editions of Integrated Behavioral and Biological Surveillance Survey (IBBSS) among FSW to assess changes in sexual behavior and the trend of HIV prevalence among FSW aged 15 years and above.

Demographic, behavioral and biological data were collected using interview questionnaire administration and blood draws. HIV testing was performed according to national algorithms among consenting FSW.

Trend analysis for proportions and test for proportion differences were performed using STATA v17. Chi-square statistic for both trends and proportion test were calculated, corresponding slope and p-values were presented.

Results: We included 5,057 FSW in the three studies: 1,338 in 2010, 1,978 in 2015 and 1,741 in 2019.

Overall, HIV prevalence among FSWs in Rwanda over the last ten years at each of the three-time points were 51.0% (95%CI:47.9-53.8) in 2010 46.8% (95%CI:43.5-50.1) in 2015 and 35.5% (95%CI:31.5-39.8) in 2019.

An overall decline slope of -3.4% (p-value; 0.001) in HIV prevalence among FSW is observed over the last ten years. A pairwise comparison of the two study periods shows a high decrease from 2015-2019: 2010 vs 2015 3.8% decline with p-value: 0.025 while from 2015 vs 2019, the decline was 11.3% with p-value; 0.001.

Conclusions: Declines in HIV prevalence among FSW is observed over the past decade, primary due to intensified

biomedical interventions HIV control among FSWs. We recommend the mainstay of interventions to control HIV among key population and to assess their impact.

EPC0313

Understanding gender differences in key HIV risk factors among people who inject drugs: systematic review and meta-analysis

S. Larney¹, C. Zolopa², F. Vakili¹, S. Udhesister¹, N. Kronfli³, M. Maheu-Giroux³, H. Valerio⁴, A. Levinsson²

¹Université de Montréal, Department of Family Medicine and Emergency Medicine, Montréal, Canada, ²Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montréal, Canada, ³McGill University, Montréal, Canada, ⁴University of New South Wales, Sydney, Australia

Background: Gender can play a key role in risk of HIV acquisition. Among people who inject drugs (PWID), women's agency to enact harm reduction measures or access interventions may be constrained by social and structural factors.

We aimed to assess gender differences in two key HIV risk factors among PWID: needle and syringe sharing and engagement with opioid agonist therapy (OAT).

Methods: We conducted a systematic review and random effects meta-analysis. We included studies published from 2012 onwards that presented sex- or gender-stratified findings. We did not assess how sex or gender was defined and no studies reported findings for transgender or gender-diverse people.

We accepted various definitions of "sharing" (e.g. receptive or distributive sharing). OAT engagement was defined as enrollment in OAT. Data could refer to any exposure period.

Results: Fifty-six studies with needle and syringe sharing data were analysed. Women reported higher levels of sharing in studies measuring the past 12-months (risk ratio [RR] 1.10, 95% confidence interval [CI] 1.05-1.16; 6 studies), 6-months (RR: 1.15; 95% CI 1.00-1.31; 16 studies) and 3-months (RR 1.47; 95% CI 1.26-1.70; 6 studies).

Weak evidence was observed for a difference in sharing over the lifetime (RR 1.07, 95% CI 0.98-1.17; 15 studies), and no evidence of a difference in past-month sharing (RR 1.04, 95% CI 0.84-1.29; 13 studies). Heterogeneity was low to moderate for all exposure periods. Only four studies presented gender-stratified data on OAT.

For lifetime (1 study) or "lifetime or current" OAT (2 studies), there was no evidence of a gender difference. One study of past 6-month OAT reported higher engagement among women relative to men (RR 1.62; 95% CI 1.42-1.86).

Conclusions: The strength of association between gender and needle and syringe sharing varied by exposure period but women were generally more likely to report sharing than men.

Few studies reported gender-specific data on OAT engagement. These two key indicators of HIV risk are variably defined and measured, complicating attempts to

synthesise data or determine public health implications or responses. A better understanding of how gender shapes HIV risk among PWID may inform intervention design and reduce HIV burden.

EPC0314

Global associations of key populations with HIV-1 recombinants: a systematic review, global survey, and individual participant data meta-analysis

N. Nchinda¹, R. Elangovan¹, J. Yun¹, L. Dickson-Tetteh¹, S. Kirtley², J. Hemelaar¹, WHO-UNAIDS Network for HIV Isolation and Characterisation

¹University of Oxford, National Perinatal Epidemiology Unit, Infectious Diseases Epidemiology Unit, Oxford Population Health, Oxford, United Kingdom, ²University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: Global HIV infections due to HIV-1 recombinants are increasing and impede prevention and treatment efforts. Key populations suffer most new HIV infections, but their role in the spread of HIV-1 recombinants is unknown.

We conducted a global analysis of the associations between key populations and HIV-1 recombinants.

Methods: We searched PubMed, EMBASE, CINAHL, and Global Health for HIV-1 subtyping studies published from 1/1/1990 to 31/12/2015. Unpublished data was collected through a global survey. We included studies with HIV-1 subtyping data of key populations collected during 1990-2015.
