IAS 2025, the 13th IAS Conference on HIV Science

ias2025.org

IAS 2025 Organizing Committee

Co-Chairs

Beatriz Grinsztejn, Brazil

Jeanine Condo, Rwanda

Members

Akarin Hiransuthikul, Thailand
Birgit Poniatowski, Switzerland
Darrell Tan, Canada
Deo Mutambuka, Rwanda
Erika Castellanos, the Netherlands
Joseph Robert Linda, Uganda
Kenneth Ngure, Kenya
Mary Ann Torres, Canada
Meg Doherty, Switzerland
Sarah Read, USA
Christian Gaebler, Germany
Gabriela Turk, Argentina
Julien Nyombayire, Rwanda
Roy (Trip) Gulick, USA
Benjamin Bavinton, Australia
Didier Ekouevi, Togo
Rivet Amico, USA
Veronicah Mugisha, Rwanda
Michelle Rodolph, Switzerland
Stefan Baral, USA

Track Committees

Track A – Basic Science

Co-leads

Christian Gaebler, Germany
Gabriela Turk, Argentina

Members

Fernanda Heloise Côrtes, Brazil
Henning Grüll, Germany
Marianne Wanjiru Mureithi, Kenya
Reena Rajasuriar, Malaysia
Sarah Palmer, Australia

Track B – Clinical Science

Co-leads

Julien Nyombayire, Rwanda
Roy (Trip) Gulick, USA

Members

Claudia Cortes, Chile
Gail Matthews, Australia
Kara Chew, USA
Karine Lacombe, France
Omu Anzala, Kenya

Track C – Epidemiology and prevention science

Co-leads

Benjamin Bavinton, Australia
Didier Ekouevi, Togo

Members

Gallican Nshogoza Rwibasira, Rwanda
Heather-Marie Schmidt, Switzerland
Ines Aristegui, Argentina
Pande Putu Januraga, Indonesia
Perrine Roux, France

Track D – Social and behavioural sciences

Co-leads

Rivet Amico, USA
Veronicah Mugisha, Rwanda

Members

Clarisse Musanabaganwa, Rwanda
Gastón Devisich, Argentina
Joseph Larmarange, France
Sybil Hosek, USA
Thomas Guadamuz, Thailand

Track E – Implementation science, economics, systems and synergies

Co-leads

Michelle Rodolph, Switzerland
Stefan Baral, USA

Members

Brenda Asiimwe Kateera, Rwanda
Jirair Ratevosian, USA
Marcos Benedetti, Brazil
Miriam Sabin, USA
Omar Syarif, Indonesia

Track Mpox

Lead

Darrell Tan, Canada

Members:

Alexandra Calmy, Switzerland
Mayara Secco, Brazil
Placide Mbala Kingebeni, the Democratic Republic of the Congo (DRC)

Abstract submission

Over 5,250 abstracts were submitted to IAS 2025, the 13th IAS Conference on HIV Science. The Organizing Committee (OC) is very grateful for all the abstract submissions received. While the OC found many very high-quality abstracts among the submissions, due to limitations in the conference programme, more abstracts were rejected than accepted – with an overall acceptance rate of 38% (which includes the late breaker abstracts). All abstracts went through a blind peer-review process completed by over 840 abstract reviewers. These reviewers are international experts in the field of HIV, including members of the OC and track committees. Each abstract was reviewed by three to four reviewers. The abstracts were reviewed for the quality and originality of the work.

Late-breaking abstract reviews included an additional assessment of the late-breaking nature of the research.

All reviewers were instructed to abstain from scoring any abstract on which they were an author or co-author, had a financial or personal conflict of interest, or did not have the appropriate expertise to evaluate. Each abstract was scored numerically against five pre-determined criteria, which were equally weighted to get a final score. The final score ranged from one (the lowest) to six (the highest). Any abstracts that received less than two reviews or where there was a scoring discrepancy between reviewers were additionally reviewed by the track committees.

Statistics for abstracts

4,899	Regular abstracts submitted
1,881	Regular abstracts accepted
110	Oral abstracts
569	Poster exhibition abstracts
1,202	E-poster abstracts
267	Late-breaking abstracts submitted
106	Late-breaking abstracts accepted
31	Late-breaking oral abstracts
51	Late-breaking poster exhibition abstracts
24	Late-breaking E-poster abstracts
91	Mpox abstracts submitted
29	Mpox accepted
4	Mpox oral abstracts
15	Mpox poster exhibition abstracts
10	Mpox E-poster abstracts
5,257	Total abstracts submitted
2,016	Total abstract accepted

IAS 2025

IAS 2025 International Abstract Review Committee

IAS 2025, the 13th IAS Conference on HIV Science received more than 5,250 abstract submissions, which went through a blind, peer-reviewed process carried out by an international panel of reviewers who play a critical role in designing a strong scientific programme.

More than 840 specialists from around the world volunteered their time and expertise to serve as peer reviewers, helping to ensure that the abstracts presented were selected on the basis of rigorous review and were of the highest scientific quality.

We extend our special thanks to the large pool of abstract reviewers for the time they dedicated to the success of the conference.

TABLE OF CONTENTS

Oral abstract sessions

OAA01	Targeting the HIV reservoir: Emerging discoveries and novel interventions	15
OAA02	Here to stay: Renewed momentum for bNAbs in HIV treatment and cure studies	17
OAA03	Advances in HIV vaccine platforms	19
OAA04	From cells to systems: The power of omics in HIV research	21
OAA05	Basic science highlights: Cutting-edge research and implications	24
OAB01	ART strategies	26
OAB02	A multitude of complications	28
OAB03	Special issues in paediatrics	31
OAB04	HIV treatment and prevention in pregnancy	33
OAB05	Tuberculosis: From research to the field	36
OAC01	From PrEP to harm reduction: Scaling up comprehensive HIV prevention strategies	39
OAC02	Destination zero new acquisitions: Hailing a CAB to PrEP success	41
OAC03	From distribution to linkage: Strategies to improve HIV self testing, diagnosis and care across diverse settings	43
OAC04	The emerging landscape of PrEP choice	46
OAC05	Purposeful PrEP: New insights on lenacapavir for prevention	48
OAC06	Big money and the big picture: Funding and HIV epidemiology	52
OAD01	Centring mental health in the HIV response	54
OAD02	Health equity in challenging times: Threats and opportunities	56
OAD03	Innovative community approaches to HIV prevention, care and rights	58
OAD04	Climate change, mobility and HIV	60
OAD05	"I will not lower my voice": Experiences from trans and gender-diverse communities	63
OAD06	Harnessing technology: Digital health applications	65
OAE01	Advancing equity in the HIV response: Key populations, human rights and quality intervention	68
OAE02	No retreat, no surrender: Sustaining the HIV response in times of turmoil	70
OAE03	Zero AIDS-related deaths: Scaling up advanced HIV disease response	71
OAE04	Accelerating integration in a new operating environment	73

OAA01 Targeting the HIV reservoir: Emerging discoveries and novel interventions

OAA0102

HLA-E restricted HIV-1 TCR transductants efficiently reduce the size of the HIV reservoir

J.V. Garcia[1], H. Yang[2], A. McMichael[2], G. Doyon[3]
[1]University of Alabama at Birmingham, Microbiology, Birmingham, United States, [2]University of Oxford, Dept. of Clinical Medicine, Oxford, United Kingdom, [3]University of North Carolina, Infection Diseases, Chapel Hill, United States

Background: To effectively cure HIV-1, it's essential to maintain ongoing antiviral T cell responses to achieve long-term suppression or clearance of the virus. This study examines the ability of nonpolymorphic Human Leukocyte Antigen-E (HLA-E) restricted T cells to suppress HIV-1 replication in humanized mice, utilizing a T cell receptor (TCR)-based immunotherapy approach.
Methods: Bulk CD8+ T cells derived from humanized mouse tissues were transduced with HLA-E restricted TCRs specific for GAG epitope RMYSPTSIL (RL9) and REV epitope ILVESPAVL (IL9). TCR transductants were enriched and expanded in *vitro* prior to infusion into autologous humanized mice. To determine if the presence of the HIV-1-specific TCRs has an effect on suppressing HIV-1 virus replication, we infected humanized mice with HIV-1_{JRCSF}, separately humanized mice receiving non-HIV-1 TCR transductants were used as controls.
Results: Significant higher frequencies of TCR transductants were detected in PB and tissues in mice receiving HIV-1 TCRs compared to control mice, suggesting HIV-1 antigen specific expansion and long-term survival of HIV-1 TCR^+ cells *in vivo*. HIV-1 TCR^+ transduced cells were detected in all tissues analyzed. Importantly, during acute HIV-1 infection in the absence of antiretroviral therapy (ART), we observed significant reductions in plasma viral load (~90%, p=<0.04) and in cell associated viral RNA from tissues (>80%, p=0.0016). We then evaluated the efficacy of HLA-E restricted HIV-1 TCR transductants to reduce the size of the HIV reservoir in animal where HIV replication had been suppressed by ART. Using intact proviral DNA analysis we were able to demonstrate a 50% reduction in the levels of intact provirus in tissues (p=0.04).
Conclusions: Our findings demonstrate that HLA-E restricted HIV-1 TCR transductants are effective in reducing viral replication in vivo. Additionally, we have shown that these transductants efficiently decrease the size of the HIV reservoir. Combined, our results indicate that cell therapy-based approaches targeting the minimally polymorphic HLA-E molecules can provide a robust therapeutic effect in vivo, reducing the intact proviral DNA load in HIV-infected T cells. HLA-E based cell therapy, with its "universal" nature, holds significant potential as a novel approach to curing HIV.

OAA0103

Association between reservoir size and markers of cardiovascular inflammation in children living with HIV

Y. Fougère[1], M.T. Hawkes[2], J. Brophy[3], S. Read[4], A. Bitnun[4], H. Soudeyns[5], F. Kakkar[1], EPIC4 Study Group
[1]University of Montreal, Pediatrics, Montreal, Canada, [2]University of British Columbia, Pediatrics, Vancouver, Canada, [3]University of Ottawa, Pediatrics, Ottawa, Canada, [4]University of Toronto, Pediatrics, Toronto, Canada, [5]University of Montreal, Microbiology and Immunology, Montreal, Canada

Background: There are limited data on long-term cardiovascular disease risk among children with living with perinatal HIV infection (CHIV). Our objective was to assess the association between HIV reservoir size and biomarkers of cardiovascular inflammation among Canadian CHIV.
Methods: Sub-study of the « Early Pediatric Initiation, Canada Child Cure Cohort Study » (EPIC[4], 2014-2019). In CHIV with sustained viral suppression (SVS) in whom the inducible HIV-1 reservoir in $CD4^+$ T cells was previously measured (prostratin stimulation assay), serum levels of CRP, IL-1β, IL-6, IL-18, VEGF-1, TNF-α and IFN-γ were measured using the Luminex 200™ XMAP multiplex assay at the time of reservoir measurement. Multiple linear regression was used to assess potential associations. To avoid overadjustment, factors predictive of reservoir size (age at treatment initiation, duration of SVS) were not included in the models.
Results: Out of 225 EPIC[4] participants, 121 had measures of inducible HIV-1 RNA (iRNA) at baseline. Median age was 13 years (range=6 months-23 years), age at initiation of combination antiretroviral therapy (cART) iwas 1.6 years (IQR=4 months – 4.7 years), and duration of SVS was 5.6 years (IQR=2.1–8.3). There was an equal distribution of female and male participants (50%), and 81% had serological evidence of cytomegalovirus (CMV) co-infection. Median number of copies of iRNA produced by 10^6 $CD4^+$ T cells was 5.8 (IQR=1.1-57.5). Age at cART initiation, duration of cART and proportion of life with SVS were all predictors of iRNA levels (p=0.004, p=0.02, and p=0.01, respectively). There was a significant association between levels of iRNA and serum levels of CRP (p=0.009), IL-6 (p=0.04), IL-1β (p=0.002), and IL-18 (p=0.014), though no association with IFN-γ, VEGF-1 or TNF-α were observed. These association all remained significant after adjusting for age and CMV serostatus.
Conclusions: Reservoir size as measured by iRNA was strongly associated with biomarkers of cardiovascular inflammation in CHIV. These data reinforce the need for early SVS in CHIV to mitigate long-term comorbidities, and the potential use of these biomarkers as proxy measures of long-term cardiovascular disease risk.

OAA0104

Unique cellular signatures and HIV transcripts identified in CD4 lymphoid T cells - HOPE Act organ transplantation collaboration

M. Tuyishime[1], D. Nattere[1], N. Alavian[2], S. Carr[3], J. Granek[4], T. Schappe[4], N. Archin[5], D. Margolis[5], J. Pollara[1], G. Ferrari[1], C. Wolfe[2]

[1]Duke University Medical Center, Surgery, Durham, United States, [2]Duke University Medical Center, Medicine, Durham, United States, [3]Duke University Medical Center, Pediatrics, Durham, United States, [4]Duke University Medical Center, Center for Human Systems Immunology, Durham, United States, [5]The University of North Carolina, Chapel Hill, Medicine, Chapel Hill, United States

Background: The inability of ART to eradicate HIV-1 infection is primarily due to the establishment of a latent reservoir that is resistant to current therapies. Lymphatic tissues, including lymph nodes (LN), are the major tissue reservoirs where latent HIV persists in tissue resident CD4 T cells. We sought to analyze LN tissue from virologically suppressed people living with HIV (PLWH) to analyze the size of the reservoir and define transcriptional changes and impact of latency reversing agents (LRAs) on the tissue resident cells. The results can inform future efforts to target and eliminate HIV harboring cells.

Methods: Through the Duke HOPE Act organ transplantation program, PLWH were consented to the collection of otherwise discarded deep lymphatic tissue. We collected LNs from 24 PLWH during abdominal or thoracic transplantation. LNs were manually disassociated and washed with media prior to Ficoll separation if cell count was over 50 million. The frequency of latently infected cells was evaluated by quantitative viral outgrowth assay in 6/24 samples. For transcriptional changes following LRA treatment, CD4+ T cells were isolated from lymph nodes in 6/24 samples and were stimulated for 24 hours with LRA combinations (VOR+AZD5582, VOR+AZD5582+IL-15 and VOR+AZD5582+IL-15+iBet-151) prior to single cell RNA sequencing (scRNAseq).

Results: Using scRNA analysis of a total 94,716 cells we identified 57 cells with HIV transcripts most of which mapped to viral LTR. The majority of the HIV-harboring cells were identified in the VOR+AZD5582-treated sample. Treatment with LRAs induces upregulation of transcripts related to activation and regulation, protein and lipid synthesis and post-translational modifications, trafficking to cell membrane. Addition of other LRAs to VOR+AZD5582 combination did not produce significant changes in transcriptome analysis.

Interestingly, LRA treatment downregulated TcR transcripts in CD4 cells affecting the ability to identify unique clonotypes of latently-infected reactivated cells.

Conclusions: Lymph nodes obtained from PLWH undergoing solid organ transplantation represent a high yield source for deep lymphatic tissue. We identified LRA-induced HIV reactivation and defined effects of LRA combinations on transcriptomic profiles of tissue resident CD4 T cells. This data can be used to evaluate future LRAs and assess their combination efficacy and their ability to unmask the lymphatic reservoir.

OAA0105

The impact of acute stress on the HIV reservoir: a prospective interventional trial and analysis in vitro of stress compounds and latency reversal

J. Stern[1,2], R.A. Shepherd[1], M. Roche[1,3], W. Hartogensis[4], P. Moran[4], L. Cockerham[5], A. Rhodes[1], P.U. Cameron[1], J.J. Chang[1], N. Kumar[6], W.B. Mendes[7], S.G. Deeks[6], F.M. Hecht[4,6], S.R. Lewin[1,8,9]

[1]University of Melbourne/Doherty Institute, Department of Infectious Disease, Melbourne, Australia, [2]University of Melbourne/Doherty Institute, Department of Microbiology and Immunology, Melbourne, Australia, [3]Royal Melbourne Institute of Technology (RMIT), School of Health and Biomedical Sciences, Melbourne, Australia, [4]University of California San Francisco, Osher Center for Integrative Health, San Francisco, United States, [5]Medical College of Wisconsin, Division of Infectious Diseases, Milwaukee, United States, [6]University of California San Francisco, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States, [7]Yale University, Department of Psychology, New Haven, United States, [8]Monash University/Alfred Hospital, Infectious Diseases, Melbourne, Australia, [9]Victorian Infectious Disease Service, Royal Melbourne Hospital at the Doherty Institute, Melbourne, Australia

Background: The persistence of latently infected CD4+ T cells is the major barrier to cure of people with HIV (PWH) on antiretroviral therapy (ART). While most latently infected cells are transcriptionally silent, some express low levels of cell associated (CA) HIV RNA.

In this prospective controlled interventional study, we tested the hypothesis that acute psychological stress could drive HIV transcription in PWH on ART.

Methods: PWH on suppressive ART underwent the Trier Social Stress Test (TSST) and comparisons were made to a similar period of time without an intervention (control). After 10, 30 and 65 minutes of the acute stressor, we quantified: the stress markers salivary cortisol, pre-ejection period, cardiac output and respiratory sinus arrhythmia; CA HIV RNA and HIV DNA in CD4+ T cells by qPCR; and markers of immune activation and exhaustion via flow cytometry.

The direct effect of stress-associated compounds (glucocorticoid agonists, hydrocortisone and dexamethasone; catecholamines, epinephrine and norepinephrine; the protein kinase A agonist, forskolin; the pituitary hormone, prolactin; and Triiodothyronine (T3)) on HIV transcription in the latently infected cell lines J-Lat A2 and TZM-bl was measured by GFP and luciferase expression, respectively.

Results: Physiological markers of acute psychological stress including pre-ejection period and cardiac output changed in all participants, as anticipated. Compared to the control day, at the 65-minute timepoint, the TSST did not affect HIV DNA levels (p=0.12) but led to a 1.57-fold increase in CA HIV RNA (p=0.04) which was correlated with pre-ejection period (rho=-0.59, p=0.002) and cardiac output (rho=0.6, p=0.003). CA US HIV RNA was positively correlated with CD38+HLADR- CD4+ T-cell frequencies (rho=0.52, p=0.048). HIV DNA was negatively correlated

with the proportion of CD8+ T cells expressing CD69 (rho=-0.52, p=0.05). Stress-associated compounds did not up-regulate HIV expression in latently infected cell lines.
Conclusions: In PWH on ART, HIV transcription increases shortly following acute stress. There was no direct effect of stress compounds on the HIV long terminal repeat. Changes in the half-life of activated CD4+ T-cells in circulation following stress could potentially contribute to the increase in CA HIV RNA. Our findings have implications on the importance of stress and the design of cure strategies for PWH.

OAA02 Here to stay: Renewed momentum for bNAbs in HIV treatment and cure studies

OAA0202

Altered viral rebound dynamics in chronically treated people with HIV given long-acting broadly neutralizing antibodies and N-803

M. Caskey[1], K. Millard[1], M. Turroja[1], D. Dong[1], A. Nicola[1], M. Fumagalli[1], G. Breton[1], K. Seaton[2], J. Berardi[3], E. Logue[4], J.T. Safrit[5], G. Tomaras[2], R.B. Jones[6], M.J. Glesby[6], T. Wilkin[7], P. Tebas[4], M. Nussenzweig[1]
[1]The Rockefeller University, New York, United States, [2]Duke University, Durham, United States, [3]Rutgers New Jersey Medical School, Newark, United States, [4]University of Pennsylvania, Philadelphia, United States, [5]ImmunityBio, Inc., Culver City, United States, [6]Weill Cornell Medicine, New York, United States, [7]University of California San Diego, San Diego, United States

Background: Broadly neutralizing antibodies (bNAbs) are promising therapies for HIV. Clinical studies have suggested that bNAbs administered during analytical treatment interruption (ATI) or at ART initiation may affect reservoir dynamics and enhance autologous immune responses, with some participants achieving long-term control. The interleukin-15 superagonist, N-803, enhances NK and cytotoxic T cell activity. In SHIV-infected macaques two bNAbs with N-803 led to sustained virologic control. The effects of this combination in humans are not known.
We report preliminary results of the antiviral activity of the combination of two long-acting bNAbs and N-803 in people with HIV (PWH) during ATI.
Methods: This open-label, single arm study enrolled chronically-treated PWH to receive single infusions of 3BNC117-LS (30 mg/kg) and 10-1074-LS (10mg/kg) followed by up to 8 subcutaneous injections of N-803 (6 mcg/kg) 3 weeks apart. Participants were not pre-selected for bNAb sensitivity. They underwent ATI 2 days after bNAb administration.
Participants resumed ART after 4 consecutive HIV-1 RNA > 1,000 copies/ml. Study objectives included safety, viral suppression through 24 weeks and sustained virologic control. All participants reached the first primary virologic endpoint and long-term follow up is ongoing.
Results: Twenty-eight participants enrolled in the study; 3 discontinued before viral rebound (weeks 8, 10 and 10). Most reported adverse events were grade 1 or 2 injection site reactions following N-803. By week 24, 15 of 25 participants (60%; 95% CI: 40.8%–79.2%) remained off ART.
Interestingly, 4 of these 15 participants experienced long periods of low level viremia, 2 had low level viremia followed by ongoing suppression and 2 continued to maintain suppression for 72 weeks. In contrast, individuals with early rebound typically resumed ART an average of 3 weeks after the initial return of viremia.
At 24 weeks, the average concentrations of 3BNC117-LS and 10-1074-LS were 40 mcg/ml and 36 mcg/ml, respectively. Reservoir and immunologic analyses are ongoing.
Conclusions: In this ongoing study, we found that 15 of 25 chronically-treated PWH receiving a combination of bNAbs and N-803 controlled viremia for at least 6 months. Of these, 53% experienced prolonged low levels of or no viral rebound.

OAA0203

Complementary bnAbs: CD4 binding site and Interface bnAbs demonstrate bidirectional phenotypic antagonism

R. Lynch[1], H. Garg[2], M. Kelly[1], A. Mcfarland[2], T. DeStefanis[1], W. Jin[3], R. Krause[2], H. Schrader[2], J. Best[1], S. Docken[3], D. Cromer[3], M. Davenport[3], K. Bar[2]
[1]George Washington University, Microbiology, Washington, United States, [2]University of Pennsylvania, Medicine, Philadelphia, United States, [3]University of New South Wales, Kirby Institute, Sydney, Australia

Background: Broadly neutralizing antibodies (bnAbs) show promise in HIV cure and prevention, but their efficacy is limited by pre-existing or emergent resistance. Current best practice calls for combination therapy, using bnAbs from distinct classes to maximize breadth and potency. When virus populations have resistance to one or more bnAbs, however, bnAbs targeting unrelated epitopes act as monotherapy and viruses readily escape.
Akin to the bidirectional phenotypic antagonism observed with early antiretroviral therapy, we aim to identify 'complementary bnAbs' with inverse susceptibility patterns due to conformationally-linked epitopes such that evolving resistance to one would lead to enhanced susceptibility to the other.
Methods: We sequenced plasma virus *envs* by single genome sequencing from 42 participants of treatment interruption and viremia clinical trials of CD4bs bnAbs. We performed phylogenetic analyses to identify 56 *envs*, representing the consensus of rebound lineages or replicating virus populations. The 56 Envs were tested for neutralization sensitivity to a panel of 20 bnAbs (CD4bs, V2, V3, Interface, MPER) in the TZM.bl assay. Env-antibody pair IC50s were compared via Spearman correlation, with correction for multiplicity requiring a $P < 0.00026$.
Results: A total of 1,120 Env-Antibody pairs were tested for bnAb neutralization sensitivity, generating susceptibility patterns similar to published Env panels. IC50s of all 56 Envs were compared between bnAbs, identifying many

statistically significant direct correlations *(i.e.*, similar resistance patterns), but just two statistically significant inverse relationships: CD4bs bnAb N49.P9.6FR and interface bnAb 8ANC195 (Spearman R=-0.53, p=2.7e-05); and CD4bs bnAb VRC01.23 and 8ANC195 (R=-0.51, p=6.9e-05).
Modeling of CD4bs and Interface epitopes reveals substantial epitope overlap. Structure-function analysis of Envs sampled in viremic study participants pre- and post-CD4bs bnAb treatment revealed mutations within epitope overlap region (within V5) that confer increased resistance to CD4bs bnAbs and increased sensitivity to 8ANC195, without impacting MPER, V3 or V2 bnAbs.
Conclusions: Leveraging authentic HIV-1 Envs sampled from participants in bnAb clinical trials, we identified highly statistically significant inverse bnAb susceptibility patterns between interface bnAb 8ANC195 and two CD4bs bnAbs: N49.P9.6FR and VRC01.23, putatively related to epitope overlap.
Ongoing mechanistic and in vivo studies aim to determine if combination use 8ANC195 and N49/VRC01.23 will complementarily prevent emergent resistance.

OAA0204

CAR-T cell-secreted bNAbs mediate Fc-effector functions and reduce viral load in humanized mouse model of HIV infection

Z. Stylianidou[1], S. Gerlo[1], M. Wejda[1], E. Burg[1], E. De Smet[1], Y. Noppe[1], L. Vandekerckhove[1], W. Witkowski[1]
[1]HIV Cure Research Center, Ghent University, Faculty of Medicine and Health Sciences, Ghent, Belgium

Background: Combining cell and gene therapies with broadly neutralizing antibody (bNAb) administration to achieve a functional HIV cure is gathering interest. Here, we explored the concept of Hybrid CAR T-cells, combining the cytotoxic effect of a CAR with the antiviral properties of bNAbs.
The Hybrid CAR-T cells are engineered to secrete bNAbs with an Fc-IgG1 domain, which trigger secondary immune effector functions such as Antibody-Dependent Cellular Cytotoxicity (ADCC) and Phagocytosis (ADCP) on top of cell-free HIV neutralization.
Methods: We engineered a bicistronic lentiviral vector encoding a 3rd generation CD4-based CAR and the 3BNC117 bNAb. Hybrid CAR CD8+ T cells were generated from HIV-negative donors and assessed for their cytotoxic activity against autologous HIV-infected CD4+ T cells, in real-time fluorescent imaging- and flow cytometry-based assays. The quantity and HIV neutralization capacity of secreted 3BNC117 was tested by ELISA and TZM-bl assays, respectively.
Evaluation of 3BNC117-Fc-mediated functions was performed by antibody-dependent NK cell degranulation assay (ADNKDA) and by an in-house developed ADCP assay quantifying phagocytosis of HIV Env-expressing target cells by primary macrophages with real-time fluorescent imaging. In vivo efficacy of Hybrid CAR-T cells was studied in PBMC-humanized NSG-SGM3 mice infused with HIV-infected CD4+ T cells and autologous CD8+ Hybrid CAR-T cells.
Results: In vitro data demonstrated that upon coculture with autologous, HIV-infected T cells, anti-HIV Hybrid CAR-T cells suppressed HIV replication to the same extent as the CD4 CAR control, while simultaneously secreting 3BNC117 (≈40ng/ml) capable of neutralizing cell-free HIV.
The secreted antibody induced NK cell degranulation in the presence of recombinant HIV gp120 and mediated phagocytosis of Env-expressing cells by primary macrophages. In vivo, Hybrid CAR T-cell treated mice demonstrated 6.7-fold lower median plasma HIV levels as compared to non-transduced CD8-treated mice (NTD) control.
Conclusions: We successfully engineered Hybrid CAR-T cells that secrete bNAbs, exert cytotoxic killing against HIV-infected cells, neutralize cell-free HIV and mediate Fc-dependent functions in vitro. The anti-HIV activity of Hybrid CAR-T cells was confirmed in vivo. Combining CAR-T cells and bNAbs, the Hybrid CAR concept harnesses multiple arms of the immune system and therefore holds a strong potential for a functional HIV cure.

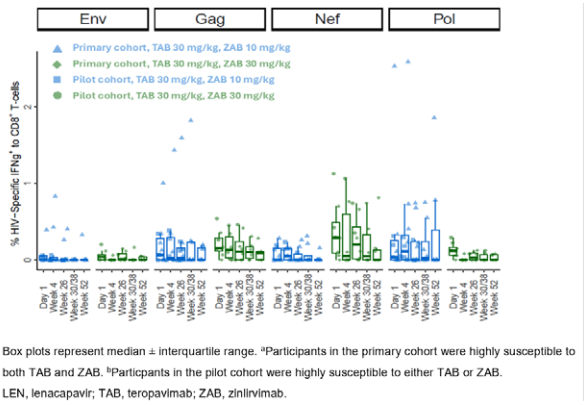
OAA0205

HIV-specific T-cell responses in suppressed people with HIV-1 receiving lenacapavir, teropavimab, and zinlirvimab

J. Eron[1], Y. Cai[2], H. Takata[3], A.-M. Ferreira[2], J. Pacheco Mendez[3], S. Nathanson[3], S.J. Little[4], J.J. Wallin[2], S.E. Collins[2], A. Okoye[3], L. Trautmann[5]
[1]University of North Carolina, Chapel Hill, NC, United States, [2]Gilead Sciences, Inc., Foster City, CA, United States, [3]Vaccine and Gene Therapy Institute, Oregon Health and Science University, Portland, OR, United States, [4]University of California, San Diego, CA, United States, [5]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States

Background: HIV-specific T-cell responses are detectable in virologically suppressed (VS) people with HIV-1 (PWH) on antiretroviral therapy (ART). Small increases in these responses were observed when the broadly neutralizing antibodies (bNAbs) 3BNC117 and 10-1074 were dosed during analytical treatment interruption or at ART initiation. In a Phase 1b study (NCT04811040), VS PWH who switched to long-acting lenacapavir (LEN; HIV-1 capsid inhibitor) plus the bNAbs teropavimab (TAB) and zinlirvimab (ZAB) maintained virologic suppression for 6 months. We report HIV-specific T-cell responses in PWH receiving LEN+TAB+ZAB in this study.
Methods: VS PWH on ART for ≥18 months, with $CD4^+$ T-cells ≥500 cells/μL and high susceptibility to TAB (n=5), ZAB (n=5), or both (n=20) (IC_{90} ≤2 μg/mL [Monogram PhenoSense mAb assay]) discontinued ART and received subcutaneous LEN 927 mg (with oral loading) plus intravenous TAB 30 mg/kg and ZAB 10 mg/kg or 30 mg/kg. Blood specimens were collected at baseline and Weeks 4, 26, 30, 38, and 52. Peripheral blood mononuclear cells were isolated and stimulated *in vitro* with overlapping 15-mer peptide pools spanning Clade B HIV-1 consensus sequences, followed by intracellular cytokine staining and flow cytometry to measure HIV-specific T-cell frequencies. Changes from baseline were assessed using Kruskal-Wallis tests.

Results: We observed no significant changes in HIV-specific IFN-γ⁺CD8⁺ or IFN-γ⁺CD4⁺ T-cells between baseline and any subsequent timepoints, with/without stratification by bNAb susceptibility or ZAB dose (*Figure*). No durable changes in HIV-specific IFN-γ⁺CD8⁺ or IFN-γ⁺CD4⁺ T-cells were observed in two participants with transient low-level plasma viremia (50–200 copies/mL) during follow-up.



Box plots represent median ± interquartile range. [a]Participants in the primary cohort were highly susceptible to both TAB and ZAB. [b]Particpants in the pilot cohort were highly susceptible to either TAB or ZAB.
LEN, lenacapavir; TAB, teropavimab; ZAB, zinlirvimab.

Figure. Treatment with LEN+TAB+ZAB did not impact HIV-specific IFN-γ⁺CD8⁺ T-cells.

Conclusions: Lack of increase from baseline in HIV-specific T-cell response following LEN+TAB+ZAB treatment in VS PWH suggests virologic suppression by LEN+TAB+ZAB did not increase viral antigen expression, which may have limited expansion of HIV-specific T-cells. This has implications for HIV-1 cure studies if greater antigen exposure if required for increased HIV-specific T-cell responses after bNAb administration.

OAA03 Advances in HIV vaccine platforms

OAA0302

Protection from pathogenic SHIV by T cell-based vaccine targeting highly networked SIV epitopes

A. Alrubayyi[1], M. Getz[1], M. Melo[2], H. Huang[1], S. Bhattacharyya[1], B. Goldberg[1], L. Rodriguez[2], A. Nathan[1], E.Y. Jeon[1], R. Yim[1], L. Maiorino[3], D. Lim[4], D.G. Carnathan[4], A.V. Nacimento[4], G. Silvestri[4], D. Irvine[2], G.D. Gaiha[1,5]
[1]Ragon Institute of Mass General, MIT and Harvard, Cambridge, United States, [2]Scripps Research, La Jolla, United States, [3]Massachusetts Institute of Technology, Koch Institute for Integrative Cancer Research, Cambridge, United States, [4]Emory University, Emory National Primate Research Center, Atlanta, United States, [5]Massachusetts General Hospital, Division of Gastroenterology, Boston, United States

Background: Functional CD8⁺ T cell responses targeting highly networked HIV epitopes (i.e. those derived from structurally constrained regions of the viral proteome and involved in important noncovalent interactions) have been strongly associated with HIV control. Based on this work, a highly networked HIV T cell vaccine is moving towards clinical evaluation. In this study, we evaluated whether a T cell-based vaccine targeting highly networked simian immunodeficiency virus (SIV) epitopes could confer protection in the well-established non-human primate (NHP) model following simian-human immunodeficiency virus (SHIV) challenge.

Methods: A replication-incompetent chimpanzee adenovirus serotype 68 (ChAd68) vector and LNP-mRNA vaccines encoding six highly networked epitopes from the SIV proteome (identified using structure-based network analysis) were generated. Twenty Indian rhesus macaques (2 females and 18 males) aged between 4-5 years that express Mamu *A*01* or *A*02* were selected. RMs (10 per group) received either PBS control or ChAd68 vector prime (2.5x10^10 viral particles) followed by two doses of LNP-mRNA (100ug) at weeks 0, 4, and 12. At week 16, animals were administered up to 10 weekly intrarectal challenges with low-dose SHIV BG505.N332 until infected. Vaccine-induced T cell responses were assessed by IFN-γ ELISpot, intracellular cytokine staining, and six-day CFSE-based proliferation assay following stimulation with either individuals or a pool of vaccine-incorporated SIV epitopes.

Results: Vaccination with ChAd68/LNP-mRNA vaccines encoding highly networked SIV epitopes elicited detectable SIV-specific CD8⁺ T cell responses in an appropriate Mamu-restricted manner and highly proliferative responses in a subset of animals (n=5; >5% of CFSE^{low}CD8⁺ T cells). Individual responses were enriched for those targeting Mamu A*01 CM9 (Gag) following ChAd68 prime and became additionally enriched for Mamu A*01 CL9 (Env) responses following LNP-mRNA boost. Importantly, after exposure to the pathogenic intrarectal SHIV challenge, the acquisition was delayed in vaccinated animals relative to controls, with the five animals with highly proliferative networked CD8⁺ T cell responses exhibiting significant protection from acquisition (p=0.0048).

Conclusions: A ChAd68/mRNA vaccine encoding highly networked epitopes is immunogenic in NHP and resulted in delayed acquisition from SHIV challenge. These data serve as a basis for continued investigation of highly networked CD8⁺ T cell vaccines currently advancing towards a human clinical trial evaluation.

OAA0303

HVTN 307: phase 1 clinical trial of a ferritin nanoparticle preventive HIV vaccine with different adjuvants to induce HIV-1 Env V3-glycan-specific broadly neutralizing antibody precursors

A.E. Shapiro[1,2], C.F. Kelley[3], K.O. Saunders[4], B.F. Haynes[4], R. Parks[4], M. Barr[4], D. Montefiori[4], A. Eaton[4], W.O. Hahn[2], O. Hyrien[2], S. Regenold[5], L.W.P. Church[2], HVTN 307 Study Team

[1]University of Washington, Global Health and Medicine, Division of Allergy & Infectious Diseases, Seattle, United States, [2]Fred Hutchinson Cancer Center, Seattle, United States, [3]Emory University, Atlanta, United States, [4]Duke University, Durham, United States, [5]National Institutes of Health, NIAID, Division of AIDS, Rockville, United States

Background: V3G CH848 Pr-NP1, a ferritin nanoparticle, was designed to expand precursors to the DH270 broadly neutralizing antibody (bnAb) lineage, targeting a GDIR/K motif at the V3 loop base and N301 and N332 glycans. V3G CH848 Pr-NP1 prime elicited potent immune responses in mice and macaques.

We tested this approach in human participants without HIV, comparing two adjuvants.

Methods: Participants in 4 groups received 3 intramuscular (IM) vaccinations with 60 or 100 mcg of V3G CH848 Pr-NP1 adjuvanted with 3M-052-AF + alum or empty LNPs on months 0, 2 and 6. Sera and PBMCs were collected to assess safety and immunogenicity.

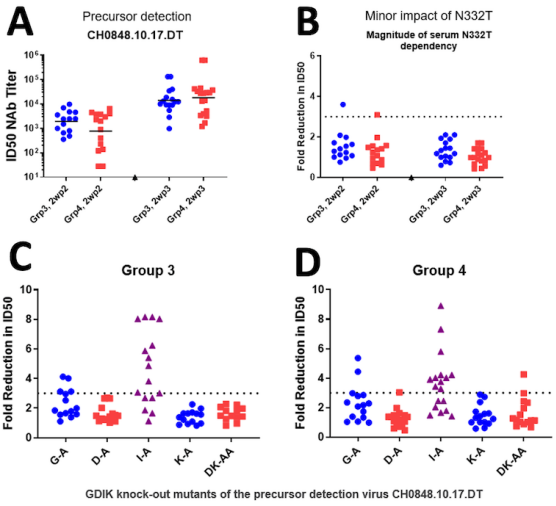
Results: Thirty-six participants ages 19-51 enrolled (16 AMAB, 20 AFAB). The frequency of local and systemic reactogenicity was similar between groups following the first 3 priming vaccinations, with more frequent grade 3 systemic reactogenicity and grade 1/2 fevers in participants receiving 3M-052-AF + alum.

After 3 doses of V3G CH848 Pr-NP1, serum IgG binding to the priming protein was similar between 60 and 100 mcg doses and slightly better with 3M-052-AF + alum adjuvant vs. LNPs. Binding to an N332A knockout protein was similar. Neutralizing antibody levels after 3 100 mcg doses were similar between adjuvants (Figure 1A). Envelope base binding antibodies to gp41 were not detected after 3 vaccinations.

Differential serum autologous virus neutralization between the precursor detection virus CH0848.10.17.DT and the knockout CH0848.10.17.DT/N332T virus showed limited dependency of N332 on the magnitude of response (Figure 1B).

However, after 3 priming immunizations, substitution of "A" for "I" in the GDIK binding motif reduced serum neutralization ID50 approximately 4-fold in both adjuvant groups (Figures 1C and 1D).

Conclusions: In healthy adults, V3G CH848 Pr-NP1 priming X3 induced high-titered serum neutralizing antibody responses to the V3-glycan precursor detection virus that depended on the bnAb epitope GDIR/K motif but less so on the N332 glycan.



GDIK knock-out mutants of the precursor detection virus CH0848.10.17.DT

Legend to Figure 1. Serum neutralization signatures of targeting at or near the V3-glycan bnAb precursor binding site. Figure A shows serum antibodies potently neutralize a tier 2 autologous precursor-detection virus (CH0848.10.17.DT) 2 weeks post 2nd (2wp2) vaccination and increase post 3rd (2wp3) vaccination. **Panel B** shows infrequent dependency on the N332 Env glycan (as determined by the differential neutralization between CH084810.17.DT and CH0848.10.17.DT/N332A viruses). **Panel C** shows **Group 3 (100 mcg priming Env/3M052+Alum as adjuvant)** and **Panel D** shows **Group 4 (100 mcg priming Env/ empty LNP as adjuvant)** serum neutralization knock-out by mutations in the GDIK motif in the bnAb binding site at the base of the V3 loop in both groups. Targeting the GDIK epitope was demonstrated by showing >3-fold reduction in neutralization ID50 by serum on viruses with the indicated GDIK mutations.

OAA0304

Enhancement of neutralization potency and breadth by a nanoparticle vaccine containing TLR7/8 agonists

X. Xin[1,2], Y. Chen[3], H. Li[1,2], Y. Zhang[3], M. Li[2], W. Zhou[2], Y. Yang[3], W. Cao[2], J. Yu[4], W. Yao[4], Y. Liu[4], J. Qiu[1], Q. Zhang[2], Z. Fang[1], X. Jiang[3], F. Gao[1,2]

[1]Jinan University, Guangdong Second Provincial General Hospital, Integrated Chinese and Western Medicine Postdoctoral Research Station, School of Medicine, Guangzhou, China, [2]Jinan University, Institute of Molecular and Medical Virology, Key Laboratory of Ministry of Education for Viral Pathogenesis & Infection Prevention and Control, School of Medicine, Guangzhou, China, [3]Southern University of Science and Technology, Shenzhen Key Laboratory of Smart Healthcare Engineering, Guangdong Provincial Key Laboratory of Advanced Biomaterials, Department of Biomedical Engineering, Shenzhen, China, [4]Jiangsu Rec-biotechnology Co. Ltd, Taizhou, China

Background: Despite over 40 years of intensive research, effective HIV-1 vaccines still remain elusive. The extensive genetic diversity of HIV-1 underscores the need for vaccines capable of eliciting broadly neutralizing antibodies (bnAbs). However, this goal remains to be highly challenging. Therefore, innovative strategies to improve the neutralization breadth and potency of HIV-1 vaccines are pivotal for advancing the vaccine design.

Methods: A novel TLR7/8-activating nanoparticle (TNP) was developed using the microfluidic technology. TNP consists of poly(lactic-co-glycolic acid) (PLGA), poly(lactide-co-glycolide)-b-poly(ethylene glycol)-N-hydroxysuccinimide (PLGA-PEG-NHS), TLR7/8 agonist 1 and lipid (DLin-MC3-DMA).

We then conjugated native-like HIV-1 Env trimers on the surface of TNP to generate an Env nanovaccine (Env_TNP). Lymphocytes obtained from lymph nodes and spleens of immunized BALB/c mice were analyzed for antigen presentation and B cell proliferation by flow cytometry.
Sera from three groups of guinea pigs immunized with Env_TNP, Env with BFA03 or Env alone were assessed for the HIV-1 specific binding antibodies and neutralizing antibodies (nAbs) against a panel of 20 viruses (three tier 1s and seventeen tier 2s).
Results: TNP containing lipid (DLin-MC3-DMA) formed uniform nanoparticles with better monodispersity and were more enriched in lymph nodes than TNPs containing other lipids. The final Env_TNP formed spheres with a diameter at ~150 nm.
After immunization in mice, Env_TNP enriched more Env in the lymph nodes, enhanced dendritic cell (DC) activation, increased expression of MHC-II on DC surface and elicited strong B cell proliferation compared to Env alone or Env with BFA03.
In immunized guinea pigs, Env_TNP induced significantly higher nAb titers against three tier 1 viruses compared to Env alone (P<0.04).
Importantly, sera from guinea pigs immunized with Env_TNP neutralized an average of 5.5 tier 2 viruses, significantly more than Env with BFA03 (2 viruses, P=0.0138) and Env alone (2.3 viruses, P=0.0140).
Conclusions: The new Env_TNP nanoparticles enhances the potency and breadth of nAb responses by presenting the Env trimers as large particles and through the TLR7/8 agonist's ability in promoting antigen presentation and B cell activation.
Our study demonstrates that this new strategy has strong potentials to improve the immunogenicity of HIV vaccines and can be applied to other protein-based vaccines.

OAA0305

Luciferase-based viral inhibition assay demonstrates ChAdOx1–MVA HIVconsvX vaccine elicits functional HIV-1 specific CD8+ T cells capable of inhibiting replication of a diverse panel of HIV-1 isolates

N. Fernandez[1,2], P.J. Hayes[1,2], N. Borthwick[3], E.G.-T. Wee[3], P. Cicconi[3], T. Hanke[3,4]
[1]IAVI Human Immunology Laboratory, Imperial College, London, United Kingdom, [2]IAVI, New York, NY, United States, [3]The Jenner Institute, Nuffield Department of Medicine, Oxford University, Oxford, United Kingdom, [4]Joint Research Center for Human Retrovirus Infection, Kumamoto University, Kumamoto, Japan

Background: The ChAdOx1–MVA-vectored HIVconsvX vaccine candidate targets conserved regions of the HIV-1 proteome, thereby aiming to elicit robust, protective CD8+ T-cell responses. In this first-in-human phase 1 trial (HIV-CORE 0052, NCT04586673) we evaluate the vaccine's potential efficacy by assessing the functional capacity of induced CD8+ T-cells to inhibit HIV-1 replication in autologous CD4 T cells, using a luciferase-based viral inhibition assay (VIA).
Methods: CD4+ and CD8+ T-cells were polyclonally expanded from peripheral blood mononuclear cells (PBMCs) isolated from trial participants. CD8+ T-cells from pre-vaccination day 0 (D0), day 35 (D35) and day 140 (D140) time points were co-cultured with pre-vaccination autologous CD4+ T-cells infected with a panel of eight replication-competent HIV-1 infectious molecular clones (IMC) expressing the *Renilla reniformis* luciferase (LucR) reporter gene. CD8+ T-cell-mediated inhibition was calculated as $\log_{10}$ relative light units (RLU) reduction in CD4+/CD8+ T-cell co-cultures, compared with cultures of infected CD4+ T-cells alone.
Results: HIVconsvX vaccination induced CD8+ T-cells with broad, cross-clade HIV-1 inhibition against a panel of viruses derived mostly from transmitted/founder HIV-1s isolates from different countries representing the major global clades A, B, C, and D. Peak post-vaccination CD8+ T-cell responses at day 35 inhibited a mean of 7.8 (SD 0.4) IMCs, decreasing to a mean of 6.4 (2.7) at day 140.
Conclusions: The ChAdOx1–MVA HIVconsvX vaccine candidate induces functional HIV-1 specific CD8+ T-cell responses capable of inhibiting HIV-1 replication *in vitro*. These CD8+ T-cell effectors inhibited HIV-1 IMCs originating from diverse geographical regions, types (founder/transmitter vs lab-adapted) and tropisms (CCR5 vs CXCR4).
The luciferase-based VIA provides a valuable tool for evaluating the potential efficacy of HIV-1 vaccines in inducing protective CD8+ T-cells, thereby informing on further vaccine development and testing.

OAA04 From cells to systems: The power of omics in HIV research

OAA0402

Spatial transcriptomics reveals persistent reservoirs in the rhesus macaque gut are associated with tertiary lymphoid organs and stress response activation

T. Hope[1], Y. Thomas[1], S.P. Pascoe[1], M.S. Arif[1], C. Thuruthiyil[1], M.A. Shaaban[2], F.A. Engelmann[1], J.M. Hasson[2], I. Clerc[2], M.D. McRaven[1], F. Villinger[3], R. Lorenzo-Redondo[2]
[1]Northwestern University, Cell and Developmental Biology, Chicago, United States, [2]Northwestern University, Department of Medicine, Chicago, United States, [3]New Iberia Research Center, New Iberia, United States

Background: Despite effective antiretroviral therapy (ART), HIV-1 persistence is the major obstacle to a functional cure. Thus, understanding the tissue microenvironment of the reservoirs of persistence during ART is key.
Methods: Utilizing immunoPET/CT-identified foci of SIV gene expression utilizing the rhesus macaque model, we compared the spatial transcriptomics (10x Visium) of the local gut tissue neighborhood of the rebound eclipse-phase foci (4-6 days post-ATI) from animals initiating ART 4 days (early-seeded reservoir with short lifespan) or 10 weeks (persistent reservoir) after high-dose chal-

lenge. Adjacent sections from tissues containing foci of rebounding virus were evaluated with SIV proviral PCR, immunofluorescence, and spatial transcriptomics.

Results: SIV presence was always associated with higher transcriptional levels and up-regulation of genes related to SIV infection and innate immune responses was observed for both types of reservoirs. Notably, we also detected significant differences between the short lifespan and persistent reservoirs. The biomarkers and pathways for the persistent reservoir revealed the activation of the integrated stress response with its characteristic translational reprograming through the disruption of cap-dependent translation and cellular adaptation.

Collectively, the pathway analyses show many parallels between the foci of the rebound of the persistent reservoir 5 or 6 days after ATI and the tumor microenvironment (TME) which is the contextual basis of modern cancer research. SIV in persistent reservoirs was distinctly associated with IgA plasma cells, monocytes, and cycling gamma-delta T-cells, while in short lifespan reservoir was associated with IgG plasma cells, Th17 cells, DCs and epithelial cells suggesting that persistent reservoirs are associated with gut tertiary lymphoid organs and characterized by a status of reprogramed translation and transcriptional activation of genes associated with the integrated stress responses function to restore cellular homeostasis.

Conclusions: We propose that the integrated stress response facilitates the development of a viral microenvironment characterized by altered cell metabolism, reduced viral translation (IRES-dependent), altered extracellular matrix, and compromised immune cell function very analogous to the well-defined TME. The immune checkpoint markers that are remarkably identical between cancer and HIV infection (PD-1, PDL-1, CTLA-4, etc.) are consistent with both utilizing the altered microenvironment as a physiological sanctuary where they can persist while evading immune responses.

Alterations in plasma metabolomic biomarkers following HIV acquisition and association with reservoir size in people on antiretroviral therapy

O.O. Baiyegunhi[1], K. Naidoo[2], M. Mohamed[3], M. Maimela[1], K. Reddy[1], Z. Zhang[4], L. Mazibuko[1], A. Harms[4], T. Hankemeier[4], H. Mwambi[5], M.J. Bunders[6,7], M. Alfeld[2,8], J. Mann[9], T. Ndung'u[1,9,10]

[1]Africa Health Research Institute, Basic and Translational Science, Durban, South Africa, [2]Leibniz Institute of Virology, Department of Virus Immunology, Hamburg, Germany, [3]University of KwaZulu-Natal, Statistics, Durban, South Africa, [4]Leiden University, Metabolomics and Analytics Center, Leiden, Netherlands, the, [5]University of KwaZulu-Natal, School of Mathematics, Statistics and Computer Science, Pietermaritzburg, South Africa, [6]University Medical Center Hamburg-Eppendorf, III. Department of Medicine, Hamburg, Germany, [7]Ragon Institute of MGH, MIT, and Harvard University, Boston Massachusetts, United States, [8]German Center for Infection Research (DZIF), Partner Site Hamburg-Lübeck-Borstel-Riems, Hamburg, Germany, [9]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, [10]University College London, Division of Infection and Immunity, London, United Kingdom

Background: Metabolic disorders are common in people living with HIV with or without antiretroviral therapy (ART) compared to population controls. Metabolic biomarkers have also been associated with immune dysfunction and HIV post-treatment control. The metabolic state of immune cells determines their susceptibility to the virus and the establishment of latency, but the mechanisms have not been fully explored in African populations with a high burden of HIV.

We performed an unbiased investigation of alterations in plasma metabolic biomarkers in a longitudinal cohort of individuals who were followed before and after HIV acquisition and explored association with clinical outcomes and HIV reservoir size.

Methods: We studied 47 participants living with HIV, of whom 18 were diagnosed in hyperacute phase (before peak viremia). Samples from before HIV acquisition, during untreated acute disease, and after 1 year on ART were analysed. The plasma metabolome was measured using liquid chromatography-mass spectrometry, and HIV reservoir size was measured using droplet digital PCR.

Results: We measured 209 metabolites, comprising amines and signalling lipids, with 46 metabolites [26 were higher (30% amines) and 20 (25% amines) lower] differing between HIV-negative and acute HIV groups, confirmed by Random Forest analysis with 87.5% accuracy. These were linked to various metabolic pathways, including alanine, aspartate, glutamine metabolism, sphingolipid and butanoate metabolism, and the TCA cycle. One year post-ART initiation, reservoirs were undetectable in 4 of 18 participants. Twelve metabolites previously linked to rebound were quantified, with glutamic acid and glycoursodeoxycholic acid correlating negatively and positively with reservoir size, respectively. Factors associated with reservoir size also included CD4/CD8 counts and CD4:CD8 ratio.

Conclusions: These findings highlight metabolome alterations during HIV, and potential metabolomic associations with reservoir size, guiding future studies. Metabolic biomarkers of HIV reservoir size will enhance the understanding of HIV pathogenesis and inform safer analytical treatment interruption strategies.

OAA0404

Elevated CCR7 ligands CCL19 and CCL21 in aorta of PLWH promote immune cell recruitment

L.M. Obare[1], X. Zhang[1], K. Nthenge[1], V.R. Stephens[1], Y.R. Su[1], T. Absi[1], C. Gabriel[1], M. Mashayekhi[1], S. Bailin[1], J.R. Koethe[1], C.N. Wanjalla[1]
[1]Vanderbilt University Medical Center, Medicine, Nashville, United States

Background: People Living with HIV (PLWH) face a 1.5–2-fold higher risk of cardiovascular disease (CVD), partly driven by chronic immune activation despite viral suppression. CCL19 and CCL21, ligands for C-C chemokine receptor 7 (CCR7), play critical roles in immune cell migration and inflammation.
We hypothesize that increased CCL19/CCL21 expression in the aorta contributes to immune cell recruitment, vascular inflammation, and atherosclerosis in PLWH.
Methods: We used matched Formalin-fixed paraffin-embedded thoracic aorta from the National Disease Research Interchange (NDRI; PLWH, n=4 and People without HIV(PWoH, n=4). The whole transcriptional profile of the aorta with spatial resolution was performed using Visium v1. Differential expression of CCL19/CCL21 was analyzed using a negative binomial model. For single-cell resolution, spatial transcriptomics of coronary arteries from PLWH (n=2) and PWoH (n=2) were profiled using CosMX with the 1000-plex RNA panel.
Results: Aortas of PLWH had significantly upregulated CCL19 (p = 1.25e-9) and CCL21 (p = 5.20e-63) compared to PWoH *(Figure 1A).* Spatial resolution shows that CCL19 and CCL21 transcripts are expressed by cells in the media and the adventitia *(Figure 1B)*.
In a separate analysis of coronary arteries from both PLWH and PWoH, CCL19 transcripts were expressed by vascular smooth muscle cells and CCL21 by endothelial cells.

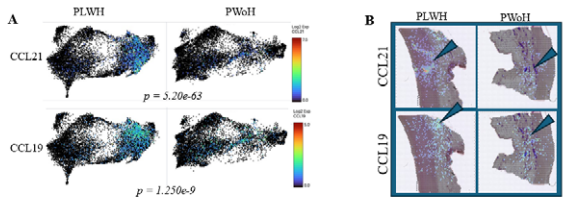

Figure 1. Spatial gene expression of CCL19/CCL21 using the Visium platform. (A) Uniform Manifold Approximation and Projection (UMAP) was used to integrate sections from PWoH (n=4) and PLWH (n=4), showing CCL19/CCL21 gene expression. (B) CCL19/CCL21 gene transcripts from Visium are shown on representative 5µm sections from PLWH and PWoH. Blue arrows highlight areas of gene expression.

Conclusions: CCL19 and CCL21 have previously been implicated in atherosclerotic cardiovascular disease. Up-regulated expression of CCL19/CCL21 in the aorta of PLWH may increase naïve CD4 and CD8 T cell recruitment and promote arterial inflammation. Additional studies are needed to investigate this potential mechanism contributing to heightened CVD risk in PLWH and the potential therapeutic value of targeting CCR7-mediated pathways to mitigate vascular inflammation.

OAA0405

The predominant effects of ART and sex on the plasma metabolomes of virally suppressed children living with perinatally acquired HIV: implications for cure studies

C. Herbert[1], L. Kuhn[2], N. Tobin[3], F. Li[3], R. Strehlau[4], F. Patel[5], T. Wang[2], S. Wang[2], G. Aldrovandi[3], C. Tiemessen[1]
[1]National Institutes for Communicable Diseases, and Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, Johannesburg, South Africa, [2]Columbia University, Irving Medical Center, New York, United States, [3]University of California Los Angeles, Department of Pediatrics, Los Angeles, United States, [4]University of the Witwatersrand, VIDA Nkanyezi Research Unit, Rahima Moosa Mother and Child Hospital, Department of Paediatrics and Child Health, Faculty of Health Sciences, Johannesburg, South Africa, [5]University of the Witwatersrand, Wits RHI, Faculty of Health Sciences, Johannesburg, South Africa

Background: The influence of host factors, such as the metabolome, on HIV remission and cure interventions has garnered increasing interest. Metabolism in children living with perinatally-acquired HIV (CLWH) is less well understood than in adults.
Methods: To characterise the metabolic profiles of CLWH, plasma from pre-pubescent, virally-suppressed CLWH (n=155) and HIV-negative controls (HNCs, n=155) were analysed by Metabolon using untargeted ultra high-performance liquid chromatography/tandem accurate mass spectrometry. CLWH were on efavirenz (EFV, n=101) or lopinavir/ritonavir (LPV, n=54)-based antiretroviral therapy (ART) regimens. Three main comparisons were used to explore the major metabolic patterns in CLWH and their relation to clinical parameters.
Results: The specific ART regimen produced the most pronounced patterns in the metabolic profiles of CLWH. The two regimens (comparison 1) were distinguished predominantly by altered bile acids, bilirubin, bilirubin catabolites, and androgenic steroids. These changes likely originated from divergent antiretroviral interactions with human enzymes, transporters and the gut microbiome.
The sexes (comparison 2) in all groups were consistently distinguished by cholesterol sulphate levels, but most of the sex differences in the CLWH were distinct from those in HNCs.
Within a subset of EFV-CLWH with long-term viral suppression [comparison 3, undetectable viral load with occasional blipping, for >6 years, with no blips >1000 HIV RNA copies/ml, n=49], two metabotypes were identified and compared. Metabotype A showed significantly more impaired mitochondrial oxidative metabolism relative to Metabotype B and had significantly lower contempora-

neous (p<0.001) and longitudinal (p=0.008) CD4 T-cell percentages (CD4%). Metabotypes were not associated with age at ART initiation, pre-ART CD4% and viral load, time to suppression, longitudinal viral load, or HIV DNA Ct value (reservoir size proxy).

Conclusions: The specific ART regimen dominated the plasma metabolic profile and significantly influenced the presentation of metabolic sexual dimorphism in CLWH. Two metabotypes among CLWH on the same regimen suggested divergent, sub-clinical responses to the same treatment even among those with long-term viral control and CD4% approaching healthy levels. It is unlikely that metabolic biomarkers will be reliable in predicting or monitoring intervention outcomes across regimens. Grouping of treated individuals in metabolic studies should be done with careful consideration for the ART regimen used.

OAA0502

Early-treated children with perinatal HIV show elevated monocyte activation into adolescence

C. Davies[1], F. Vaida[2], T. Webber[3], P. Bouic[4], B. Tang[5], K. Otwombe[6], M.F. Cotton[7], S. Browne[8], S. Innes[7]

[1]Stellenbosch University, Division of Epidemiology and Biostatistics, Cape Town, South Africa, [2]University of California San Diego, Division of Biostatistics and Bioinformatics, San Diego, United States, [3]Stellenbosch University, Division of Immunology, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [4]Stellenbosch University, Division of Medical Microbiology, Cape Town, South Africa, [5]University of California San Diego, Department of Psychiatry, San Diego, United States, [6]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [7]Stellenbosch University, Family Center for Research with Ubuntu, Department of Paediatrics & Child Health, Cape Town, South Africa, [8]University of California San Diego, School of Public Health, San Diego, United States

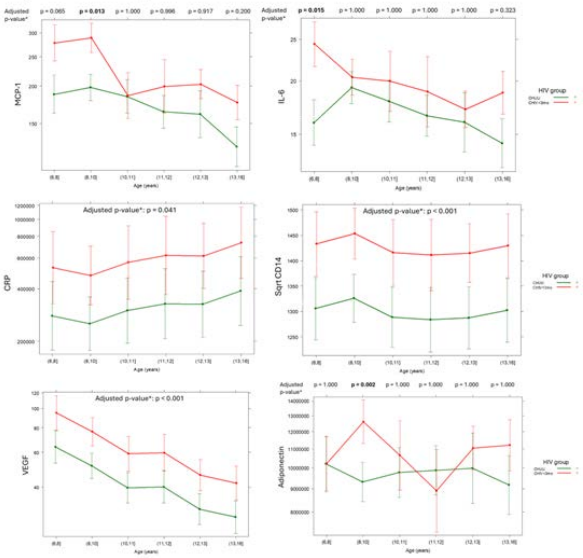
Background: Universal early ART for infants born with HIV has dramatically improved long-term outcomes in children living with perinatal HIV (CHIV). However, these children face decades of ART exposure and immune activation. Neither the long-term inflammatory profile nor risk of non-communicable diseases are yet known. We compared longitudinal biomarkers associated with inflammation, metabolic and cardiovascular damage and response markers in early ART-treated children and controls unexposed to HIV.

Methods: 185 children (67 CHIV, 118 HIV-unexposed) aged 7-16 years (87 female, 98 male) previously part of CHER early ART trial, were followed at Tygerberg Hospital, South Africa. CHIV initiated ART within 3 months of birth, and were virologically suppressed (>90%), asymptomatic, with preserved CD4+ cell count and clinically well at the time of blood tests. Unexposed children arose from the same communities and socio-economic background. Children had multiple measurements (median 2, four years apart), yielding 321 total observations. We measured 26 biomarkers in blood serum using ELISA and Luminex™ multiplex immunoassays, comprising monocyte and lymphocyte-derived biomarkers, response, metabolic and cardiovascular markers.

We used mixed effects models with child-specific random effects to investigate the association between HIV group and each biomarker, adjusting for age, sex, ethnicity, smoke exposure and batch, and considered an interaction between age and HIV group. Results are adjusted for multiple comparisons.

Results: Early treated children had significantly higher CRP, sCD14 and VEGF than unexposed. Age-specific effects were observed with significantly higher MCP-1, IL-6, and P-selectin in CHIV aged 6-8 years, significantly higher MCP-1, Adiponectin, and IL1a in ages 8-10 years, and significantly higher MCP-1 in ages 13-16 years. All other biomarkers showed no significant difference.

Figure 1: Graph of selected predicted biomarkers by age for unexposed (CHUU) and early-treated children living with HIV (CHIV). P-values are adjusted for age, sex, smoke exposure, batch, ethnicity and multiple comparisons. Error bars represent 95% confidence intervals.



Conclusions: Despite early-ART and sustained viral suppression, early treated children displayed extensive immune marker elevations, clustered around monocyte activation and markers associated with cardio-metabolic disease. These children remain at high risk of premature vascular disease in adulthood.

OAA0503

Impact of BCG vaccination on innate immune responses in HIV-exposed infants who have not acquired HIV: a randomized controlled trial in Uganda

R. Namakula[1], S. Cose[2,3], V. Nankabirwa[4], O. Namugga[1], M.G. Netea[5], H. Steinsland[1], H. Sommerfelt[1], K. Hanevik[1,6]
[1]University of Bergen, Centre for International Health, Bergen, Norway, [2]MRC/UVRI and LSHTM Uganda Research Unit, Department of Immunology, Kampala, Uganda, [3]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [4]Makerere University School of Public Health, Department of Epidemiology and Biostatics, Kampala, Uganda, [5]Radboud University Medical Centre, Department of Internal Medicine, Nijmegen, Netherlands, the, [6]Haukeland University Hospital, Department of Medicine, Bergen, Norway

Background: Bacillus Calmette-Guérin (BCG) vaccination has been shown to train the innate immune system, leading to enhanced responsiveness to subsequent triggers. However, induction of training is not well understood in the growing population of HIV-1 exposed infants who have not acquired HIV (HEU) in sub-Saharan Africa. We aimed to compare the trained immune response in HEU infants who received BCG at birth with the response in HEU infants who received BCG 14 weeks of age.
Methods: A randomized controlled trial was performed among 182 HEU infants born at a health facility in Kampala, Uganda, where 91 received BCG at birth (early arm) and 91 received BCG at age 14 weeks (late arm). Whole-blood cultures stimulated with Toll-like receptor (TLR) agonists (TLR2/1, TLR4, TLR7/8) and MTB lysate antigens for 18hr were done using venous blood drawn at birth, and at weeks 6, 14, and 52. Cytokine concentrations (TNF, IL-1β, IL-6 and IL-10) were measured using Luminex immunoassay of culture supernatants. Statistical analyses were done with Student's t-test on log-transformed cytokine concentration responses.
Results: Among 182 randomized infants, 4 died and 1 was lost to follow up before 52 weeks. Randomization successfully balanced relevant baseline characteristics. All TLR agonists generally elicited stronger responses in the early BCG arm than in the late arm, at both week 6 and week 14.The IL-1β and IL-10 responses increased significantly following TLR2/1 stimulation in BCG vaccinated infants compared to infants who had not yet been vaccinated, with 1.41 [95%CI 1.00 to 1.98; p=0.048] and 1.33 [95%CI 1.02 to 1.73; p=0.031] fold increases at week 14, respectively. Significantly higher IL-6 response at week 6 and IL-10 response at week 14 after TLR7/8 stimulation in the group receiving BCG at birth compared to the group yet to receive BCG was observed. At week 52, there were no significant differences in cytokine production between the two groups.
Conclusions: This study with low attrition rate, TLR agonists induced stronger innate cytokine responses in BCG vaccinated HEU infants. Our data indicates that BCG vaccination at birth induces robust trained immunity in HEU infants until 14 weeks of age and recommended in this vulnerable population.

An immunoinformatics analysis pipeline (IMAP) identifies novel genetically-conserved and immunogenic peptides found in rebound HIV-1 during analytical treatment interruption

J. Marin-Rojas[1,2], E. Lee[1], S. Cronin[1,2], K. Fisher[1,2], J. Simpson[1,2], S. Deeks[3], A. Kelleher[4], G. Duette[1,2], S. Palmer[1,2]
[1]The Westmead Instutite for Medical Research, Center for Virus Research, Sydney, Australia, [2]University of Sydney, Faculty of Medicine and Health, Sydney, Australia, [3]University of California, Department of Medicine, San Francisco, United States, [4]University of New South Wales, Kirby Institute, Sydney, Australia

Background: HIV-specific CD8 T-cell responses directed against genetically-conserved HIV-1 protein regions are associated with viral control. Therefore, we applied a novel **IM**munoinformatics **A**nalysis **P**ipeline (IMAP) to identify 182 peptides (IMAP-peptides) from 5 HIV-1 protein regions (Gag, Pol, Vif, Vpr, and Env), which were genetically conserved across global HIV-1 variants while avoiding known immune escape mutations. We assessed whether the selected IMAP-peptides were found within rebound virus derived from participants who experienced analytic treatment interruption (ATI). Furthermore, we characterized the corresponding CD8 T-cell response.
Methods: During the PULSE clinical trial, 68 men who have sex with men living with HIV-1 in Australia underwent three consecutive ATIs. Remarkably, seven participants transiently controlled HIV rebound during the 3rd ATI. We obtained plasma and/or blood-derived mononuclear cells from four non-controllers (NCs) who experienced rapid viral rebound during all ATIs, and five transient-controllers (TCs) who exhibited control during the 3rd ATI. We assessed whether the IMAP-peptides were present within HIV-1 RNA sequences from rebound virus across the ATIs in NCs and TCs. In addition, the effector response to these IMAP-peptides and NIH-provided control peptide pool (without IMAP-peptides) were determined by IFN-γ/TNF-α production and degranulation (CD107a/b).
Results: Near full-length HIV-1 RNA sequencing of rebound virus from 3 NCs and 2 TCs revealed the Gag, Pol, Vif, Vpr, and Env IMAP-peptides were found in 52-100% of the viral sequences obtained from these five participants across three ATI time points. Moreover, the CD8 T-cells from 3 TCs had a 15-53-fold higher effector response to the IMAP-peptides compared to the CD8 T-cells from 2 NCs. Notably, in NCs, the relative response to the IMAP-peptides was 20-fold lower compared to the control peptides, whereas in TCs, the IMAP-peptide response was similar to the control response (1-1.58-fold change).
Conclusions: The novel IMAP-peptides were found within the HIV-1 RNA sequences during viral rebound in transient-controllers and non-controllers, indicating these peptides are expressed during HIV-1 infection. The higher potential of CD8 T-cells from transient-controllers to recognize and respond to mutational-constrained HIV epitopes, may contribute to their virological control. These results highlight the potential of IMAP for identifying novel immunogens for therapeutic strategies to enhance CD8 T-cell response.

OAA0505

Plasma extracellular vesicles and their association with hepatocellular carcinoma in individuals living with HIV and hepatitis C virus: potential biomarkers

A.A. Osegueda Peña[1], L. Leicaj[1], A. Adamczyk[1], N. Cruz Molina[2], L. Cruces[1], L. Baquero[1], T. Langer[1], V. Gonzalez Polo[1], M. Ostrowski[1], N. Laufer[1,2]
[1]CONICET – Universidad de Buenos Aires. Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Buenos Aires, Argentina, [2]División Infectología, Hospital Fernández, Buenos Aires, Argentina

Background: Plasma extracellular vesicles (pEV) play a crucial role in immune modulation. Natural killer (NK) cells are essential for immune surveillance, particularly in targeting tumor cells. Advanced liver fibrosis (LF) increases hepatocellular carcinoma (HCC) risk, even after successful HCV clearance with direct-acting antivirals (DAA). We previously showed that NK cells exhibit an exhausted phenotype and reduced function in individuals with advanced LF post-DAA.
This study aimed to assess the impact of pEV from individuals with HIV/HCV:
a. with advanced LF, and;
b. those with advanced LF who later developed HCC.
Methods: Plasma samples were collected from individuals with advanced liver disease (METAVIR F4, n=11) achieving sustained virologic response (SVR) post-DAA. Samples were taken at baseline (pre-DAA) and post-SVR intervals; 5 developed HCC with a median of 5.75 years (IQR 4-8) post-clearance. Plasma from 6 healthy controls was also included.
pEV were isolated via size exclusion chromatography from plasma (2mL), resuspended in PBS (60µL), and incubated with healthy PBMC for 1 hour. NK cell degranulation was assessed by FACS analysis of CD107a, CD3, CD56, and a viability marker after coculture with K562 cells (10:1 ratio) for 2 hours.
Results: pEV from all participants, including controls, reduced NK CD107a expression compared to NK cells without pEV. pEV from individuals with advanced LF at baseline were more suppressive than controls (0.71[0.60-0.85] vs 0.88[0.78-0.97]; p=0.023). After ≥1 year post-DAA, pEV from those who developed HCC remained more suppressive than those who did not (0.75[0.71-0.78] vs 0.86[0.84-0.90]; p=0.008). In non-HCC individuals, NK suppression decreased over time (p=0.052), unlike in those who developed HCC. At ≥1 year, suppression by pEV in non-HCC individuals was similar to controls (p=0.79), whereas pEV from future HCC cases remained more suppressive (p=0.03).
Conclusions: pEV from individuals with advanced LF contribute to the exhausted NK cell phenotype, and could be associated with the increased risk of HCC among those individuals. Notably, pEV from those who developed HCC sustained long-term suppression of NK functionality, unlike pEV from non-HCC individuals, which resembled healthy controls ≥1 year post-treatment. These findings suggest that persistent NK suppression by pEV after HCV clearance could serve as a biomarker for HCC risk.

OAB01 ART strategies

OAB0102

A double-blind, active-controlled, phase 2b study to evaluate the efficacy and safety of ulonivirine in combination with islatravir in virologically suppressed adults living with HIV-1

J.-M. Molina[1], M.N. Ramgopal[2], C. Katlama[3], D.L. Cunningham[4], D.P. Hagins[5], D.L. Braun[6], O.O. Osiyemi[7], E. Hofmann[8], C.A. Dietz[9], G. Lin[10], K. Beckey[10], S. Rawlins[10], R.P. Matthews[10], W. Greaves[10]
[1]St-Louis and Lariboisière Hospitals, APHP, University of Paris Cité, Paris, France, [2]Midway Immunology and Research Center, Fort Pierce, United States, [3]Institut Pierre Louis d'Epidémiologie et de Santé Publique, APHP, Sorbonne Université, Paris, France, [4]Pueblo Family Physicians Ltd, Phoenix, United States, [5]Chatham County Health Department, Savannah, United States, [6]University of Zurich, Zurich, Switzerland, [7]Triple O Research Institute, West Palm Beach, United States, [8]Department of Infectious Diseases, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland, [9]KC Care Health Center, Kansas City, United States, [10]Merck & Co., Inc., Rahway, United States

Background: Ulonivirine (ULO, MK-8507) is a non-nucleoside reverse transcriptase inhibitor (NNRTI) suitable for once-weekly (QW) oral dosing, being developed with islatravir (ISL) for the treatment of HIV-1. This double-blind, phase 2b trial evaluated the efficacy and safety of ISL+ULO QW in virologically suppressed adults living with HIV-1 (MK-8591-013; NCT04564547).
Methods: Participants without known NNRTI resistance who were virologically suppressed for ≥6 months on bictegravir/emtricitabine/tenofovir alafenamide (BIC/FTC/TAF), were randomized (1:1:1:1) to receive ISL 20 mg plus ULO (100, 200, or 400 mg) QW, or remain on BIC/FTC/TAF once-daily. Due to decreases in total lymphocyte counts (TLC) and CD4+ counts observed across ISL programs, the trial was stopped early and participants were transitioned to non-study antiretroviral therapy with continued monitoring until recovery. Efficacy assessments included the proportion of participants maintaining virological suppression and measurement of CD4+ counts; safety assessments included adverse event (AE). ISL+ULO data were pooled across doses.
Results: 161 participants were randomized (121 ISL+ULO, 40 BIC/FTC/TAF); 80.7% were male and 64.6% were White, with a mean age of 45 years and baseline CD4+ of 748 cells/mm^3. When dosing of ISL+ULO was discontinued, 113 participants had reached Week 24. Virologic suppression (HIV-1 RNA <50 copies/mL) was maintained in all participants who had available data across groups at Week 24. Participants receiving ISL+ULO reported similar rates of AEs (76.9% vs 67.5%), drug-related AEs (17.4% vs 10.0%), and AEs leading to study discontinuation (2.5% vs 0.0%), as participants receiving BIC/FTC/TAF. There was no increase in the incidence of infection among participants receiving ISL+ULO (ISL+ULO: 36.4% vs BIC/FTC/TAF: 32.5%). Mean percentage change from baseline in TLC and CD4+

counts showed decreases for participants receiving ISL+ULO (−26.6% and −23.9%) versus BIC/FTC/TAF (-2.5% and -0.8%) at Week 24. Recovery in TLC and CD4+ counts towards baseline was observed in all ISL+ULO groups at Week 24 post-treatment.

Conclusions: ISL+ULO showed efficacy in maintaining viral suppression through Week 24. Consistent with previous studies of ISL, decreases in TLC and CD4+ counts were observed with ISL 20 mg + ULO QW followed by a trend to recovery after discontinuation. Development of ISL 2 mg + ULO QW is ongoing.

Background: Switching to DTG/3TC or boosted protease inhibitor/3TC had demonstrated long-term non-inferior efficacy vs continuing tenofovir (TDF) 3 drugs based regimens and are recommended in guidelines from northern countries, but not in WHO recommendations.

The MODERATO trial in West and Central Africa aims to demonstrate the non-inferiority at 96 weeks of two arms of maintenance dual therapy DTG/3TC or ATV/r/3TC compared to CARs with TDF/3TC/efavirenz (EFV) (TLE) or TDF/3TC/DTG (TLD) in person living with HIV with virological success.

Methods: From November 2020 to February 2023, in three countries, we randomized HIV-1 infected adults on CARs with TLE or TLD for at least 2 years, without a history of virological failure, AgHbs- and CD4 cell count > 200/m. The primary endpoint was the proportion of randomized participants demonstrating non-inferiority of a switching to dual-drug maintenance therapy vs continuation of the 3 drugs CARs in terms of virological success at week 96, with no change in strategy. Virological success was estimated using the FDA Snapshot approach, with a 10% non-inferiority margin.

Results: Overall 480 adults (79% women; 52 % aged ≥50 years, median duration on ARV regimen 9 years, mean CD4 count 768/mm3) were randomized. The ITT population included 480 participants (160 on DTG/3TC, 160 on ATV/r/3TC and CARs (TLE n=149 and TLD n=11). At week 96, in the ITT population, the treatment success rate was 95.0 % (304/320) in the dual-drug group and 96.9 % (155/160) in the CARs group (adjusted difference -1.9%, 95% CI -5.5% to 1.7%). 10 (3.1%) and 5 (3.1%) participants experienced virological failure, respectively. Comparisons by each dual-drug vs CARs also show non-inferiority.

One patient died in dual-drug group. Grade 3/4 adverse events were reported in 39 (12.2%) and 15 (9.4%) participants, respectively (p=0.36). There was no difference in mean change CD4 value at S96 (+70 vs +65, p=0.84).

Conclusions: Switching to dual maintenance therapy was non-inferior to continuing CARs with 3 drugs regimen including TDF for maintaining virologic suppression on long term week 96 analysis and good safety profile. This first experience in West and Central Africa supports dual maintenance therapy as an option in Sub Saharan African countries.

Real-world effectiveness of CAB+RPV LA in individuals with HIV viremia at therapy initiation

R. Hsu[1,2], M. Sension[3], J.S. Fusco[4], L. Brunet[4], B. Levis[4], Q. Cochran[5], G. Sridhar[6], V. Vannappagari[6], J. van Wyk[7], M. Wohlfeiler[8], G.P. Fusco[4]

[1]AIDS Healthcare Foundation, New York, United States, [2]NYU Langone Medical Center, New York, United States, [3]CAN Community Health, Fort Lauderdale, United States, [4]Epividian, Inc., Raleigh, United States, [5]AIDS Healthcare Foundation, Fort Lauderdale, United States, [6]ViiV Healthcare, Durham, United States, [7]ViiV Healthcare, London, United Kingdom, [8]AIDS Healthcare Foundation, Miami, United States

Background: Cabotegravir + rilpivirine long-acting injectable therapy (CAB+RPV LA) is indicated for people with HIV (PWH) who are virologically suppressed (HIV-1 RNA viral load [VL] <50 copies/mL) on a stable antiretroviral regimen. However, in the OPERA cohort, viremic (VL ≥50 copies/mL) PWH have been observed initiating CAB+RPV LA. We describe these individuals and their outcomes in this real-world setting.

Methods: Treatment-experienced adults with viremia switching to CAB+RPV LA from 21JAN2021-31DEC2023 were followed through 29FEB2024. Complete initiation was de-

fined as receiving 2 injections ≤67 days apart. Discontinuation was 2 consecutive missed injections (monthly: >67 days without injection; every 2-months: >127 days without injection). Non-response (failure to suppress to <50 copies/mL) and confirmed virologic failure (CVF; suppression to <50 copies/mL followed by 2 VL ≥200 copies/mL or 1 VL ≥200 copies/mL + discontinuation) were assessed among those with ≥1 follow-up VL.

Results: Of 3,304 PWH initiating CAB+RPV LA, 368 (11%) initiated with viremia (median VL: 120 copies/mL [IQR: 61, 2535]). Median age was 41 (IQR: 32, 51), 30% were female, 57% were Black, 18% were Hispanic, and 63% received care in the Southern US. Median years since HIV diagnosis was 9 (IQR: 3, 17), 29% had a BMI ≥30 kg/m^2, median CD4 cell count was 578 cells/μL (IQR: 353, 808), 80% had ≥1 comorbidity, and 69% were on an INSTI and 13% on 2 core agents prior to CAB+RPV LA. Among 331 (90%) PWH who completed initiation, 258 individuals (78%) were on CAB+RPV LA with median follow-up of 12 months (IQR: 8, 19) at the time of analysis, mostly (93%) dosed every 2-months. Of 313 PWH with ≥1 follow-up VL, 277 (88%) suppressed to VL <50 copies/mL during follow-up while 36 (12%) had non-response during follow-up. Fewer than 2% experienced CVF.

Conclusions: In the OPERA real-world cohort, individuals with VL ≥50 copies/mL at CAB+RPV LA initiation had long-standing HIV, a high prevalence of comorbidities, and were failing an INSTI or multiple core agents. Most successfully initiated CAB+RPV LA and were able to suppress their VL to <50 copies/mL. A majority remained on CAB+RPV LA at study end with few failures.

Is long-acting injectable antiretroviral therapy safe in countries with high hepatitis B prevalence?: insights from the IMPALA study

U. Bahemuka[1], V. Ankunda[1], V. Tumusiime[1], P. Kafeero[1], C. Norcross[1], N. Garrett[2], S. Mahomed[2], S. Kassim[3], L. Achieng Ombajo[4], E. Laker Odongpiny[5], N. Owarwo[5], I. Yawe[6], D. Grint[7], A. Idahosa[8], I. Eshun-Wilsonova[9], W. van Rein-van der Horst van[10], F. Addo Boateng[11], F. Cresswell[7], E. Ruzagira[7]

[1]MRC/UVRI & LSHTM, Viral Pathogens theme, Entebbe, Uganda, [2]Centre for the AIDS Programme of Research in South Africa (CAPRISA), HIV pathogenesis and vaccine research, Durban, South Africa, [3]Desmond Tutu HIV Foundation, Cape town, South Africa, [4]University of Nairobi, Department of medicine, Nairobi, Kenya, [5]Infectious Diseases Institute, Kampala, Uganda, [6]Joint Clinical Research Centre, Fort Portal, Uganda, [7]London School of Hygiene and Tropical Medicine, London, United Kingdom, [8]Johnson & Johnson, Lagos, Nigeria, [9]Johnson & Johnson, Cape town, South Africa, [10]Johnson & Johnson, South Holland, Netherlands, the, [11]Johnson & Johnson, Accra, Ghana

Background: Hepatitis B is a significant health concern among people living with HIV. The WHO recommended first-line HIV regimen (tenofovir disoproxil, lamivudine, dolutegravir, TLD) both prevents and treats hepatitis B disease. Novel long-acting (LA) injectable antiretrovirals including cabotegravir (CAB) and rilpivirine (RPV), are not active against hepatitis B, raising concerns about reactivation in individuals with prior hepatitis B exposure. In addition, CAB+RPV LA HIV treatment is not recommended in individuals with active hepatitis B (HepBsAg+).

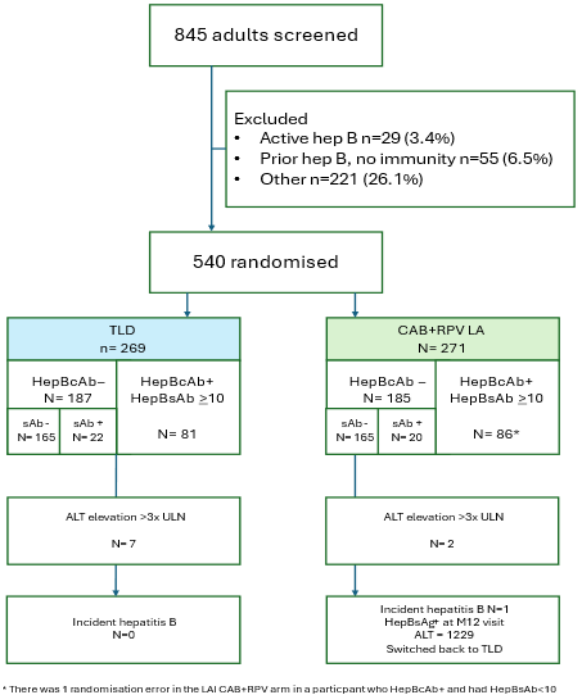
Methods: IMPALA (NCT05546242) is a phase 3b clinical trial in Uganda, Kenya and South Africa investigating efficacy of CAB+RPV LA in virally suppressed adults. Participants with active hepatitis B (HepBsAg+) or prior infection without immunity (HepBcAb+ with HepBsAb <10 IU) were excluded.

Eligible participants were randomized 1:1 to continue TLD or switch to CAB+RPV LA given 2-monthly. Regular assessments were conducted to monitor liver enzyme elevations and hepatitis infection/reactivation, with comparisons made between arms.

Results: Between Dec/2022 -Mar/2024, 845 volunteers were screened, of whom 222 (26.3%) had evidence of prior infection (HepBcAb+). Hepatitis B-related reasons precluded 84 (9.9%) from randomization [29 (3.4%), active hepatitis B; 55 (6.5%), prior infection but no immunity].

Among 540 randomized participants, 42 (7.8%) had evidence of vaccine-mediated immunity. ALT elevations were observed in 7 (2.6%) participants in the TLD arm versus 2 (0.7%) in the LAI arm.

One incident hepatitis B infection occurred in a participant in the LA arm without vaccine-mediated immunity. No reactivation of hepatitis B was detected during the study.



Conclusions: The high number of hepatitis B-related screen-outs highlights challenges for LA therapy in hepatitis B endemic countries. While hepatitis B reactivation did not occur in individuals with immunity (HepBsAb ≥10 IU), the risk of *de novo* infection remains in those receiving CAB+RPV LA without immunity. This demonstrates the need for strengthened vaccination efforts, particularly among those switching to CAB+RPV LA.

OAB0203

Topical trichloroacetic acid versus electrocautery for the treatment of anal intraepithelial neoplasia in patients living with HIV: a multicentre randomized non-inferiority trial (TECAIN-study)

S. Esser[1], A. Kreuter[2], A. Potthoff[3], K. Bilbilis[4], M. Oette[5], U. Wieland[6]

[1]University Hospital Essen, University Duisburg-Essen, Department of Dermatology and Venereology, Essen, Germany, [2]Helios St. Elisabeth Hospital Oberhausen; University Witten/Herdecke, Department of Dermatology, Venereology and Allergology, Oberhausen, Germany, [3]St. Elisabeth Hospital, Ruhr University Bochum, Interdisciplinary Immunological Outpatient Clinic, Department of Dermatology, Venereology and Allergology, Bochum, Germany, [4]University Hospital Essen, University Duisburg-Essen, Centre for Clinical Studies, Institute for Medical Informatics, Biometry and Epidemiology, Essen, Germany, [5]Augustinerinnen Hospital Cologne, Department of Internal Medicine, Gastroenterology and Infectious Diseases, Cologne, Germany, [6]University of Cologne, Faculty of Medicine and University Hospital Cologne, Institute of Virology, National Reference Center for Papilloma-and Polyomaviruses, Cologne, Germany

Background: People living with HIV (PLWH) have a strongly increased risk for Human papillomavirus (HPV)-associated anal cancer compared to the general population. Therefore, screening for and treatment of anal intraepithelial neoplasia (AIN) for the prevention of anal cancer are recommended for PLWH. Currently, there is no gold standard for the treatment of AIN and the available options have rarely been evaluated in prospective randomized trials

Methods: The TECAIN-study was a prospective, multicentre, randomised, non-inferiority trial investigating the efficacy and safety of TCA vs. ECA for the treatment of AIN. PLWH with histologically confirmed AIN were recruited from seven anal dysplasia units in Germany between 2015 and 2020.

The primary endpoint (PE) was therapeutic success defined as a combination of complete clinical response evaluated by high-resolution anoscopy and histological resolution/regression of AIN four weeks after the end of treatment (4-weeks-follow-up, 4WFU).

Secondary endpoints comprised therapeutic success 24 weeks after the end of treatment (24WFU), adverse events (AE), and HPV-parameters (prevalence, multiplicity, DNA-load, oncogene-mRNA-expression) at 4WFU and 24WFU.

Results: 257 PLWH with AIN were enrolled and randomly assigned to TCA (n=129) or ECA (n=128). 118 patients were treated with TCA, 115 with ECA (intention-to-treat population). The PE was reached in 52.5% of the TCA-group and in 61.7% of the ECA-group. Histological resolution/regression was documented in 66.9% (TCA-group) and 67.0% (ECA-group) at 4WFU. While non-inferiority of TCA could not be shown at 4WFU, TCA was non-inferior to ECA at 24WFU (50.8% vs. 48.7% therapeutic success). Treatment-related AEs were reported in 64.4% of the TCA- and in 65.2% of the ECA- group until 4WFU, without any persistent conditions. HPV-parameters did not differ significantly between treatment groups and within the groups between baseline and 4WFU or 24WFU.

Conclusions: TCA is a well-tolerated, inexpensive and simple to use treatment option for AIN in PLWH.

OAB0204

Predictors of weight gain among people with HIV (PWH) over 3-year period

R. Elion[1], J. Gruber[2], J. Radtchenko[1], M. Dunbar[2], N. Prata Menezes[2], J. Eron[3], C. Cohen[2], G. McComsey[4], P. Sax[5], G. Moyle[6]

[1]Trio Health, Louisville, United States, [2]Gilead Sciences, Foster City, United States, [3]University of North Carolina at Chapel Hill, Chapel Hill, United States, [4]Case Western Reserve University, Cleveland, United States, [5]Brigham and Women's Hospital, Boston, United States, [6]Chelsea and Westminster Hospital, London, United Kingdom

Background: Trio previously reported no difference in 3-year mean weight change in virally suppressed [VS] PWH vs non-PWH after propensity score matching. This study assessed the effects of ART on weight gain among PWH.

Methods: Retrospective study using Trio Health HIV EMR data (US). Eligibility: ≥18 years, in care Jan 2015-Aug 2023, treatment-experienced VS (viral load <200 copies/ml) at baseline or on 1st ART for ≥6 months ≥12 months since

start, VS at 3 years; with baseline and 3-year weights. Baseline characteristics were compared (X-square, t-test) for PWH with gain <5% vs. gain ≥10% and either shift to higher body mass index [BMI] or baseline obese [10% gain + BMI shift]. Classification regression trees [CRT] and logistic regression [LR] identified predictors of 10% gain + BMI shift including ART and baseline demographic and clinical characteristics.

Results: Of 10413 PWH, 41% lost/did not gain weight, 26% gained <5%, 12% had ≥ 10% gain + BMI shift. Compared to PWH with gain <5%, those with 10% gain + BMI shift were younger (median age 44 vs. 51 years), more likely female (28% vs. 16%), Black (49% vs. 37%), with normal BMI (39% vs. 30%), substance use (12% vs. 7%) and less likely with cardiovascular disease (23% vs. 28%), and hyperlipidemia (8% vs. 15%); 88% received INSTI. In CRT, younger PWH, female, Black, with lower baseline BMI and CD4 were predictors of 10% gain + BMI shift. In LR, Black, female, age 18-29, normal baseline BMI and CD4 <200 cells/mm^3, no TAF/TDF exposure 12 months pre-baseline were associated with 10% gain + BMI shift (Figure).

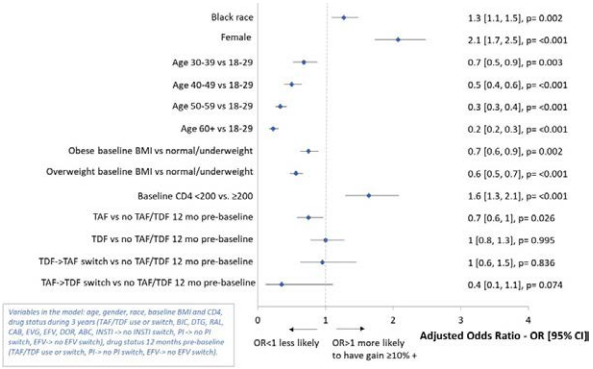


Figure. Predictors of gain ≥10% with shift to higher BMI.

Conclusions: This is the largest study evaluating weight change over 3-year period among VS PWH. Among gainers, we observed limited impact of ART on ≥10% weight gain and socio-demographic and clinical predictors were similar to non-PWH findings from the prior study.

OAB0205

Prevalence and correlates of sleep apnea using WatchPAT™: Chicago Women's Interagency HV Study (WIHS)

K. Weber[1], E. Daubert[2], R. Hernandez[2], D. Johnson[2], R. Morack[2], R. Ross[3], M. Cohen[2], A. French[4]

[1]Hektoen Institute of Medical Research, Chicago, United States, [2]Hektoen Institute, Chicago, United States, [3]Rush University Medical Center, Chicago, United States, [4]University of Illinois, Chicago, United States

Background: Obstructive sleep apnea (OSA) is often undiagnosed due to cumbersome lab-based diagnostics. Midlife women with/without HIV (WWH/WWoH) have OSA risks, making home sleep apnea testing (HSAT) desirable.

Methods: Chicago WIHS women had sleep apnea assessed (2019-2024) using an overnight multi-sensor, wrist-worn HSAT device with finger-probe peripheral arterial tonometry (WatchPAT™). Validated automated algorithms determined apnea-hypopnea index (AHI) using ≥ 3% oxygen desaturation threshold and categorized OSA severity based on number of hourly apnea-hypopnea events: none (<5), mild (5-14), moderate (15-30), severe (>30). Bivariate and multivariable logistic regression models controlling for age, income, education, employment, menopausal and HIV status determined factors associated with odds of moderate/severe vs. none/mild OSA.

Results: 169 (63% WWH) without previously diagnosed OSA had valid AHI (26 were invalid due to technical issues or <3 hours sleep); 83.4% were African American with median(IQR) age in years 54.6 (47.6, 60.2); 73.2% postmenopausal; 67.5% ≤$18,000 household income; 64% unemployed; 64.5% completed ≤ high school.

Current substances use included: 18.5% crack/cocaine/heroin, 25% cannabis, and 46.7% smoke tobacco. Chronic conditions included: 58.9% obesity, 25.6% diabetes, and 72.8% hypertension; 52.4% reported poor sleep quality (Pittsburgh Sleep Quality Index >5); 28.7% used sleep medications (prescribed/non-prescribed). Mean/standard deviation (m/sd) body mass index (BMI) and waist circumference (WC) were 32.9(8.6) and 103.4(18.1) respectively.

Overall, 151 (89.4%) had any degree of OSA; 24.9% severe, 34.3% moderate, 30.2% mild. Only 10.6% had no sleep apnea per guidelines. There were no significant differences by HIV status. In bivariate analyses (none/mild vs. moderate/severe), lower income ≤$18,000 (58.8% vs 73.5%, p=.048), higher m(sd)BMI [29.7(6.9) vs. 35.1(9.0), p<.0001], larger m(sd)WC [96.8(14.8) vs. 107.8(18.9), p<.0001], and being obese (43.5% vs. 69.7%, p=.0008) were associated with OSA severity.

In adjusted logistic regression models, only higher mBMI [aOR 1.11 (1.05-1.16; p<.0001)] and larger mWC [aOR 1.04 (1.02-1.06; p=.0002)] were associated with increased odds of moderate/severe OSA. Substance use and other chronic conditions were not significantly associated with OSA severity.

Conclusions: Undiagnosed sleep apnea was highly prevalent, nearly 90% among midlife WWH/WWoH, with 59% classified as moderate/severe OSA. HSAT screening is warranted to identify women likely to benefit from further evaluation and treatment by a sleep specialist.

Ford[1], and the ODYSSEY Trial Team

[1]University College London, MRC Clinical Trials Unit, Institute of Clinical Trials and Methodology, London, United Kingdom, [2]Enhancing Care Foundation, King Edward VIII Hospital, Durban, South Africa, [3]University of Zimbabwe, Harare, Zimbabwe, [4]Baylor College of Medicine Children's Foundation, Kampala, Uganda, [5]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [6]Mahasarakam Hospital, Pediatric Department, Maha Sarakham, Thailand, [7]Joint Clinical Research Centre (JCRC), Mbarara, Uganda, [8]Stellenbosch University, Family Center for Research with Ubuntu, Department of Paediatrics & Child Health, Tygerberg, South Africa, [9]Joint Clinical Research Centre (JCRC), Kampala, Uganda, [10]HIVNAT, Thai Red Cross AIDS Research Center, Bangkok, Thailand, [11]Goethe University Frankfurt, Department of Paediatrics and Adolescent Medicine, Frankfurt, Germany, [12]Africa Health Research Institute (AHRI), Kwazulu-Natal, South Africa, [13]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom, [14]INSERM/ANRS SC10-US19, Essais thérapeutiques et maladies Infectieuses, Villejuif, France, [15]Centro Materno-infantil do Norte, ULSSA, Porto, Portugal, [16]Makerere University-Johns Hopkins University (MU-JHU) Research Collaboration, Kampala, Uganda, [17]University of Padova, Department of Women and Child Health, Padova, Italy, [18]Hospital 12 de Octubre, Pediatric Infectious Diseases Unit, Madrid, Spain

Background: There are few data on predictors of treatment failure in children starting antiretroviral therapy-(ART) on dolutegravir-based regimens(DTG).

Methods: The ODYSSEY randomised trial demonstrated superior efficacy for DTG versus standard-of-care (SOC). The prognostic value of baseline characteristics across 4 domains (anthropometrics, HIV indicators, haematology, demographics) for treatment failure by 96 weeks in children starting first-line ART was investigated using Cox models, adjusting for trial arm and weight; fractional polynomials were considered for continuous covariates.

Results: 381 children started first-line ART (82% Africa, 13% Thailand, 5% Europe), 309 weighing ≥14kg (154 DTG, 155 SOC (92% efavirenz-based)) and 72<14kg (35 DTG, 37 SOC (78% boosted lopinavir-based)). At baseline, median age was 10.5 years (IQR:6.5-14.0), CD4% 20% (IQR:12-28), BMI-for-age z-score -0.58 (IQR:-1.48-+0.25;15%<-2) and 73 (19%) children had ongoing WHO-stage 3/4 events. 75 children experienced treatment failure by 96 weeks (24 DTG, 51 SOC). DTG-based ART protected against risk of treatment failure, and risk declined as weight increased, particularly in children<14kg. Within domain-specific models, after adjustment for weight and trial arm, low BMI-for-age, low CD4%, an ongoing WHO-stage 3/4 event, high neutrophils, and being at an African site independently predicted treatment failure (p<0.2). Age and middle-upper arm circumference were collinear with weight, and CD4/CD8 ratio with CD4%. Log viral load, haemoglobin, platelets, sex and caregiver were dropped due to lack of prediction (p≥0.2).

In a full multivariable model, DTG-based ART, weight, CD4%, ongoing WHO-stage 3/4 event and region were retained (p<0.1); neutrophils were not retained after adjustment for ongoing WHO-stage 3/4 event, and BMI-for-age was not retained after adjustment for CD4% and region. There was no evidence that predictors differed between trial arms (interactions p>0.1).

Baseline predictors of treatment failure in children starting ART	Univariable Model (adjusting for weight and trial arm)			Multivariable Model		
	HR	95% CI	p-value*	HR	95% CI	p-value*
DTG (vs SOC)	0.44	(0.27-0.72)	0.001	0.45	(0.27-0.72)	0.001
Weight	**	**	<0.001	**	**	<0.001
BMI-for-age z-score (per 1 unit increase)	0.77	(0.66-0.91)	0.002	-	-	-
CD4 percentage (per 1 percent increase)	0.97	(0.95-0.99)	0.002	0.97	(0.95-0.99)	0.007
Ongoing WHO-stage 3/4 event	1.94	(1.19-3.17)	0.01	1.57	(0.94-2.62)	0.09
Neutrophil count (per 1 cell/mm^3 increase)	1.17	(1.05-1.31)	0.01	-	-	-
Region (African vs non-African site)	2.07	(0.81-5.25)	0.09	2.09	(0.82-5.31)	0.09

*All p-values are based on likelihood ratio tests.
**Weight was transformed using the reciprocal (1/weight) based on the best-fitting fractional polynomial. In the multivariable model, the HR for risk of outcome in a child weighing 14kg vs 4kg was 0.83 (95% CI 0.71-0.97), and in a child weighing 24kg vs 14kg was 0.97 (0.95-0.99).

Conclusions: Children living with HIV starting ART would benefit from screening for ongoing WHO-stage 3/4 events and CD4 testing to identify those at high risk of treatment failure, with low-weight/younger children particularly vulnerable.

OAB0303

Prevalence of suicidal behaviour and its associated factors among young people living with HIV accessing care at a primary healthcare centre in Zambia

S. Simwanza[1], B. Tapisha[1], D. Ngosa[2], L. Sigande[3], C. Mulungu[4,5], O. Mwenya[6], J. Mwamba[1], L. Moyo[5], C. Moyo[7], T. Mbambara[5], G. Lungu[8], M. Mbewe[9], G. Moonga[10], K. Shanaube[1], B. Maila[5,11,12]

[1]Zambart, Research, Lusaka, Zambia, [2]CIDRZ, Analysis Unit, Lusaka, Zambia, [3]Zambart, Data, Lusaka, Zambia, [4]University of Lusaka, Lusaka, Zambia, [5]Ministry of Health, Lusaka, Zambia, [6]Serenity Harm Reduction Programme Zambia, Lusaka, Zambia, [7]Lifeline Childline Zambia, Lusaka, Zambia, [8]Ministry of Health, Clinical Care and NCD Unit, Lusaka, Zambia, [9]Seed Global Health, Lusaka, Zambia, [10]University of Zambia, School of Public Health, Department of Epidemiology and Biostatistics, Lusaka, Zambia, [11]University of California, San Diego, Department of Psychiatry, San Diego, United States, [12]San Diego State University, School of Social Work, San Diego, United States

Background: Adolescents and young people living with HIV (AYPLHIV) are more likely to exhibit suicidal behaviour than their HIV-uninfected peers. Up to half of AYPLHIV in Sub-Saharan Africa struggle with mental health disorders (MHDs) associated with suicidal behaviour and most remain undiagnosed. While piloting integrated MHD screening using a locally co-developed digital application in routine HIV care, we determined the prevalence of suicidal behaviour and its associated factors among AYPLHIV.

Methods: We conducted a cross-sectional study among AYPLHIV aged 15 to 24 years at a primary healthcare centre (PHC) in Lusaka, completely enumerating AYPLHIV in the hospital antiretroviral therapy (ART) register from September 2023 to May 2024. We measured suicidal behaviour using the Ask Suicide Questionnaire Toolkit administered by a research assistant at the PHC.

Descriptive statistics, including frequencies and proportions, were used to determine prevalence, while logistic regression models identified factors associated with suicidal behaviour.

Results: We reached 432/583 (74.1%) AYPLHIV in the ART register, 416/432 (96.3%) consented, with 268/416 (64.4%) females and a median age of 20 (IQR: 18 to 23). The prevalence of suicidal behaviour was 127/416 (30.5%; [95% CI: 26.1% to 35.2%]) overall, higher among females (34.3%) than among males (23.6%).

Being female (AOR 1.69; 95% CI 1.18, 3.32; P=0.009), feeling stigmatised because of HIV (AOR 1.54; 95% CI 0.89, 2.65; P=0.120), having stigmatising attitudes towards people living with HIV (AOR 1.75; CI 95% 1.08, 2.83; P=0.022), having a positive PHQ 9 depression screen (AOR 3.02; CI 95% 1.63, 5.60; P<0.001) and positive GAD 7 anxiety screen (AOR 2.61; CI 95% 1.60, 4.27; P<0.001) increased the odds of exhibiting suicidal behaviour.

Conversely, compared to living alone, living with parents (AOR 0.33, CI 95% 0.13, 0.83, P=0.018), a partner (AOR 0.32; CI 95% 0.11, 0.98; P=0.046), or any other relative (AOR 0.29; CI 95% 0.11, 0.78; P=0.014) was protective against suicidal behaviour.

Conclusions: Suicidal behaviour is prevalent among AYPLHIV in Lusaka, strongly influenced by stigma, common MHDs, and sociodemographic factors. It is feasible to integrate MHD and suicidal behaviour screening into routine HIV care among AYPLHIV. Comprehensive suicide prevention interventions addressing the drivers of suicidal behaviour among AYPLHIV should be explored.

OAB0304

Electronic monitoring device adherence intervention improves viral suppression in young people living with HIV at risk of virological failure

N.V. Dzavakwa[1,2], C. Mackworth-Young[1,2], T. Bandason[1], N. Redzo[1], M. Paradza[1], M. Chidembo[1], D. Kembo[1], D. Munemo[1], M. Makamba[3], R.A. Ferrand[1,2], P.Y. Khan[2], V. Simms[1,2]

[1]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Centre for Sexual Health and HIV AIDS Research Zimbabwe, Harare, Zimbabwe

Background: Adherence to antiretroviral therapy (ART) among young people living with HIV (YPLWH) is lower than in other age-groups. We conducted an individually randomised controlled trial to investigate the impact of an electronic monitoring device (EMD) paired with text message reminders and monthly adherence feedback on HIV viral suppression among YPLWH with suboptimal adherence in Harare, Zimbabwe

Methods: YPLWH aged 16-30 years taking ART with viral load (VL)>200copies/ml were recruited from five HIV clinics and randomised 1:1 to intervention or standard of care (existing enhanced adherence counselling). The EMD (Wisepill) was used for six months. and was configured to send SMS reminders if not opened within 30-minutes of scheduled ART intake time. Monthly individualised in-person feedback sessions were conducted using EMD data.

The primary outcome was proportion of participants with VL<50 copies/ml at six months. A mixed methods process evaluation was conducted concurrently to understand fidelity, feasibility and acceptability of the intervention.

Results: 205 YPLWH (101 randomised to intervention, mean age 22.6 (SD 3.8) years; 52% female) were enrolled between September 2023 and April 2024 with no significant differences in participant baseline characteristics between the two arms. Median VL at baseline was 12700 copies/ml (IQR 1020, 105686); 143 (69.8%) were on a dolutegravir regimen and 62 (30.2%) on an atazanavir regimen. Eighty-seven (42.4%) had interrupted ART for ≥2 days in the three-months preceding enrolment, the longest interruption being >4 weeks (n=17).

Overall, 194 participants had a six-month VL, (10 withdrew, 1 died) with a median VL of 104 copies/ml (IQR 19, 21762); 85/194 (43.8%) were virally suppressed. At six-months, 51.0% (n=49/96) in the intervention vs 36.7% (n=36/98) in the standard of care arm had a VL <50 copies/ml (OR 1. 80, 95%CI:1.01,3.19, p=0.045). Adjusting for baseline VL and site, corresponding OR was 1.76 (95%CI:0.97-3.19, p=0.061).

Qualitative findings showed that EMD-supported adherence monitoring enabled YPLWH to have open and supportive conversations about adherence, which were otherwise difficult.

Conclusions: This EMD-supported adherence intervention was feasible and acceptable and improved viral suppression among YPLWH at risk of virological failure in an age group where adherence has been a persistent challenge.

OAB0305

Pharmacokinetic modeling to support WHO-weight band dosing of the new pediatric Darunavir/ritonavir (120/20 mg) fixed-dose combination tablet for children

S. Abdalla[1], M. Lallemant[2], A. Compagnucci[3], A. Nardone[4], C. Giaquinto[5], D. Gibb[6], C. Chabala[7], D. Burger[8], D. Hirt[1,9], T.R. Cressey[2], UNIVERSAL-2 Study Team

[1]Hôpital Cochin, APHP centre, Université Paris cité, Service de pharmacologie Clinique,, Paris, France, [2]Chiang Mai University, AMS-PHPT Collaboration, Chiang Mai, Thailand, [3]INSERM, SC10-US019 Essais Thérapeutiques et Maladies Infectieuses, Villejuif, France, [4]Fondazione Penta ETS, Padova, Italy, [5]Fondazione Penta ETS, Padova,, Italy, [6]University College London, Medical Research Council Clinical Trials Unit, London, United Kingdom, [7]University of Lusaka, Department University Teaching Hospital, Lusaka, Mozambique, [8]Radboud University Medical Center, Department of Pharmacy, Radboudumc Research Institute for Medical Innovation, Nijmegen, Netherlands, the, [9]INSERM 1343, Université Paris cité, Pharmacologie et évaluation des thérapeutiques chez l'enfant et la femme enceinte, Paris, France

Background: Darunavir-boosted with ritonavir (DRV/r) is an HIV protease inhibitor used in children ≥3 years old but no child-friendly fixed-dose combination (FDC) is available. Following prioritization by the WHO-PADO group, a 120/20 mg DRV/r FDC tablet was developed (Laurus Labs), in collaboration with Penta and CHAI under the framework of the Global Accelerator for Paediatric Formulations (GAP-f). We performed a pharmacokinetic (PK) modeling/simulation study to support DRV/r dosing using this FDC once-(OD) and twice-(BID) daily per WHO-weight bands for children ≥3 years old weighing 10 to <35 kg.

Methods: Darunavir plasma concentration data from 3 clinical trials in children living with HIV (DELPHI, ARIEL and CHAPAS-4 studies) were combined to develop a population PK model. Simulations were performed in a virtual population of children receiving DRV/r OD and BID dosing regimens to determine the dose that would achieve geometric mean (GM) DRV exposure ($AUC_{0\text{-}tau}$) in each WHO-weight band within 80%-130% of the value reported in adults.

Results: DRV/r concentration data from 162 children aged 3-16 years old were included. DRV PK was described using a 2-compartment model with first-order absorption (lag-time for DRV tablets vs. suspension) and linear elimination. Clearance and volume of distribution parameters were allometrically scaled to body weight, and alpha1-glycoprotein concentrations inversely influenced DRV clearance. Simulations predicted the following DRV/r doses achieved target exposures: DRV/r OD: 480/80 mg (4 tablets) from 10 to <14 kg and 600/100 mg (6 tablets) from 14 to <35 kg. DRV/r BID: 240/40 mg (2 tablets) from 10 kg to <14 kg; 360/60 mg (3 tablets) from 14 kg to <25 kg; and 480/80 mg (4 tablets) from 25kg to <35 kg (Figure 1).

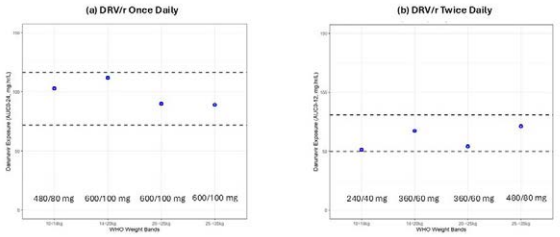

Figure 1: Predicted GM DRV $AUC_{0\text{-}tau}$ in children 10 to <35 kg receiving DRV/r FDC (120/10 mg) per WHO weight bands (a) once daily and (b) twice daily. Dotted lines represent target 80-130% range of the GM reported in adults

Conclusions: The model-based dosing of the new pediatric DRV/r FDC tablets supports once- and twice-daily dosing according to WHO weight bands in children aged ≥3 years and weighing 10 to <35 kg.

OAB04 HIV treatment and prevention in pregnancy

OAB0402

Pregnancy and neonatal outcomes following prenatal exposure to cabotegravir (CAB): data from The Antiretroviral Pregnancy Registry (APR)

V. Vannappagari[1], J. Albano[2], L. Ragone[1], A. Scheuerle[3], L. Mofenson[4], W. Short[5], C. Thorne[6], N. Carneal-Frazer[2], T. Cook[2], C. Zhang[2], K. Brown[1], A. de Ruiter[7]

[1]ViiV Healthcare, Durham, United States, [2]Syneos Health, Morrisville, United States, [3]University of Texas Southwestern Medical Center, Dallas, United States, [4]Elizabeth Glaser Pediatric AIDS Foundation, Silver Spring, United States, [5]The Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States, [6]University College London Great Ormond Street Institute of Child Health, London, United Kingdom, [7]ViiV Healthcare, London, United Kingdom

Background: Cabotegravir (CAB) is indicated for the treatment of HIV-1 infection in combination with rilpivirine and as a single agent for prevention of HIV. There are limited human data on the use of CAB during pregnancy to adequately assess effect on pregnancy outcomes.

Methods: The APR is a prospective, international exposure-registration cohort study, monitoring for early warning signals of major teratogenic effects of antiretrovirals (ARVs) used during pregnancy. This descriptive analysis assesses pregnancy and neonatal outcomes including birth defects among infants with prenatal exposure to CAB using APR data through 31 July 2024.

Results: Forty-two reported pregnancies with exposure to CAB (28 (66.7%) as CAB for treatment and 14 (33.3%) as CAB for pre-exposure prophylaxis (PrEP)) resulted in 43 out-

comes including 35 (81.4%) live births, 1 (2.3%) stillbirth, 3 (7.0%) spontaneous abortions, and 4 (9.3%) induced abortions (Table 1). Among live births, 1 (2.9%) reported a birth defect (congenital ptosis). Among 33 singleton, live births without defects, 5 (15.2%) were preterm and 6 (18.2%) had low birth weight (LBW) including 3 (9.1%) very LBW. Of the 42 CAB-exposed pregnancies, 39 had CAB pre-conception exposure (27 with earliest exposure 0-6 months prior to pregnancy and 12 with earliest exposure 6-12 months prior to pregnancy) and 3 had earliest exposure during pregnancy (1 each in the 1st, 2nd and 3rd trimester). For the 41 pregnancies where route of administration was known, 38 (92.7%) were exposed to injectable CAB while 3 (7.3%) were exposed to oral CAB.

Total Pregnancy Outcomes	43
Live Births	35 (81.4)
Stillbirths	1 (2.3)
Spontaneous Abortions	3 (7.0)
Induced Abortions	4 (9.3)
Total Live Births	35
Birth Defect Cases	1 (2.9)
Total Singleton, Live Births without Defects	33
Gestational Age >= 37 weeks	27 (81.8)
Gestational Age < 37 weeks (preterm)	5 (15.2)
Missing	1 (3.0)
Birth Weight >= 2500 grams	22 (66.7)
Birth Weight < 2500 grams (LBW)	6 (18.2)
Birth Weight < 1500 grams (very LBW)	3 (9.1)
Missing	5 (15.2)

Table 1. Pregnancy and neonatal outcomes of pregnant individuals exposed to CAB using APR data through 31 July 2024.

Conclusions: While no significant safety concerns were seen, definitive conclusions on the safety of CAB use in pregnancy cannot be drawn due to a limited number of pregnancies reported and the data should be interpreted with caution. Providers are encouraged to register ARV exposed pregnancies, especially those exposed to newer ARVs such as CAB, at APR (apregistry.com).

OAB0403

Determinants of increased antenatal viral load and its association with pregnancy adverse outcomes in pregnant women living with HIV

A. Mendes Muxlhanga[1], A. Figueroa-Romero[2], G. Mombo-Ngoma[3], J. Mischlinger[4], M. Mazuze[5], M. Esen[6], A. Tchouatieu[7], L. Stoeger[8], E. Sevene[9], N. Bortella[2], C. Menendez[2], T. Nhampossa[1], R. González[8]

German Center for Infection Research, partner site Hamburg-Lübeck-Borstel-Riems and Tübingen, Hamburg-Lübeck-Borstel-Riems, Germany, [7]Medical University of Vienna, Department of Medicine I, Division of Infectious Diseases and Tropical Medicine, Vienna, Austria, [8]Barcelona Institute for Global Health, Maternal and Child Health initiative, Barcelona, Spain, [9]Centro de Investigação em Saúde de Manhiça, Maternal and Child Health, Manhiça, Mozambique

Background: An estimated 1.3 million HIV-positive women are pregnant annually. Without any intervention, the mother-to-child HIV transmission rate ranges from 15% to 45%, with maternal HIV viral load being the strongest risk factor. This study investigated the determinants of elevated antenatal viral load and its association with adverse pregnancy outcomes in African women.

Methods: This is a secondary analysis of data collected in a randomized controlled trial conducted in Gabon and Mozambique (2019-2023) evaluating dihydroartemisinin-piperaquine for malaria prevention in HIV-positive pregnant women. Pregnant women attending their first antenatal care visit were enrolled and monitored until delivery. Descriptive statistics, and bivariate and multivariable logistic regression analyses were conducted to identify factors associated with high viral load and its association with adverse pregnancy outcomes.

Results: Among 666 enrolled women, 35% (n=232) presented with high viral load (>150 copies/ml). Anaemia at baseline (OR 1.75, 95% CI 1.18-2.59, p=0.005) and delayed antenatal care antiretroviral therapy (ART) initiation (OR 7.71, 95% CI 5.04-11.81, p=0.000) were significantly associated with high viral load. Regarding the adverse pregnancy outcomes, high viral load was associated with a threefold increased risk of placental malaria (OR 3.28, 95% CI 1.54-7.11, p=0.002).

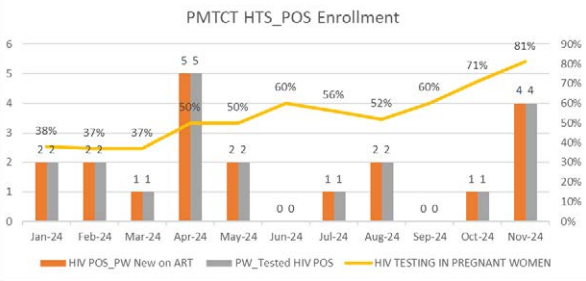
Conclusions: Anaemia and delayed ART initiation were associated with elevated viral load, which in turn increased the risk of placental malaria. These findings highlight the need for comprehensive antenatal care, including early ART access, to improve pregnancy outcomes and reduce vertical transmission risk. Further research should explore the interplay between viral load and placental malaria.

OAB0404

Enhancing HIV screening in pregnant women across 17 quality improvement (QI) supported LGAs : a scalable QI model for PMTCT in Jigawa State, Nigeria

S.J. Abdullahi[1], O. Ogundare[1], R. Abba[1], C. Anoke[1], P. David Gbado[1], R. Atteh Omolade[2], T. Ilori[2], M. Abdulwahab[3], S. Magaji[1]
[1]Jhpiego, Abuja, Nigeria, [2]National Agency for Control of AIDS, Abuja, Nigeria, [3]Jigawa State Ministry of Health, Department of Public Health, Dutse, Nigeria

Background: HIV testing at initial antenatal care (ANC1) is essential for preventing mother-to-child transmission (PMTCT). In Jigawa state, Nigeria, where HIV prevalence is 0.3%, average HIV testing coverage among pregnant women during ANC1 in 17 QI project-supported LGAs was just 37% from January to March 2024, posing significant challenges to PMTCT efforts.
This study evaluates the impact of a Quality Improvement approach in addressing poor testing in low-resource communities.
Description: A QI training facilitated by Jhpiego, a multidisciplinary team—comprising a midwife, facility manager, lab technician, and Ward Development Committee chairman—was established at the LGA. Trained in the WHO Point of Care QI methodology, the team aimed to achieve 90% HIV testing coverage for first antenatal care (ANC1) attendees by December 2024. Utilizing the Plan-Do-Study-Act cycle, they identified challenges—including interrupted kit supplies, poor inventory management, complex client flows, and inadequate staff coordination—using Fishbone diagrams, flow charts, and the 5 Whys. Interventions such as securing alternative procurement channels via the Basic Health Care Provision Fund (BHCPF) or Drug Revolving Fund (DRF), role reassignment, weekly inventory reporting, and prompt requisitions at 70% stock depletion were tested in 3–4 cycles. Monthly data from PMTCT registers, analyzed via the National HMIS and monitored with run charts, guided the scaling up of successful strategies across 17 LGAs, supported by on-site coaching to ensure sustained improvements
Lessons learned: HIV testing coverage for ANC1 improved from 37% in March to 82% in November 2024, identifying 16 positive cases placed on treatment. Sustained gains through monthly performance reviews, inventory management, and real-time data collection.



Conclusions/Next steps: QI demonstrated the potential for targeted improvements in HIV testing and case findings, where service providers identify key barriers to care and propose solutions. This model has the potential for scalable, context-specific improvements in PMTCT programs and can be replicated in similar settings.

OAB0405

Improving data quality as a key strategy towards achieving triple elimination of the vertical transmission of HIV, syphilis, and hepatitis in Chikwawa district, Malawi

B. Sato[1], C. Issah[2], A. Mdolo[3], B. Gausi[2], A. Mwansambo[1], D. Telela[4]
[1]National AIDS Commission, Lilongwe, Malawi, [2]Ministry of Health-Chikwawa District Health Office, Chikwawa, Malawi, [3]United Nations Children's Fund, Malawi Country Office, Lilongwe, Malawi, [4]Clinton Health Access Initiative, Lilongwe, Malawi

Background: Malawi targets to eliminate vertical transmission of HIV, syphilis and Viral Hepatitis B (HepB) by 2027. This requires effective decision-making and interventions informed by consistently high-quality data.
However, non-reporting and poor and incomplete data have been consistent challenges, including in high-prevalence districts like Chikwawa.
UNICEF supported the National AIDS Commission and the Chikwawa District Council to pilot an intervention to improve the quality of HIV, syphilis and HepB data for pregnant and breastfeeding women and their infants
Description: The pilot was implemented from July to September 2024, in ten high-volume health facilities in Chikwawa district. Facility staff including nurses, clinicians, diagnostic assistants, data clerks and expert clients were trained in correct data recording and reporting to ensure complete high-quality data.
Complete data was defined as the record of every mother, showing tests for HIV, syphilis and HepB, with clear results, appropriate actions taken and follow-up actions recommended.
The staff were further trained to analyse and use the data to inform appropriate actions; identifying eligible mothers, initiating their tests, and following up on those requiring further support.
The district team supervised the facility teams fortnightly to reinforce their capacity.
Lessons learned: The pilot intervention improved the data completeness in antenatal registers from 93% in Q2/2024 to 99.1% in Q3/2024 across the ten facilities. This improved decision-making at the facility and district levels resulting in improved testing services and case management for mothers returning positive results.
The intervention further improved quantification for test kits leading to uninterrupted integrated testing services. This resulted in Chikwawa's highest-ever syphilis testing rate among pregnant women (99%) from an annual rate of 75.8% from July 2023 to June 2024. Similarly, HIV retesting in the third trimester improved from 5% at baseline to 33% after the pilot phase.
The progress was, however, undermined by the deployment of new staff who were yet to be trained in data quality in the target facilities.

Conclusions/Next steps: Continuous mentorship and combined efforts of clinical and non-clinical facility staff are key in ensuring data completeness and quality. Future plans include mentoring all new facility staff and scaling up the intervention to other high-prevalence districts

OAB05 Tuberculosis: From research to the field

OAB0502

A two-by-two factorial randomized trial of immediate and/or sepsis-specific dose anti-tuberculosis therapy to improve mortality for adults with sepsis and HIV in East Africa

S. Heysell[1], S. Mpagama[2], M. Null[1], B. Said[2], E. Nuwagira[3], T. Thomas[1], D.R. Boulware[4], M. Conaway[1], C. Muzoora[3], C.C. Moore[1], ATLAS Trial Study Group
[1]University of Virginia, Charlottesville, United States, [2]Kibong'oto Infectious Diseases Hospital, Sanya Juu, Tanzania, the United Republic of, [3]Mbarara University of Science and Technology, Mbarara, Uganda, [4]University of Minnesota, Minneapolis, United States

Background: The greatest global burden of sepsis is found in persons living with HIV (LWH) in Africa, in whom tuberculosis (TB) is an often overlooked but leading cause of underlying infection. We aimed to determine whether empiric immediate and/or increased dose anti-TB therapy improved 28-day mortality for participants LWH and admitted to hospital with sepsis in Tanzania or Uganda.
Methods: We conducted a phase 3, multisite, open-label, randomised controlled clinical 2×2 factorial superiority trial of (1) immediate and (2) sepsis-specific dose anti-TB therapy in addition to standard of care for adults LWH admitted with sepsis at four hospitals in Tanzania or Uganda. Standard of care antibiotic regimen was ceftriaxone daily for seven days. The primary endpoint was 28-day mortality with a superiority margin of 13% and assuming 20% unevaluable.
Results: We randomized 437 participants of whom 44 were excluded, leaving 393 analyzable. Of these, 224 (57%) were male. The mean (+SD) age was 43 (+13) years. The median CD4+ T-cell concentration was 125 (IQR, 30-326) cells/mcL, and 202 (51%) were ultimately diagnosed with TB by urine, sputum, or blood-based tests.
No difference occurred in 28-day mortality between the four treatment groups: immediate/conventional dose (22%; 22/99), immediate/sepsis-specific dose (28%; 28/99), diagnosis-dependent/conventional dose (28%; 27/96), and diagnosis-dependent/sepsis-specific dose (23%; 23/99); chi-squared p=0.66.
Among those with TB, a significant difference in 28-day mortality occurred across treatment groups (p=0.045). Compared to a 28-day mortality of 35% (18/52) for the 52 participants with TB who received standard diagnosis-dependent/conventional dose anti-TB therapy, the 28-day mortality for the 50 participants with TB who received immediate/conventional dose anti-TB therapy was 12% (6/50) (adjusted odds ratio [aOR] 0.26, 95%CI, 0.09-0.73, p=0.01), and for the 57 participants with TB who received diagnosis-dependent/sepsis-specific dose anti-TB therapy, the 28-day mortality was 19% (11/57) (aOR 0.42, 95%CI, 0.17-1.03, p=0.06). No differences in adverse events occurred between treatment groups.
Conclusions: No overall benefit in 28-day mortality was observed with immediate or sepsis-specific dose anti-TB therapy in adults with HIV-related sepsis. However, immediate conventional anti-TB therapy significantly reduced 28-day mortality in those later confirmed to have TB.

OAB0503

Same-day antiretroviral therapy initiation in people with HIV and presumptive tuberculosis: a randomized, non-inferiority trial in Lesotho and Malawi (SaDAPT)

F. Gerber[1,2,3], R. Semphere[4], B. Lukau[5], P. Mahlatsi[5], G. Sanchez-Samaniego[1,3], M. Molatelle[6], N.B. Marake[7], T. Tarumbiswa[7], A. Amstutz[1,3,8], M. Nliwasa[4,9], I. Ayakaka[5], P. MacPherson[10], T.R. Glass[2,3], R.M. Burke[11], N.D. Labhardt[1,3]
[1]University Hospital Basel, Department of Clinical Research, Division of Clinical Epidemiology, Basel, Switzerland, [2]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [3]University of Basel, Basel, Switzerland, [4]Kamuzu University of Health Sciences, Helse Nord Tuberculosis Initiative, Blantyre, Malawi, [5]SolidarMed Lesotho, Maseru, Lesotho, [6]Seboche Mission Hospital Laboratory, Seboche, Lesotho, [7]Ministry of Health Lesotho, Disease Control Department, Maseru, Lesotho, [8]Osloo University, Oslo Center for Biostatistics and Epidemiology, Oslo, Norway, [9]Malawi-Liverpool-Wellcome Trust, Clinical Research Programme, Blantyre, Malawi, [10]University of Glasgow, School of health and Wellbeing, Glasgow, United Kingdom, [11]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Same-day initiation of antiretroviral therapy (ART) is recommended for most people with HIV (PWH) to promote retention in care, but may increase the risk of tuberculosis-immune reconstitution inflammatory syndrome (TB-IRIS). It is unknown whether same-day ART should be offered to PWH with TB symptoms or whether ART should be initiated only after TB diagnostic results are available.
Methods: We conducted an open-label, 1:1, individually-randomized, non-inferiority trial comparing "ART-first" versus "TB-results-first" initiation among PWH in Lesotho and Malawi, aged ≥12 years, (re)initiating ART who had at least one TB symptom (cough, fever, night sweats or weight loss) and no signs of meningitis. Participants in the "ART-first" arm were offered same-day ART; those in the "TB-results-first" arm were offered ART after TB was confirmed or refuted. The primary analysis was a non-inferiority comparison of viral suppression (<400 copies/ml) 26 (22-40) weeks after enrolment (non-inferiority margin 10%). Secondary outcomes included: retention in care; mortality; non-fatal serious adverse events (SAEs); ART initiation within seven days; and TB-IRIS. NCT05452616.

Results: From 19/10/2022-21/02/2024, 581 participants were randomized and included in intention-to-treat analysis (60% male; median age 37 years; median CD4 201 cells/mm³); 573 included in per-protocol analysis. 296/297 (99%) and 60/284 (21%) in the "ART-first" and "TB-results-first" arms started ART on enrolment day and 59/297 (20%) and 55/284 (19%) were diagnosed with TB by 30 weeks. Viral suppression rates at 26 weeks were 209/296 (71%) in the "ART-first" arm and 196/277 (71%) in the "TB-results-first" arm in the per-protocol population (absolute risk difference -0.8%; 95% CI: -8.4%-6.8%) with similar results in the intention-to-treat population, confirming non-inferiority of "ART-first". Retention in care was 81% in both arms; ART initiation within seven days was higher in "ART-first" (99% versus 86%). Nine and six deaths, eleven and ten non-fatal SAEs, and six and five TB-IRIS events occurred in "ART-first" and in "TB-results-first" arms respectively.

	ART-first arm	TB-results-first arm	Adjusted % risk difference (95% CI)
1° endpoint VL <400 copies/ml after 26 (22-40) weeks (per-protocol)	209/296 (71%)	196/277 (71%)	-0.8 (-8.4 - 6.8)
1° endpoint VL <400 copies/ml after 26 (22-40) weeks (intention-to-treat)	209/297 (70%)	201/284 (71%)	-1.0 (-8.5 - 6.5)
2° endpoint retention in care after 22-30 weeks	240/297 (81%)	229/284 (81%)	0.1 (-6.3 - 6.6)
2° endpoint ART initiation within seven days	296/297 (99%)	243/284 (86%)	14.2 (10.0 - 18.3)

Conclusions: Outcomes of same-day initiation, and ART initiation after TB investigations were comparable and implementation should be guided by program and client preference.

OAB0504

Post-tuberculosis treatment mortality in children and youth initiating ART in the International Epidemiology Databases to Evaluate AIDS (IeDEA) Network

I.G.N.G. Ngoerah General Hospital, Udayana University, Pediatrics, Bali, Indonesia, [23]School of Health Sciences & Practice, New York Medical College, Valhalla, United States, [24]Albert Einstein College of Medicine, Medicine, Bronx, United States

Background: Tuberculosis (TB) is a major cause of death among children and youth living with HIV (CYLWH). In adults, even after cure, those with former TB are 3-7 times more likely to die following TB treatment. However, the risk of mortality after TB treatment in CYLWH is unknown. We sought to compare the post-treatment mortality in CYLWH who were treated for TB disease with those without TB.

Methods: We analyzed data from CYLWH (0-24 years) who initiated ART at <25 years old from 2004-2021 at IeDEA-participating sites in six regions and who had at least 9 months of follow-up from time of ART initiation. Participants who had initiated treatment for active TB disease 3 months prior to or after ART initiation were the TB disease group; those without documentation of any TB treatment through 9 months after ART initiation were the TB-negative/control group. Cumulative incidence of death (CID) from 9 months after ART initiation onward was calculat-

ed with lost-to-follow-up and transferred-out treated as competing risks. Fine-Gray competing proportional hazard modeling was used to compare the hazard of death, adjusting for age, sex, CD4, WHO Stage, and weight-for-age Z-score.

Results: Among 75,259 CYLWH included, 3,622 had been treated for TB disease and 62,495 had no TB history. The CID rose constantly from 2-15 years post-ART initiation from 3.8% (95%CI: 3.2%-4.5%) to 20.4% (95%CI: 18.3%-22.5%) in the TB disease group vs 1.6% (95%CI: 1.5%-1.7%) to 10.9% (95%CI: 10.2%-11.5%) in the control group respectively (figure 1). In bivariate analysis, the sub-hazard risk of death among those in the TB disease group was 2.2 (95%CI: 2.0-2.4) times that of the controls. This difference remained unchanged after adjustment (aHR 2.1 [1.9-2.4]).

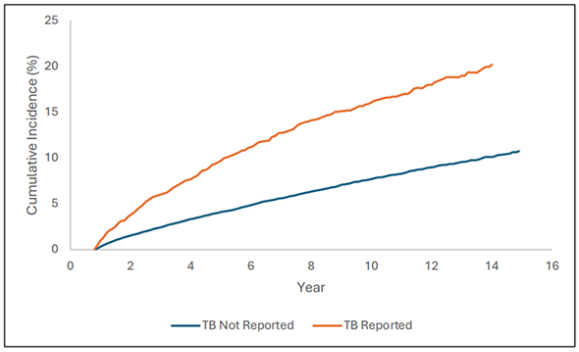

Figure 1: Cumulative incidence of death from 9 months after date of ART initiation among those treated for TB disease (orange) and those without TB (blue). Log-Rank P <0.0001.

Conclusions: Among CYLWH on ART, receiving TB treatment near ART initiation (vs those without TB) was associated with increased mortality even 15 years after TB treatment.

OAB0505

Predictors of recurrent tuberculosis among people living with HIV under routine ART care: an observational cohort study, Andhra Pradesh, India, 2024

M. Thogarucheeti[1], S. Attada[1], K. Prasad[1], N. Chava[2], G. Ramesam[2], P. Kumar[2], A. Rao[2], J. Kurada[2], V. Yeldandi[2], P. Turaka[2], R.P. Poluru[2], C. Sriramulu[1], P. Nadol[3], R. Allam[3], C. Das[4]

[1]Andhra Pradesh State AIDS Control Society, Vijayawada, India, [2]Society for Health Allied Research & Education India, Hyderabad, India, [3]U.S Centres for Disease Control and Prevention, DGHT, Delhi, India, [4]National AIDS Control Organization, Delhi, India

Background: Recurrent tuberculosis (TB) is associated with poor treatment outcomes compared to primary TB infection and has implications for TB control. India's national guidelines recommend post anti-TB treatment (ATT) follow-up for two years from the last date of ATT, spaced at 6-month intervals. The TB recurrence rate among non-people living with HIV (PLHIV) under program settings is 2.7%. However, limited data is available on recurrent TB predictors among PLHIV in India.

Methods: We analysed secondary program data from 14 antiretroviral therapy (ART) clinics located in three high-burden districts (East Godavari, Krishna, and Guntur) of Andhra Pradesh. PLHIV were screened for TB (4 symptom screening) during every visit for ART pill pick-up. We included adult PLHIV aged >15 years who initiated and completed ATT successfully during January 2017–December 2021 and followed-up for two years from ATT completion and calculated recurrent TB incidence rate (IR) per 100 person-years (PY). We used adjusted Cox proportional hazard models and calculated hazard ratios (HR) to determine predictors of recurrent TB.

Results: The 3,357 PLHIV meeting the inclusion criteria accounted for 6,372 PY of follow-up. A total of 270 PLHIV were diagnosed with recurrent TB during follow-up (IR:4.24 PY, 95%CI:3.75-4.77). Select variables, such as microbiologically diagnosed pulmonary TB (HR:1.79, 95%CI:1.12-2.88), CD4 count ≤200 cells/mm^3 at recurrent TB diagnosis (HR:1.38, 95%CI:1.03-1.87), HIV treatment interruption during follow-up (HR:2.38, 95%CI:1.79-3.16), no exposure to dolutegravir-based regimen during follow-up (HR:2.38, 95%CI:1.79-3.16), HIV viral load ≥1000 copies/ml at recurrent TB diagnosis (HR:3.25, 95%CI:2.14-4.94), no exposure to secondary prophylaxis of isoniazid (HR:1.32, 95%CI:1.04-1.68), and >9-month delay of isoniazid preventive therapy initiation after completion of ATT (HR:1.66, 95%CI:1.21-2.28), were associated with significantly higher risk of recurrent TB.

Conclusions: The higher rate of incidence for post-ATT recurrent TB could be due to increased opportunity for TB screening at ART clinics compared to community-based or non-HIV settings. ART clinic staff may focus on modifiable risk factors, such as preventing HIV treatment interruption, enabling viral load suppression, and ensuring early initiation of secondary TB preventive treatment to reduce the rates of recurrent TB among PLHIV.

OAC01 From PrEP to harm reduction: Scaling up comprehensive HIV prevention strategies

[1]Joint Clinical Research Centre, Programs, Kabale, Uganda

Background: Uganda still experiences challenges in identification of new HIV acquisitions despite commendable progress towards attainment of the UNAIDS global 95-95-95 targets. To end AIDS by 2030, more efficient and targeted case finding approaches need to be employed to reach the remaining pockets of the population with unknown HIV status. USAID LPHS Kigezi & Lango Activity piloted use of precision targeting to guide community interventions focused to reaching the most at-risk populations with HIV services geared at averting new acquisitions.

Description: Patient level data on viral load non-suppression, interruption in treatment, and HIV positivity was extracted from Uganda EMR and utilized to make geospatial maps that informed identification of geographical locations with highest HIV transmission risk. Nyarutojo parish in Kanungu district was identified as one of the 'hottest hotspots' parishes. Dialogue meetings were conducted with health workers at health facilities serving this parish, key population peers and key community gate keepers. Profiling of these hotspots revealed; many bars with high numbers of "trafficked" adolescent girls and young women working as bar attendants but also engaged in commercial sex work, mobile men with disposable income from coffee trade and high prevalence of STIs. Client HIV charts were reviewed to validate the missing services for clients with non-suppressed viral load and those that had dropped out of care. Integrated outreaches to provide HIV prevention, care and treatment services have been conducted and linkages established with livelihood programs.

Lessons learned: 427 individuals were reached with HIV prevention services. 92.3% (394) were offered risk based HTS with 8 HIV positives and linked into care. 298 (85%) of the 386 that tested HIV negative were screened for PrEP and 103 (67%) of the 152 PrEP initiated.

- Community livelihood skilling project that attracts AGYW can provide a platform for accessing HIV combination prevention packages and testing services.
- Missed opportunity for HIV testing for STI clients majorly presenting at HC IIs without HIV testing services.
- Precision targeting revealed new hot spots beyond the traditional ones.

Conclusions/Next steps: Precision targeting optimizes access to a combined HIV prevention package for the most at risk populations.

OAC0103

High acceptability and accuracy of combined HIV self-testing and genital secretion self-collection for oncogenic HPV molecular detection among female sex workers in Democratic Republic of the Congo

S. Tonen-Wolyec[1,2], J. Muwonga Tukisadila[3,4], L. Belec[5]

[1]University of Bunia, Infectious Diseases, Bunia, Congo, the Democratic Republic of the, [2]University of Kisangani, Infectious diseases, Kisangani, Congo, the Democratic Republic of the, [3]University of Kinshasa, Clinical biology, Kinshasa, Congo, the Democratic Republic of the, [4]Ecole Doctorale Régionale d'Infectiologie Tropicale, Franceville, Gabon, [5]Laboratoire de Virologie, Hôpital Européen Georges Pompidou and Faculty of Medicine Paris Descartes, University of Paris Cité, Paris, France

Background: HIV infection is one of the major cofactors of oncogenic high-risk Human papillomavirus (HR-HPV) which is associated with cervical cancer. Female sex workers (FSWs) in sub-Saharan Africa (SSA) are at very high risk of both HPV- and HIV- co-infections. Synergy of innovative methods such as genital self-sampling (GSS) and HIV self-testing (HIVST) constitute promising way of controlling both viral infections. This study aimed to assess the effect of peer education-based rapid training (PERT) on the acceptability and usability of GSS and HIVST in adult FSWs living in Kisangani and Bunia, Democratic Republic of the Congo (DRC).

Methods: The study is a community-based, individually randomized controlled trial (1:1). In control group, FSW were asked to execute in private setting at home, at their own pace and in an autonomous way the GSS with vaginal veil (V-Veil Up UP2™, V-Veil-Up Production SRL, Romania) and HIVST using capillary-based HIV self-test (Biosynex, Strasbourg, France). In intervention group, FSW received approximately one hour of PERT by two trained peer educators. PERT was systematically carried out with the help of a *vade-mecum* including key education messages concerning HIV infection, HPV and the simplified instructions for GSS and HIVST.

Results: A total of 613 FSWs were prospectively included, with 309 in control group and 304 in intervention group. Rates of acceptability (GSS: 98% *versus* 76%; OR: 4.3 [95% CI: 2.0-6.6] and HIVST: 96% *versus* 84%; OR: 2.3 [95% CI: 1.1-4.8]) and usability (GSS: 99% *versus* 81%; OR: 3.8 [95% CI: 1.5-5.6] and HIVST: 100% *versus* 89%; OR: 3.2 [95% CI: 1.8-7.3]) of GSS and HIVST were higher in FSWs offered PERT than in those not offered. The educational level and age of FSWs were not associated with acceptability and usability in multivariate analyses. Moreover, the average of satisfaction level on Likert scale (1-5) after performing GSS and HIVST was higher among FSWs receiving PERT than those not receiving it (GSS: 4.2 *versus* 3.7; *P*=0.003 and HIVST: 4.4 *versus* 4.1; *P*=0.012).

Conclusions: This study highlights the need for educational intervention adapted to vulnerable poorly educated populations living in SSA to support innovative interventions such as combined HIVST and GSS.

OAC0104

Upscaling HIV testing and clinical service uptake among male sexual partners of adolescent girls and young women in rural Eswatini communities through invitation cards for adolescent boys and young men

T. Dlamini[1], M. Maseko[2], M. Dlamini[2], H. Nxumalo[2], H. Mkhatshwa[1]

[1]World Vision, Programs, Mbabane, Eswatini, [2]World Vision, Strategic Information, Mbabane, Eswatini

Background: World Vision Eswatini (WVE) is implementing a project that is targeting orphaned and vulnerable children as well as adolescent girls and young women, with the goal of reducing new HIV infections in Eswatini. HIV testing is essential for awareness of HIV status and an important component of HIV epidemic control. According to a recent HIV incidence survey (SHIMS 3), 38.9% of males between the ages of 15-24 reported to have received an HIV test in the last 12 months before the survey while females were at 61.4%.

The Multi-Indicator cluster survey (MICS) 2021 findings show that 56.4% of males aged 15-24 years who are sexually active tested for HIV and know the results while their female counterparts reported 80.8%. Observed low clinical service uptake among men necessitates innovations in demand creation.

Description: WVE piloted an innovation themed "Lisango – The Men Cave" which uses an exclusively designed invitation card to invite males between the ages of 15-45 years, who are sexual partners of enrolled AGYW. AGYW shared the card with their sexual partners and other male counterparts. Community based mentors also distributed the invitations on behalf of AGYW that expressed discomfort in personally extending the invitation to their sexual partners. Males confirmed their attendance on the cards. Sessions end with an officer issuing health referrals prioritizing combination HIV prevention services including HIV Testing Services (HTS), and other clinical services. In 2024, WVE reached 564 males who accessed health services including HTS, 44 were initiated on PrEP, 100 were screened for STI while 441 accessed condoms.

Lessons learned: Empowering AGYW to advocate for themselves with their sexual partners is important in the efforts to end HIV. AGYW led mobilization strategies of strategies yielded improvements in HIV Testing and PrEP and condom uptake among Sexual partners. and can be prioritized for scale up.

Conclusions/Next steps: Upscaling HIV prevention service uptake requires innovative demand creation strategies and using AGYW in mobilizing their sexual partners can increase case finding in communities.

OAC0105

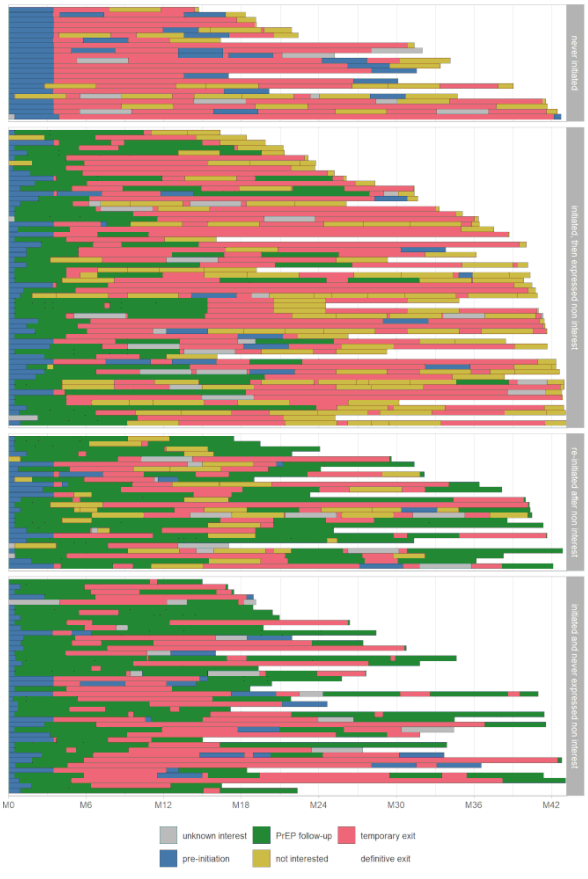
Adoption of HIV preexposure prophylaxis (PrEP) among female sex workers (FSWs) in Côte d'Ivoire: complex trajectories and early adopters

J. Larmarange[1,2], M. Plazy[3], M. Nouaman[4,5], E. Kissi[4], R.-M. Dedocoton[4], P.A. Coffie[4,5], S. Eholié[4,5], V. Becquet[2,1], ANRS 12381 PRINCESSE Study Group

[1]Institut de Recherche pour le Développement (IRD), Ceped (Centre Population et Développement, UPC, IRD, Inserm, USPN), Paris, France, [2]Institut National des Etudes Démographiques (Ined), DemoSud, Aubervilliers, France, [3]Université de Bordeaux, GHiGS, Bordeaux Population Health, Bordeaux, France, [4]Programme PAC-CI, Abidjan, Côte d'Ivoire, [5]Université Félix Houphouët Boigny, Abidjan, Côte d'Ivoire

Background: The ANRS 12381 PRINCESSE project (11/2019-06/2023) enrolled 489 FSWs and implemented community-based sexual and reproductive health care, including PrEP, delivered through mobile clinics at prostitution sites in the San Pedro region. This presentation aims to describe PrEP trajectories and the factors associated with its use, focusing on "early adopters".

Methods: This analysis included 400 FSWs eligible for PrEP (HIV-negative, HBsAg-negative) enrolled up to December 2022 (>6 months of follow-up). Clinical records were analyzed to describe PrEP cascade, follow-up, and PrEP trajectories. A multivariable logistic regression identified factors associated with PrEP early adopters.



Results: Although 98% of eligible FSWs were interested in PrEP, only 62% initiated PrEP, and 39% renewed it at least once. Follow-up was very short (<6 months) for 48%, short

(6-12 months) for 15%, seasonal (>12 months with a gap of 6 months between two visits) for 31%, and regular (>12 months with no gap) for 6%.
PrEP initiation was high among FSWs with regular (96%), seasonal (83%), or short (80%) follow-up, vs. 39% for those with very short follow-up. Among those who initiated, only 88% (regular), 70% (seasonal), 74% (short), and 35% (very short) renewed PrEP.
Among 148 FSWs with regular/seasonal follow-up, four PrEP trajectories were identified (cf. figure showing individual trajectories): 15% "never initiated" PrEP, 39% "initiated and were later not interested anymore", 18% "re-initiated after non-interest", and 28% "initiated and never expressed non-interest", the last two groups being considered as "early adopters".
Factors associated with early PrEP adoption included the usual price of intercourse with clients <1500 FCFA (aOR=2.4 [1.2-4.8]) and working in brothels (aOR=3.2 [1.6-6.6]).
Conclusions: In PRINCESSE, loss-to-follow-up and seasonality of risks limited PrEP adoption. FSWs who were more precarious and less mobile became early adopters of this new prevention tool and could serve as potential ambassadors for promoting its uptake.

OAC02 Destination zero new acquisitions: Hailing a CAB to PrEP success

OAC0202

USAID-supported PrEP introduction and scale up, 2016- 2024

A. Kimmel[1], A. Dam[2], M. Cobourne[1], J. Rodrigues[3], T. Mukherjee[3]
[1]Unaffiliated, Washington, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]Unaffiliated, New York, United States

Background: Pre-exposure prophylaxis (PrEP) is a safe and highly efficacious form of biomedical HIV prevention; however, only an estimated 3.5 million people in 2023 were using oral PrEP, short of the UNAIDS global target of 21.2 million users by 2025. The U.S. Agency for International Development (USAID), through PEPFAR and in partnership with host countries' ministries of health, provided support for PrEP implementation beginning in fiscal year 2017 (FY17) until ordered to stop work by the Trump administration in January 2025.
Methods: This analysis used the PEPFAR Monitoring, Evaluation, and Reporting data to describe USAID-supported PrEP initiations globally from October 1, 2016 (FY17 quarter 1) through September 30, 2024 (FY24 quarter 4), by prioritized population (adolescent girls and young women age 15-24 [AGYW], pregnant and breastfeeding women [PBFW], and key populations [KP] (female sex workers [FSW], men who have sex with men [MSM], transgender people [TG], people who inject drugs [PWID], and persons in prisons and other closed settings)) and geographies.
Results: USAID expanded support for PrEP initiation from 14 countries in FY17 to 43 countries in FY24. In total, USAID supported 3,776,559 people to initiate PrEP. Ninety-two percent of these initiations occurred between FY21-FY24, following a PEPFAR-wide initiative to initiate 1 million people on PrEP in FY21. Distribution by population was: 2,187,746 (58%) KP (FSW: 1,199,332; MSM: 773,304; people in prisons and other closed settings: 33,648; PWID: 109,150; TG: 72,492); 2,724,770 (72%) AGYW; and 57,628 (1.5%) PBFW (FY24 data only). In FY24, USAID supported the introduction of long-acting injectable cabotegravir (CAB-LA), with 2,490 CAB-LA initiations. Distribution by geography was: 47,304 (1.3%) the Americas; 149,165 (3.9%) Southeast Asia; and 3,580,090 (95%) sub-Saharan Africa.
Conclusions: USAID contributed an estimated 18% towards the UNAIDS 2025 global target. The U.S. Secretary of State has stated that USAID will not operate after September 1, 2025. Without USAID-supported PrEP, global populations will be more vulnerable to infection, erasing decades of work towards HIV epidemic control and creating preventable HIV morbidity and mortality.

OAC0203

Cost-effectiveness of cabotegravir long-acting for HIV pre-exposure prophylaxis (PrEP): a systematic review of modelling studies

F. Effiong[1], E. Ekpor[2], R. Dine[3], D. Olawuyi[4], D. Adewole[5]
[1]University of Calabar Teaching Hospital (UCTH), Medical Laboratory Services, Calabar, Nigeria, [2]School of Nursing and Midwifery, University of Ghana, Legon, Ghana, [3]Rinda-Ubuzinma, Kigali, Rwanda, [4]University of Ibadan, Department of Medicine and Surgery, Faculty of Clinical Science, College of Medicine, Ibadan, Nigeria, [5]University of Ibadan, Department of Health Policy and Management, College of Medicine, Ibadan, Nigeria

Background: Cabotegravir long-acting (CAB-LA) is a promising HIV prevention strategy; however, its cost-effectiveness compared to oral pre-exposure prophylaxis (PrEP) varies across settings. This systematic review examines the economic viability of CAB-LA interventions using modelling studies in diverse populations.
Methods: We searched literature databases for modelling studies on the cost-effectiveness of CAB-LA in various settings. The search was executed in PubMed, Web of Science, Scopus, and the Cochrane Library. The search was conducted in January, 2025, and was limited to English studies; but there was no limitation on year of publication. Quality assessment was based on the 2022 CHEERS checklist for economic evaluation studies.
A narrative synthesis was conducted to summarize the findings. Key outcomes to be extracted included study characteristics and design, incremental cost-effectiveness ratios (ICERs), adherence rates, and willingness-to-pay (WTP) thresholds.
Results: The search retrieved nineteen results, but only six modeling studies meeting predefined inclusion criteria were included. These studies evaluated CAB-LA among various populations, including heterosexual men, women at high risk of HIV, men who have sex with men (MSM),

transgender women (TGW), and large simulated cohorts. The studies employed static epidemiological models, deterministic compartmental models, and Markov cohort models to evaluate CAB-LA alongside oral PrEP. Quality assessment results show that studies were of moderate and high quality. CAB-LA demonstrated potential cost-effectiveness under specific conditions.

In Sub-Saharan Africa, CAB-LA achieved ICERs below $1,000 per disability-adjusted life year (DALY) averted at adherence rates exceeding 75%. In high-income settings, ICERs for CAB-LA remained below $98,000 per quality-adjusted life year (QALY) when drug costs were reduced to $4,100/year. Low-income settings required annual costs below $16 for cost-effectiveness. Epidemiological benefits included a 30%-40% reduction in HIV incidence with optimal adherence. Drug pricing, adherence, and quarterly monitoring were identified as key determinants of cost-effectiveness. Comparisons with oral PrEP indicated that CAB-LA could be more cost-effective in populations with low adherence to oral regimens.

Conclusions: CAB-LA is a cost-effective HIV prevention intervention under specific economic and adherence scenarios. Reducing drug costs and enhancing adherence strategies are critical to optimizing its economic and epidemiological impact.

OAC0204

Equivalent performance of HIV oral fluid self-testing and rapid testing compared to nucleic acid amplification test in screening adolescents for long-acting injectable cabotegravir in Brazil

B. Oliveira Leite[1], L. Magno[2], F. Soares[1], D. Zeballos[1], L. Dezanet[3], O. Ferreira[4], M. Westin[5], D. Greco[5], A. Grangeiro[6], I. Dourado[1], The PrEP15-19 Choices study group

[1]Federal University of Bahia, Institute of Collective Health, Salvador, Brazil, [2]University of State of Bahia, Life Sciences Department, Salvador, Brazil, [3]Oswaldo Cruz Foundation, René Rachou Institute, Belo Horizonte, Brazil, [4]Federal University of Rio de Janeiro, Molecular Virology Laboratory, Rio de Janeiro, Brazil, [5]Federal University of Minas Gerais, Belo Horizonte, Brazil, [6]University of São Paulo, Medical School, São Paulo, Brazil

Background: Limited data are available on the risk of developing integrase inhibitor resistance among individuals initiating long-acting injectable cabotegravir (CAB-LA) during acute HIV infection. While nucleic acid amplification test (NAAT) is considered the gold standard in this scenario, its routine implementation during CAB-LA initiation may be impractical due to its high cost and longer processing time.

This study aimed to assess the performance of the HIV oral fluid self-test (ST) and the rapid test (RT) in comparison to NAAT for guiding CAB-LA initiation among adolescents in Brazil.

Methods: The PrEP15-19 Choices study is a real-world implementation project evaluating the use of oral and CAB-LA PrEP among cisgender men who have sex with men, transgender and non-binary individuals aged 15-19 years in three cities in Brazil. Data were collected between April 2024-January 2025. Adolescents enrolled in the CAB-LA arm underwent the HIV Detect® Oral Fluid ST. Peripheral venous blood samples were also collected to perform the fourth-generation RT (Determine™ HIV Early Detect) and the NAAT (Xpert® HIV-1 Qual), which served as the reference standard. The ST and RT were evaluated as index tests against NAAT, with sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and kappa agreement coefficients calculated.

Results: Of the 479 adolescents enrolled in the study, 180 (37.6%) opted to initiate CAB-LA and were screened for HIV infection. Two participants were excluded: one due to a missing ST result and another due to an inconclusive ST result recorded by the participant. Among the remaining 178 participants (98.9%) with completed tests, 5 (2.8%; 95% confidence interval [CI]:1.0–6.8) tested positive across all methods, while 173 (97.2%; 95%CI:93.2–99.0) tested negative across all methods. Both the oral fluid ST and the RT demonstrated a sensitivity, specificity, PPV, and NPV exceeding 99.9% (p = 0.006; kappa = 1).

Conclusions: Despite limitations in the sample size, the findings suggest that both ST and RT produced results that were consistent with the NAAT, indicating that they might be viable for diagnosing adolescents, including those from diverse sexual and gender identities. This could have implications for improving accessibility to testing and treatment for this group.

OAC0205

Evaluating HIV testing strategies to reduce drug resistance during CAB-LA rollout in Thailand. a modelling study

D. van de Vijver[1], J. van Kampen[1], A. Wongsa[2], R. Janamnuaysook[2], T. Mesplede[1], L. Matrajt[3], M.R. Jordan[4,5], N. Phanuphak[2], D. Dimitrov[3]

[1]Erasmus Medical Centre, Rotterdam, Netherlands, the, [2]Innovative HIV Research Institute (IHRI), Bangkok, Thailand, [3]Fred Hutchinson Cancer Center, Seattle, United States, [4]Tufts Medical Center, Boston, United States, [5]Tufts University School of Medicine, Boston, United States

Background: Long-acting cabotegravir (CAB-LA), an integrase strand transfer inhibitor (INSTI), is effective as pre-exposure prophylaxis (PrEP). CAB-LA delays HIV detection, allowing its continued use after HIV acquisition and increasing the risk of INSTI resistance mutations. Resistance to CAB-LA leads to cross-resistance with dolutegravir, a key drug in WHO-recommended HIV treatment regimens. CDC recommends sensitive antigen and RNA tests for timely HIV detection in CAB-LA users, but these tests are expensive and not widely available.

We study the impact of testing strategies on HIV transmission and drug resistance after CAB-LA implementation.

Methods: An HIV transmission model calibrated to the Thai HIV epidemic among men-who-have-sex-with-men (MSM) assumed an increase in PrEP users from the current 50,000-70,000 to 100,000 by 2034. CAB-LA use ranged from

0% to 100% of PrEP users by 2034. Literature indicated CAB-LA during HIV carries a 50%–100% risk of resistance development, and INSTI resistance reduces viral transmissibility by 30%–40%. The study compares CAB-LA implementation to the current situation (0%-5% resistance during viral failure with a dolutegravir containing regimen, no transmission of INSTI resistance). The model assumed CAB-LA use for one year with HIV testing every two months.
Three HIV testing scenarios were assessed:
1. The most sensitive scenario in which all new infections are identified, and two less sensitive testing scenarios:
2. Acute infections undetected, and;
3. 50% of infections undiagnosed during the first year.
Results: Without CAB-LA, 40,000 new infections occur between 2024 and 2034, and 524 individuals are expected to have INSTI drug resistance during viral failure with a dolutegravir containing regimen. CAB-LA can avert 1,600-6,200 infections (20%–100% uptake) but increases INSTI drug resistance cases by 28–94 individuals during viral failure (increase 5-18%) and by 4–15 individuals through transmitted INSTI resistance. More sensitive HIV testing reduced resistance during viral failure by 9–36 (reduction 32-38%) individuals and transmitted resistance by 2–6 individuals (40-50%).
Conclusions: CAB-LA introduction in Thailand can reduce new HIV infections but may simultaneously increase drug resistance to INSTIs. More sensitive HIV testing will prevent INSTI resistance. However, given the low INSTI resistance incidence, more sensitive testing is not critical for CAB-LA rollout.

OAC03 From distribution to linkage: Strategies to improve HIV self testing, diagnosis and care across diverse settings

Evaluating the impact of HIV self-test distribution on HIV diagnosis across health facilities in Kenya

A. Bershteyn[1], K. Bhamidipati[1], E. Kirui[2], A. de Nooy[3], H.-Y. Kim[1], B.E. Nichols[3,4,5], A. Monroe-Wise[6], C.C. Johnson[6], C. Kisia[7], B. Mambo[7], J.O. Magare[8]
[1]NYU Langone Health, Department of Population Health, New York, United States, [2]Ministry of Health, National Public Health Laboratory, Nairobi, Kenya, [3]Amsterdam University Medical Center, Department of Global Health, Amsterdam, Netherlands, the, [4]University of the Witwatersrand, Wits Diagnostic Innovation Hub, Faculty of Health Sciences, Johannesburg, South Africa, [5]Boston university School of Public Health, Department of Global Health, Boston, United States, [6]World Health Organization, Global HIV, Hepatitis and STI Programmes, Geneva, Switzerland, [7]World Health Organization, Kenya Country Office, Nairobi, Kenya, [8]Ministry of Health, National AIDS and STI Control Program, Nairobi, Kenya

Background: HIV self-testing (HIVST) can reduce barriers to HIV diagnosis, especially in resource-limited settings with limited staffing and high HIV burden. While the impact of HIVST roll-out on HIV diagnosis rates has been evaluated in randomized controlled trials, few studies have assessed its effects in routine practice at a national scale.
This study evaluates the impact of HIVST on HIV diagnosis across Kenyan health facilities using routine programme data.
Methods: We used multivariable linear regression models to evaluate the association between the number of HIVST kits distributed and the number of HIV-positive diagnoses monthly at the health-facility level. As a sensitivity analysis, we adjusted the model for either the monthly facility-based HIV testing volume or the number of facility-based HIV-negative tests, as two separate models. Both models were further adjusted for county-level HIV prevalence. In the subgroup analyses, we modeled the effect of total HIVST kits distributed on HIV-positive diagnoses by age and sex subgroups.
These models were also adjusted for either facility-based HIV testing volume or HIV-negative tests within the respective subgroup, as well as county-level HIV prevalence. Analyses were restricted to health facilities with available data for both HIVST and facility-based tests.
Results: From 2019 to 2023 in Kenya, across 5,883 health facilities, 1,399,865 HIVST kits were distributed and 20,556,949 facility-based tests were conducted. Every 1,000 distributed HIV self-tests were associated with an estimated 4.33 additional HIV-positive diagnoses (95% CI: 4.30–4.35; p<0.001), in the facility-based tests adjusted model, and 4.61 (95% CI: 4.58–4.63; p<0.001) in the HIV-negative tests adjusted model. Subgroup analysis showed the largest impact among women aged 25+, in whom every 1,000

distributed self-tests (regardless of the age/sex of recipient) was associated with an additional 38.85 (95% CI: 38.17, 39.52; p<0.001) HIV-positive diagnoses in the facility-based tests adjusted model, and 42.69 (95% CI: 42.00, 43.38; p<0.001) in the HIV-negative tests adjusted model.

Conclusions: HIVST was associated with large numbers of HIV-positive diagnoses at Kenyan health facilities, especially among women aged 25+. These findings support continued integration of HIVST into national HIV programs. Strengthening routine data systems is essential for ongoing evaluation of HIVST impact.

OAC0303

Closing the gap: the impact of HIV self-testing distribution on newly diagnosed cases in South Africa

A. de Nooy[1], M. Majam[2], A. Tembo[2], K. Bhamidipati[3], H.-Y. Kim[3], T. Chidarikire[4], S. Rosen[5,6], WDF. Venter[2], A. Marsh[7], A. Bershteyn[3], C.C. Johnson[8], B.E. Nichols[1,5,9]

[1]Amsterdam UMC, Global Health, Amsterdam, Netherlands, the, [2]Ezintsha, Faculty of Health Sciences, Univeristy of the Witwatersrand, Johannesburg, South Africa, [3]New York University Grossman School of Medicine, Department of Population Health, New York, United States, [4]World Health Organization, Johannesburg, South Africa, [5]Boston University School of Public Health, Department of Global Health, Boston, United States, [6]Health Economics and Epidemiology Research Office, Wits Health Consortium, Johannesburg, South Africa, [7]National Department of Health, Pretoria, South Africa, [8]World Health Organization, Geneva, Switzerland, [9]Wits Diagnostic Innovation Hub, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

Background: HIV self-testing (HIVST) provides convenient and confidential HIV testing. However, these characteristics can make evaluating the impact of HIVST investment challenging.

We used routine programme data to assess the impact of HIVST based on the number of people confirmed HIV-positive at healthcare facilities in South Africa.

Methods: The association between district-level HIVST distribution in 2022 and district-level confirmed HIV-positive tests at public healthcare facilities in 2023 was analyzed using multivariable linear regression (temporal lag to account for potential delays between self-testing and facility-based, provider administered, HIV testing [FTs] uptake). Models were adjusted for total FTs conducted and HIV prevalence.

Subgroup analyses stratified models by sex and distribution type, distinguishing between tests intended for the recipient's use (primary) and those for recipient contacts (secondary). Sex and age for FTs and confirmed HIV-positive tests were unavailable.

Results: Routine data showed 884,493 HIVSTs distributed across 34 districts in 2022 and 17,512,893 FTs conducted in all 52 districts in 2023. Every 100 FTs were associated with 2.4 (SE 0.1, p<0.0001) people confirmed HIV-positive at healthcare facilities (Table).

Every 100 HIVST distributed were associated with 3.2 (SE 1.3, p=0.02) additional individuals confirmed HIV-positive. Impact was concentrated among men, with 31.0 (SE 13.5, P=0.03) confirmed HIV-positive individuals per 100 HIVST distributed to men, and no significant association for HIVST distributed to women. Distribution type was not statistically significant: primary HIVST distribution showed a non-significant increase of 7.5 (SE 4.4, P=0.1); secondary distribution showed a non-significant decrease of 3.4 (SE 8.4, P=0.69).

Model	Explanatory Variables	Estimate (Number of new facility-confirmed HIV-positive cases per 100 tests distributed)	Standard Error	p-Value
1 [r-squared 0.94]	Total HIVST 2022 [n=884,493]	3.2	1.3	0.02*
	Facility HIV tests 2023 [n=17,512,893]	2.4	0.1	<0.0001 ***
2 [r-squared 0.94]	Female [n=449,552]	-10.4	8.8	0.25
	Male [n=290,337]	31.0	13.5	0.03*
	Sex unknown [n=144,604]	-2.3	5.5	0.67
	Facility HIV tests 2023 [n=17,512,893]	2.3	0.2	<0.0001 ***
3 [r-squared 0.94]	Primary [n=549,945]	7.5	4.4	0.10
	Secondary [n=55,884]	-3.4	8.4	0.69
	Facility HIV tests 2023 [n=17,512,893]	2.4	0.2	<0.0001 ***

Table: Prevalence-adjusted multiple linear regression estimates: new facility-confirmed positives per 100 tests distributed.

Conclusions: HIVST is associated with a significant increase in identification of new HIV-positive cases in South Africa, with the impact primarily observed among men. Routine HIVST distribution can address gaps in HIV testing and linkage, particularly for engaging men.

OAC0304

Overcoming stigma: applying peer-based outreach and linkage strategies to enhance linkage to care after HIV self-testing (HIVST) among key populations (KP) in Uganda

J.T. Komunyena[1], B. Mirembe[1], P. Kikobye[1], P. Kyambadde[2], G. Taasi[2], D. Canagasabey[3], C. Tendo-Bugondo[4], K. Granger[5], I. Thior[5], K. Green[6]

[1]PATH-Uganda, Primary health Care, Kampala, Uganda, [2]Ministry of Health, AIDS Control Program, Kampala, Uganda, [3]PATH-Washington DC, Primary health Care, Washington DC, United States, [4]PATH, Primary health Care, Lubumbashi, Congo, the Democratic Republic of the, [5]PATH, Primary health Care, Washington DC, United States, [6]PATH, Primary health Care, Gevena, Switzerland

Background: Uganda's KP communities face a higher burden of HIV, with prevalence rates two to five times higher than the general population. Stigma, social exclusion, harsh cultural and political environments limit access to HIV testing and care. Despite the increased accessibility of and privacy offered by HIVST, KP communities still encounter social and self-imposed stigma that hinders linkage to care. Through the Unitaid HIVST Africa III initiative, PATH and Uganda Ministry of Health leveraged peer-driven HIVST distribution and follow-up strategies to improve linkage to testing and care among KPs.

Description: The project introduced peer-based community distribution models, using peer supporters recommended by KP communities who shared similar identities. Peer supporters and their supervisors (health care providers/contact points at linkage health facilities) were trained on HIVST, basic counseling techniques, including HIV stigma reduction strategies. Peer supporters distributed HIVST kits at popular congregation points, and through door-to-door and community outreach. They leveraged KP networks on social media platforms to share information and videos on HIVST, and used phone calls, WhatsApp, or a toll-free line for client follow up for post-test counseling and results. Clients with reactive HIVST results were escorted to health facilities by peer supporters and linked to supervisors for guided referrals through confirmatory diagnosis and care.

Lessons learned: 104,739 (51%) among 203,377 people provided with HIVST kits from November 2020 through May 2022 were from KP communities. 35,087 (33%) individuals from KP communities self-tested reactive, among whom 29,578 (84%) were successfully linked to diagnosis and care, reflecting a higher linkage than the national average (79%).

Leveraging peer supporters and facility-based supervisors trusted among KP communities and training them on HIV stigma reduction counseling was crucial for establishing a foundation of trust that facilitated follow-up and linkage. Using technology and social media to counsel and follow up with KP communities afforded greater privacy that contributed to higher follow-up and linkage rates.

Conclusions/Next steps: Peer-led outreach and follow-up can significantly improve linkage to care following HIVST among KP communities in Uganda, highlighting the importance of introducing and scaling tailored peer-based interventions and stigma reduction strategies to enhance continuity in HIV care among KP.

OAC0305

Acceptability and feasibility of HIV self-testing for partner notification among sexual and drug-injecting partners of people living with HIV in low- and middle-income countries: a systematic review

L. Khandu[1], J. Hallett[1], G. Crawford[1], J.E. Leavy[1], D. Vujcich[2]
[1]Curtin University, School of Population, Faculty of Health Sciences, Bentley, Perth, Australia, [2]WAAC, Perth, Australia

Background: HIV self-testing (HIVST) enhances HIV diagnosis, but information on its integration for index testing to partner notification is limited in middle-income countries. Assessing the acceptability and feasibility of index HIVST and partner testing among people living with HIV (PLHIV) and undiagnosed key populations is critical to ending the AIDS epidemic.

Methods: A mixed-method systematic review using a convergent segregated approach was conducted using Joanna Brigs Institute's methodology. Four databases were used for a literature review from October 2023 to March 2024 and included studies published between 2016-2023. Rayyan software was used for full-text screening. Meta-analysis was found infeasible, but qualitative meta-aggregation was conducted.

Results: A total of 4076 studies were retrieved, and 72 studies met the inclusion criteria after a full review. Most of these studies were from the African region, with only one from South Asia and a few from East Asia. Index HIVST and partner testing were found acceptable and feasible among PLHIV and undiagnosed key populations. Despite low partner elicitation ratios by assisted partner notification, a higher positivity rate among notified individuals was noted. Preferences for index HIVST and partner testing varied with more inclination for assisted and passive partner referrals to overcome the risk concerning HIV status disclosure. The index HIVST showed a low cost per infection averted, indicating that it was a cost-effective intervention. Findings were skewed towards married couples, with less evidence on unmarried and undiagnosed key populations. The need for uniform policy, legal power, and standardized protocol for trained providers was highlighted.

Conclusions: Index HIVST were found acceptable and feasible in reaching index partners, including untested and undiagnosed partners of key populations, provided various testing approaches are used. Assisted partner notification resulted in high positivity rates despite low-index partner elicitation, suggesting the need for various referral options to address social harms, stigma, and discrimination. There is a critical need to study unmarried HIV index cases and undiagnosed key populations, particularly in the Southeast Asian region, to bridge HIV case detection gaps.

Further research should address the overrepresentation of married couples and focus on key population for a more holistic understanding of index HIVT and partner testing.

OAC04 The emerging landscape of PrEP choice

OAC0402

Lessons learned from the introduction of PEPFAR supported Long-Acting injectable Cabotegravir (CAB-LA) in shaping global prevention efforts

T. Mukherjee[1], A. Kimmel[1], L. Martindale[1], R. Eakle[2,1], C. LoVullo[3], A. Vij[3,1], N. Thaweesee[3], M. Maulidi[4], A. Muchara[5], A. Abubakar[4]

[1]Independent researcher, Washington DC, United States, [2]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom, [3]Global Health Security and Diplomacy, Department of State, Washington DC, United States, [4]Independent researcher, Lilongwe, Malawi, [5]Independent researcher, Harare, Zimbabwe

Background: 1.3 million people acquired HIV in 2023, falling short of UNAIDS's goal of fewer than 370,000 individuals by 2025. In fiscal year (FY) 2024, PEPFAR supported 90% of global PrEP programming, and introduced long-acting injectable cabotegravir (CAB-LA) in Eswatini, Malawi, Ukraine, Zambia, and Zimbabwe.

This analysis summarizes CAB-LA uptake, oral PrEP to CAB-LA switching, and the contribution of CAB-LA to overall PrEP uptake in the first year of introduction.

Methods: PEPFAR Monitoring, Evaluation, and Reporting (MER) indicators PrEP_NEW (PrEP naive individuals initiated on PrEP) and PrEP_CT (individuals returning or re-initiating PrEP at least once that quarter), disaggregated by PrEP type were analyzed. FY24 results were restricted to quarters that CAB-LA was available.

The number of individuals returning for PrEP was averaged across quarters that CAB-LA was available in all five countries. Switching from oral PrEP to CAB-LA was only measured in the first quarter CAB-LA was introduced in each country using PrEP_CT.

Results: Across all five countries, 441,269 individuals initiated PrEP and, on average, 127,292 returned for PrEP when both PrEP options were available. In FY24, 3,772 PrEP-naive individuals initiated CAB-LA, and 900 switched from oral PrEP to CAB-LA in the first quarter of CAB-LA introduction. Eswatini, Malawi, and Zambia reported more PrEP-naive individuals initiated on CAB-LA, compared to individuals switching from oral PrEP to CAB-LA. Compared to the same quarters in FY23, CAB-LA introduction correlated with a 25% increase in PrEP initiations and a 33% increase in PrEP return.

Conclusions: PEPFAR has been instrumental in introducing and scaling new prevention products worldwide. The introduction of CAB-LA demonstrates the potential to increase uptake and reach PrEP-naive populations across countries. By diversifying prevention options, CAB-LA complements oral PrEP programming and catalyzes PrEP uptake, enabling broader coverage.

Lessons learned from early introduction informs scale-up and expansion of long-acting PrEP (LA-PrEP), including CAB-LA and Lenacapavir. With HIV at the cusp of epidemic control, interruptions in PEPFAR financing undermines gains made over the past two decades, results in significant delays in introducing and scaling LA-PrEP, and limits access to life-saving prevention for populations at high risk of HIV acquisition.

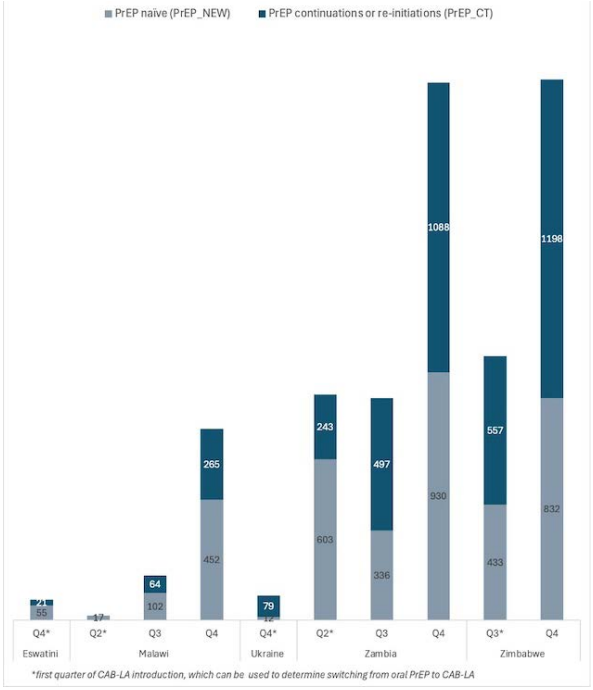

Figure. PEPFAR supported CAB-LA uptake by country and quarter, October 2023 - September 2024.

OAC0403

Choices in motion: how young people in the PrEPared to Choose study (Cape Town, South Africa) navigate PrEP product switching

K. Lebelo[1], C. Pike[1], E. Rousseau[1], P. Macdonald[1], P. Mapukata[1], O. Vanto[1], L.-G. Bekker[1]

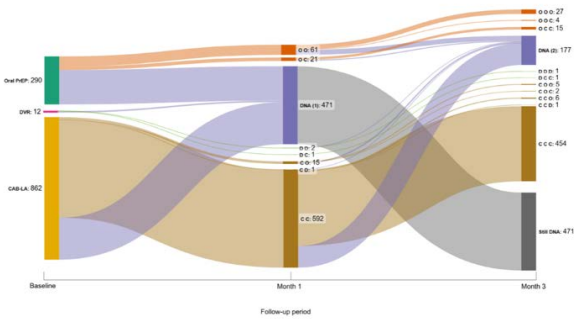
[1]Desmond Tutu Health Foundation, Woodstock, South Africa

Background: The introduction of novel, long-acting HIV pre-exposure prophylaxis (PrEP), including injectables and the vaginal ring, ushers in an era of PrEP choice. While much focus has been on the initial choice of PrEP product, PrEP users are likely to show dynamic PrEP product preference and use over time. PrEPared to Choose (PtC) is one of the first implementation studies allowing for unscheduled PrEP product switching between three available PrEP formulations.

Methods: PtC delivers PrEP choice, including oral PrEP, Cabotegravir long-acting (CAB-LA) injectable PrEP, and the Dapivirine-containing vaginal ring (DVR), to 1164 adolescents and young people (15-29 years) and their intimate male partners in Cape Town, South Africa. HIV counsellors provide comprehensive PrEP counselling that prioritizes accurate PrEP information and supports individual choice. Participants can switch between PrEP products, if clinically eligible, at any time over the 18-month study period. We report early product switching patterns between baseline and month three follow-up.

Results: 1164 individuals initiated PrEP, including oral PrEP (n=290), DVR (n=12), and CAB-LA (n=862). The median age was 24 (20–28) years, with adolescent girls and young women (AGYW) comprising 62.8% of participants. Of 82 oral PrEP users that returned at month 1, 25.61% transitioned to CAB-LA, with 71.43% of those transitioning being AGYW (see Diagram 1).
Of 21 individuals who switched to CAB-LA, 15 (71.43%) continued with CAB-LA at month 3. Of 608 individuals who initiated and continued CAB-LA at month 1, 97.37% remained on CAB-LA.

Diagram 1. Pathways of PrEP Usage: Transitions Between Oral PrEP, DVR, and CAB-LA from Initiation to 3-Month Follow-Up.



NOTE: Oral PrEP = O; DVR or D = Dapivirine-containing ring; CAB-LA or C = Cabotegravir long-acting; DNA = did not attend. Numbers at each time point indicate the total number of participants in a given stream. Each acronym follows the same logical pattern: The first letter represents the type of PrEP initiated at baseline. The middle letter indicates the continuity or switch at Month 1. The final letter describes the continuity or switch at Month 3. For example, OOC=initiated oral PrEP and continued with oral PrEP at Month 1 and switched to CAB-LA at Month 3.

Conclusions: Early continuation on PrEP overall and on the initiated PrEP product was substantially greater amongst PrEP users initiating CAB-LA compared to oral PrEP. With a quarter of persistent oral users at month 1 opting to switch to CAB LA, it is evident that true choice is an ongoing process that requires appropriate counselling support and clinical management for transitioning between products.

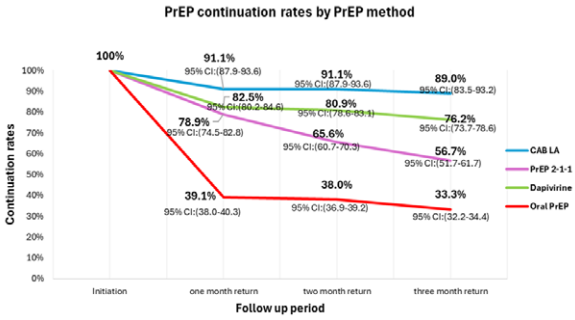
OAC0404

Continuation rates across different pre-exposure orophylaxis (PrEP) modalities of cabotegravir long-acting (CAB-LA), event-driven PrEP (PrEP 2-1-1), dapivirine ring (DPV-R) and oral PrEP: evidence from Zimbabwe

M. Munjoma[1], J. Mavudze[1], N. Zimuto[1], L. Bidi[1], N. Shoko[1], G. Ncube[2], T. Moga[1], B. Mutede[1], N. Taruberekera[1], O. Mugurungi[2]
[1]Population Solutions for Health, Harare, Zimbabwe, [2]Ministry of Health and Child Care, Harare, Zimbabwe

Background: Pre-exposure prophylaxis (PrEP) is now widely recognized as a viable HIV prevention method globally. In Sub-Saharan Africa, including Zimbabwe, while PrEP coverage is increasing, continuation rates are low. Recent data from Zimbabwe's Ministry of Health shows about 40% continuation at one month, dropping to less than 30% by the third month. To address low PrEP continuation, the World Health Organization (WHO) has approved various PrEP options beyond oral PrEP. Population Solutions for Health (PSH), in partnership with the Ministry of Health and with USAID support, conducted a study comparing oral PrEP continuation rates with newly introduced alternatives.

Methods: A retrospective cohort study was conducted among high-risk key populations of Adolescent girls and young women (AGYW), Female Sex workers (FSW), and Men who have sex with other men (MSM) eligible and enrolled across each PrEP modality per WHO guidelines between May 2023 and December 2025. Data were collected using an electronic record management system (Bahmni) and exported into STATA 17 for cleaning and analysis. Cohort analyses were conducted calculating PrEP continuation rates at one, two- and three months following initiation. Further, 95% confidence intervals were plotted around the point estimates for statistical significance tests across the different proportions.
Results: A total of 9,609 unique individuals were initiated across the four modalities. The figure below shows continuation rates by PrEP method. CAB-LA had the highest PrEP continuation rates, followed by Dapivirine Ring and PrEP 2-1-1 with oral PrEP having significantly the lowest continuation rates by the third month (p<0.001).



Conclusions: The study showed that PrEP continuation rates differ significantly by PrEP method. The more recent PrEP methods have higher continuation rates and should be scaled up urgently to reduce HIV transmission among high-risk key populations.

OAC0405

PrEP awareness, willingness, and behavioral characteristics of men who have sex with men and transgender individuals in the Philippines: a latent class analysis of the PrEP-APPEAL study

R.A. Olete[1,2], P. Eustaquio[3], W. Tieosapjaroen[4], K. Leyritana[1], J. Ong[4], H.-M.A. Schmidt[5,6], N. Phanupak[7], C. Chan[8], B.R. Bavinton[8]

[1]Sustained Health Initiatives of the Philippines, Mandaluyong City, Philippines, the, [2]National Cheng Kung University, Department of Public Health, Tainan City, Taiwan, Province of China, [3]Independent Researcher, Manila, Philippines, the, [4]Faculty of Medicine, Nursing and Health Sciences, Monash University, Melbourne, Australia, [5]Joint United Nations Programme on HIV/AIDS (UNAIDS), Geneva, Switzerland, [6]World Health Organization (WHO), Geneva, Switzerland, [7]Institute of HIV Research and Innovation (IHRI), Bangkok, Thailand, [8]Kirby Institute, UNSW Sydney, Sydney, Australia

Background: Despite increasing PrEP enrollment in the Philippines, the number of Filipino men who have sex with men (MSM) and transgender individuals (TGIs) using PrEP remains below the national target. This research examined distinct demographic and behavioral patterns associated with PrEP awareness, willingness to adopt specific PrEP options, and willingness to pay among Filipino MSM and TGIs.

Methods: A total of 1662 Filipino respondents were included from the 2022 multinational cross-sectional PrEP-APPEAL dataset. Latent class analysis (LCA) models were developed using STATA, segmenting the population into distinct subgroups based on associations between key variables (i.e., PrEP awareness, willingness towards various PrEP options (e.g., daily, event-driven, or monthly pills, CAB-LA), willingness to pay, and sexual behaviors (e.g., multiple sexual partners, condom use). Subsequently, multinomial logistic regression was employed to identify significant covariates of class membership.

Results: Among the respondents, 79.6%(1323/1662) were cisgender men, 5.3%(88/1662) self-identified as transgender individuals (men and women), mean age was 29.2 years old (SD=8.00), 17.9%(297/1662) were PrEP-experienced, and 14.0% (297/1662) were currently taking PrEP. LCA revealed three classes of Filipino MSM/TGIs: (1) Unaware and Reluctant (154/1662,9.3%)—with lowest PrEP awareness, lowest willingness to pay, lowest willingness to adopt any PrEP options, and lowest number of sex partners; (2) Informed Condom-Users (1282/1662,77.1%)—with higher PrEP awareness, moderate willingness to daily and monthly oral PrEP but low willingness to CAB-LA, high condom use, and higher number of sex partners; and (3) Enthusiastic Adopters (226/1662,13.6%)—having the high PrEP awareness, substantial willingness to adopt all PrEP options, and highest number of sex partners. The Enthusiastic Adopters were more likely to have previously taken PrEP (RRR=3.64,p<0.001) while the Informed Condom-Users were more likely from urban areas (RRR=1.84,p=0.015).

Conclusions: Person-centered community outreach should prioritize increasing PrEP awareness among the "unaware and reluctant", emphasizing availability of free oral PrEP and education on all PrEP options. For "Informed condom-users", address indirect cost barriers and simplify access to free oral PrEP. Introducing CAB-LA to "Enthusiastic Adopters" with integrated STI test-and-treat programs can mitigate behavioral risks.

Holistic strategies that combine education, accessibility, and PrEP innovations are essential to achieving national PrEP targets among Filipino MSM and TGIs.

OAC05 Purposeful PrEP: New insights on lenacapavir for prevention

OAC0502

Preference for twice-yearly injections vs daily oral pills for HIV PrEP in cisgender men, transgender women, transgender men, and gender nonbinary people enrolled in PURPOSE 2

K. Mngadi[1], N. Phanuphak[2], J.C. Hinojosa[3], K. Mounzer[4], R. Vasconcelos[5], M. Ramgopal[6], P. Wong[7], L.B. Brown[7], D. Mezzio[7], C.C. Carter[7], N. Shah[8]

[1]The Aurum Institute, Clinical Research Tembisa, Tembisa, South Africa, [2]Institute of HIV Research and Innovation – Pribta Tangerine Clinic, Bangkok, Thailand, [3]Asociación Civil Selva Amazónica, Iquitos, Peru, [4]Philadelphia FIGHT Community Health Centers – Jonathan Lax Treatment Center, Philadelphia, United States, [5]Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [6]Midway Immunology and Research Center, Fort Pierce, United States, [7]Gilead Sciences, Inc., Foster City, United States, [8]Whitman-Walker Health, Washington DC, United States

Background: Daily oral pre-exposure prophylaxis (PrEP) is efficacious for HIV prevention; however, consistent adherence, a predictor of effectiveness, can be challenging, especially among some populations disproportionately affected by HIV.

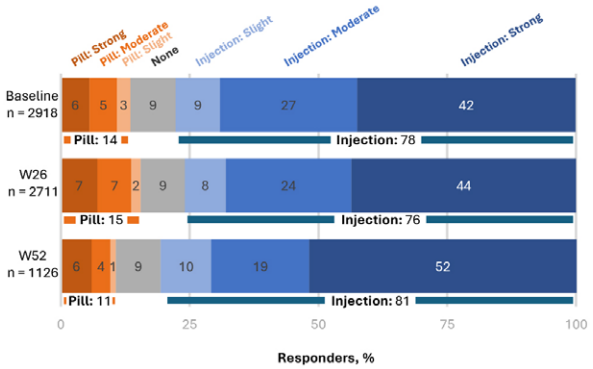
In the Phase 3 PURPOSE 2 trial (NCT04925752), twice-yearly subcutaneous (SC) lenacapavir lowered HIV incidence by 96% compared with background incidence and by 89% compared with oral emtricitabine–tenofovir disoproxil fumarate (F/TDF), with no safety concerns, in cisgender men, transgender women, transgender men, and gender nonbinary people who have sex with partners assigned male at birth.

We present PrEP administration preferences reported among PURPOSE 2 participants.

Methods: Participants were randomized 2:1 in a blinded fashion to receive SC lenacapavir every 26 weeks or oral F/TDF daily, plus an alternative injection/tablet placebo. During injection visits, participants completed an electronic questionnaire about PrEP administration preference (twice-yearly injections or daily pills) and how administration type impacts HIV risk perception and PrEP adherence. Data were collected at baseline (prior to injection), Week (W) 26, and W52. Categorical responses were analyzed descriptively.

Results: Of 3271 treated participants, 2918 and 1126 completed the questionnaire at baseline and W52 (primary analysis), respectively. Over 75% of participants preferred twice-yearly injections over daily pills; 11–15% preferred daily pills (Figure).

Among those with a preference for injections, over half reported a strong preference. Most participants reported that they would feel more protected from HIV (baseline: 66%; W26: 66%; W52: 69%) and be more confident about not missing a dose (baseline: 76%; W26: 73%; W52: 77%) with twice-yearly injections versus daily pills. Results were generally consistent across geographies included in the trial.



Participants who reported a preference for pills or injections were asked their level of preference (slight, moderate, or strong). Percentages may not sum to 100%, or align, due to rounding.
PrEP, pre-exposure prophylaxis; W, week.

Figure. PrEP administration preferences (daily oral pills vs twice-yearly injections) among all participants in the PURPOSE 2 trial.

Conclusions: Most participants preferred and felt more protected from HIV with twice-yearly injectable PrEP, although results highlighted the importance of choice. These data indicate twice-yearly lenacapavir could increase the uptake of, adherence to, and persistence with PrEP among men and gender-diverse people.

OAC0503

Efficacy, safety, and pharmacokinetics of twice-yearly subcutaneous lenacapavir for PrEP among adolescents and young people in the phase 3 trials PURPOSE 1 and PURPOSE 2

K. Gill[1], Q. Abdool Karim[2], S. Anugulruengkitt[3], L.-G. Bekker[1], J.A. Gallardo-Cartagena[4], A. Gaur[5], M. Manentsa[6], M. Naidoo[2], D. Potloane[2], Y. Singh[1], A. Kintu[7], P. Wong[7], Y. Zhao[7], P. Arora[7], R. Singh[7], L.B. Brown[7], C.C. Carter[7], M. Das[7], A. Agwu[8]

[1]The Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [2]Centre for the AIDS Programme of Research in South Africa, University of KwaZulu Natal, Durban, South Africa, [3]Department of Pediatrics, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [4]Centro de Investigaciones Tecnológicas, Biomédicas y Medioambientales, Universidad Nacional Mayor de San Marcos, Lima, Peru, [5]St. Jude Children's Research Hospital, Memphis, United States, [6]The Aurum Institute, Johannesburg, South Africa, [7]Gilead Sciences, Inc., Foster City, United States, [8]Division of Infectious Diseases, Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, United States

Background: Adolescents and young people are disproportionately affected by HIV globally and experience unique challenges with uptake of, adherence to, and persistence on daily oral HIV pre-exposure prophylaxis (PrEP). PURPOSE 1 (NCT04994509; P1) and PURPOSE 2 (NCT04925752; P2) demonstrated that twice-yearly subcutaneous lenacapavir was efficacious and safe for PrEP. We describe lenacapavir's efficacy, safety, and pharmacokinetics (PK) in participants aged 16-25 years (youth) from both studies.

Methods: P1 and P2 were parallel Phase 3 trials assessing lenacapavir for PrEP in cisgender women aged 16-25 years (P1) and cisgender men and gender-diverse persons aged ≥16 years (P2). We report incident HIV infections and compared a pooled analysis of safety and PK in youth in both studies with that in adults (aged >25 years) in P2.

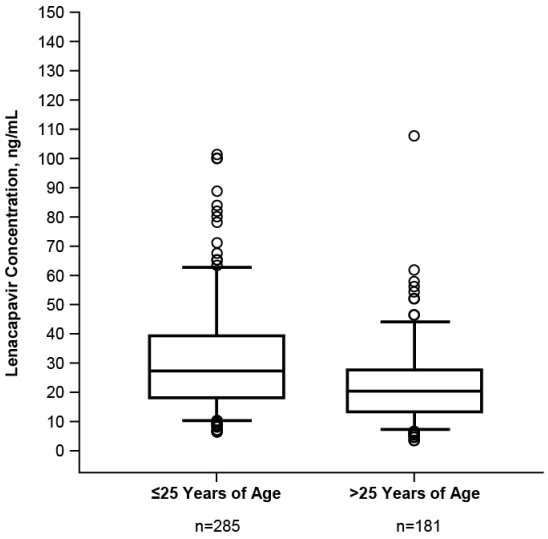
Results: Among youth, two incident HIV infections occurred on lenacapavir (in P2); six incident infections in P2 and all 55 incident infections in P1 occurred in those on daily oral PrEP. The most common adverse events (excluding injection-site reactions [ISRs]) were chlamydial infection, upper respiratory tract infection, and headache (Table).

N (%)	Youth (aged 16-25 years)	Adults (aged >25 years)*
HIV-1 infection	N=2884	N=1429
Lenacapavir[†]	2	0
Daily F/TAF or F/TDF[‡]	61	3
Adverse event	N=2892	N=1431
Chlamydial infection[§]	326 (11)	171 (12)
Upper respiratory tract infection	319 (11)	100 (7)
Headache	321 (11)	83 (6)
Urinary tract infection	317 (11)[¶]	23 (2)
Injection-site reaction		
PURPOSE 1	N=2140	
Pain	669 (31)	–
Nodules	1365 (64)	–
Swelling	96 (4)	–
Induration	91 (4)	–
PURPOSE 2	N=752	N=1431
Pain	404 (54)	827 (58)
Nodules	428 (57)	955 (67)
Induration	123 (16)	219 (15)
Erythema	77 (10)	300 (21)
Swelling	49 (7)	100 (7)

*No participants aged >25 years at screening in PURPOSE 1.
†Subcutaneous lenacapavir regimen 927 mg administered every 26 weeks.
‡3547 youth and 743 adults on daily F/TAF or F/TDF.
§Genitourinary infection in PURPOSE 1, anal infection in PURPOSE 2.
¶307 were from the PURPOSE 1 population of adolescent girls and young women.
F/TAF, emtricitabine/tenofovir alafenamide; F/TDF, emtricitabine/tenofovir disoproxil fumarate.

Table. HIV infections, adverse events, and injection-site reactions in youth vs adults in PURPOSE 1 and PURPOSE 2.

The most common ISRs were nodules, pain, induration, and swelling (and erythema in P2 only). Lenacapavir was well tolerated in youth and adults. Lenacapavir plasma concentrations were generally comparable between youth and adults (Figure).



Participants who became pregnant, received oral lenacapavir bridging, or were diagnosed with HIV-1 were excluded. Black boxes indicate 1st and 3rd quartiles with the median as a horizonal line inside the box; whiskers indicate 5th and 95th percentiles. Values BLQ were treated as 0 for summary statistics.

[a]Lenacapavir administered as subcutaneous injection 927 mg.

[b]Category for ≤25 years of age includes PURPOSE 1 and PURPOSE 2 participants; category for >25 years of age includes only PURPOSE 2 participants.

BLQ, below the limit of quantitation; C_{trough}, trough concentration.

Figure. Boxplots of lenacapavir[a] plasma concentrations at week 26 (C_{trough}) in the randomized blinded phase of the PURPOSE 1 and PURPOSE 2 studies (youth vs adults)[b].

Conclusions: Twice-yearly subcutaneous lenacapavir had high efficacy, favorable safety, and no clinically relevant PK differences in youth and adults, supporting the potential of lenacapavir to address challenges with daily oral PrEP and help reduce new HIV infections among youth.

OAC0504

Inclusion of pregnant and lactating people in the PURPOSE 1 study: efficacy, safety, and pharmacokinetics

Background: Pregnant and lactating people (PLP) are disproportionately vulnerable to HIV-1 acquisition but historically excluded from Phase 3 HIV trials. PURPOSE 1 (NCT04994509) was the first pre-exposure prophylaxis (PrEP) trial to intentionally include PLP to address their urgent unmet need for HIV prevention options.

Methods: We engaged community stakeholders, regulatory agencies, ethics committees, and maternal/pediatric health experts to responsibly include PLP in PURPOSE 1. To respect autonomy and reproductive choice, contraception was offered but not required; participants who became pregnant could remain on study drug following additional informed consent. We describe pregnancy outcomes, adverse events (AEs), and HIV infections in PLP randomized to twice-yearly subcutaneous lenacapavir up to the primary analysis. Lenacapavir plasma concentrations in PLP during each trimester/postpartum were compared with non-PLP using a population pharmacokinetics (popPK) model. Lenacapavir concentrations in breastmilk and infant plasma were measured (smaller subset).

Results: Of 2140 participants receiving lenacapavir, 184 participants had 193 pregnancies, of which 88 (45.6%) were ongoing. The 105 pregnancies with outcomes included 52 live births (49.5%) and 53 losses (50.5%), including 30 induced/elective abortions (28.6%), 20 spontaneous abortions (19.0%), and 3 stillbirths (2.9%). Maternal pregnancy-associated AEs were uncommon, with gestational hypertension/pre-eclampsia (n=4) and hyperemesis gravidarum (n=3) most reported. No HIV infections occurred in PLP receiving lenacapavir. In the PopPK analysis, predicted lenacapavir exposure was not statistically significantly different by pregnancy trimester or postpartum status compared with non-PLP (Table). Lenacapavir was pres-

ent in breastmilk (median milk-to-plasma ratio: 0.63 [n=8 matched pairs]); however, lenacapavir exposure in infant plasma was minimal (median breastfed-infant-to-mother plasma ratio: 0.05 [n=11 matched pairs]).

	Did not become pregnant	Non-pregnant period	First trimester (EGA 1-84 days)	Second trimester (EGA 85-189 days)	Third trimester (EGA > 189 days)	Postpartum (within 13 weeks after pregnancy)[b]
	Mean (% CV) [N]	Mean (% CV) [N]	Mean (% CV) [N]	Mean (% CV) [N]	Mean (% CV) [N]	Mean (% CV) [N]

C_{trough}, ng/mL	30.5 (45) [245]	30.2 (46) [66]	27.8 (41) [43]	29.5 (40) [38]	21.7 (69) [4]	30.3 (44) [12]
Week 26 to Week 52[d]						
C_{max}, ng/mL	83.5 (45) [205]	87.2 (32) [45]	82.5 (36) [29]	78.1 (32) [25]	93.4 (40) [8]	90.6 (39) [8]
C_{trough}, ng/mL	37.0 (46) [205]	33.2 (40) [30]	34.8 (53) [25]	34.3 (42) [33]	33.3 (42) [17]	42.4 (54) [10]

[a]Includes participants who had PK samples analyzed as part of the PopPK cutoff date (February 28, 2024).
[b]Following childbirth or pregnancy termination.
[c]Participants who took both oral lenacapavir 600 mg loading doses within 72 hours and had a lenacapavir 927 mg dose on Day 1 were included. C_{trough} = Week 26.
[d]Participants who took both oral lenacapavir 600 mg loading doses within 72 hours and had a lenacapavir 927 mg dose on Day 1, had an on-time SC lenacapavir 927 mg dose at Week 26 (26 weeks ± 2 weeks), and did not take the oral bridging regimen between Day 1 and Week 52, were included. C_{trough} = Week 52.
% CV, percentage coefficient of variation; C_{max}, maximum concentration; C_{trough}, trough concentration; EGA, estimated gestational age; pop(PK), (population) pharmacokinetics; SC, subcutaneous.

Table. Summary of model-predicted lenacapavir exposures stratified by pregnancy groups[a].

Conclusions: Lenacapavir was efficacious, safe, and well tolerated, with no clinically significant exposure differences in PLP and minimal exposure in breastfed infants. Proactive evaluation of lenacapavir efficacy, safety, and PK data in PLP can support accelerated access to lenacapavir for PLP who need or want PrEP.

OAC0505

Estimation of the counterfactual HIV incidence in the PURPOSE trials

C. Kelley[1], F. Matovu Kiweewa[2], O. Ogbuagu[3], S. Facente[4], E. Grebe[5], D.V. Glidden[6], Y. Shao[7], Y. Zhao[7], S. Cox[7], A. Kintu[7], L.B. Brown[7], C.C. Carter[7], M. Das[7], L.-G. Bekker[8]
[1]Division of Infectious Diseases, Emory University School of Medicine and Grady Health System, Atlanta, United States, [2]Makerere University-Johns Hopkins University Research Collaboration, Kampala, Uganda, [3]School of Medicine, Yale University, New Haven, United States, [4]School of Public Health, University of California, Berkeley, United States, [5]Vitalant Research Institute, San Francisco, United States, [6]Department of Epidemiology and Biostatistics, University of California, San Francisco, United States, [7]Gilead Sciences, Inc., Foster City, United States, [8]The Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa

Background: PURPOSE 1 (NCT04994509;P1) and PURPOSE 2 (NCT04925752;P2) evaluated twice-yearly lenacapavir for HIV pre-exposure prophylaxis. These trials employed a novel counterfactual HIV-incidence design comparing observed HIV incidence among participants receiving investigational agents to estimated background HIV incidence (bHIV) using a recent infection testing algorithm (RITA) in a pre-randomization cross-sectional cohort of screened participants. We report bHIV in P1/2, estimated by a RITA, with varying parameters and additional counterfactual estimates.

Methods: Samples from participants diagnosed with HIV during screening underwent testing for recent infection; bHIV was calculated using a RITA with recency assay parameters reported in Kassanjee 2016 (mean duration of recent infection and false recent rate based on weighted average of included subtypes; T=2 years).
Multiple counterfactual estimates of HIV incidence were also considered: observed and RITA-estimated incidence in the ECHO trial, predicted HIV incidence using modified VOICE score among participants (P1) and predicted HIV incidence calculated using emtricitabine-tenofovir disoproxil fumarate (F/TDF) efficacy-adherence relationship and correlation with rectal gonorrhea incidence (P2).
Additionally, bHIV was compared using varying recency assay parameters.

Results: Estimated bHIV in P1 was 2.41/100 person-years (py; 95% confidence interval 1.82,3.19) and 2.37/100py (1.65,3.42) in P2 [Figure]. Predicted HIV incidence in P1 using modified VOICE score was 9.35/100py (8.11,11.09); observed HIV incidence in ECHO was 4.77/100py (4.24,5.35). Predicted HIV incidence in P2 ranged from 2.87/100py (1.09,6.72) using the F/TDF efficacy-adherence relationship to 6.19 (3.53,8.85) using rectal gonorrhea incidence. Varying RITA parameters had minimal impact on the bHIV estimate.

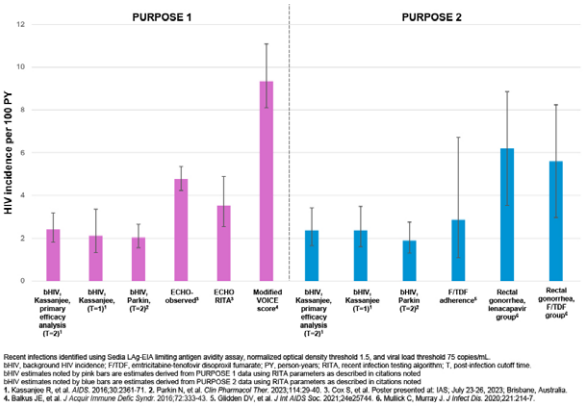

Figure. Comparison of estimated background HIV incidence and 95% CI using RITA and alternative counterfactual estimates in PURPOSE 1 and PURPOSE 2.

Conclusions: RITA-based bHIV for P1/2 were consistent with conservative incidence estimates. Of additional counterfactual estimates evaluated, the F/TDF efficacy-adherence estimate was most similar to RITA-based bHIV. Modified VOICE score and rectal gonorrhea correlation yielded higher HIV-incidence estimates, which may be explained by calibration of these methods earlier in the HIV epidemic. These findings support RITA-based bHIV estimates as comparators in future HIV prevention trials.

OAC06 Big money and the big picture: Funding and HIV epidemiology

OAC0602

If funding falls short: projecting the impact of international HIV budget cuts across 26 countries

A. Bowring[1], D. ten Brink[1], R. Martin-Hughes[1], N. Wulan[1], S. Dalal[2], N. Scott[1]
[1]Burnet Institute, Melbourne, Australia, [2]World Health Organization, Geneva, Switzerland

Background: International funding for HIV has been critical in reducing new HIV transmissions and deaths. While treatment financing is commonly prioritized domestically, HIV prevention and testing, especially for key populations, remain more vulnerable to cuts in international funding. Reductions in international aid of 10%-70% (19% weighted average) have been announced commencing in 2026, in the five countries that account for over 90% of international HIV funding. We investigated the impact of these funding reductions on the HIV epidemic in 24 countries through mathematical modelling.

Methods: We used existing, country-validated Optima HIV models in 24 countries (Albania, Armenia, Azerbaijan, Belarus, Bhutan, Cambodia, Colombia, Cote d'Ivoire, Eswatini, Georgia, Kazakhstan, Kenya, Kyrgyzstan, Malawi, Malaysia, Moldova, Mongolia, Mozambique, South Africa, Sri Lanka, Tajikistan, Uganda, Uzbekistan, Zimbabwe). We compared a status quo scenario, with most recent HIV spending continued from 2024-2040, to scenarios with 18.8% cuts to international funding from 2026. Country-specific impacts of funding cuts on HIV prevention and testing program coverage were derived based on proportion of international funding, with lower bounds assuming equal spending reductions across all programs and overheads and upper bounds assuming all spending reductions directly impacted service coverage. Treatment and facility-based testing were assumed to continue through domestic funding. We projected HIV incidence, HIV-related deaths and cascade outcomes to 2040.

Results: Across the 24 countries considered, a 19% reduction in international funding could lead to a 10-64% reduction in HIV prevention and testing program coverage, a cumulative increase of 14-68% in new HIV transmissions and a 4-13% in HIV-related deaths across 2026 to 2040. In addition, there was a 4-21% increase in total people living with HIV and a 2-16% increase in people on ART by 2040 (despite lower diagnosis rates), which could lead to higher long-term domestic financial costs. Impacts were greatest in countries with a higher percentage of international funding, and those with increasing incidence among key populations.

Conclusions: Persistent reductions in international HIV funding could significantly reverse progress by 2040, disproportionately affecting key and vulnerable populations. Establishing sustainable funding mechanisms to safeguard prevention, testing, and care programs is critical to reducing HIV transmission and mortality.

OAC0603

How have policies influenced PrEP uptake? An analysis of 139 countries and 33 African countries

J. Tailor[1], K. Segal[1], W. Nyagah[2], M. Warren[1]
[1]AVAC, New York City, United States, [2]AVAC, Nairobi, Kenya

Background: Oral PrEP is at varying stages of scale-up globally, as longer-acting PrEP products enter the market in limited supply. This analysis evaluates which policies significantly enable PrEP uptake to understand how to expand access to PrEP options.

Methods: Data on cumulative PrEP initiations (dependent variable) for 139 countries, as of September 2024, was collected from AVAC's Global PrEP Tracker. Data on the status of 54 policies (independent variable (IV)) related to HIV testing and prevention, structural changes, and health systems across all 139 countries, as of July 2024, was collected from the HIV Policy Lab. Multiple and individual regressions, using RStudio (2024.12.0+467), assessed the significance of policies altogether and individually (p=0.05). A separate analysis was done for 33 African countries. Correlation analyses of IVs assessed multicollinearity using the Pearson coefficient. Ridge regression analysis assessed if multicorrelated variables should be eliminated from the model to remove confounding in multiple regressions.

Results: The global analysis showed that eight policies on task-shifting (1), decriminalizing same-sex sex (3), decriminalizing HIV exposure (3), and HIV self-testing (1) were significantly associated with PrEP uptake in individual regressions. Multiple regression showed only one policy on task-shifting is significantly associated with PrEP uptake.
The analysis of African countries showed that four policies decriminalizing HIV exposure (2), prohibiting compulsory HIV testing (1), and loosening age restrictions on testing and treatment (1) were significantly associated with PrEP uptake in individual regressions. None were significantly associated with PrEP uptake in multiple regression.
The discrepancy in the individual and multiple regressions indicates multicollinear IVs. Correlation analyses confirmed that at least four pairs of policies are highly correlated in enabling PrEP uptake. Ridge regression results showed that these same variables were very strongly contributing to the predictive power of the model and cannot be eliminated.

Conclusions: Policies found to significantly enable PrEP uptake making access easier, reduce discrimination, and align with user preferences. While the effect of individual policies is reduced when considering several altogether, they influence PrEP uptake both individually and systemically. Differences in policies that significantly enable PrEP uptake at global and regional levels imply that context affects which policies should be implemented.

OAC0604

Evaluating global PrEP implementation progress over time: an analysis of the PrEP-to-Need ratio from 2018-2023 across eleven countries with high HIV incidence and/or burden

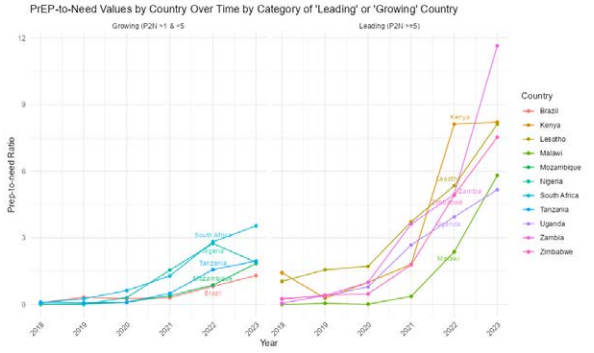
L. Sheira[1], C. Verde Hashim[2], J. Tailor[3], M. Prochazka Nunez[4], H.-M.A. Schmidt[4,5]

[1]University of California, San Francisco, School of Nursing, San Francisco, United States, [2]AVAC, London, United Kingdom, [3]AVAC, New York, United States, [4]World Health Organization, Geneva, Switzerland, [5]UNAIDS, Geneva, Switzerland

Background: Pre-exposure prophylaxis (PrEP), which is highly effective at preventing HIV, could end the HIV epidemic if used at scale effectively and by those who need it. Despite market availability for at least 5-10 years globally, implementation has varied, with substantial differences between countries in terms of meeting in-country PrEP need. Comprehensive data comparing countries over time can unlock critical insights in implementation facilitators and challenges.

Methods: Using UNAIDS data on HIV incidence and AVAC data on PrEP initiations (2018-2023), we calculated the PrEP-to-Need ratio (PNR) among all countries with available data (higher = greater PrEP coverage than HIV incidence). We categorized the PNR as leading (>5), growing (1.00-4.99), and emerging (<1.00) based on prior work by AVAC. Among countries with high PrEP volumes (initiations >100,000 cumulative) in 2023, we compared the PNR ratio over time by PNR category.

Results: Of 111 countries with PrEP-to-need data available, eleven were high PrEP volume countries: six were leading (Kenya, Lesotho, Malawi, Uganda, Zambia, and Zimbabwe) and five were growing (Brazil, Mozambique, Nigeria, South Africa, Tanzania); none were emerging. While HIV incidence was stable or decreasing across all countries over time, increases in PrEP initiations drove the PNR. Transition to leading took an average of 4.4 years; for growing countries, average time from emerging to growing was 3.8 years.



Conclusions: Leading countries were characterized by consistent and sustained increases in PrEP initiations per year. Countries in the growing category must increase their PrEP delivery substantially and among populations at substantial HIV acquisition risk to become leading. Targeting a minimum of five PrEP initiations among those with PrEP need per projected incident HIV case will promote higher PNR. Data in aggregate form may mask epidemics in key populations (KPs); specific, disaggregated coverage data for key populations needed to further characterize progress in meeting key PrEP goals among KPs.

OAC0605

Viral load suppression at first viral load after shifting from six to three months post-ART initiation: a retrospective analysis of early outcomes in the South African public sector HIV program

K. Rees[1,2], B. Mugisa[3], C. O'Connor[1], N. Davies[1], L.S. Wilkinson[4,5]

[1]Anova Health Institute, Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Community Health, School of Public Health, Johannesburg, South Africa, [3]USAID, Pretoria, South Africa, [4]International AIDS Society, Geneva, Switzerland, [5]University of Cape Town, Centre for Infectious Epidemiology and Research, Cape Town, South Africa

Background: In April 2023, South Africa updated anti-retroviral (ART) guidelines to advance the first viral load (VL) from six to three months post-initiation. This aimed to leverage Dolutegravir's faster suppression rates and enable earlier enrolment into differentiated service delivery (DSD) models and adherence support. We evaluated the impact of this guideline change on VL suppression rates, and DSD enrolment and timing in four South African districts.

Methods: We analysed ART initiations May-December 2023, excluding those recorded as deceased, transferred out or with a baseline VL (suggesting prior treatment and/or re-engagement) but including those who may have disengaged during follow-up (168 days following guideline-mandated first VL timing). VL<200 copies/ml, VL suppression (<50 copies/ml), and DSD enrolment were analyzed using logistic regression. DSD enrolment timing was assessed using a Cox proportional hazards model, adjusting for age, gender, and district.

Category	Early (29–77 days)	3 months (78–112 days)	3–6 months (113–161 days)	6 months (162–196 days)	Late (>196 days)
VL <200 copies/ml (%)	1671 (80.07%)	11813 **(87.75%)**	3814 (83.33%)	3194 **(86.23%)**	1833 (81.07%)
Adjusted OR (p-value, 95% CI)	0.57 (<0.01, 0.51-0.64)	Ref	0.73 (<0.01, 0.67-0.80)	0.93 (0.18, 0.83-1.03)	0.66 (<0.01, 0.58-0.74)
Suppressed VL <50 copies/ml (%)	1191 (57.07%)	8758 **(65.06%)**	2946 (64.37%)	2476 **(66.85%)**	1451 (64.18%)
Adjusted OR (p-value, 95% CI)	0.71 (<0.01, 0.64-.078)	Ref	0.99 (0.89, 0.93-1.07)	**1.13 (<0.01, 1.05-1.22)**	1.02 (0.63, 0.93-1.13)
Suppressed enrolled in DSD (%)	473 (39.71%)	4322 (49.35%)	1109 (37.64%)	895 (36.15%)	412 (28.39%)
Adjusted OR (p-value, 95% CI)	0.68 (<0.01, 0.60–0.77)	Ref	0.63 (<0.01, 0.58–0.69)	**0.59 (0.01, 0.53–0.64)**	0.42 (<0.01, 0.37–0.48)
Suppressed median time to DSD enrolment (days)	143	**162**	196	**252**	306
Adjusted HR (p-value, 95% CI)	1.12 (0.02, 1.02-1.24)	Ref	0.65 (<0.01, 0.61-0.70)	0.44 (<0.01, 0.40-0.47)	0.36 (<0.01, 0.32-0.39)

Table 1: Viral Suppression and DSD Enrolment by VL Timing

Results: Among 26,091 individuals initiating ART with a VL, 65.1% achieved VL suppression and 87.8% had VL<200 copies/ml with a three-month VL, compared to 66.9% and 86.2% with a six-month VL. Adjusted analysis showed that clients with VLs taken at six months had 13% higher odds of suppression (p-value<0.01) and 41% lower odds of DSD enrolment compared to those at three months. Median time to enrolment was 162 days for clients with suppressed VLs taken at three months compared to 252 days for six months.

Conclusions: Advancing the first VL to three months enabled earlier DSD enrolment for suppressed ART initiators, supporting retention efforts. Although suppression rates were slightly lower at three compared to six months, earlier VL also enables expedited identification of clients who could benefit from targeted adherence support and require follow-up testing. Maximizing the benefits of an earlier VL requires promptly offering DSD or multi-month dispensing to all suppressed clients and providing proactive, early support for unsuppressed clients.

OAD01 Centring mental health in the HIV response

OAD0102

Mental health challenges and sexual health resource access among LGBTQ+ young people in Peru: findings from an online national survey

J.C. Jauregui[1], F. León-Morris[2,3], M. Reyes-Diaz[2,3], R. Nath[4], A.B. Taylor[4], K.A. Konda[2,5]

[1]University of California, Los Angeles, Social Welfare, Los Angeles, United States, [2]Investigaciones Médicas en Salud, Lima, Peru, [3]Universidad Peruana Cayetano Heredia, Center for Interdisciplinary Studies in Sexuality, AIDS and Society, Lima, Peru, [4]The Trevor Project, West Hollywood, United States, [5]Keck School of Medicine, University of Souther California, Population and Public Health Sciences, Los Angeles, United States

Background: The purpose of this study is to investigate how clinically significant levels of depression (PHQ-2), anxiety (GAD-2), and lifetime suicidal ideation are associated with access to sexual health resources among LGBTQ+ young people (ages 14-24) in Peru.

Methods: Data were drawn from a national mental health survey of LGBTQ+ young people in Peru (n=4,643) conducted from October-December 2022 with funding and collaboration from The Trevor Project (USA) and ethical approval from INMENSA (Peru). Logistic regression was used to assess the association between mental health indicators (depression, anxiety, and lifetime suicidal ideation) and access to three sexual health resources: 1) Pre-exposure prophylaxis (PrEP), 2) HIV/STI treatment/consultation, and 3) condoms. Each outcome was dichotomized comparing: wanted but did not receive versus wanted and received resource. Adjusted odds ratios (aOR) were calculated, controlling for key socio-demographic variables.

Results: Most of the 4,643 respondents were 18 years or older (62.5%), 16.1% were transgender or non-binary, 48.9% identified as bisexual, and 28% as gay or lesbian. Most had clinically significant depression (58.2%), anxiety (54.6%), and 73.4% endorsed lifetime suicidal ideation. Some wanted each sexual health resource: PrEP 40.6%, HIV/STI treatment/consultation 47.7%, and condoms 55.4%. In the PrEP model, individuals with a history of suicidal ideation were 43% less likely to access PrEP.

In the HIV/STI treatment/consultation model, no mental health variables were significantly associated with access. In the condom access model, anxiety was associated with a 25% increase, and depression to a 25% decrease in the likelihood of condom access (Table 1).

Model 1: n=1447, 17% accessed PrEP		Model 2: n=1720, 30% accessed STI/HIV treatment or consultation		Model 3: n=1986, 40% accessed condoms	
	aOR (95% CI)		aOR (95% CI)		aOR (95% CI)
Depressive symptoms (Ref: No)	1.06 (0.74-1.54)	Depressive symptoms (Ref: No)	1.11 (0.84, 1.46)	Depressive symptoms (Ref: No)	**0.75 (0.60-0.95)**
Symptoms of anxiety (Ref: No)	1.24 (0.87-1.78)	Symptoms of anxiety (Ref: No)	1.07 (0.82-1.40)	Symptoms of anxiety (Ref: No)	**1.25 (1.00-1.58)**
Lifetime Suicide Ideation (Ref: No)	**0.57 (0.39-0.83)**	Lifetime Suicide Ideation (Ref: No)	0.77 (0.57-1.03)	Lifetime Suicide Ideation (Ref: No)	0.90 (0.70-1.16)

Note: Bolded aOR and 95% CI reflects statistically significant associations (p < 0.05). All models adjusted for age, sex assigned at birth, gender, region of residence, migration status, education, employment, and socioeconomic status. Depression was measured using the PHQ-2 and anxiety using the GAD-2; both measures were dichotomized, with a "yes" indicating a score of ≥3 (range: 0-6), which reflects clinically significant symptoms.

Table 1: Models Examining the Associations between Sexual Health Access (PrEP, STI/HIV Treatment, Condoms) and Mental Health Indicators.

Conclusions: Our findings highlight mental health needs among LGBTQ+ Peruvians and their potential connection with sexual health resource access. Suicidal ideation was associated with impeded PrEP access, while anxiety and depression were associated with differential condom access. These results emphasize the need for integrated mental health and sexual health services to address the unique needs of LGBTQ+ young people, particularly those facing severe mental health challenges.

OAD0103

Addressing alcohol use to improve mental health among men living with HIV (LWH): impact of the Kisoboka intervention on depressive symptoms among fisherfolk in Uganda

A.P. Miller[1], D. Tuhebwe[1,2], M. Ediau[2], R. Naigino[1,2], A. Ancho[2], K. Sileo[3], N. Tumwesigye[2], E. Reed[1], J.A. Hahn[4], R. Wanyenze[2], S.M. Kiene[1]

[1]San Diego State University, San Diego, United States, [2]Makerere University School of Public Health, Kampala, Uganda, [3]Boston College, Boston, United States, [4]University of California, San Francisco, San Francisco, United States

Background: Harmful alcohol use and depression are interrelated barriers to optimal ART adherence. Kisoboka, a multilevel intervention aimed at reducing alcohol use and improving HIV treatment outcomes through eco-

nomic strengthening, unexpectedly reduced depressive symptoms. We examined whether its impact on depression varied by baseline alcohol use.

Methods: We conducted a pilot randomized controlled trial to evaluate Kisoboka. We enrolled fisherfolk men, aged 18-50, LWH, reporting suboptimal adherence and recent hazardous alcohol use, between January 2021 and March 2022. Linear generalized estimating equations (GEE) were built to examine potential moderation of intervention effect on depressive symptoms (measured using the CESD) over time (baseline, 3 and 6 months follow-up) in adjusted models using a three-way interaction term (time*arm*baseline AUDIT).

Results: Analysis of 160 participants and 466 observations revealed a significant three-way interaction between continuous AUDIT score, time, and study arm on depressive symptoms (B = -0.0970, 95% CI -0.1555, -0.0386, p=0.001). To illustrate this effect (Figure 1), we plotted the probability of depressive symptoms over time for participants with higher (+1 SD) and lower (-1 SD) baseline AUDIT scores by study arm. Among those with higher AUDIT scores, the probability of depressive symptoms in the intervention decreased from 57% to 3% at 6 months, while it increased in the control arm from 37% to 66%. For participants with lower AUDIT scores, the probability of depressive symptoms declined in the intervention (27% to 2%) and slightly improved in the control arm (44% to 33%).

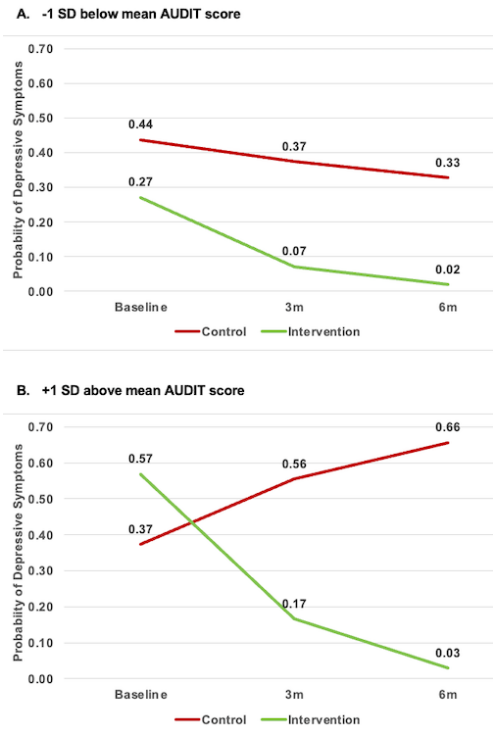


Figure 1A-B. Probability of depressive symptoms by time and condition.

Conclusions: The intervention's mental health benefits were most pronounced among those with higher baseline alcohol use. These findings suggest that addressing alcohol use may play a crucial role in improving mental health outcomes. Furthermore, the intervention's impact on depressive symptoms varied by alcohol use severity, highlighting the potential need for tailored approaches to maximize effectiveness across different risk profiles.

OAD0104

The double burden: a cross-sectional study of the intersection between mental health and access to HIV Prevention services for female sex workers in internally displaced camps in Calabar, Nigeria

L. Efobi[1,2]

[1]University of Nigeria, Clinical Pharmacy and Pharmacy Management, Nsukka, Nigeria, [2]Person-Centered HIV Research Team, Nsukka, Nigeria

Background: Female sex workers (FSWs) are vulnerable to HIV acquisition, occupational discrimination, and mental health challenges. However, understanding the intersection of mental health and their access to HIV prevention services will guide policymakers in improving accessibility of FSWs in internally displaced persons (IDP) camps having a dual burden.

This study assessed the relationship between mental health and accessibility of HIV prevention services for FSWs in IDP camps in Calabar, Nigeria.

Methods: A cross-sectional study was conducted on 187 randomly selected FSWs in IDP camps in Calabar (Dec 2024-Jan 2025). A three-part validated 17-item questionnaire measuring mental health status, perceived discrimination, and accessibility to HIV prevention services was used to collect data. Data analysis involved frequencies, cross-tabulations, and chi-square tests using IBM SPSS (version-27), with significance set at p<0.05

Results: Out of 187 FSWs, 108 participated in the study. Most participants, 25(23.1%), were aged 25-34 and 39(36.1%) had worked for >6 years. There were 43(39.8%), and 42(38.9%), respondents who *sometimes or often,* respectively, felt sad, down, or hopeless in the past month. Substance use was reported as the primary coping strategy for stress (n=91, 84.3%).

Occupational discrimination was prevalent, with 63.9% and 19.4% reporting *frequent* and *occasional* experiences, respectively. HIV testing [79(73.1%)] and condom use [65(60.2%)] were common, while PrEP access was low, 9(8.3%). Among condom users, 50.8% *sometimes* felt sad, while 44.2% of non-users *often* felt sad, linking mental health and access.

Age influenced access to services (*p=0.001*), with condom use highest in 25-34-year-olds (29.2%), but lowest in those <18 years (10.8%). Likewise, HIV testing was more accessed by 25-34 years (27.8%) and <18 years (26.6%), and least in >45 years (8.9%). Respondents older than 45 years (83.3%,) reported not accessing any HIV prevention services. Perceived discrimination correlated with poor access, especially among those with over 6 years' experience; 83.3% reported no access (*p=0.001*).

Conclusions: Mental health, perceived discrimination, and access to HIV prevention services intersect in FSWs living in IDP camps, especially in older, more experienced populations, suggesting a need for age and experience-specific interventions. Future research should investigate underlying factors contributing to low service utilization in older populations.

OAD0105

Depression, suicidal ideation, and HIV risk among young mothers in South Africa

A.P. Miller[1], Z. Essack[2], D. Joseph Davey[3,4], C. Groenewald[2], Z. Petersen[2], L.M. Filiatreau[5], H. van Rooyen[6]
[1]San Diego State University, San Diego, United States, [2]Human Sciences Research Council, Pretoria, South Africa, [3]University of California, Los Angeles, Los Angeles, United States, [4]University of Cape Town, Cape Town, South Africa, [5]Washington University in St. Louis, St Louis, United States, [6]University of Washington, Seattle, United States

Background: The burden of mental illness in African countries is rising, driven by poverty, unemployment, and limited upward mobility. Many women face high rates of intimate partner violence (IPV), unplanned pregnancies, and motherhood-related stresses, exacerbating mental health challenges. Poor mental health can lead to reduced quality of life, disability, and, in severe cases, death. Depression and suicidal ideation are linked to high-risk behaviors, including sexual activities that increase HIV risk. Despite these dynamics, few studies have examined mental health and HIV risk in African mothers.
Methods: This study examined associations between depression, suicidal ideation, and HIV risk behaviors among pregnant and/or parenting young South African women. Data were collected from unemployed women aged 18–24 years as part of an evaluation in KwaZulu-Natal (June–September 2018).
The analysis included those reporting sexual activity in the past year. Baseline data were analyzed using Poisson regression, with primary exposures of past year (i) prolonged sadness and (ii) suicidal ideation.
The composite HIV risk outcome included transactional sex, partners with unknown HIV/STI status, and substance-influenced sex. Models adjusted for age, IPV, and HIV serostatus.
Results: We analyzed data from 1,026 participants. Median age was 22 years (IQR: 21–23), with a mean of 1.1 children. Three in ten reported ever drinking alcohol (29.7%). Past year IPV was reported by 9.1% and HIV prevalence was 8.7%. Two percent (n=17) were currently pregnant, and most (97%) indicated their most recent pregnancy was unplanned. One-third (34%) reported prolonged sadness, while 10% reported suicidal ideation. In unadjusted models, prolonged sadness and suicidal ideation in the past year were associated with increased composite HIV risk, with PRRs of 2.11 (95% CI: 1.75–2.52) and 1.99 (95% CI: 1.58–2.47), respectively. Adjusted models showed HIV risk PRRs of 1.79 (95% CI: 1.41–2.27) for sadness and 1.67 (95% CI: 1.24–2.27) for suicidal ideation.
Conclusions: Depression and suicidal ideation are critical challenges for unemployed pregnant or parenting young South African women. Antenatal, postnatal, well-baby, and HIV care offer crucial opportunities for mental health screening and referral, which can reduce HIV risk and improve long-term health for both mothers and children.

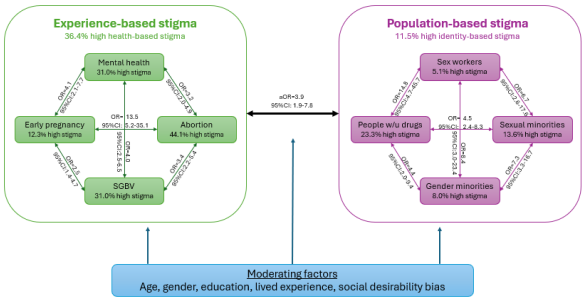
OAD02 Health equity in challenging times: Threats and opportunities

OAD0202

High stigma in one area strongly predicts high stigma in others: testing the idea of a 'universal' approach to anti-stigma intervention to improve healthcare for key populations

A. Adam[1], D. Callander[2,3], D. Kirongo[2], C. Kithinji[1], A. Guadarrama[4], K. Makobu[5], L. Ledenski[2], S. Dombojena[2], M. Pastrana[4], K. Khabala[2], J.P. Ouamba[2], I. Ciglenecki[4], G. Mwendar[2], P. Owira[6]
[1]Mombasa County Department of Health, Mombasa, Kenya, [2]Médecins Sans Frontières, Mombasa, Kenya, [3]University of New South Wales, Sydney, Australia, [4]Médecins Sans Frontières, Geneva, Switzerland, [5]Kenya Medical Research Institute, Kilifi, Kenya, [6]International Centre for Reproductive Health, Mombasa, Kenya

Background: While traditional anti-stigma intervention has used education around specific topics (e.g., sexuality), some contend this topical approach is ineffective for healthcare workers already overwhelmed with information. Instead, theorists argue for stigma as a universal concept best addressed through interventions promoting overall acceptance and equity.
To explore the possibility of a universal anti-stigma intervention, our study examined different stigmas among healthcare workers in the Kenyan city of Mombasa. Specifically, we tested the hypothesis that high stigma in one domain would predict high stigma in others.
Methods: A prospective cohort of healthcare workers from six public clinics in Mombasa was established (June 2023-December 2024). Every 3-6 months, participants completed a survey of attitudes towards stigmatized topics. Scale scores were standardized from 1 (low stigma) to 5 (high stigma), and a factor analysis with varimax rotation investigated potential stigma groupings.
Multivariable regression analyses investigated associations between different stigmas while controlling potential confounders (i.e., age, education, social desirability).
Results: Over four waves,925 data points were collected (n=395). The factor analysis defined two stigma groups: experiences (i.e., mental health, abortion, early pregnancy, sexual violence; λ=2.45) and populations (i.e., sex workers, people who use drugs, sexual and gender minorities; λ=2.20). Strong two-way associations were observed between all topics. For example, high sex work stigma predicted high sexual minority stigma (aOR=6.7, 95%CI:2.6-17.6), while stigma towards people who use drugs predicted gender minority stigma and *vice versa* (aOR=4.4, 95%CI:2.0-5.5). Even across factors, strong associations were observed: in a composite measure, high experience-based stigma was associated with a 3.9 times greater likelihood of high population stigma (aOR=3.9, 95%CI: 1.9-7.8).



Conclusions: Study results support our hypothesis, suggesting stigma can be understood as a ‚universal' experience. Anti-stigma interventions should focus on promoting acceptance overall rather than engaging with specific topics, which offers exciting possibilities to improve healthcare for key populations and beyond.

OAD0203

Promoting equity for pregnant adolescents in research: ethics guidance from the PREPARE working group

R.V. Masese[1], H.C. Baron[1], A.D. Lyerly[1], S. Day[2], The PREPARE Working Group
[1]University of North Carolina at Chapel Hill, School of Medicine, Department of Social Medicine, Center for Bioethics, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Department of Medicine, Division of Infectious Diseases, Chapel Hill, United States

Background: Exclusion of pregnant adolescents from clinical HIV research participation has led to significant evidence gaps in the safety, effectiveness, and uptake of HIV treatment and prevention strategies for this population. These gaps underscore the urgent need for ethics guidance to support the inclusion of pregnant adolescents in clinical HIV research. Inclusive research is essential to inform safe and effective treatment and prevention strategies and improve health outcomes for pregnant adolescents and their children.
Description: To address this urgent need, the PRomoting Equity for Pregnant Adolescents in REsearch (PREPARE) Working Group, an international and interdisciplinary team of 44 experts, has developed actionable ethics guidance for the equitable and responsible inclusion of pregnant adolescents in clinical HIV research. This guidance incorporates diverse expertise and perspectives from bioethicists, adolescent and HIV researchers, policy experts, and adolescents with lived experience.
Lessons learned: The guidance comprises nine recommendations based on a reproductive justice framework, highlighting the ethical principles of respect, access, and protection.
Per the principle of respect:
1. Pregnant adolescents should be central to decisions about research participation;
2. Studies must address the full range of their reproductive options;
3. Their lived experiences should inform the design, conduct, and reporting of research.
Per the principle of access:
4. Trials involving pregnant adults should be designed to include pregnant adolescents unless exclusion is strongly justifiable;
5. Age alone should not determine inclusion; decisions should rely on scientific rationale, public health priorities, and cultural context;
6. Post-trial access to therapeutics must be ensured.
Per the principle of protection:
7. Exclusion harms must be considered during study reviews;
8. Innovative study designs, such as phased inclusion, should be utilized where safety concerns would typically result in exclusion;
9. Study design should consider what specific data are needed to determine safety among pregnant adolescents.
Conclusions/Next steps: Pregnant adolescents require earlier and intentional inclusion in research to ensure timely access to the benefits of advancements in HIV treatment and prevention. Adopting these recommendations will support their ethical inclusion in research, promote responsible study design, ensure access to appropriate therapies, and improve health outcomes for both pregnant adolescents and their children.

OAD0204

We fear the day this bill is passed: The Criminalization of LGBTQ+ and its effect on public health efforts in Ghana

N.A. Acheampong[1], E.O. Ankrah[1]
[1]Ghana AIDS Commission, Research, Monitoring and Evaluation, Accra, Ghana

Background: The criminalization of lesbians, gay, bisexual, transgender, and queer (LGBTQ+) individuals remains a global issue with discriminatory laws, stigma and violence affecting their well-being. Health and human rights. Ghana is currently in the process of criminalizing LGBTQ+. A bill proscribing LGBTQ+-related activities was proposed to the parliament of Ghana in 2021. The bill proposes to promote proper human sexual rights and family values whiles proscribing all
LGBTQ+-related activities. The bill as it stands now prohibits all forms of advocacy for LGBTQ+. Thus making it illegal to provide HIV prevention services to LGBTQ+. The prevalence of HIV in Ghana is 1.3%, compared to 18.1% among men who have sex with men (MSM). We sought to investigate the effects of LGBTQ+ criminalization on HIV prevention and treatment efforts in Ghana.
Description: We elicited respondents' perceptions of the effect the bill will have on MSM and HIV-related activities in May 2024. We conducted 26 semi-structured in-depth qualitative interviews with peer social networks of MSM within Greater Accra Region. A thematic analytical framework was used to analyze audio recordings.
Lessons learned: The major findings indicated that MSM will be less willing to access HIV prevention services from drop-in centers due to fear of being arrested. It was indicated that stigma and discrimination currently discour-

age the majority of MSM from accessing HIV prevention services. Further criminalization of LGBTQ+-related activities will worsen the situation. Respondents also reported that the majority of MSM have gone underground out of fear of penalization due to their
sexual behavior. This poses a challenge for public health organizations to implement targeted intervention and outreach programmes for MSM.

Conclusions/Next steps: Laws criminalizing all forms of LGBTQ+ advocacy can fuel the HIV epidemic as they dissuade MSM from seeking treatment. Penalization of same-sex intercourse also contributes to a cycle of stigma and discrimination.
Such a hostile legal and social environment will exacerbate mental health issues among LGBTQ+ individuals, leading to higher rates of stress, anxiety and depression. The criminalization of LGBTQ+ in Ghana will significantly impact the country's HIV response.

OAD0205

New HIV diagnoses, social determinants of health, and systemic racism by US region 2013 to 2021

C. Garrett[1], Z. Li[2], H. Xia[1], B. Olatosi[3], X. Li[1], S. Qiao[1]
[1]University of South Carolina, Health Promotion, Education, and Behavior, Columbia, United States, [2]Penn State, Geography, University Park, United States, [3]University of South Carolina, Health Services Policy and Management, Columbia, United States

Background: The social determinants of health (SDOH) and systemic racism are drivers of health inequities but remain under investigated in relation to HIV acquisition across geographic regions.
We aim to assess the effect of SDOH inequities and systemic racism on new HIV diagnosis rates across the five major regions of the United States.

Methods: Publicly available data (2013-2021) from AIDSVu and ACS were merged using unique, county-level FIPS codes (i.e., geographic identifier). County-level data were extracted and aggregated to the regional level. A generalized estimation equation model was run, within each region, to explore the associations between the SDOH, systemic racism, and new HIV diagnoses across time. Variables included in the final model were age group among men; race/ ethnicity; poverty; less than a high school degree; no insurance coverage; and measures of residential segregation: Gini, Delta, Spatial Proximity Index.

Results: Overall, 3,013 counties across the United States were included in the analysis (i.e., Deep South=712, South=636, North=237, West=398, Midwest=1,030). Prior to the COVID-19 pandemic, county-level rates of new HIV diagnoses were highest in the Deep South, declining in the North and South, and rising in the West. New diagnoses fell in all regions during the pandemic (2019-2020), reflecting service interruptions, and have since began rising (2021), nearing pre-pandemic levels.
By region, counties with a higher proportion of men aged 35-54 (Deep South: IRR=1.07, West: 1.06, Midwest: 1.14, North: 0.96; $p \leq 0.05$) and Black populations (Deep South: 1.45, South: 1.46, North: 1.17, West: 1.49, Midwest: 2.62; $p \leq 0.001$) were associated with higher rates of new HIV diagnoses. Systemic racism was found to be positively associated with new HIV diagnoses in all regions but the Midwest. Two interaction terms were found, Black x Delta (Deep South: 1.05, West: 1.28, North: 0.92; $p \leq 0.01$) and Poverty x Gini (Deep South: 0.91, South: 0.89, Midwest: 0.65, North: 1.08; $p \leq 0.001$).

Conclusions: These findings reflect regional patterns of interplay between SDOH, systemic racism, and new HIV diagnoses. Overall, these findings inform regionally tailored public health efforts that address health disparities and systemic racism due to their effect on new HIV diagnoses.

OAD03 Innovative community approaches to HIV prevention, care and rights

OAD0302

Community-based participatory research analysis with transgender individuals as peer research associates in a qualitative study on female sex workers' health and rights in Argentina

I. Aristegui[1], E. Panizoni[1], V. Zalazar[1], N. Cardozo[1], M. Duarte[1], S. Fabian[1], R. Acuña[1], C. Serrao[1], M. Loufty[2], M. Romero[3], G. Orellano[4], M.I. Figueroa[1], P. Cahn[1], S. Walmsley[5], A. Duran[6], V. Fink[1], MAS por Nosotras Study Group
[1]Fundacion Huesped, Research Department, Buenos Aires, Argentina, [2]University of Toronto, Women's College Hospital, Toronto, Canada, [3]Asociación de Travestis, Transexuales y Transgénero de Argentina, Research Department, Buenos Aires, Argentina, [4]Sindicato de Trabajadorxs Sexuales de Argentina, Buenos Aires, Argentina, [5]University of Toronto, University Health Network, Toronto, Canada, [6]Ministry of Health, Coordination of Sexual Health, HIV and Sexually Transmitted Infections, Buenos Aires, Argentina

Background: The DEPICT Model is a collaborative, inclusive qualitative health research analysis approach integrating community and researcher perspectives to inform health research. This study aimed to describe the adaptation and benefits of the DEPICT model with the transgender community in the context of „MAS por Nosotras," a project on the sexual and reproductive health of female sex workers with and without HIV in Argentina after COVID-19 pandemic.

Methods: We adapted and followed the six sequential steps of the DEPICT Model (Dynamic reading, Engaged codebook, Participatory coding, Inclusive reviewing, summarizing categories, Collaborative analysis, and Translating). We analyzed twenty-four interviews conducted with policymakers and key actors at local and national levels to explore perceptions of access to healthcare and financial aid during and after COVID-19 pandemic using Monitoring of Results for Equity (MoRES) and Conservation of Resources Theory (COR) frameworks.

Results: Six steps were adapted and one added:
1. Training and organization: in methodology analysis of DEPICT for the social researchers (SR) and peer research associates (PRA), ensuring the approach is understood. We organized two pairs, one SR and one PRA for each.
2. Dynamic reading: team members reading the transcripts with an open mind, actively engaging, asking questions, identifying themes, and linking ideas.
3. Engaged codebook selection: selecting the MoRES and COR frameworks.
4. Participatory coding: analyzing two/three daily interviews to complete the twenty-four transcripts.
5. Inclusive reviewing and summarizing categories: SR and a third researcher harmonizing summaries.
6. Collaborative analyzing: results analysis and incorporation into policy briefs to amplify their impact.
7. Translating: Performing a Deliberative Dialogue to disseminate and translate the knowledge into concrete actions.

Benefits included a collaborative learning environment, strengthening the defense of community values, empowering teamwork, facilitating implementation, and improving research rigor.

Conclusions: Adapting the DEPICT Model to the transgender community highlighted the potential of participatory approaches in addressing complex health and social challenges. Fostering collaboration between researchers and PRAs, this model enhanced analysis rigor while empowering the community.

Incorporating a deliberative dialogue ensured research findings were translated into actionable policies, ensuring that the voices and needs of vulnerable populations were central to decision-making processes.

OAD0303

Unlocking success: recruitment and retention of CHWs for effective HIV prevention in West Virginia

H. Arnold[1], T.A. Young[1], J. Lucas[1]
[1]Community Education Group, Lost City, United States

Background: The opioid crisis has increased HIV outbreaks from injection drug use in West Virginia. In response, the Community Health and Mobilization Prevention Program (CHAMPS) fostered a network recruitment model addressing the crisis in hard-to-reach areas. CHAMPS recruited individuals with histories of substance use and incarceration while serving socially and geographically isolated populations. This approach expanded access to education, resources, and peer education, strengthening community resilience.

Description: CHAMPS was established in Washington, D.C., by the Community Education Group (CEG) to address health disparities faced by communities of color. Training 150+ community health workers (CHWs), screening 10,000+ for HIV and 5,000+ for HCV annually, achieving a 90% linkage and retention rate. CEG adapted CHAMPS to address underserved and geographically isolated Appalachian communities. By incentivizing CHAMPS graduates for referrals, CHAMPS recruited, trained, and retained BIPOC individuals, former substance users, and the formerly incarcerated. Notably, 35% of all CHAMPS graduates were recruited by earlier participants, highlighting sustainability.

Participants graduated:	185
% Participants graduated:	89%
% Grads w/ history of substance use:	53%
% Grads identifying as female:	69%
% Grads identifying as BIPOC:	35%
% Grads w/ history of incarceration:	41%

Recruitment efforts prioritize areas with the highest overdose mortality rates, strategically placing graduates in communities most vulnerable to HIV outbreaks. Utilizing graduates' social networks as a recruitment strategy has facilitated high participation in outreach, with an ~82% retention rate. Graduates complete a comprehensive 147-hour CHW paid training program, including 22+ hours of specialized HIV education, equipping them with the knowledge and skills to address the opioid crisis.

Lessons learned: CHAMPS successfully recruited 35% of graduates across four cohorts through alumni, prioritizing vulnerable individuals. CEG's model proved effective, with increased alumni referrals and strong graduate engagement in outreach within their already established but newly trained networks.

Conclusions/Next steps:

- Expand CHAMPS throughout Appalachia and areas with similar overdose and HIV risks.
- Leverage the CHAMPS workforce for future HIV interventions and outbreak response.
- Evaluate CHAMPS' long-term impact on HIV prevention and care in Appalachia.

OAD0304

Breaking barriers: a community-led policy to address structural determinants of HIV care in rural Ghana

N. Azebah[1]
[1]Ejura Municipal Hospital, Midwifery, Kumasi, Ghana

Background: Structural determinants such as stigma, geographic inaccessibility, and limited resources continue to impede equitable access to HIV prevention and care in rural Ghana. In Navrongo, an indigenous community in the Upper East Region, these barriers disproportionately affect adolescents, women, and key populations.

This policy intervention aimed to dismantle these barriers by integrating community voices into health system strengthening while fostering sustainable, inclusive HIV care practices.

Description: Between 2023 and 2024, this initiative leveraged a community-driven model to adapt UNAIDS-recommended frameworks into localized policy action. Key activities included:

1. Stakeholder Integration: Active involvement of people living with HIV, traditional leaders, and healthcare seekers in policy design and implementation.
2. Capacity Building: Comprehensive training for healthcare workers on person-first approaches, U=U strategies, and tackling intersectional stigma.

3. Mobile Access: Deployment of mobile clinics that provided HIV testing, counseling, and antiretroviral therapy (ART) initiation, reaching underserved households.
4. Cultural Alignment: Culturally tailored communication campaigns that emphasized the role of community cohesion in health outcomes.

Lessons learned: The intervention achieved measurable success:

- Uptake of Services: A 45% increase in HIV testing rates, with 98% of people living with HIV starting ART within 30 days of diagnosis.
- Stigma Mitigation: A 70% reduction in reported stigma among healthcare seekers, as assessed through community surveys.
- Community Empowerment: Traditional leaders and local organizations played pivotal roles in normalizing HIV discussions and sustaining intervention efforts.
- Policy Adaptability: The approach highlighted the value of flexible, locally informed policies that reflect specific community needs.

Challenges included limited financial resources and the need for scalable mental health integration.

Conclusions/Next steps: This initiative underscores the potential of community-led, culturally sensitive policies to transform HIV prevention and care in rural settings. By addressing structural determinants, this approach aligns with UNAIDS' 95-95-95 targets, bridging gaps in health equity for people living with HIV. Future plans focus on scaling this model to other underserved regions, expanding mental health services, and increasing investment in mobile health delivery systems. These findings affirm the critical importance of collaborative, inclusive policy-making to advance global HIV care objectives.

OAD0305

Community-driven approaches to reducing HIV stigma and enhancing care

A. Alitsi[1]

[1]*Tangaza University, Social Science, Nairobi, Kenya*

Background: Background: In Nairobi's informal settlements, young people face significant challenges related to HIV stigma and access to care. This project aimed to explore community-driven interventions to tackle these issues and improve well-being. The scope included a grassroots initiative from January 2022 to December 2023, focusing on adolescents and young adults (15-24 years). Objectives were to reduce HIV stigma, improve treatment adherence, and enhance community awareness and participation.

Description: Description: From January 2022 to December 2023, we launched a grassroots HIV education and support program in Nairobi's informal settlements. The initiative targeted adolescents and young adults (15-24 years) and involved peer education, training community health workers, and collaborating with local organizations. Key activities included interactive workshops, personalized counselling sessions, and distribution of educational materials. The program aimed to reduce stigma, improve treatment adherence, and enhance HIV knowledge.

Lessons learned: Peer education built trust, with over 150 workshops reaching about 3,000 young people. Training local community health workers led to a 25% increase in HIV treatment adherence. Collaborative workshops with local organizations increased community participation by 40%, enhancing HIV knowledge and attitudes. Interventions reduced stigma by fostering open discussions and creating safe spaces, leading to a 30% decrease in self-reported stigma.

Conclusions/Next steps: The findings highlight the significance of community-driven approaches in addressing social and behavioral barriers to HIV prevention and care.

The reduction in stigma, improved treatment adherence, and increased community participation demonstrate the effectiveness of these interventions.

Future Implications:

- Leverage Peer Education: Continue involving young peer educators to build trust and share accurate information.
- Involve Community Health Workers: Train and support local health workers to ensure ongoing, personalized care and support.
- Enhance Local Partnerships: Collaborate with local organizations to maximize resources and broaden the program's impact.
- Scale Up: Expand these initiatives to reach more informal settlements and other vulnerable communities.

Scaling up these community-driven initiatives could further reduce stigma and improve health outcomes for young people in informal settlements, significantly contributing to the overall goal of HIV prevention and care.

These findings underscore the importance of community involvement in achieving sustainable and impactful health interventions.

OAD04 Climate change, mobility and HIV

OAD0402

Health disparities among migrant transgender women: results from TransCITAR cohort study in Argentina

I. Aristegui[1], E. Panizoni[1], R. Caballero[1], E. Frontini[1], R. Acuña[1], M.C. Trejo[1], S. Fabian[1], N. Cardozo[1], C. Cesar[1], V. Fink[1], V. Zalazar[1], M.I. Figueroa[1], TransCITAR Study Group

[1]*Fundacion Huesped, Research Department, Buenos Aires, Argentina*

Background: Transgender woman (TGW) migrants faced increased health disparities, including stigma and limited healthcare access. Studies on migrants' health in Latin America remains scarce.

This study analyzed psychosocial and clinical factors associated with migration (international and internal) in TGW participating in the TransCITAR cohort study in Argentina.

Methods: From September/2019 to December/2022, TGW enrolled in TransCITAR prospective cohort completed baseline data on socio-demographics, HIV status, transgender-related stigma (TIS), depression (SCL-27 sub-scale), suicide attempts, substance use (tobacco use, sexualized drug use [SDU], alcohol [AUDIT-C]). Chi-squared tests with studentized residuals and ANOVA with Tukey's post hoc test were used to compare groups (international, internal/non-migrants).

Results: Among 423 TGW (Table 1), internal migrants comprised 46.80% (n=198), international 31.21% (n=132, 18.7% with permanent residency, 66.7% Argentine national ID), and non-migrants 21.99% (n=93). Internal migrants were younger (M=31.03±8.10 years) than international migrants (34.23± 9.16, p=006). HIV prevalence was highest in international (53.0%) and internal migrants (42.7%; p<.001). Sex work prevalence was 68.7% for internal migrants, 53.8% in international migrants, and 22.6% in non-migrants (p<.001). Unstable housing was more frequent in migrants (both 50.5%) than non-migrants (8.6%, p<.001). Depressive symptoms and suicide attempts were more frequent in internal migrants (p = .036, p=.013). Substance use, including tobacco (52.6%) and SDU (36.6%), was significantly higher among internal migrants (p<.001). Discrimination by security forces was more frequent among internal migrants (p=.003), and levels of transgender stigma in international migrants (p=.006).

Characteristics	Total n=423 (100%)	Non-migrants n=93 (21.99%)	International migrants n=132 (31.21%)	Internal migrants n=198 (46.80%)	p-value
Financial aid support, yes	190(45.0)	33(33,5)[a]	41(31.1)[a]	116(58.9)[b]	.000
Gender Identity Discrimination for security forces, yes	95(22.5)	15(16.1)[a]	21(15.9)[a]	59(29.8)[b]	.003
Transgender Identity Stigma score, M (SD)	6.05(7.37)	6.34(6.88)[a,b]	4.39(5.94)[b]	7.02(8.25)[a]	.006
Depressive Symptoms Sub-scale Score, M (SD)	0.55(0.63)	0.54(0.58)[a,b]	0.45(0.54)[a]	0.63(0.70)[b]	.036
Suicide Attempts, lifetime, yes	128(26.4)	30(21.6)[a]	28(20.9)[a]	70(33.2)[b]	.013
Tobacco use, yes	206(40.6)	53(38.1)[a]	42(31.3)[a]	111(52.6)[b]	.000
Sexualized drug use (last month), yes	159(36.6)	34(27.4)[a]	32(27.6)[a]	93(47.9)[b]	.000
Alcohol use score total (last month), M (SD)	3.56(2.87)	3.94(3.00)[a]	3.57(2.82)[a,b]	2.75(2.52)[b]	.004

Table 1. Descriptive statistics and comparison of sociodemographic, psychosocial, and clinical characteristics among migrants (international and internal) and non-migrants.

Note. [a,b,c] Categories that share the same letter do not have statistically significant differences in proportions within that row.

Conclusions: TGW migrants face significant health disparities, with international migrants showing high HIV prevalence and internal migrants exhibiting worse social and health outcomes. Tailored interventions are critical to improving the HIV continuum of care for international migrants.

OAD0403

HIV transmission risk, sexual and mobility behaviors among men, women, and female sex workers living with HIV in informal gold mining sites in Mali: the ANRS-12392 – Sanu Gundo study

L. Sagaon-Teyssier[1], M.A. Guindo[2], A. Kamissoko[2], F. Traoré[2], G. Maradan[3], F. Cavaro[1], F. Diallo[2], Z. Diarra[2], M. Mora[1], M. Bourrelly[1], M. Cissé[2], B. Dembélé Keita[2], B. Spire[1], M. Fiorentino[1]

[1]IRD, Aix Marseille Univ, Inserm, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France, [2]ARCAD Santé PLUS, Centre Intégré de Recherche, de Soins et d'Action Communautaire (CIRSAC), Bamako, Mali, [3]ORS PACA, Observatoire régional de la santé Provence-Alpes-Côte d'Azur, Marseille, France

Background: In Mali, circular migration, sex work, geographic isolation, and limited access to HIV care services and prevention information create a potential risk for HIV transmission in and from informal gold mining sites (IGMS). We aimed to compare vulnerabilities, mobility, behaviors, and HIV transmission risk among men, female sex workers (FSW), and non-FSW-women living with HIV at IGMS.

Methods: We used data from the ANRS-SANU Gundo trial conducted in 2019-2022 at the Kofoulatiè and Diassa IGMS. Baseline characteristics of participants (newly HIV-diagnosed), and ART adherence and HIV transmission risk six months after initiating ART were compared using Chi-square tests.

Results: Of the 149 PLHIV, 34% were men, 26% were FSW, and 40% were non-FSW women. Men and non-FSW-women were more likely to report condomless sex with HIV-negative/unknown-status spouses at baseline (31%, 55% *vs.* 13% in FSW, p<0.001) and to have no education (69%, 79%, *vs.* 16%, p<0.001). Non-FSW-women were more likely to have a precarious socioeconomic status (55%, *vs.* 33% in men, 16% in FSW, p<0.001) and to self-perceive at risk of transmitting HIV (34% *vs.* 13%, 5%, p=0.007). FSW reported 90[60; 90] sexual partners in the past month (*vs.* 1[0;1] in the other groups). They were more likely to be foreigners and non-residents of IGMS (79% *vs.* 2% in men, 15% in non-FSW women, p<0.001), to report sex under alcohol or drugs (26% *vs.* 2%, 1%, p<0.001), and condomless sex with HIV-negative/unknown-status occasional partners (18% *vs.* 3%, 2%, p=0.004). Six months after initiating ART (n=72), 36% of men and 30% of non-FSW-women were at risk of HIV transmission (i.e., uncontrolled viral load and condomless sex with any HIV-negative/unknown-status partner), compared to 18% of FSW (p=0.05). ART adherence was similar across groups.

Conclusions: Our findings highlight the urgent need to strenghten and tailor HIV care and information campaigns in IGMS in Mali, not only for key populations such as FSW, where the risk of transmission may primarily stem from high mobility, multiple partners, and substance use, but also for men and other women living with HIV, who are also at risk of transmission due to unprotected sex with their spouses and socio-economic vulnerabilities.

OAD0404

The perfect storm? Impact of climate change on HIV treatment access and adherence in Zimbabwe

R.W. Mukondwa[1], C. Christian[2], K. Takarinda[1], W. Mukuwapasi[3], T. Makoni[3], C. Aviles Guaman[2], A. Ayer[2], M. Hudson[2], N. West[2], K. Webb[1], P. Shete[2]

[1]Organization for Public Health Interventions & Development, Programs, Harare, Zimbabwe, [2]Center for Tuberculosis, University of California San Francisco, Health, California, United States, [3]Zimbabwe National Network of People Living with HIV, SIE, Harare, Zimbabwe

Background: People living with HIV (PLHIV) face compounded challenges due to climate change, such as drought, extreme temperatures, and water scarcity. These environmental stresses can interfere with HIV care adherence and exacerbate poor health outcomes.

We explored the effects of climate change on HIV care and treatment adherence in 15 districts of Zimbabwe.

Methods: We conducted a mixed method study. Quantitative analyses utilized retrospective cross-sectional data from client satisfaction surveys (CSS) among PLHIV (≥18 years) on antiretroviral therapy (ART) from November–December 2024. We summarized demographic characteristics, climate related disruptions and barriers to HIV care across 321 health facilities in 15 districts of Zimbabwe.

We conducted three focus group discussions (FGDs) with recipients of HIV care. These were audio recorded, transcribed, translated into English, then uploaded to Dedoose for coding using deductive and inductive approaches.

Results: Among 896 PLHIV in ART care completing the CSS, 587 (66%) were female. Median age was 45 years (IQR: 36-52 years). Overall, 665 (74%) reported observed changes in climate in their communities over the past 5 years;75% (n=497) of whom reported disruptions to HIV care due to climate change. Among those reporting disruptions to HIV care due to climate change, 432 (87%) reported adherence challenges related to lack of food, while 315 participants (63%) cited insufficient water access. Half of the participants identified transportation and financial barriers as critical issues affecting their ability to access HIV care;129 (26%) reported inability to safely store medication due to extreme temperatures.

Qualitative findings revealed that climate change exacerbated pre-existing vulnerabilities which impeded HIV care such as food insecurity, particularly, crop failures and livestock deaths, which disrupt household access to food and income required for accessing health facilities. Climate effects were cited as causes for taking HIV medications without adequate food or water, leading to side effects which decreased adherence.

Conclusions: Climate change create and exacerbate a cascade of challenges, such as food insecurity and water shortages, that reduce adherence to care for PLHIV. These challenges require integrated climate adaptation and resilience strategies within routine HIV care programs to improve health outcomes for PLHIV in climate vulnerable regions.

OAD0405

Investigating the associations between weather, climate and HIV outcomes in sub-Saharan Africa: a systematic review

M. Buczkowska[1], A. Trickey[2], G. Charnley[3,4], A. Gabot[1], G. Hutchings[1], C. Iwuji[5,6], I. Kelman[1,7]

[1]University College London, London, United Kingdom, [2]University of Bristol, Bristol, United Kingdom, [3]Global Health Resilience Group, Barcelona Supercomputing Center - Centro Nacional de Supercomputación, Barcelona, Spain, [4]Imperial College London, London, United Kingdom, [5]University of Sussex, Brighton, United Kingdom, [6]Africa Health Research Institute, DurbanSousou, South Africa, [7]University of Agder, Kristiansand, Norway

Background: The increasing frequency and intensity of extreme weather events in sub-Saharan Africa pose unique challenges for public health. While the potential links between weather, climate, and HIV outcomes have been hypothesised, evidence remains limited.

This systematic review aimed to explore existing studies and identify gaps in understanding how weather and climate influence sexual behaviours, HIV transmission, and HIV progression in sub-Saharan Africa.

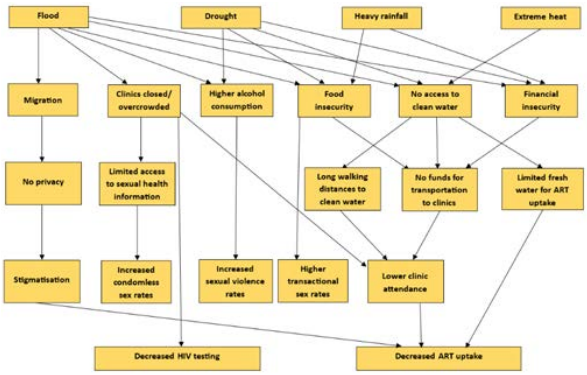
Methods: A systematic search of five databases was conducted to identify qualitative and quantitative studies examining weather and climate variables and HIV-related measures in sub-Saharan Africa. A narrative synthesis approach was used to summarise findings.

Studies were assessed for quality, and descriptive trends were identified. A framework representing causal pathways between weather, climate and HIV outcomes was developed, based on the results from the qualitative studies.

Results: Twenty studies (14 quantitative, six qualitative) were included. Drought was the most frequently studied exposure and was associated with increased HIV prevalence, higher transactional sex rates, and ART disruptions, especially in rural areas.

Heavy rainfall and extreme heat were associated with food insecurity, migration, and reduced healthcare access, further exacerbating HIV risks. Research gaps included limited longitudinal data, underrepresentation of children and key populations, and little focus on Western and Central Africa regions.

Variability in weather and climate metrics and reliance on cross-sectional designs limited the generalisability of findings.



Conclusions: Weather and climate might significantly impact HIV outcomes through indirect pathways such as food insecurity, migration, and healthcare access. Vulnerable populations, including rural women and adolescents face disproportionate risks.
Future research should prioritise longitudinal studies, standardised metrics for weather and climate variables, and targeted investigations into underrepresented regions and populations. Integration of climate resilience strategies into HIV programmes, investment in data collection systems, and policies addressing climate-driven health vulnerabilities are critical.

OAD05 "I will not lower my voice": Experiences from trans and gender-diverse communities

OAD0502

HIV prevalence, risks, and vulnerabilities of trans and gender diverse people in Saint Petersburg, Russia

M. Kandolsky[1]
[1]Independent Researcher, Yerevan, Armenia

Background: Trans and gender diverse people (TGD) play a critical role in the context of the HIV epidemic, yet significant knowledge gaps persist. These gaps include limited regional diversity and a particular scarcity of data from Eastern Europe, with a predominant focus on trans feminine individuals, leaving data on trans masculine and other gender diverse people notably sparse. So far no data on TGD living in Russia, country with the largest HIV epidemic in the region has been available.
This study represents the first exploration of Russian TGD individuals, focusing on Saint Petersburg, a city attracting TGD people from across the country.
Methods: We conducted a bio-behavioral surveillance study using respondent-driven sampling (N=300). Behavioral data was collected through face-to-face structured interviews, and capillary blood HIV tests were conducted following WHO protocols.
Results: Transgender men (45.9%) and non-binary individuals (32.4%) predominate within the group, while transgender women constitute only 14.6%, yet bear the entirety of HIV cases (HIV prevalence 14.1% (95% CI: 0% – 28.3%). Social transition is common, with 45.8% undergoing hormonal therapy. However, this poses health risks, as 60.0% lack medical supervision, and 45.6% use non-pharmacy drugs.
Overall, the study indicates low prevalence of risk behaviors among TGD individuals: needle sharing during hormonal injections is rare (0.6%), so as injection drug use (0.9%) and sexual activity (39.6% reported sex in the last 6 months).
Yet, coverage by HIV prevention (11.5%) and testing (61.8% ever tested) services remains insufficient. Despite often concealing their identity, TGD individuals encounter various forms of discrimination and violence, with a significant proportion exhibiting signs of depression (63.5%). The newly enacted law prohibiting gender transitions had a significant negative impact on the TGD lives: 65.1% reported deterioration in their psychological well-being, 22.4% accelerated gender transition, 39.3% began to seriously consider emigration.
Conclusions: While the overall HIV prevalence among TGD individuals in Saint Petersburg does not suggest a concentrated epidemic (1.9%), transgender women remain at heightened risk of HIV acquisition. Inadequate coverage by HIV prevention and testing services coupled with negative social changes in the country services underscores the urgent need for targeted interventions addressing the unique vulnerabilities of this population.

OAD0503

PrEP experiences and challenges among transgender women in the United States and Puerto Rico in the era of PrEP choice: findings from the ENCORE cohort

E. Cooney[1], T. Poteat[2], A. Radix[3,4], C. Beyrer[5], J. Schneider[6], M. Miller[7], V. Vannappagari[8], L. Ragone[8], A. Guignard[9], A. de Ruiter[10], S. Reisner[11], A. Wirtz[1], ENCORE Study Group
[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]Duke University School of Nursing, Durham, United States, [3]Callen-Lorde Community Health Center, New York City, United States, [4]Columbia University Mailman School of Public Health, Department of Epidemiology, New York City, United States, [5]Duke Global Health Institute, Durham, United States, [6]Emory University School of Medicine, Atlanta, United States, [7]Trans Solutions Inc., Indianapolis, United States, [8]ViiV Healthcare, Durham, United States, [9]ViiV Healthcare, Wavre, Belgium, [10]ViiV Healthcare, London, United Kingdom, [11]University of Michigan School of Public Health, Ann Arbor, United States

Background: Real-world data on PrEP choice and experience following approval of long-acting PrEP are limited. We sought to characterize the experiences of transgender women using PrEP in a large nationwide cohort.
Methods: From March 2023 to September 2024, we enrolled English and Spanish-speaking adult transgender women without HIV (laboratory-confirmed) into the ENCORE cohort. Data were collected via self-reported baseline surveys. Descriptive statistics characterized self-rated PrEP experience (0-100 scale with 100 indicating completely positive experience), challenges taking PrEP, and reasons for PrEP method selection. We assessed for differences by race, ethnicity, age, insurance, income, and geographic region.
Results: We enrolled 2,506 participants, 591 of whom had ever used PrEP (24%). At baseline, 439 used PrEP in the prior 6 months. Of these, 415 (95%) used daily oral, 15 (3%) received long-acting injections (LAI), and 9 (2%) used both. Participants rated their PrEP experiences positively: mean (standard deviation): 87(22); median (IQR): 100 (82-100). Ratings did not significantly differ by PrEP modality or sociodemographic characteristics. Commonly reported pill challenges were: difficulty remembering daily dose (28%),

side effects (25%), and assumptions about sexual behavior from others (22%). Reported LAI challenges were: injection site pain and/or side effects (38%), required clinical visits (33%), and assumptions about sexual behavior from others (21%).

Black and Latina participants were more likely than non-Hispanic White participants to report stigmatizing experiences related to their PrEP use including assumptions about their HIV status and number of partners and disapproval from partners.

Top reasons for choosing oral over LAI were: using pills before LAI FDA-approval (35%), healthcare provider recommendation (32%), and unaware of LAI (31%). Top reasons for choosing LAI over pills were: dosing frequency (79%), dislike pills (38%), and healthcare provider recommendation (21%).

Black participants were more likely to cite concern that the effectiveness of long-acting would decrease over time as a reason for choosing oral PrEP. Latina participants were more likely to cite greater confidence in pills as a reason for choosing oral PrEP.

Conclusions: Transgender women generally report positive PrEP experiences, but motivations and challenges may differ by race and ethnicity. Shared decision-making interventions may support effective PrEP use.

OAD0504

Stigma leads to substance use among MSM and transgender women living with HIV: insights from Vietnam

N.T. Minh[1,2], D. J. Colby[1], A. Bao[1], L.A. Do[3], T.C. Le[1], H.T. Tran[1], B.Q. Luong[4], P. Doan Thi Kim[5], K. Do Quang[6]

[1]Center for Applied Research on Men and Community Health (CARMAH), Ho Chi Minh, Viet Nam, [2]University of Medicine and Pharmacy at Ho Chi Minh City, Epidemiology, District 5, Viet Nam, [3]Pham Ngoc Thach University of Medicine, Public Health, Ho Chi Minh, Viet Nam, [4]HCMC Center for Disease Control, Epidemiology, Ho Chi Minh, Viet Nam, [5]Can Tho Center for Disease Control, Epidemiology, Can Tho, Viet Nam, [6]Galant Clinic, Ho Chi Minh, Viet Nam

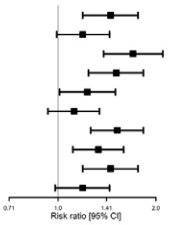
Background: Previous research on stigma as a driver of substance use among men who have sex with men (MSM) and transgender women (TW) living with HIV has been limited in establishing causality. We aimed to evaluate the association between stigma experiences and the subsequent initiation of opiates and amphetamine-type stimulants (methamphetamine, heroin, and ecstasy) in a prospective cohort of MSM and TW with HIV in Vietnam.

Methods: A community-based study was conducted in the Mekong Delta, Vietnam (2019–2022), involving MSM and TW with HIV who had no prior substance use. Five stigma dimensions—mockery, negative judgment, physical attack, sense of exclusion, and emotional/mental trauma—were assessed at baseline, and substance use initiation was evaluated after a follow-up period (median: 394 days). Univariable and multivariable Poisson models were used to estimate prevalence differences (PD), attributable risk (AR), and 95% confidence intervals (CIs).

Results: Among 504 participants, 76.0% were MSM and 24.0% were TW. By the end of the follow-up, 30.1% had initiated substance use (21.8% methamphetamine, 16.5% ecstasy, and 0.8% heroin). Overall, 66.8% of participants reported experiencing at least one form of stigma (57.7% sense of exclusion, 49.4% emotional/ mental trauma, 47.4% mockery, 45.8% physical attack, and 22.8% negative judgment). Physical attacks, sense of exclusion, and emotional/mental trauma were significantly associated with increased risk of substance use. Among MSM, stigma led to 14 new substance users per 100 annually (PD=0.14 [95% CI: 0.08–0.19]; AR=36.7% [24.8–47.1];). Among TW, it resulted in 18 new users per 100 annually (PD=0.18 [0.07–0.30]; AR=37.9% [16.0–54.1]).

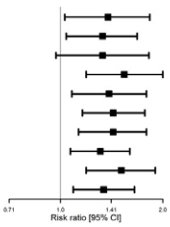
A. MSM (n= 383)

Stigma	Model	Risk ratio [95% CI]	p-value
Mockery	Model 1	1.45 [1.19 - 1.76]	<0.001
	Model 2	1.19 [0.99 - 1.44]	0.069
Physical Attacks	Model 1	1.70 [1.38 - 2.10]	<0.001
	Model 2	1.51 [1.24 - 1.83]	<0.001
Negative Judgments	Model 1	1.23 [1.01 - 1.50]	0.038
	Model 2	1.12 [0.93 - 1.34]	0.220
Sense of Exclusion	Model 1	1.52 [1.26 - 1.83]	<0.001
	Model 2	1.33 [1.11 - 1.59]	0.002
Emotional Trauma	Model 1	1.45 [1.19 - 1.76]	<0.001
	Model 2	1.19 [0.98 - 1.44]	0.075



B. Transgender women (n= 121)

Stigma	Model	Risk ratio [95% CI]	p-value
Mockery	Model 1	1.38 [1.03 - 1.83]	0.029
	Model 2	1.33 [1.04 - 1.68]	0.021
Physical Attacks	Model 1	1.33 [0.97 - 1.82]	0.080
	Model 2	1.54 [1.19 - 2.00]	<0.001
Negative Judgments	Model 1	1.39 [1.08 - 1.79]	0.011
	Model 2	1.43 [1.16 - 1.77]	<0.001
Sense of Exclusion	Model 1	1.43 [1.13 - 1.79]	0.002
	Model 2	1.31 [1.07 - 1.60]	0.009
Emotional Trauma	Model 1	1.51 [1.19 - 1.90]	<0.001
	Model 2	1.34 [1.09 - 1.65]	0.006



Conclusions: Stigma is a critical social determinant of health. Beyond its psychosocial toll, stigma drives harmful risk behaviors that undermine treatment adherence, exacerbate HIV transmission risks, and amplify health inequities among MSM and TW, necessitating the integration of stigma-reduction strategies into clinical practice and public health policy.

OAD0505

Exposure to violence among transgender women living with HIV in France, engaged or not in sex work: results from the national ANRS-14056 TRANS&VIH study

M. Fiorentino[1], A. Faye[1], M. Mora[1], R. Van Huizen[1], M. Bourrelly[1], G. Maradan[2], C. Berenger[2], F. Michard[3], Y. Yazdanpanah[3], A.F. Maresca[4,5], E. Rouveix[4], L. Balhan[6,7], M. Costa[6,7], D. Michels[7], L. Blanquart[8], G. Rincon[8], B. Spire[1], M. Annequin[1], the ANRS-Trans&HIV study group

[1]IRD, Aix Marseille Univ, Inserm, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France, [2]ORS PACA, Observatoire régional de la santé Provence-Alpes-Côte d'Azur, Marseille, France, [3]Service de Maladies Infectieuses, Hôpital Bichat - Claude-Bernard, APHP, Paris, France, [4]Service de Médecine Interne, UFR Paris Île-de-France Ouest, Hôpital Ambroise-Pare, Boulogne-Billancourt, France, [5]Service de Maladies Infectieuses et Tropicales, Hôpital Avicenne, APHP, Bobigny, France, [6]AIDES, Pantin, France, [7]Community-Based Research Laboratory, Coalition PLUS, Pantin, France, [8]ACCEPTESS-T, Paris, France

Background: Worldwide, stigma and violence experienced by transgender women (TGW) and by sex workers (SW), negatively impacting health and access to HIV care. This is the first national-level study investigating typologies of recent violence experienced by TGW living with HIV (TGWHIV), engaged or not in sex work, in France.

Methods: The ANRS-TRANS&HIV study was a national, cross-sectional, retrospective survey conducted in 2020-2022 among 536 TGWHIV recruited from 36 HIV care centers. Typologies of recent violence exposure were identified using latent class analysis based on 24 violence-related variables (by type and perpetrator), separately for TGWHIV-SW and non-sex workers (TGWHIV-nSW). We used multinomial logistic regression to assess factors associated with TGWHIV-SW typologies.

Results: Among the 501 participants with complete violence data, five violence typologies emerged: in TGWHIV-SW, "clients/street violence" (17%), "multiple perpetrators violence" (involving clients, passersby, police, colleagues, partners, family, and friends) (8%), and "low violence" (42%); in TGWHIV-nSW, "multiple perpetrators violence" (3%) and "no violence" (30%).

In TGWHIV-SW, "clients/street violence" was associated with antiretroviral treatment (ART) interruption for ≥2 days in the previous month (aOR: 1.9 95% CI [1.0–3.4]) and stimulant consumption (2.3[1.2–4.3]), compared to "low violence". "Multiple perpetrators violence" was associated with a lack of moral support (2.9[1.3–6.7]) and depression (4.2[1.9–9.2]). Both typologies of violence were associated with inadequate housing conditions (2.3[1.2–4.4]; 2.0[0.9–4.5]), daily cannabis use (4.4[1.8–10.9]; 3.1[0.9–10.7]), and engaging in transactional sex in public or outdoor locations (4.0[1.9–8.8]; 4.2[1.4–12.8]).

Conclusions: Whether or not involved in sex work, TGWHIV face multidimensional violence in France. Among TGWHIV-SW, this appears to be exacerbated by precarious housing and sex work conditions, with varying health implications. These include ART interruptions among those exposed to street violence in the context of sex work, and mental health issues among those subjected to violence by multiple perpetrators, including from their close social circle and the police. In a context of structural transphobia and sex work criminalization, ensuring equitable access to HIV care and mental health services for TGW is critical and inseparable from protecting their fundamental human rights and improving their socio-economic conditions.

OAD06 Harnessing technology: Digital health applications

OAD0602

Ai-powered preventive intervention for stigma and suicidal ideation in HIV self-management: development, evaluation, and user testing of the MARVIN chatbot's integrated mental health management module

S. Villanueva[1,2], Y. Ma[2,1], S. Achiche[1], A. Cadri[2], B. Lebouché[2]

[1]Polytechnique Montreal, Biomedical Engineering, Montreal, Canada, [2]Research Institute of McGill's University Health Center, Infectious Diseases and Immunity in Global Health (IDIGH) and Centre for Outcomes Research & Evaluation, Montreal, Canada

Background: Stigma and mental health challenges like anxiety and depression which are major concerns for people with HIV (PWH) can sometimes lead to self-harm and suicidal ideation. Our AI-powered MARVIN chatbot supports HIV self-management by providing knowledge, assisting with medication adherence. To address extreme user intentions effectively, we developed and incorporated a preventive intervention module.

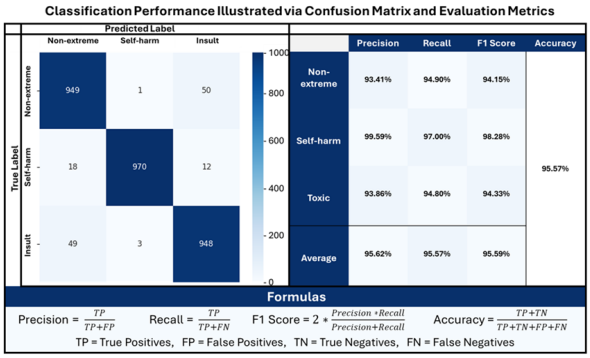
Methods:

1. MARVIN/ChatGPT Hybrid Module: Using the CO-STAR framework (i.e., providing Context, Objective, Style, Tone, Audience, and Response format), we prompt-tuned ChatGPT to classify message intent into self-harm, insult, or non-extreme (i.e., any other intent). We tested performance with three public hate speech datasets (hatespeechdata.com), MARVIN-user conversations, and a synthetic dataset (N=1000/class), evaluating precision, recall, F1 score, and overall accuracy. The algorithm was integrated into MARVIN.
2. Multidisciplinary Validation: Six testers (three Canadian PWH, a Chinese engineer, an Algerian engineer, and a French doctor; all male, based in Canada) tested MARVIN for two hours through 14 conversational scenarios without sharing sensitive data and completed a two-item questionnaire on clarity and satisfaction.

Results: With one-shot prompting, the hybrid module attained 97.00% and 94.90% for recall on self-harm and insult intent, respectively.

Overall accuracy reached 95.57%, with the remaining metrics shown in the figure below. The MARVIN-ChatGPT hybrid module successfully generated appropriate re-

sponses containing:
1. Emergency contact information for self-harm intents;
22. Messages guiding users to use stigma-free expressions for insult messages, and;
3. A response reviewed by a medical expert for a non-extreme intent.
All six male testers found MARVIN's responses to be clear and concise and were satisfied with the overall experience. However, one PWH participant suggested including links to additional resources.



Conclusions: Testing this anti-stigma/suicidal ideation module within MARVIN demonstrated its ability to detect extreme intents and deliver concise responses, highlighting AI-driven chatbots' potential in fostering virtual stigma-free self-management and mental health support for PWH.

OAD0603

"Superbees Awakened" - development of a digital game to enhance understanding of germline-targeting vaccine trials among communities and site staff in South Africa and India

J. Mukherjee[1], S. ul Hadi[1], P. Saha[1], K. Goyal[1], A. Baveja[2], F. Gonsalves[2], P. Sandbhor[3], T. Aurora[2], E. Landais[4], H. Makkan[5], S. Rawat[6], Y.W. Machira[7], K. Ondeng'e[7], Z. Ciko[8], A. Chauhan[2]

[1]International AIDS Vaccine Initiative Inc, Gurugram, India, [2]Quicksand Design Studio, New Delhi, India, [3]University of York, York, United Kingdom, [4]International AIDS Vaccine Initiative, Neutralizing Antibody Centre, San Diego, United States, [5]The Aurum Institute, Johannesburg, South Africa, [6]The Humsafar Trust, Mumbai, India, [7]International AIDS Vaccine Initiative Inc, Nairobi, Kenya, [8]International AIDS Vaccine Initiative Inc, Cape Town, South Africa

Background: With advances in rational HIV vaccine design, discovery medicine vaccine trials (DMVTs) involve testing of complex scientific hypothesis, require intensive clinic visits and often include invasive sampling. Thus, it becomes critical for trial participants, participating communities and site staff to understand the scientific rationale behind these trials to enhance awareness, motivation and trust. To address this unmet need, IAVI partnered with Quicksand to develop digital games that explain germline targeting concepts using behavioral science, gamification and interactive digital design.

Description: We conducted 10 co-creation workshops with HIV vaccine scientists (n=5), clinical trial site staff (n=10) and community representatives (n=10) to (a) understand information needs; (b) identify metaphors; (c) develop sequential story line (d) devise game play. Through immersive engagement and iterative prototyping, a 4-module digital game "Superbees Awakened" was developed to (1) elaborate the human immune system and role of a research lab (*Exploring the "Weza Forest" and "Forest Health Centre"*) (2) explain non-conventional sampling like large blood draws, leukapheresis and fine needle aspirations (*Scan the large, filtered and focused samples*); (3) identify conserved HIV epitopes and design whole protein or mRNA delivered immunogen (*Spot the "Common Point"*); and (4) explain B-cell maturation, prime-boost vaccine schedules and germline targeting (*Train and target*). Post-game discussions enabled players to link game metaphors with HIV science.

Lessons learned:

- When scientific information is conveyed to communities through relatable stories and culturally relevant metaphors, it **facilitates self-driven exploration of scientific concepts** leveraging indigenous knowledge as opposed to prescriptive top-down information sharing.
- The self-discovery of science is less intimidating and **leads to greater self-confidence and higher retention of information**.
- The metaphors need to be carefully identified and vetted by scientific experts to avoid miscommunication, thus **balancing scientific accuracy and clarity of content**.
- Digital modules should **bring together variety of game types** (puzzles, action, adventure, skill-based) rather than a singular experience to cater different learning styles.

Conclusions/Next steps: Digital gamification represents an impactful strategy for simpler, clearer and relatable science communication relevant to communities. Given the broad reach and high familiarity of digital technologies among youth, this game serves as a complementary tool to routine information, education and communication methodologies.

OAD0604

Efficacy of a clinic-integrated HIV prevention app "JomPrEP" among men who have sex with men in Malaysia: preliminary findings of a randomized control trial

S.H. Sujan[1], J.A. Wickersham[2], E.E. Hui[3], K. Paudel[1], K. Gautam[1], I. Azwa[3], P. Phiphatkhunarnon[4], R. Shrestha[1]
[1]University of Connecticut, Storrs, United States, [2]Department of Medicine, Yale School of Medicine, New Haven, United States, [3]Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, [4]Love Foundation, Chiang Mai, Thailand

Background: Men who have sex with men (MSM) are disproportionately affected by HIV. In Malaysia, where MSM face high levels of stigma and discrimination, including in healthcare settings, mobile health platforms offer promising opportunities for advancing HIV prevention. Thus, to scale up HIV prevention endeavors among this vulnerable group, we created a clinic-integrated HIV prevention app called "JomPrEP" which provides a virtual platform for them to engage in HIV prevention services. In collaboration with the local clinics in Malaysia, JomPrEP offers a number of HIV prevention (ie, HIV testing and pre-exposure prophylaxis [PrEP]) and other support services without having to interface with clinicians.
This study aimed to measure the efficacy of the JomPrEP app to increase HIV testing and PrEP uptake among MSM in Malaysia
Methods: We conducted a randomized controlled trial on 268 MSM (intervention group=134, control group=134) in Malaysia. Participants were recruited online from November 2023 to September 2024. Participants were randomly assigned to either access the JomPrEP app or receive standard healthcare services.
Measures like demographics, HIV and STI testing history, PrEP uptake, sexual behavior, drug and alcohol use, stigma, and depression were evaluated at baseline and 3, 6, and 9-month periods.
Results: Participant's mean age was 28.8 (5.7) years. Overall, the intervention group showed a 26.8% increase in HIV testing and 5.9% increase in PrEP uptake compared to control group. Of the intervention participants, 43.3% initiated PrEP, with 36.6% opting for on-demand PrEP and 6.0% choosing traditional PrEP.
Interestingly, HIV testing had significantly increased over time in both groups (F (2,711) = 81.38, p < 0.001). Participants at 3 (OR = 16.83, 95% CI, 8.85–32.02) and 6 months (OR = 7.90, 95% CI, 4.13–15.12) showed higher odds of HIV testing than baseline.
In addition, compared to the control group, participants in the intervention group had significantly higher odds of PrEP uptake at 3 months (*OR*=2.32, *95% CI* 1.00–5.37) and 6 months (*OR*=2.99, *95% CI* 1.26–7.13).
Conclusions: Our study demonstrated that the JomPrEP app is an effective tool for increasing HIV testing and PrEP uptake among MSM in Malaysia as compared to the standard of care.

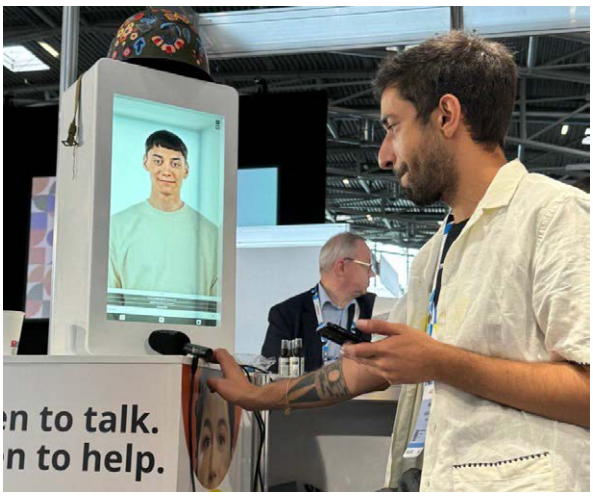
OAD0605

TWIIN: a digital assistant for enhancing health access among key populations

M. Malakhova[1], O. Marouniak[1]
[1]Alliance for Public Health, Kyiv, Ukraine

Background: TWIIN is an AI-powered digital assistant designed to address barriers faced by key populations, such as people who use drugs (PWUD) and men who have sex with men (MSM). It provides 24/7, anonymous support for HIV prevention, mental health, and harm reduction, aiming to reduce stigma and improve service access.

Description: Piloted in Ukraine, TWIIN integrates artificial intelligence with culturally relevant digital humans to provide tailored information and connect users to essential services. Focus areas include HIV prevention, harm reduction, sexual health, and mental health.
During the pilot, over 5,000 unique users generated nearly 39,000 sessions. To maximize outreach, TWIIN utilized social media campaigns, NGO partnerships, and collaborations with community representatives. Anonymity and accessibility were prioritized, especially in wartime conditions.



Lessons learned: Feedback showed high satisfaction, with 85% rating TWIIN as 4-5/5 and 87% recommending it. Piloted targetting PWUD and MSM we observed user experience from various perspectives. Onboarding over 400 doctors and 70 NGOs supported integration into existing services. Challenges included response delays and contacts ipresentation, which are being addressed through system improvements. The pilot emphasized the importance of cultural relevance, user anonymity, and iterative feedback to refine the platform.
Conclusions/Next steps: TWIIN has shown great promise in expanding health access for marginalized populations, particularly in challenging settings. Plans include enhancing response times and developing additional modules. In 2025, TWIIN will launch in Moldova and Georgia, with localized adaptations to meet country needs. This scalable, digital health innovation offers a replicable model for addressing HIV prevention, mental health, and harm reduction globally.

OAE01 Advancing equity in the HIV response: Key populations, human rights and quality intervention

OAE0102

Improving the health and human rights of PLHV and key populations in Myanmar: Community Feedback Mechanism project by Puu Paung Swann Saung Myanmar (2021-2024)

K.K. Win[1], E.T. San[2], K. Taung[3]
[1]Puu Paung wann Saung Myanmar / MINA, Central Steering Committee Member, Yangon, Myanmar, [2]Puu Paung wann Saung Myanmar / MINA, Project Officer, Yangon, Myanmar, [3]Myanmar Interfaith Network on AIDS_MINA, Secretary, Yangon, Myanmar

Background: Myanmar established Community Feedback Mechanism (CFM) in 2014 by the leadership of Community Network Consortium on HIV which consists of (8) HIV National Networks. The CFM focused on issues related to PLHIV , KP and implemented through networks collaborating with target groups in townships. The PPSSM is one of the network implementing CFM in six townships since 2021.
Description: CFM collects feedback related to health services, law and justice issues, workplace and socially related issues. The feedback were gathered through MyRights Application and then directed to relevant townships for further action. At the local level, local CFM committees, with the guidance and support of National AIDS Program (NAP), oversee the activities, verify the cases and decide how to proceed with concerns. Supports such as legal assistance, emergency support, and counseling are provided as necessary to resolve these issues.
Lessons learned: Since 2021, a total of (449) cases were received via MyRights Application. The Key Population classification on the total cases of (n=449), the cases were classified as 369 (82%) were PLHIV, 57 (13%) were FSW, 22 (5%) were MSM and 1 (0.22%) were PWID. Of which 10 cases (2%) were invalided and 439 cases (98%) were approved. Among the approved cases of (n=439), 358 cases (82%) were resolved and the rest were unresolved. The cases were identified as follows: Healthcare related - 30 cases (7%), Law and Justice Related – 20 (5%), Socially Related - 358 (82%), and Workplace Related - 31 cases (7%). The resolved cases were 358 (80%), unable to resolved case were 79 (18%) and 2 (0.4%) of cases were in process of case handling by CFM. During this period, a total of 57 (13%) cases were provided 55 (12.5%) for Nutrition Support and 2 (0.5%) for Referral Transportation Allowance to health facility sites as the emergency support of CFM by PPSSM.
Conclusions/Next steps: Since its inception, the project has proven to be the most successful community-led system which significantly impacted the development of successful communication strategies and monitoring of HIV-related services. Many users have provided positive feedback and praised the service for its accessibility and the quality of information and guidance offered.

OAE0103

Leaving no one behind: implementation of informal female sex workers intervention for fast-tracking HIV case detection in Andhra Pradesh: a sustainable, scalable program experience from India

J. Williams[1], A. Vijayaraman[1], P. Venkateswara Rao[1], B. Aparna[1], K. Priya[1], R. Shanmuganathan[1], Y. Kameswara Prasad[2]
[1]The Voluntary Health Services, Chennai, India, [2]Andhra Pradesh State AIDS Control Society, Andhra Pradesh, India

Background: In the rapidly changing sex work milieu, there has been a major shift in the traditional forms of soliciting sex by female sex workers resulting in emergence of more discreet spaces, working under network operators (NWOs) and are referred as informal female sex workers (iFSWs). Based on our implementation experience, the iFSWs are part-time sex workers and are most often engaged as home makers or does petty work. The fact that these iFSWs are not covered by HIV helps them in seeking confidentiality and secrecy, but poses multiple risks and vulnerabilities, including HIV.
Description: We conducted community listening exercise that helped discover the characteristics and needs of iFSWs and the role of NWOs in reaching iFSWs. A comprehensive package of services were offered ranging from HIV/STI education, testing and treatment, condom distribution, TB screening and treatment, NCD services, mental health counseling, addressing violence faced by iFSWs, linkages with government departments for social protection, etc. The primary goal is to improve the health and well-being of iFSWs and aid in achieving HIV epidemic control in the Andhra Pradesh state.
Lessons learned: During May 2022 to September 2024, 4,039 iFSWs were reached and all of them were provided HIV education. HIV testing was done for 66.94% (2,704), of which 10.1% (274) were detected positive and 94.5%

(259) were initiated on ART. The mean age of iFSWs is 29.3 (±5.05) years, 79.6% (3,216) of the iFSWs possess 1-2 years of experience in sex work. Around 93% (3,768) were married and majority of them 87.2% (3,521) were living with their spouse. Most of the iFSWs (93.9% (3,795)) solicit sex through NWOs. Around 20.6% (833) migrate for sex work and majority of them (53.7%, 282) migrate for a week's time.

Conclusions/Next steps: Given the secretive nature of sex work and being outside of the radar of routine HIV interventions, the importance of implementing programs targeting iFSWs through NWOs cannot be over-emphasized. The iFSW intervention strategy to reach the unreached KPs at early detection of HIV, can be sustainable and scalable by integrating it with the existing targeted intervention.

OAE0104

Survival is not enough: enhancing mental health integration in key population HIV focused programming in Kalangala islands post Uganda's Anti Homosexuality Act 2023

E. Jjemba[1], H.D. Kayemba[2], S. Kobugabe[1], S.P. Ssonko[3], C. Koote[4]
[1]Action for integrated for Sustainable Development (AISDA), Health, Kampala, Uganda, [2]Action for integrated for Sustainable Development (AISDA), Prevention, Kampala, Uganda, [3]Smart Children Africa, Monitoring and Evaluation, Kampala, Uganda, [4]Action for integrated for Sustainable Development (AISDA), Care and Treatment, Kampala, Uganda

Background: The enactment of Uganda's Anti Homosexuality Act (AHA) in 2023 intensified stigma and discrimination among Key Population (KPs) especially gay and other men who have sex with men and Transgender. Although efforts in HIV treatment have improved survival rates, many KPs in Kalangala islands have continuously experienced profound mental health challenges including anxiety, depression, suicidal thoughts which undermine ART adherence and treatment outcomes. In response to this outcry, Action for Integrated Sustainable Development (AISDA) through its KP program embarked on integrating mental health support to KPs to enhance ART adherence and mental wellbeing by addressing stigma and discrimination in the aftermath of AHA. This followed attendance of one of its staff at AIDS 2024 and gained insights on integrating mental health in KP programming.

Description: A self-reporting questionnaire with 20 questions was designed and administered to KPs by trained social workers during home visits and clinic days to screen for mental health issues. Social workers assessed responses to specific questions to identify immediate risks. Scores on suicidal thoughts triggered immediate interventions employing safety planning approaches including referrals for specialized care. Recognizing geographical isolation of islands, tele-mental health support was integrated through follow-up calls and virtual counselling sessions. Regular home visits were conducted by social workers to provide holistic support to KPs including monthly intensive adherence counselling to non-suppressing KPs, post disclosure counselling and psychosocial support.

Lessons learned: Mental health integration improves ART adherence and viral load suppression; Adherence improved from 75% to 92% and viral load suppression increased by 15% since August to December 2024 among 288 KPs.

Tele-mental health support enhances access to care in island settings. 85% of clients flagged for follow-up utilized virtual sessions with 80% reporting satisfaction and reduced symptoms after engagement.

Peer-led support groups create safe spaces and reduce stigma; self-reported cases of discrimination reduced by 40% and participants expressed increased confidence in accessing care.

Involvement of community leaders in the project fostered acceptance in communities.

Conclusions/Next steps: Integration of mental health support for KPs post AHA 2023 has fostered purposeful living, enhanced mental wellbeing significantly improving HIV treatment outcomes, underscoring the need for holistic stigma-free care.

OAE0105

Making HIV care affordable: cost-effectiveness of interventions for refugee women and girls in Nakivale refugee settlement, Southwestern Uganda

M. Umar[1], N. Zahara[2]
[1]Mbarara University of Science and Technology, Medicine and Surgery, Mbarara, Uganda, [2]International University of Africa, Medicine and Surgery, Khartoum, Sudan, the

Background: Refugee women in Nakivale, face disproportionate risk of acquiring HIV due to combination of social and structural challenges. High levels of poverty, stigma, limited access to healthcare services exacerbate their vulnerability. Despite global progress in HIV prevention and care, interventions in refugee contexts fail to address unique needs of these populations, regarding affordability and accessibility. Resource-constrained settings like Uganda lack evidence on cost-effectiveness of localized strategies, hindering informed decision-making and sustainable program design.

This research addresses gaps by evaluating costs, affordability, and effectiveness of tailored HIV interventions in Nakivale, providing critical insights to guide resource allocation, policy formulation.

Methods: Cost-effectiveness analysis was conducted between January-June 2024, focusing on three interventions: mobile HIV testing counseling services, women's economic empowerment programs, community-led stigma reduction campaigns. Cost data were collected from healthcare providers, implementing partners, local organizations, while effectiveness measures included increased HIV testing uptake, improved linkage to care, reductions in new acquisitions. Data were analyzed using incremental cost-effectiveness ratio (ICER) framework in Uganda Shillings (UGX) from community and provider perspectives. Affordability was assessed by comparing intervention costs to household and community income levels.

Results: Mobile HIV testing services were most cost-effective, with an ICER of UGX 185,000 per additional HIV diagnosis compared to standard facility-based testing. Women's economic empowerment programs reduced new HIV acquisitions by 18% over six months, with an ICER of UGX 440,000 per acquisition averted.
Community-led stigma reduction campaigns significantly increased HIV testing uptake (by 34%) and linkage to care (by 27%), with an ICER of UGX 310,000 per additional client linked to care.
Affordability assessments indicated that while these interventions are effective, their sustainability remains heavily reliant on external donor funding, as household income levels within the settlement are insufficient to cover implementation costs.
Conclusions: The study highlights that mobile HIV testing, economic empowerment, stigma reduction interventions are cost-effective and impactful in reducing HIV-related risks in Nakivale Refugee Settlement. Achieving long-term affordability requires integration of these interventions into Uganda's health financing systems and continued support from development partners.
These findings provide critical guidance for policymakers and implementers to design scalable, cost-effective, locally sustainable HIV programs in refugee contexts.

OAE02 No retreat, no surrender: Sustaining the HIV response in times of turmoil

OAE0202

Domestic resource mobilisation for HIV in Africa: a comparative analysis of country policies and practices

R.M. Ochanda[1], A. Mwangomale[2], A. Banda[3], A. Ngwenya[4], J. MacWilliam[5], W. Chikanya[6], S. Shilagwa[7], S. Wambua[8], K. Mutale[9], I. Tandolkar[5], S. Malunga[8], M. Luba[10], V. Adula[11]
[1]AVAC, Policy Advocacy, Ngong, Kenya, [2]Sikika, Policy Advocacy, Dar es Salaam, Tanzania, the United Republic of, [3]COMPASS, DRM, Lilongwe, Malawi, [4]Pangaea Zimbabwe, COMPASS, Harare, Zimbabwe, [5]AVAC, Policy Advocacy, New York, United States, [6]ZiCHIRe, Policy Advocacy, Harare, Zimbabwe, [7]Focus for the Future Generation, Policy Advocacy, Dar es Salaam, Tanzania, the United Republic of, [8]Key Population Transnational Collaboration, Policy Advocacy, Nairobi, Kenya, [9]Key Population Transnational Collaboration, Policy Advocacy, Lusaka, Zambia, [10]AVAC, Policy Advocacy, Lilonge, Malawi, [11]Consolation East Africa, Nairobi, Kenya

Background: This research explored how seven African countries are adapting their Domestic Resource Mobilization (DRM) policies and strategies for HIV/AIDS in response to potential declines in international funding. The study analyzed the challenges faced, prioritized strategies, and innovative approaches adopted.

Methods: This study examined Domestic Resource Mobilization (DRM) strategies for HIV/AIDS in seven African countries: Nigeria, Zambia, Ethiopia, Malawi, Kenya, Tanzania, and Zimbabwe. Employing a mixed-methods approach, it analyzed secondary data, including academic literature, grey literature (policy documents, and reports), and each country's DRM strategies. Thematic analysis identified key themes such as common trends, challenges, best practices, and the impact of DRM on national HIV/AIDS outcomes. Country selection criteria included receiving support from PEPFAR or the Global Fund and having established DRM policies. Focus Group Discussions (FGDs) in select countries corroborated findings from the secondary data analysis.
Results: While international funding remains crucial for HIV responses, its reliance varies significantly. PEPFAR data reveals that only one country contributed over 60% of its HIV funding from internal sources in FY 2024, while others contributed between 1% and 15%. UNAIDS data shows international health assistance persistently plateaued at annualized rate of 1.2% since 2012. This highlights the urgent need for countries to prioritize self-financing strategies for their health and HIV programs.
Common DRM strategies found included public-private partnerships, earmarked taxes, health insurance, community contributions, integrated financing mechanisms, and sector-wide approaches. Emerging innovations include service integration, leveraging retrieved illicit funds for health, social contracting, utilizing technology, and adopting innovative financing mechanisms. Other strategies include concessionary loans, debt conversions, and risk pooling.
Key weaknesses hindering effective DRM include constrained budgets due to limited fiscal space, significant human resource for health (HRH) gaps, mismanagement of funds, and weak health systems. While some countries have dedicated HIV or health financing policies, others lack such frameworks.
Conclusions: This research underscores the critical need for specific policies and practices to strengthen Domestic Resource Mobilization (DRM) for HIV/AIDS in Africa. Its findings aim to guide policymakers and stakeholders in designing and implementing more effective and sustainable strategies, ultimately contributing to the global goal of ending the HIV/AIDS epidemic by 2030.

OAE0203

From donor to domestic HIV financing in sub-Saharan Africa: a review of transition models, challenges, and success factors (2015-2024)

P. Agboola[1], B. Aderounmu[2]
[1]Sage and Enamel Foundation, Osogbo, Nigeria, [2]John Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: The transition from donor to domestic financing for HIV programs in Sub-Saharan Africa is a critical challenge faced by many countries as they strive to sustain their HIV response amidst dwindling external support. This narrative review examines transition models, challenges, and success factors from 2015 to 2024, providing insights into how countries can effectively manage this shift and ensure the continuity of essential services.
Methods: We conducted a narrative review of evidence for combined terms related to HIV financing, donor transition, domestic resource mobilization, and Sub-Saharan African countries. Evidence published between February 2015- September 2024 was included.
Data reported in this research article were obtained from reports, literature in peer-reviewed journals found in PubMed, PubMed Central, and ScienceDirect, grey literature, UNAIDS database, and other data sources. The authors also snowball further data to gather information for this review.
Results: 42 studies were included in this review. Our findings reveal diverse transition models employed by countries in the region. For instance, Zimbabwe established an AIDS Trust Fund through a tax mechanism that generated approximately $52.7 million for HIV programs.
Botswana utilized a debt conversion instrument through its National HIV/AIDS Prevention Support program, generating $20 million to enhance prevention efforts.
Côte d'Ivoire implemented a Debt2Health agreement that provided $27 million for treatment and prevention initiatives.
Uganda has creatively leveraged government funding from other health sectors to maintain HIV services amid donor transitions.
However, significant challenges persist, including the risk of service disruption for key populations and reliance on unpredictable domestic funding sources.
Successful transitions are often characterized by strong political commitment, effective stakeholder engagement, and the adoption of innovative financing strategies that leverage local resources.
Conclusions: This review highlights the complexity of transitioning from donor to domestic HIV financing in Sub-Saharan Africa. While some countries have made significant progress through innovative approaches and strong leadership, others continue to struggle with dependency on external funding.
To ensure the sustainability of HIV programs, it is crucial for countries to enhance domestic resource mobilization and develop comprehensive strategies that address identified challenges.

OAE03 Zero AIDS-related deaths: Scaling up advanced HIV disease response

OAE0302

Point-of-care community delivery of the advanced HIV disease care (AHD) package during door-to-door TB-case finding

S. Misra[1], T.P. Pita[1], T. Thahanyane[2], M. Kamele[2], M. Keitseng[2], A. Tshazi[1], I. Ayakaka[2], T. Madonsela[1], S. Bosman[1], T. Decroo[3], F. Vanobberghen[4], E. Vlieghe[5,6], K. Reither[4,7], L. Lynen[3], A. van Heerden[8], T. Gils[3,5]
[1]Human Science Research Council, Pietermaritsburg, South Africa, [2]SolidarMed, Butha Buthe, Lesotho, [3]Institute of Tropical Medicine, Clinical Sciences, Antwerp, Belgium, [4]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [5]University of Antwerp, Global Health Institute, Antwerp, Belgium, [6]University Hospital Antwerp, Antwerp, Belgium, [7]University of Basel, Basel, Switzerland, [8]University of the Witwatersrand, Johannesburg, South Africa

Background: People with HIV (PWH) with AHD (PWAHD) (re)presenting to care are at high mortality risk. Community delivery of the AHD care package allows early AHD detection and management. The package was provided to PWH during door-to-door TB screening in (semi) rural Lesotho and South Africa (SA) (clinicaltrials.gov-:NCT05526885).
We evaluated the burden of AHD and implementation of the package.
Methods: Between September 2022-2024, consenting adult PWH were offered point-of-care CD4-testing (VISITECT until a batch recall in April 2023, PIMA after that) and if CD4≤200cells/µl, serum cryptococcal antigen (CrAg) and urine TB lipoarabinommaman (TB-LAM) testing. PWH (re)-entering care (with TB symptoms in Lesotho) and those eligible by a triage algorithm were offered sputum Xpert MTB/RIF Ultra (Xpert).
A PIMA CD4≤200cells/µl or positive Xpert (among those with access to both, others have "unknown" AHD status) was considered AHD. VISITECT results were inaccurate and not presented.
Treatment initiation included anti-retroviral treatment (ART), cotrimoxazole if CD4≤200cells/µl and TB preventive therapy (TPT; if new HIV-positive or not previously received), and Xpert-positives were referred for TB treatment. PWAHD were referred to their health facility and traced after 56 days.
Results: 20,024 people were enrolled; 65.1% in Lesotho and 34.9% in SA. HIV-positives represented 22.7% (4536); 19.7% (2568) of Lesotho and 28.2% (1968) of SA participants (Table). 1917 (42.3%) had valid CD4 results following the VISITECT recall and PIMA supply delays.
Among them, 49 (2.6%) had CD4≤200cells/µl and 7 (0.4%) were Xpert-positive. Fifty-five (2.9%) had AHD. All 46 CrAg and 45 TB-LAM tests performed were negative.
Among eligible PWAHD, 54/55 were on ART, 6/7 on TB treatment, 7/28 on cotrimoxazole, and 1/8 on TPT on day 56.

		Total PWH (n, col%)		Unknown AHD status (n,% of PWH)		Evaluated for AHD (n,% of PWH)		AHD (% of evaluated)		no AHD (% of evaluated)	
		4536	100	2619	57.7	1917	42.3	55	2.9	1862	97.1
Sex	Female	3269	72.1	1902	58.2	1367	41.8	23	1.7	1344	98.3
	Male	1264	27.9	716	56.6	548	43.4	32	5.8	516	94.2
	Ambiguous	3	0.1	1	33.3	2	66.7	0	0.0	2	100.0
HIV status	Known HIV-positive on ART	4453	98.2	2556	57.4	1897	42.6	51	2.7	1846	97.3
	Known HIV-positive not on ART	22	0.5	16	72.7	6	27.3	1	16.7	5	83.3
	Newly diagnosed with HIV	61	1.3	47	77.0	14	23.0	3	21.4	11	78.6
Country	Lesotho	2568	56.6	1592	62.0	976	38.0	12	1.2	964	98.8
	South Africa	1968	43.4	1027	52.2	941	47.8	43	4.6	898	95.4

Conclusions: AHD prevalence was 3% among PWH during community recruitment. Community implementation of the AHD care package is conditional on the availability of appropriate CD4 tests. Prophylactic treatment initiation needs improvement.

OAE0303

Reducing mortality and sustaining gains in advanced HIV disease management: a comparative analysis of transitioning support to the Ministry of Health in Malawi

T. Maphosa[1], L. Denoeud[2], L. Kalitera[1], L. Chilikutali[1], E. Matiya[3], J. Songo[4], A. Mayi[2], R. Nyirenda[5], R. Machekano[2], A. Tiam[2]

[1]Elizabeth Glaser Pediatric AIDS Foundation, Research, Lilongwe, Malawi, [2]Elizabeth Glaser Pediatric AIDS Foundation, Research, Washington DC, United States, [3]Elizabeth Glaser Pediatric AIDS Foundation, Programmes, Lilongwe, Malawi, [4]Elizabeth Glaser Pediatric AIDS Foundation, Strategic Information Systems, Lilongwe, Malawi, [5]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi

Background: To enhance sustainability and improve outcomes, the responsibility for advanced HIV disease (AHD) services transitioned from a project-based approach to the Ministry of Health (MoH). This study evaluated the impact of this transition on AHD screening, CD4 testing uptake, tuberculosis (TB), cryptococcal meningitis (CM) management, and 12-month survival.

Methods: A retrospective cohort study was conducted at 22 health facilities during pre-transition (June–December 2021) and post-transition (April–September 2023). HIV client's records were reviewed to capture 12-month follow-up data. Inclusion criteria included individuals aged >5 years with CD4 < 200 cells/mm³, WHO Stage 3/4 disease, newly diagnosed HIV, ART initiation <12 months, or ART instability >12 months, as well as all children <5 years initiating ART. Outcomes analyzed included WHO staging, CD4 coverage, ART experience, TB and CM screening, and mortality. Statistical analyses included Cox proportional hazards modeling and competing risk regression.

Results: Among the 1,042 clients enrolled (pre-transition: N=553; post-transition: N=489), 49.7% (N=275) and 52.7% (N=258) were female, respectively. The median age was 38 years (IQR: 30–46) pre-transition and 40 years (IQR: 32–48) post-transition. Hospital-based care increased post-transition (55.7% vs. 71.2%; p=0.001).

Advanced WHO Stage 3/4 presentations rose (47.6% vs. 65.3%; p=0.001), as did ART-experienced patients (24.2% vs. 44.6%; p=0.001), while CD4 testing coverage declined (80.6% vs. 45.9%; p=0.001). TB screening rates remained high (97.3% vs. 98.2%; p=0.528), with increases in TB diagnoses (29.5% vs. 39.2%; p=0.005) and urine LAM positivity (30.8% vs. 44.1%; p=0.001).

Mortality at 12 months significantly declined (9.4% vs. 5.5%; HR=0.59, 95% CI: 0.37–0.94, p=0.024)—see Table 1.

	Phase of AHD program implementation					
	Pre-transition			Post-transition		
N	553 (53.0%)			491 (47.0%)		
	HR*(1)	95% CI	p-value	HR**(2)	95% CI	p-value
Pre-transition	1.00			1.00		
Post-transition	0.59	[0.37 - 0.94]	0.026	0.58	[0.36 - 0.93]	0.024

*(1) Cox regression **(2) Fine and Gray competing risk regression

Table 1: Treatment outcomes and comparison of survival function between pre- and post-transition periods

Conclusions: The successful transition of AHD project activities saw sustained critical outcomes and reduced mortality but highlighted gaps in CD4 testing. This approach must be used to scale up the intervention beyond these sites.

OAE0304

Why are people living with HIV not prescribed TB preventive treatment at ART initiation? Insights from a cohort study

L. Steiner[1], K. Shearer[1], L. Genade[2], A. Pattamukkil[2], B.A.S. Nonyane[3], J.E. Golub[1], L. Lebina[2], N. Martinson[2], C.J. Hoffmann[1]

[1]Johns Hopkins University, Center for Tuberculosis Research, Baltimore, United States, [2]Perinatal HIV Research Unit (PHRU), University of the Witwatersrand, Johannesburg, South Africa, [3]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States

Background: High rates of tuberculosis (TB) preventive treatment (TPT), especially at antiretroviral therapy (ART) initiation among people living with HIV (PWH), is critical for progress towards TB elimination. We characterized reasons for non-prescription of TPT at ART initiation among PWH in the North West and Free State provinces of South Africa.

Methods: This study was nested within a cluster-randomized trial conducted in 36 public-sector primary health clinics. Medical records were abstracted for all adult (18+) PWH who had an HIV care-related visit over a one-year implementation period. This analysis was limited to PWH who initiated on ART during the implementation period (between September 2021 - August 2023), including those re-initiating treatment.

Prescribing of TPT within 12 months of ART initiation and reasons for non-prescribing TPT, as documented in the clinical file, are presented with chi-square analysis for sex, age, and province differences.

Results: Clinic records of 5,004 PWH initiating ART were abstracted; 63% were female and the median (interquartile range [IQR]) age was 36 years (29, 44).

Overall, 3,651 PWH (73%) were prescribed TPT up to 12 months after ART initiation; 86% initiated TPT on the same day as ART. TPT prescribing differed by province (70% compared to 77%, p<0.001) but not by sex or age.

Among the 1,335 (27%) PWH who were not prescribed TPT, complete data for the ART initiation visit was available for 1,124 (84%). 940 (84% of those who did not receive TPT) lacked a clear reason for non-prescribing of TPT; 82 (7%) had a TB investigation recorded, 76 (7%) were on TB treatment or completed TB treatment in the last 12 months, 6 (0.5%) completed TPT in the past 12 months, and 1 (0.1%) evidence of a contraindication (liver disease, heavy alcohol use, or hypersensitivity to INH). Nineteen (2%) additional patients had at least one TB symptom recorded without documentation of a TB investigation.

Conclusions: Approximately one-quarter of PWH initiating or re-initiating ART were not prescribed TPT with the majority not prescribed TPT appearing to meet South African TPT eligibility criteria. There remains a significant gap of people eligible, but not receiving TPT.

OAE0305

Characteristics of HIV-exposed infants testing positive on the Early Infant Diagnosis Program, in Bunyoro, mid-western Uganda, a retrospective cohort review from April 2021 to September 2024

N. Matovu[1]
[1]Baylor Foundation Uganda, medical & Psychosocial, Kampala, Uganda

Background: Early Infant Diagnosis (EID) of HIV is crucial for timely identification and antiretroviral therapy (ART) initiation among HIV-exposed infants (HEIs) that seroconvert. Bunyoro registered a decline in vertical transmission of HIV (VT) from 2.3% in April 2021 to 1.8% in September 2024.

However, HEIs still seroconvert on the EID program, undermining efforts towards zero new infections by 2030. This study aimed to characterize HEIs that seroconvert on the EID program in Bunyoro.

Description: A retrospective audit of HEI clinical charts from 91 health facilities assessed factors associated with VT using a positive infant audit tool. Ninety-two percent (239/260) seroconverted at first DNA PCR (average age 7.1 months). The majority were from facility sick entry points, mother-baby care points (MBC), community HIV testing, and Expanded Program on Immunization (EPI) at 34% (88), 28% (74), 19% (49), and 15% (39) respectively. Maternal average age was 26 years (47% adolescent girls and young women [AGYW][16-41 years].

Overall non-ANC attendance was 47% (122/260), 65% (168/260) knew their HIV status during pregnancy, of whom 69% (116/168) either tested HIV positive before pregnancy or during first ANC, 31% (52/168) were HIV negative during ANC and seroconverted late in pregnancy or while breastfeeding (BF).

HIV disclosure rates to spouses among pregnant women living with HIV stood at 49% (74/116). Despite a high ART initiation rate of 97% (253/260), (73% [185/253]) initiated ART late (after second trimester), while 3% (7/260) declined ART due to non-disclosure. Interruption in treatment (IIT) among the 116 mothers on ART before delivery was 81% (94) and, 65% (168/260) of mothers had non-skilled delivery.

Lessons learned: Facility sick entry points, MBC points, community HIV testing, and EPI (96%) were key areas for identifying HIV-positive infants, highlighting the need for strengthened EID/EPI integration. Late ART initiation (73%), IIT (81%), and low disclosure rates (49%) suggest substantial gaps in early ANC interventions. Seroconversion during BF (31%) requires intensified maternal retesting and PrEP integration.

Conclusions/Next steps: Strengthening EPI/EID integration, EID testing by 2 months, and scaling up AGYW programming, targeted community-based mobilization are some approaches that can improve timely prevention of VT and expand PrEP uptake.

OAE04 Accelerating integration in a new operating environment

OAE0402

Towards elimination of HIV, Syphilis and HBV mother-to-child transmission in The Gambia and Burkina Faso: the triple elimination model of mother-to-child transmission (TRI-MOM) program

A.E. Jallow[1], E. Vo-Quang[2], K. Jammeh[3], B. Dibba[3], G. Ndow[4,3], A.E. Jallow[1], E. Vo-Quang[1,2], J. Kitabu[2], D. Bakary[2], S. Drammeh[1], L. Perieres[3], U. D'Alessandro[1], S. Boyer[3], M. Lemoine[4], G. Ndow[1,4]
[1]Medical Research Unit, The Gambia at London School of Hygiene and Tropical Medicine, Disease Control and Elimination, Fajara, Gambia, the, [2]Univ Paris Est Créteil, INSERM, IMRB, Créteil, Paris, France, [3]Medical Research Unit, The Gambia at London School of Hygiene and Tropical Medicine, Fajara, Gambia, the, [4]Department of Metabolism, Digestion and Reproduction, Division of Digestive Diseases, Imperial College London, London, United Kingdom

Background: West Africa faces significant challenges with mother-to-child transmission (MTCT) of HIV, syphilis, and hepatitis B virus (HBV) infections. Despite this burden, MTCT of these infections can be effectively prevented with straightforward interventions. The World Health Organization (WHO) has advocated for a "triple elimination" model, integrating the prevention of these infections into maternal care services to accelerate their control and elimination.

The TRI-MOM project aims to evaluate the feasibility of integrating thes triple elimination model in two West African countries.

Methods: In The Gambia, the triple elimination strategy was deployed across four healthcare sites representing different levels of care. First, we conducted training for healthcare workers (HCWs) on the three infections to enhance awareness and capacity. Then we offered free routine antenatal screening for the three infections using rapid diagnostic tests. Pregnant women testing positive for any of the 3 infections received appropriate treatment or prophylaxis to prevent MTCT. Data on MTCT outcomes and cost-effectiveness were collected and analyzed to assess the strategy's impact.

Results: Between January-March 2024, HCWs in government facilities were trained. Simplified screening and treatment/prophylaxis SOPs were developed and adapted per health facility. Between 18th March and 23rd December 2024, 6,301 pregnant women were screened for the 3 infections. Overall, 99% of all pregnant women accepted screening.

Among these, 267 women (4.23%) tested positive for at least one infection: 75 had HIV mono-infection, 173 had HBV mono-infections, 14 had syphilis mono-infection, 4 had HIV/HBV co-infection and 1 had HIV/syphilis co-infection. All HIV-positive women were started on antiretroviral therapy (ART) following the "test-and-treat" approach. All syphilis-positive women accepted treatment with benzathine penicillin, with no adverse reactions reported. Of 173 HBV mono-infected women, 45 received TDF prophylaxis either based on high viral load (>200,000IU/mL) or based on a test-and-prophylax protocol.

Conclusions: The TRI-MOM project demonstrates that integrating triple screening for HIV, syphilis, and HBV into maternal care is both feasible and acceptable. Training of government HCWs, counselling of women and availability of rapid diagnostic tools have enabled seamless implementation. This approach can improve maternal and neonatal health outcomes and promote elimination of MTCT of these infections.

OAE0403

Leveraging community-based viral load sample collection to close treatment gaps among pediatrics and adolescents on ART in Zambia

R. Kanyinji[1], R. Mwilu[1], A. Mulenga[1], E.K. Nyundu[1], B. Walusiku-Mwewa[2], G. Chanda[3]

[1]Access to Health Zambia, USAID Empowered Children and Adolescent Program I, Lusaka, Zambia, [2]Access to Health Zambia, Lusaka, Zambia, [3]USAID/Zambia, Lusaka, Zambia

Background: Despite significant global efforts, pediatrics and adolescents living with HIV continue to experience wide treatment gaps globally. In Zambia, pediatric and adolescent viral load (VL) coverage and suppression in 2021 were at 74% and 91%, respectively, falling short of the UNAIDS 95-95-95 targets. These gaps are exacerbated by barriers such as distance to health facilities, stigma, and limited pediatric and adolescent-focused interventions. To close the treatment gap, the USAID Empowered Children and Adolescents Program I (ECAP I) partnered with PEPFAR clinical teams to implement a pediatric and adolescent-focused surge.

Description: The surge focused on training, coaching and mentorship to 493 community health workers to conduct ethical index HIV testing and ensuring initiation on ART for pediatrics and adolescents newly diagnosed with HIV. Community VL sample collection was integrated and implemented across 100 health facilities in 13 high HIV burden districts in Zambia. At each health facility setting, a multidisciplinary team of clinicians, social workers, and community health workers, jointly conducted community VL sample collection focusing on pediatrics and adolescents on ART that were due for VL testing as well as those that where in 'hard-to-reach' areas due to distance to the health facility. On average, the project covered about 5.4% of over 10,200 pediatrics and adolescents on ART that were eligible for VL testing each year from 2020 to 2024, for whom VL sample was collected, and result documented on file.

Lessons learned: The initiative has contributed to improvement in VL coverage for pediatrics and adolescents on ART from 86.4% in October 2021 to 95.6% in September 2024, while VL suppression was sustained at 96.9% from 87.0%, during the same period. Qualitative insights revealed that joint implementation of clinical and OVC program interventions by multi-disciplinary teams contributes to improving the health and well-being of marginalized priority sub-populations.

Conclusions/Next steps: This intervention demonstrated the potential to improve VL coverage and suppression among pediatrics and adolescents, reducing persistent treatment gaps. Scaling this model to additional regions and integrating it with digital health solutions could further enhance its impact.

OAE0404

Resilient HIV care in crisis: transforming access through drugs dispensing points in Haiti

D. Dorestan[1], B. Shaw[2], N.R. Labbe[1], M.C. Alcide Jean-Pierre[1]

[1]Georgetown University, Center for Global Health Practice and Impact, Port au Prince, Haiti, [2]Georgetown University, Center for Global Health Practice and Impact, Washington, United States

Background: Chronic and recent crises in Haiti, including insecurity, lockdowns, fuel scarcity, and internally displaced populations, have severely impacted healthcare workers and disrupted HIV care. In response, the Georgetown University Center for Global Health Practice and Impact launched the Drugs Dispensing Points (DDP) project to improve treatment access. Haiti remains the Caribbean country most affected by HIV, with approximately 120,000 people living with HIV (PLHIV) on antiretroviral therapy (ART). This study highlights the context, challenges, implementation, and results of the DDP strategy.

Description: Using Human-Centered Design (HCD), the implementation team collaborated with the Ministry of Health (MoH), eight implementing partners, and 261 stakeholders, including 108 PLHIV clients, to identify 159

strategic DDP locations. A DDP Priority Scale and a seven-step Team Cycle Strike guided implementation. Selected sites underwent rigorous evaluation, and were equipped with trained staff, confidentiality measures, and digital tools. Medication dispensation is monitored via the National Dispensing Interface Platform (nDIP), a web and mobile-based ecosystem developed with SOLUTIONS SA. nDIP connects 167 treatment sites and 57 decentralized DDPs, offering real-time updates on prescriptions, clinical statuses, and service management. Over 100 treatment providers were trained on client referrals to DDPs, updating statuses, and ensuring seamless care coordination to maintain robust adherence and information flow within Haiti's HIV care network.

Lessons learned: *Customization*: Tailored DDP services through four organizational models—private pharmacies, PLHIV associations, community health centers, and community-based institutions—ensured local adaptability. *Collaboration:* Partnerships with MoH and stakeholders were key to identifying and establishing DDPs. *Technology:* nDIP enabled efficient medication management and real-time care coordination. *Training:* Comprehensive provider training supported effective DDP operations and client adherence. *Crisis Response:* The DDP model proved resilient, with increased acceptance during crises.

Conclusions/Next steps: The DDP model has improved ART access for over 10,000 clients, achieving a 98% viral suppression rate. By integrating HCD, leveraging technology, and fostering collaboration, the model reduces stigma, enhances care retention, and adapts to Haiti's challenges. Continued investment will advance Haiti toward UNAIDS' 95-95-95 targets and eliminate HIV as a public health threat.

OAE0405

Unlocking access to advanced HIV disease care: lessons from Lesotho's phased strategy

T. Sefuthi[1], M. Milaham[2], T. Tarumbiswa[3], M. Thulo[4], M. Tsotako[5], M. Molapo[5], S. Morebotsane[4], N. Marake[3], I. Amamilo[1], L. Ntainyane[3], M. Mohoanyane[3], M. Dupreez[3], E. Mandara[2]

[1]Clinton Health Access Initiative, HIV Access Program, Boston, United States, [2]Clinton Health Access Initiative, Maseru, Lesotho, [3]Ministry of Health, Maseru, Lesotho, [4]Elizabeth Glaser Pediatric AIDS Foundation, Maseru, Lesotho, [5]Baylor College of Medicine Children's Foundation, Maseru, Lesotho

Background: Advanced HIV Disease (AHD) is a leading cause of death in Lesotho, with a prevalence of 14.5% among people living with HIV (PLHIV). Recognizing the severe socioeconomic toll of AHD on individuals and the health system, Lesotho prioritized a robust public health response. With support from CHAI, the Ministry of Health (MoH) introduced a comprehensive AHD treatment and management program, achieving nationwide coverage by 2024 through a phased implementation approach.

Description: In 2019, CHAI, the Ministry of Health (MoH), and other development agencies developed national AHD management guidelines, the first-ever national guidance dedicated to AHD. The MoH selected a hub and spoke model to deploy the care package. Hubs (district hospitals) provide screening, pre-emptive therapy, and treatment for all conditions, while spokes (health centers) screen and treat some opportunistic infections. In 2021, MoH introduced the AHD care package in all 18 hubs, referred to as phase I sites. Key enablers of rollout include implementation planning with MoH and partners, quantification and procurement of AHD focal commodities, healthcare worker training, and program monitoring. Applying this phased approach, MoH increased access to AHD services from 7% in 2021 to 31% and finally achieved 100% at all health care levels in 2024.

Lessons learned: The scale-up of AHD management has been successful, but challenges remain in optimizing program monitoring, increasing screening and treatment for diseases like Cryptococcal Meningitis, and strengthening the AHD supply chain. A phased implementation approach has helped address these challenges given technical assistance resource constraints experienced during supportive supervisory visits. To further address these challenges, the government will leverage continuous quality improvement initiatives and conduct data quality assessments to enhance service delivery and data quality in 2025.

Conclusions/Next steps: A phased approach has enabled Lesotho to achieve nationwide AHD service coverage despite resource constraints. This underscores the government's commitment to reducing AHD-related morbidity and mortality. Moving forward, sustained focus on high-quality, integrated service delivery will be critical to reducing AIDS-related deaths and securing long-term program success and impact.

OAE05 Nothing about us without us: Strengthening the HIV response through community-led monitoring

OAE0502

Outcomes from a community-led monitoring (CLM) intervention in Malawi and South Africa

D. Kamkwamba[1], D. Mnkandla[2], G. Oberth[3], K. Lauer[4], J. Bozinovski[5], D. Mseu[6], H. Kachepatsonga[6], M. Soboyisi[2], M. de Vos[7], S. Baptiste[8]

[1]JONEHA, The Network of Journalists Living with HIV, Lilongwe, Malawi, [2]Networking HIV/AIDS Community of South Africa (NACOSA), Johannesburg, South Africa, [3]University of Cape Town, Center for Social Science Research, Cape Town, South Africa, [4]International Treatment Preparedness Coalition (ITPC), Seattle, United States, [5]International Treatment Preparedness Coalition (ITPC), Lilongwe, Malawi, [6]Malawi Network of Religious Leaders Leaving with or Personally Affected by HIV (MANERELA+), Lilongwe, Malawi, [7]Networking HIV/AIDS Community of South Africa (NACOSA), Cape Town, South Africa, [8]International Treatment Preparedness Coalition (ITPC), Johannesburg, South Africa

Background: Since 2020, more than $100 million has been invested in community-led monitoring (CLM), globally. To date, CLM research largely centres on the identification of issues with HIV services and barriers to access. Few studies show how CLM leads to concrete changes in service uptake or health outcomes. Rigorous evaluation methods are needed to demonstrate the effectiveness of the intervention.

Methods: Community-led organizations systematically collected data on HIV prevention and treatment services from 33 health facilities in Malawi and South Africa between November 2020 and October 2024 (four years). They routinely fed this data back to decision-makers to inform service improvements.

At the end of the project, we compared outcomes at the CLM sites with the other health facilities in the focus districts by analyzing DHIS2. We also investigated whether more intensive CLM was associated with improved results. We calculated odds ratios (ORs) to determine the effect of the CLM intervention.

Results: Recipients of care at CLM sites were more likely to initiate pre-exposure prophylaxis compared to other facilities (1.32 OR 95% CI 1.27-1.38). Pregnant women at CLM sites were twice as likely to deliver in the health facility, reducing the risk of vertical transmission (1.99 OR 95% CI 1.51-2.62). The CLM sites were also more likely than non-CLM sites to find and diagnose adolescent girls and young women (AGYW) living with HIV (1.46 OR 95% CI 1.28-1.66).

As a result, the cost to diagnose one AGYW living with HIV was $2,852 at the CLM sites compared to $4,154 at the non-CLM sites.

More intensive CLM was associated with improved service coverage and health outcomes. At CLM sites with additional resources for community scorecards, community mobilization, and community dialogues, people living with HIV were six times more likely to access treatment through a differentiated service delivery model (6.79 OR 95% CI 6.04-7.63). People at the intensive CLM sites were twice as likely to be virally suppressed compared to the standard CLM intervention (2.34 OR 95% CI 2.16-2.54).

Conclusions: It is possible to evaluate CLM interventions using rigorous scientific methods. Identifying a control group can be helpful to demonstrate the effectiveness of CLM.

OAE0503

From barriers to breakthroughs: the impact of community-led monitoring on healthcare access in Liberia

B. Gibson[1], T.F. Musa[2], J. Godoe[2], M. Dahn[1], E.M. Dioukhane[3], M. Tegli[1], J. Flomo[4], A. Jaygbeh[1], P. George[1], T. Ahmad[1]

[1]Plan International, HIV /TB Program, Monrovia, Liberia, [2]Liberia Network of People Living with HIV, Program, Monrovia-, Liberia, [3]Plan International, HIV /TB Program, Toronto, Canada, [4]National AIDS Control Program, HIV, Sinkor, Liberia

Background: The Liberia Network of People Living with HIV (LibNeP+) with funding from the Global fund has made significant strides in advancing Community-Led Monitoring (CLM) to enhance accountability, equity, and quality in healthcare delivery. With technical assistance from Community-Led Accountability Working Group (CLAW) consortium, LibNeP+ piloted the CLM model in five counties——monitoring 28 sites, including 14 health facilities, 2 drop-in centers, and 12 populated areas.

This pilot aimed to identify systemic barriers, enhance service delivery, and empower communities to advocate for people-centered solutions.

Methods: The six-month pilot (July–December 2023) engaged 14 peer monitors to collect and analyze data from facility managers, nurses, people living with HIV (PLHIV), key populations (KPs), and pregnant women using qualitative and quantitative tools.

We conducted comprehensive training to 22 member organizations, including county supervisors, key population-led and PLHIV-led organization, and LibNeP+ staff, with support from the National AIDS Control Program (NACP). Training topics included CLM Setup, data analysis, and evidence-based advocacy to enhance CLM efforts by involving more community-based organizations.

Data collection included interviews with facility managers, ART clinicians, and recipients of care. Findings informed targeted interventions through rapid feedback loops with healthcare providers and decision-makers.

Results: The pilot revealed critical gaps in healthcare delivery and demonstrated the transformative impact of CLM interventions.

Conclusions: The CLM pilot in Liberia demonstrated the impact of community-driven approaches in addressing systemic healthcare barriers. Peer monitors fostered trust and provided actionable insights, leading improve quality of care. Building on its success, we plan to scale CLM nationwide. Regular data-sharing forums with key decision makers will sustain momentum and drive systemic

improvements, positioning CLM as a replicable model for equitable, community-centered healthcare transformation.

Metric	Baseline (Pre- Intervention	Post-Intervention	Change
Average Wait Time (hrs)	3.9	2.5	↓ 36%
Queue Length	22	15	↓ 32%
PrEP Awareness	67%	85%	↑ 18%
PrEP Uptake (% Offered PrEP)	50%	70%	↑ 20%
Stock-Outs	13%	5%	↓ 62%
ART Refill Periods (% Offering 3-6 months)	50%	80%	↑ 30%
KP-Specific Services Available	67%	85%	↑ 18%
Client Satisfaction	85%	92%	↑ 7%

Table. Metric Baseline (Pre- Intervention Post- Intervention Change.

OAE0504

Advancing HIV Service quality through community-led monitoring system in Chiang Mai, Thailand

S. Sittikarn[1], C. Wongwaiphanit[1], P. Patpeerapong[2], L. Mahawan[3], S. Sangtong[3], K. Khomkaew[3], P. Palee[3], P. Chaisopa[3], K. Singchaichit[3], S. Janla[3], N. Suwanphatthana[3], K. Sirisup[4], S. Santayakul[4]
[1]CAREMAT Foundation, Chiangmai, Thailand, [2]MPLUS Foundation, Chiangmai, Thailand, [3]Chiang Mai Community-Led Monitoring Committee, Chiangmai, Thailand, [4]FHI 360, EpiC project, Bangkok, Thailand

Background: People-centered HIV services that respond to the needs of clients necessitate feedback mechanisms such as Community-Led Monitoring (CLM) where stigmatized population groups can voice their concerns and perspectives on how to improve HIV testing, treatment, and Pre-Exposure Prophylaxis (PrEP).
Description: A group of civil society and at-risk population (including people-living-with-HIV (PLHIV)) representatives in Chiang Mai, Thailand launched a people-centered CLM system in January 2022. This CLM aims to improve HIV service delivery by collecting and analyzing data on service quality and clients' satisfaction through structured feedback tools, surveys and interviews with clients to identify gaps and formulate improvement plans. This initiative involved 17 committee members and 21 hospitals collaborating to enhance service quality per the evolving needs of at-risk populations.
Lessons learned: Data collection was conducted during March 2022 - November 2024 and yielded 3,425 responses from 21 hospitals across Chiang Mai.

CLM Results	Outcomes
Clients reported low or no access to PrEP in many hospitals. (2022)	Expansion of PrEP facilities from 13 to 24 hospitals across all 24 districts. (2023)
PLHIV felt that multi-month dispensing (MMD) was not offered to them by providers (2022)	Provincial Health Office-led strategy to scale up 6-month MMD at 24 hospitals. (2024)
PLHIV reported that U=U was not integrated in counseling. (2023)	Provincial Health Office launched a comprehensive U=U campaign. (2024)

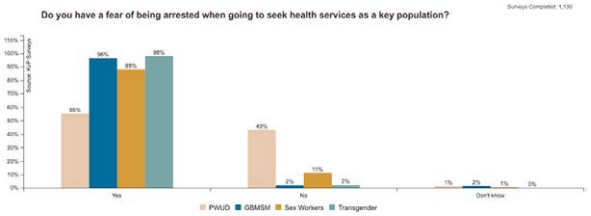
In addition to CLM findings, the structured feedback tools were formalized into Standard Operating Procedures (SOPs) for data collection and analysis and subsequently scaled up to three other provinces: Chiang Rai, Phitsanulok, and Ubonratchathani.
Conclusions/Next steps: CLM is vital in creating a participatory environment where at-risk populations monitor and review HIV services. Through the implementation in Chiang Mai during March 2022 - November 2024, CLM improved PrEP service availability to cover all districts in the province, reduced travel burden for ART refills for clients living with HIV, and increased awareness of U=U (Undetectable=Untransmittable) among the public, at-risk population communities, and service providers. With standardized tools and community leadership, CLM proves to be an effective and scalable process to enhance HIV service quality in multiple provinces.

OAE0505

Accessibility of HIV services for key and vulnerable populations (KVPs) in criminalized contexts: findings from KVP-led community monitoring in Dar es Salaam

P. Liberatus[1], M. Mutongore[1], C. Peter[1], Z. Mansoor[1], A. Nicholaus[1], M. Milanga[2], E. Lankiewicz[3]
[1]The Key and Vulnerable Populations Forum Tanzania, Dar es Salaam, Tanzania, the United Republic of, [2]Health GAP, Nairobi, Kenya, [3]amfAR, The Foundation for AIDS Research, Washington, DC, United States

Background: Ending the HIV epidemic will require closing gaps for most at-risk populations. In contexts where key and vulnerable populations (KVPs) are stigmatized and criminalized such as Tanzania, this will require continuous availability of friendly services. However, accurate assessments of the state of healthcare for KVPs are challenging in these contexts. This project aimed to fill this gap with monitoring of service accessiblity by and for KVPs.
Description: The Key and Vulnerable Populations (KVPs) Forum in Tanzania spent two weeks collecting community-led monitoring data among KVPs in Dar es Salaam in September 2024. An electronic data collection system was used, with data collected by key populations in Kiswahili at community hot spots. 1,343 KVPs consented to interviews (336 transgender individuals, 314 sex workers, 298 people who use drugs, 194 men who have sex with men (GBMSM), and 201 adolescent girls and young women (AGYWs)).
Lessons learned: These data reveal that despite promises of non-discriminatory healthcare provision, services, especially at public health facilities, remain discriminatory and inaccessible to many. More than half (54%, n=191) of KPs surveyed who use public facilities had been refused services in the last year, including 80% (n=41) of GBMSM and 75% (n=106) of transgender people. Many fear arrest when seeking services (Figure 1). More than half (53%, n=159) of KVPs felt very unsafe or unsafe at facilities. Lack of safety at facilities extended beyond criminalized populations to AGYWs as well, with 57% (n=30) of AGYWs using public health facilities reporting feeling unsafe.



Conclusions/Next steps: These data represent one of the largest samples of KVPs in Tanzania, pointing to the importance of data collection for vulnerable populations by vulnerable populations. As international funders elevate sustainability conversations where policies fail to protect human rights, programs like KVP-led CLM are critical to ensuring we have accurate pictures of the lived realities of HIV service acessibility.

OAE06 Revolutionizing HIV: AI, equity and the next frontier

OAE0602

Enhancing data quality for differentiated service delivery: lessons from Zimbabwe's multiregional DSD review

T. Matare[1], P. Mujuru[2], C. Gwanzura[1], C. Mupanguri[1], T. Apollo[1]

[1]Ministry of Health and Child Care (MOHCC), HIV, Harare, Zimbabwe, [2]Zimbabwe Technical Assistance, Training and Education Center (Zim-TTECH), HIV Care and Treatment, Harare, Zimbabwe

Background: Differentiated Service Delivery (DSD) is a client-centered approach that simplifies and adapts HIV services to reflect clients' preferences and expectations while reducing unnecessary burdens on the health system. Zimbabwe started implementing DSD models for ART in 2017 and has been conducting DSD Reviews annually since 2018. They assess implementation progress and peer-learning opportunities to share best practices, challenges and innovations. The 2024 DSD Review was conducted in July – August 2024.

Description: A total of 148 facilities in 30 districts from 4 provinces participated. Data was collected using Survey CTO and analysed using PowerBI. A facility survey and individual patient survey tools were used. Data was abstracted from 4,630 patient files for recipients of care (RoCs) in the 12-, 24- and 36-months ART cohorts. Data was collected from paper-based tools and/electronic medical records for services received across the HIV continuum of care for HIV testing, treatment, management of high viral load and integration with Tuberculosis, Family Planning, Mental Health, Opportunistic Infections and Non-Communicable Diseases.

Lessons learned: As Zimbabwe nears epidemic control, it is imperative that available data sources are robust, as we provide client centered services, for better data driven decisions. However, the review showed incompleteness on some key patient variables such as DSD model (22%), Date of Birth (4%), Date of HIV Diagnosis (4%), Sex (1%) and Date of ART initiation (1%). This is despite having Standard Operating Procedure for recording and reporting. Zimbabwe intensified development of a module for DSD models with validation rules and subsequent data visualizations within electronic health record (EHR) with support from PEPFAR. The module was refined after several validations and deployed to 795 facilities. Zimbabwe plans to decommission all paper tools, inter-connect DHIS 2 with EHR and eventually utilize EHR to do DSD reviews.

Conclusions/Next steps: The review provided an opportunity for assessing data quality. We learnt that data quality was sub-optimal on some variables. Electronic medical records provide an opportunity for improving data quality. However, there is a need for governments and implementing partners to tackle challenges around connectivity, power, hardware, software development and Human Resources for Health capacity building to sustain the system for better data quality.

OAE0603

Decentralizing HIV care: blockchain solutions for client data integrity and pharmaceutical supply chain resilience

P.C. Rupasinghe[1], N.G. Abdelrahman[2], H.M.E. Mahgoub[3], S. Asaad[4]

[1]Icahn School of Medicine at Mount Sinai, Public health- Epidemiology, New York, United States, [2]Michigan State University, Geriatric Medicine, East Lansing, United States, [3]Michigan State University, Tele-Geriatric Research Fellowship, Jeddah, Saudi Arabia, [4]Michigan State University, Tele-Geriatric Research Fellowship, Houston, United States

Background: Blockchain technology is revolutionizing HIV care by addressing critical challenges in data management and pharmaceutical supply chains. Its decentralized, tamper-proof architecture offers solutions to fragmented systems, privacy risks, and inefficiencies that undermine global treatment equity.

Description: Blockchain technology has demonstrated transformative potential across HIV care delivery, with applications spanning client data management and pharmaceutical supply chains. In Kakamega, Kenya, the *Immunify.Life* initiative replaced paper-based systems with blockchain-enabled real-time data tracking, improving treatment adherence by 25% among non-adherent clients over 12 months. Parallel efforts in Houston, Texas, utilized blockchain platforms for pre-exposure prophylaxis (PrEP) access, achieving 83% user trust and reducing administrative errors by 40% through secure, decentralized health records (Yue et al., 2022). Beyond clients care, blockchain strengthened supply chain resilience: in Malawi, tracking of ARV drugs reduced clinic stock outs from 25% to 12% and lowered counterfeit drug rates by 35% across 150 clinics (Gavi, 2023), while a Ghanaian pilot cut HIV test kit delivery delays by 50% in rural areas through blockchain-monitored shipments. These geographically diverse implementations highlight blockchain's dual

capacity to enhance care coordination and safeguard medical supply chains, addressing systemic inefficiencies in both high- and low-resource settings.

Lessons learned: Blockchain enhances data security, interoperability, and supply chain transparency. Key successes include adherence gains (25% in Kenya), error reduction (40% in the U.S.), and counterfeit drug mitigation (35% in Malawi).

Challenges such as infrastructure gaps (e.g., rural internet access) and regulatory complexities (e.g., HIPAA compliance) demand hybrid models and public-private partnerships for scalability.

Conclusions/Next steps: Blockchain's success in improving client adherence, reducing counterfeit drugs, and streamlining supply chains underscores its potential to revolutionize HIV programs globally. However, scaling these innovations requires addressing infrastructure gaps (e.g., internet access in rural areas), regulatory alignment (e.g., HIPAA compliance), and stakeholder training.

Future efforts should prioritize hybrid blockchain models to balance transparency with compliance, foster cross-sector collaboration to expand solutions, and explore broader applications in chronic disease management and cross-border health data sharing.

By integrating blockchain with emerging technologies like AI, healthcare systems can unlock predictive analytics for supply chain optimization and personalized client care, positioning blockchain as a cornerstone of equitable, client-centered healthcare worldwide.

OAE0604

Innovative use of mobile digital chest-xray equipped with artificial intelligence to improve TB diagnosis among people living with HIV at primary health centres (PHCs) in Lagos, Nigeria

O. Udunze[1], A. Agbaje[2], D. Olugbenga[1], E. Ajayi[1], D. Sokoya[3], E. Ubochioma[4], A. Omolaja[5], B. Odume[6], T. Osatuyi[7], E. Chukwu[8]

[1]Institute of Human Virology Nigeria, Strategic Information (S.I), Lagos, Nigeria, [2]Institute of Human Virology Nigeria, Lagos, Nigeria, [3]Lagos State Ministry of Health, STBLCP, Lagos, Nigeria, [4]National Tuberculosis and Leprosy Control Programme, Program, Abuja, Nigeria, [5]Grant Management Unit, Lagos State Ministry of Health, Lagos, Nigeria, [6]KNCV Nigeria, Executive Director, Abuja, Nigeria, [7]KNCV Nigeria, Project Coordinator, Abuja, Nigeria, [8]KNCV Nigeria, Regional Project Coordinator, Abuja, Nigeria

Background: Deployment of Mobile digital Chest X-Ray (CXR) vans equipped with artificial intelligence (CAD4TB) is a joint investment of the State Government and Global Fund to complement other interventions in TB program, to find and treat the missing persons with TB. The CXR intervention will further increase access to free TB screening and treatment as part of the Global Strategy to end TB. Three mobile CXR Vans, equipped with artificial intelligence (CAD4TB) was used for this activity. This provided an opportunity for adequate TB/HIV integration and collaboration at the PHCs.

The objective of this study is to highlight the effectiveness of TB/HIV service integration at the primary healthcare centers, characterized with client referrals to other designated diagnostics centers for evaluations and further follow-up examinations.

Description: The use of the of mobile digital CXR at the PHCs for active TB case finding was conceptualized and conducted from January – December 2024 to address the existing 32% TB notification gaps in Lagos Nigeria. This however, provided an opportunity to adequately screen PLHIV for TB at PHCs. DHIS2 was used to determine the PLHIV currently on Treatment across 8 flagship sites (PHCs) in the State, following facility assessment and advocacy visit. TB Facility Cascade Management Team Meeting were conducted and CXR mobile Vans deployed. WHO 3B TB screening algorithm was adopted. Specimen were collected and sent for GeneXpert test.

Lessons learned: For the A.I supported TB screening among PLHIV, the average TB yield as calculated is 23%, NNS and NNT calculated were 24 and 4 respectively given a better yield compared to the conventional TB screening (symptom screening at 8% TB yield, 123 NNS and 12 NNT calculated respectively.

Type of TB screening (Screening with A.I supported CXR versus Symptom screening)	No. of PLHIV screened for TB with A.I supported CXR mobile machine	No. of TB presumptive among PLHIV	No. of TB presumptive clinically evaluated	No. diagnosed with TB	No. linked to care	% TB yield	No. needed to screen (NNS)	No. needed to test (NNT)
TB screening using A.I supported CXR at PHCs	1,128	203	203	47	47	23%	24	4
Symptom screening at other Secondary facilities	7,898	789	789	64	57	8%	123	12

Table. Comparative Quarterly Data showing the TB Cascade for both AI Supported and Non-A. I supported screening activities.

Conclusions/Next steps: Artificial Intelligence powered Mobile Digital CXR has demonstrated efficiency in TB diagnosis among PLHIV while fostering adequate integration of TB/HIV. Therefore, the expansion of Mobile digital CXR equipped with A.I, will further strengthen this collaboration and improve quality of care among PLHIV in Nigeria.

Ethical concerns and suggested mitigations surrounding access to and use of SMS and social media data in sentiment analysis, for HIV prevention among young women in Western Kenya

A. Ochiel[1], Z. Kwena[1], K. Oware[1], P. Ochwal[1], L. Adiema[1], M. Hewa[1], J. Odoyo[1], B. Rono[1], L. Garrison[2], E. Bukusi[3], J. Haberer[2,4]

[1]Kenya Medical Research Institute, CMR-RCTP, Kisumu, Kenya, [2]Massachusetts General Hospital, Obstetrics and Gynecology, Boston, United States, [3]Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya, [4]Harvard Medical School, Obstetrics and Gynecology, Boston, United States

Background: As artificial intelligence (AI) technology gains popularity, innovative smart phone apps based on predictive algorithms are emerging. Moreover, the public is increasingly using these apps to acquire new knowledge, solve problems, and trade goods and services. Given the vast amounts of inter-personal communication via SMS and social-media, AI-driven apps could analyze these data to predict individual behaviors, and health-related risks. We sought to explore the ethical concerns and suggested mitigations in accessing young women's phone data for development of an AI-based tool to assess HIV prevention needs.

Methods: Between February and April 2024, we conducted in-depth interviews (IDIs) with 32 young women aged 18 to 24 who sought sexual and reproductive health services from four public facilities. Half of them were willing to share their SMS and social-media messages for HIV prevention analysis. Additionally, two focus group discussions were held with 11 bioethicists. Ethical concerns were explored through questions covering privacy, confidentiality, autonomy, beneficence, non-maleficence, justice, and power. Data were thematically analyzed using a deductive approach.

Results: Both groups expressed concerns about likelihood of privacy intrusion, risks of accessing third-party and deleted messages, potential for embarrassment, confidentiality breaches and data leaks during algorithm development. Bioethicists were worried about practicality of obtaining true informed consent due to complexity of sentiment analysis.

Young women suggested strict data security measures, such as de-identifying data and involving non-Kenyans in data handling. Bioethicists stressed the importance of carefully developing consent forms through iterative participation to obtain truly informed consent from participants. Some suggested exploring the feasibility of using public social media data, instead of personal data, to develop the AI-based HIV risk assessment tool prototype. Bioethicists recommended ethical bodies to define guidelines and legal thresholds for allowable confidentiality breaches in cases involving discovery of criminality.

Conclusions: These findings offer data access insights for researchers designing AI-driven prediction tools for HIV prevention and other health-related behaviors: to help with upholding critical ethical principles including privacy, confidentiality, and non-maleficence. Ethical review boards should define minimum standards for participants' protection in research employing sentiment analysis, as it is crucial for the proposed app and similar future tools.

Background: Despite improvements in HIV-1 therapies drug treatment failure and the inability to target latent viral reservoirs remain major limitations. Infection generally requires HIV recognizing the primary receptor CD4, followed by binding to either of the chemokine coreceptors, CXCR4 or CCR5. This binding mode enables cell entry by HIV gp41 fusion with the cell membrane. Investigators have believed for some time that initial binding to CD4 is required for HIV-1 infection. However, studies have shown that HIV-1 can enter cells lacking CD4 although this remains controversial, and the mechanisms are unclear.. This study aims to identify a model CD4-negative cell line that is infectable with HIV-1 to study alternate entry mechanisms and determine whether CD4-negative cells can act as latent viral reservoirs.

Methods: CD4-negative human osteosarcoma (HOS) cells expressing either coreceptor were infected with an envelope-pseudotyped, luciferase or GFP reporter HIV-1.; JR-FL-envelope for CCR5+ and HXB2-envelope for CXCR4+ cells. These cells were confirmed to be CD4 negative through flow cytometry, mRNA expression & the use of a CD4 blocking antibody (Ibalizumab) during infection assays.

Results: We found that HIV-1 can infect HOS cells, as demonstrated by post-infection luciferase and GFP expression that was blocked by the integration inhibitor Raltegravir. Infection in HOS cells is resistant to Ibalizumab but susceptible to coreceptor blockers, suggesting that infection is CD4 independent but coreceptor dependent. These results suggest that in the absence of the CD4 receptor, HIV-1 uses an alternative mechanism for viral entry into HOS cells.

Conclusions: Further studies will examine infected GFP positive cells, including single-cell RNA sequencing, determining mechanisms used for viral entry, and the use of a red/green reporter virus to investigate latency. Deepening our understanding of viral entry into CD4-negative cells may help identify unknown viral reservoirs, improve HIV-1 therapeutics, and contribute to finding an eventual cure.

HIV pathogenesis

Gene expression analysis of anorectal biopsies in PLWH receiving cART

V. Artusa[1], L. De Luca[1,2], R. Zamarato[1], M.A. Cano Fiestas[1,3], A. De Nicolò[4], A. D'Avolio[4], L. Benedetti[5], M. Compagno[5], V. Malagnino[5], M. Iannetta[5], L. Duca[6], F. Ceccherini Silberstein[6], M. Biasin[1], M.S. Clerici[2,7], D. Trabattoni[1]
[1]University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy, [2]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy, [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy, [4]University of Turin, Department of Medical Sciences, Turin, Italy, [5]Tor Vergata University, Department of System Medicine, Rome, Italy, [6]Tor Vergata University, Department of Experimental Medicine, Rome, Italy, [7]IRCCS Don Carlo Gnocchi Foundation, Milan, Italy

Background: Persistent gut inflammation, observed even in PLWH receiving ART, is closely associated with ongoing HIV replication, disruption of the gut epithelial barrier, and microbial translocation. Indeed, gastrointestinal symptoms remain a significant and highly prevalent clinical feature in this population, even in the context of ART. This study aims to evaluate differences in gut mucosal gene expression in PLWH undergoing cART.

Methods: Sixty-six PLWH on successful cART were included in the study and stratified based on both CDC clinical stage and therapy regimen. Anorectal biopsies were analyzed to assess gene expression of 14 structural genes and 14 immune-related genes by RT-PCR. Non-parametric tests were employed to compare gene expression results across groups.

Results: Considering CDC classification, PLWH in stage C (n=6), compared to individuals in stage A (n=44), displayed downregulation of tight junction-related genes *CLDN3* (p=0.04), *CLDN7* (p=0.01), and *CLDN15* (p=0.04), indicating potential compromised structural integrity of the gut epithelium.

Additionally, *TJP3*, another critical gene associated with tight junctions, was significantly downregulated in stage C (p=0.05), with similar reduction observed when comparing individuals in stage B (n=16) to stage A (p=0.05). Furthermore, *IL-17A*, a pro-inflammatory cytokine, was upregulated in stage C (p=0.04), suggesting an increase in immune activation.

When comparing therapy regimens, the INSTI-treated individuals (n=46), compared to the non-INSTI (n=20), reported a reduction in *CLDN2* expression (p=0.04) and an upregulation of *CLDN4* (p=0.02), suggesting changes in epithelial barrier dynamics. Immune-related genes also displayed notable differences, with *β-defensin 1* (p=0.02) and *IL-1β* (p=0.04) being upregulated in INSTI-treated individuals, indicating heightened antimicrobial and inflammatory responses.

Additionally, in the INSTI group *MAPK3* was significantly downregulated (p=0.001), while *STAT6* was upregulated (p=0.001), highlighting potential shifts in signaling pathways involved in inflammation and immune regulation.
Conclusions: Our data suggest that PLWH in stage C may experience heightened immune responses alongside compromised epithelial barrier function, potentially exacerbating gastrointestinal dysfunction.
Moreover, the observed differences between INSTI and non-INSTI groups highlight the molecular effects of INSTI-based regimens on gastrointestinal function. Further studies are needed to investigate the clinical significance of these findings.

Host immune responses

B-cell repertoire diversity in individuals living with HIV in a Southern African cohort: implications for vaccine design

J. Magura[1], A. Khairallah[2], M. Muthui[3], C. Kibet[4], Z. Dlamini[2], B. Onsembe[5], S. Rasehlo[2], K.L. Dong[6], L. Murungi[4], E. Nduati[7], E. Landais[8], D. Muema[5], T. Ndung'u[1]
[1]Africa Health Research Institute, Basic and Translational Science, Durban, South Africa, [2]Africa Health Research Institute, Durban, South Africa, [3]KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya, [4]International AIDS Vaccine Initiative IAVI, Kilifi, Kenya, [5]KAVI Institute of Clinical Research (KAVI-ICR), College of Health Sciences, University of Nairobi, Nairobi, Kenya, [6]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [7]KEMRI- Wellcome Trust Research Programme, Kilifi, Kenya, [8]Neutralizing Antibody Center, San Diego, United States

Background: Deep sequencing technologies have greatly advanced the study of human antibody repertoires, providing valuable information for developing therapeutic antibodies and effective HIV vaccines. However, a comprehensive understanding of the human antibody repertoire in African populations, where HIV prevalence is high, remains limited.
This study aims to evaluate the presence of broadly neutralizing antibody (bnAb)-like features in B-cell repertoires from an African cohort.
Methods: We sequenced the immunoglobulin genes of heavy and light chains from cryopreserved peripheral blood mononuclear cells (PBMCs) obtained from twenty women aged 18 to 23. Baseline samples were collected from all participants, with additional longitudinal samples taken from those who became people living with HIV (PLWH). Among these, ten PLWH had longitudinal samples available at three key time points: before HIV detection, after detection before antiretroviral therapy (ART) initiation, and after ART initiation. This cohort included five individuals who initiated ART during the chronic phase of HIV acquisition (late-treated) and five who began treatment immediately following HIV detection (early-treated).
Results: The deep sequencing analysis of immunoglobulin heavy and light chain genes (IgM and IgG repertoires) revealed a preferential usage of specific immunoglobulin gene segments, including IGHV3-30, VH4-59, and VH4-39, as well as D3 and J4 segments. Notably, the alleles IGHV3-30*02 and IGHV3-30*04 were abundantly utilized across all groups; however, they exhibited significant depletion in the late-treated group.
Furthermore, these alleles were associated with longer CDRH3 regions (≥20 amino acids) in the early-treated group compared to the negative group, suggesting a potential impact of HIV disease on the antibody repertoire. Additionally, a high frequency of DH3-10 and DH3-22 gene alleles were observed across groups. The analysis also examined the precursor frequencies of rare VRC01-class B cells in selected donors, given that immunogens designed to elicit VRC01-class broadly neutralizing antibodies (bnAbs) are currently in advanced clinical development.
We confirmed the presence of IGHV1-2 alleles compatible with VRC01-class responses across all groups in this cohort, with a more pronounced prevalence observed in the late-treated group.
Conclusions: Overall, this study informs strategies for individuals without HIV and those living with HIV, advancing understanding of antibody diversity and vaccine development.

TUPEA010

Distinct CD8 T cell immune profiles in people living with HBV and HIV/HBV co-infection

A. Alrubayyi[1], J. Preechanukul[2], B. Sun[1], E. Arbe-Barnes[2], J. Kokici[2], K. da Costa[2], I. Ghosh[3], F. Burns[4], S. Kinloch[4], P. Simoes[4], S. Bhagani[2], P.T.F. Kennedy[5], M.K. Maini[2], U.S. Gill[5], D. Peppa[2]
[1]University of Oxford, Oxford, United Kingdom, [2]University College London, Division of Infection and Immunity, London, United Kingdom, [3]Mortimer Market Centre, Department of HIV, CNWL NHS Trust, London, United Kingdom, [4]Royal Free Hospital NHS Foundation Trust, The Ian Charleson Day Centre, London, United Kingdom, [5]Barts Liver Centre, Barts & The London School of Medicine & Dentistry, QMUL, London, United Kingdom

Background: Chronic hepatitis B (HBV) infection remains a significant health challenge with a disproportionally high burden among people with HIV. However, people with HBV/HIV co-infection are often excluded from clinical trials, creating a critical gap in addressing their needs within the HBV-cure agenda. CD8 T cell responses are important for viral control, yet these responses are traditionally thought to be more compromised in people with co-infection. This study aimed to investigate the phenotypic and functional profiles of CD8 T cells in people with HIV/HBV vs HBV mono-infection under long-term therapy, to identify potential new immunotherapy targets that could bolster antiviral responses.
Methods: We performed a comprehensive analysis at the single-cell level of CD8 virus-specific responses in 62 participants (HBV (n=20), HIV mono-infection (n=21), and HBV/HIV co-infection (n=21)). All participants were virally suppressed

on antiviral therapy with dual activity against both viruses. Virus-specific responses were evaluated following stimulation with overlapping HIV and HBV peptide pools.
Results: In individuals with HIV/HBV co-infection, we observed a significant increase in terminally differentiated subsets ($CCR7^{-}CD45RA^{+}$) and a decrease in naïve T cells ($CCR7^{+}CD45RA^{+}$), resembling changes in those with HIV mono-infection. Transcriptomic analysis revealed enhanced activation of pathways linked to T cell receptor and PD-1 signalling in co-infection compared to HBV mono-infection. Proteomic profiling showed intrinsic exhaustion differences, highlighting a paradoxical increase in terminally exhausted $Tox^{high}TCF\text{-}1^{-}CD127^{-}CD8$ T cells in people with HBV mono-infection.
Conversely, people with HIV/HBV co-infection exhibited a distinct effector memory cluster with high granzyme B and CD127 expression, suggesting cytotoxic potential and stem-like properties, along with increased frequencies of precursor exhausted CD8 T cells. These differences were associated with more robust, and polyfunctional HBV-specific CD8 T cell responses in HBV/HIV co-infection against HBV surface and core, compared to HBV mono-infection
Conclusions: Our study provides the first evidence that people with HIV/HBV, in the current ART era, display functional CD8 T cell responses, despite the 'scar' of chronic infection. These findings underscore the benefits of early antiviral therapy and the importance of tailored immunotherapies to revitalize antiviral responses in different patient groups.

TUPEA011

Novel broadly neutralizing antibodies isolated using HIV-1 trimers from difficult-to-neutralize isolates

D. Martin[1,2], S. Rasebotsa[1,2], N. Mzindle[1,2], T. Naidoo[1,2], P. Kgagudi[1,2], S.R. Bala[1,2], C. Van Den Berg[3], R. Serage[1,2], D. Mhlanga[1,2], J. Woodward[3], P.L. Moore[1,2,4], N.N. Mkhize[1,2], T. Moyo-Gwete[1,2], D. Kitchin[1,2]
[1]SAMRC Antibody Immunity Research Unit, University of Witwatersrand, Johannesburg, South Africa, [2]National Institute for Communicable Diseases of the National Health Laboratory Service, Johannesburg, South Africa, [3]Electron Microscopy Unit, University of Cape Town, Cape Town, South Africa, [4]Centre for the AIDS Programme of Research in South Africa (CAPRISA), University of KwaZulu Natal, Durban, South Africa

Background: Emerging resistance to existing broadly neutralizing antibodies (bNAbs) in circulating HIV-1 variants may compromise the efficacy of these bNAbs used as prophylactics. Therefore, new bNAbs that are effective against difficult-to-neutralize strains are needed. We show the use of a soluble envelope (Env) trimer, derived from a difficult-to-neutralize HIV-1 strain, to isolate novel bNAbs from a donor with a broadly neutralizing plasma response.
Methods: Using pseudovirus-based neutralization assays, 183 African viruses were screened against various bNAbs. We identified the FRESH1388 isolate, which was resistant to multiple bNAb classes. A soluble Env trimer, based on this strain, was designed, expressed in mammalian cells and purified by affinity and size-exclusion chromatography. The trimer was further characterised by antibody multiplex binding assays and electron microscopy. Using the FRESH1388 trimer, B cells were sorted for antibody isolation from CAPRISA participant CAP287, who developed neutralization breadth. Isolated B cells were sequenced and the antibodies were screened against a heterologous six-virus panel, which predicts breadth against larger viral panels, and the epitope specificity was mapped by binding assays using antigens with mutated epitopes.
Results: The FRESH1388 isolate was resistant to bNAbs from all epitope classes, except the V3-glycan. The trimer was antigenically similar to the pseudovirus and confirmed to be in the closed conformation. Paired heavy and light chain sequences were recovered for 104 B cells, sorted using the FRESH1388 trimer. Isolated antibodies were from several clonal families, with the largest having a rarely used germline gene, VH3-13. Ten antibodies were selected, based on clonal families, percent somatic hypermutation (>20%), CDRH3 lengths (>20 residues) and neutralization screening data, for functional characterisation. Four antibodies, from different lineages, that had neutralization breadth up to 50%, were identified. Epitope mapping of these antibodies indicated that they were either N332-dependent or V2-apex targeting.
Conclusions: Four bNAbs, from different lineages, were isolated using a trimer from a difficult-to-neutralize HIV-1 strain. These bNAbs had different epitope specificities and levels of breadth. This study shows that trimers derived from difficult-to-neutralize strains can be used as highly selective sorting baits, enabling the isolation of novel bNAbs from participants with broadly neutralizing plasma responses.

TUPEA012

Impaired glucose and fatty acid uptake in monocytes and CD8+ T cells of people living with HIV

A. Mohamed[1], Y. Zungu[1], K. Naidoo[2], S. Shalekoff[3], O. Ebrahim[4], Z. Waja[5], N. Martinson[5], C. Tiemessen[3], C. Thobakgale[1]
[1]University of the Witwatersrand, School of Pathology, Faculty of Health Sciences, Johannesburg, South Africa, [2]HIV Pathogenesis Programme, University of KwaZulu-Natal, Durban, South Africa, [3]Centre for HIV and STIs, National Institute for Communicable Diseases, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [4]University of the Witwatersrand, School of Therapeutic Sciences, Faculty of Health Sciences, Johannesburg, South Africa, [5]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa

Background: Cellular metabolism is a major determining factor in immunological function with implications for antiviral immunity. Metabolic dysfunction in people living with HIV (PLWH) has been associated with non-AIDS-related conditions. However, the metabolic profiles of in-

nate immune cells in PLWH, particularly HIV controllers, are poorly reported in a South African setting. Therefore, we investigated the metabolic profiles of innate immune cells in PLWH.

Methods: We recruited 52 Black South Africans, including HIV-elite controllers (n=11), HIV-progressors (n=10), PLWH on antiretroviral therapy (ART) (n=18) and HIV-uninfected persons (n=13).

Upon voluntary consent, blood was collected and peripheral blood mononuclear cells (PBMCs) were isolated. Metabolic substrate uptake, mitochondrial health and Glut1 expression were assessed in the study participants' T-cells and innate immune cells.

Glut1 antibody for glucose transporter expression, fluorescently tagged metabolites 2-NBDG (2-[N-(7-nitrobenz-2-oxa-1,3-diazol-4-yl) amino]-2-deoxy-D-glucose) and BODIPY FL C_{16} (4,4-Difluoro-5,7-Dimethyl-4-Bora-3a,4a-Diaza-s-Indacene-3Hexadecanoic-A) for glucose and fatty acid uptake, and Mito Trackers Green and Deep Red for mitochondrial mass and membrane potential were measured by multicolour flow cytometry.

Results: HIV-elite controllers exhibited reduced glucose uptake in monocytes compared to HIV-uninfected individuals (p=0.04) and PWH-ART (p=0.004). Glut1 expression was lower in CD8+ T cells of HIV-progressors compared to HIV-elite controllers (p=0.05) and HIV-uninfected individuals (p=0.03).

Additionally, CD8+ T cells in treatment-naïve HIV-progressors showed reduced glucose uptake compared to ART-treated PWH (p=0.05). Fatty acid uptake was lower in monocytes of HIV-progressors compared to PWH-ART (p=0.0002) and HIV-uninfected individuals (p=0.02).

No significant differences in mitochondrial mass were observed between groups. Glucose uptake positively correlated with tumour necrosis factor-α (r=0.34, p=0.04) and interferon-α (r=0.34, p=0.03) production in monocytes of PLWH.

Conclusions: Innate immune cells in PLWH exhibit metabolic dysfunction demonstrated by impaired uptake of essential metabolites. These metabolic irregularities were also observed in HIV-elite controllers, despite spontaneous viral control, and may contribute to non-AIDS-related conditions.

Understanding and targeting persistent HIV reservoirs

TUPEA013

Factors associated with HIV-1 DNA dynamics in early treated children with perinatal HIV

K. Reddy[1], A. Tagarro[2], S. Dominguez-Rodriguez[2], T. Smit[1], M. Spyer[3], S. Barnabas[4], M. Lain[5], K. Otwombe[6], A. Maiga[7], T. Nhampossa[8], C. Molechan[1], P. Rojo[2], C. Giaquinto[9], P. Rossi[10], T. Ndung'u[1], EPIICAL Consortium

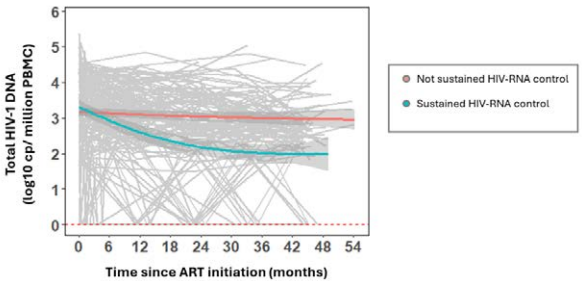
[1]AHRI, Durban, South Africa, [2]Instituto de Investigación 12 de Octubre, Madrid, Spain, [3]UCL, London, United Kingdom, [4]Stellenbosch University, Cape Town, South Africa, [5]Fundaçao Ariel Glaser, Maputo, Mozambique, [6]PHRU, Johannesburg, South Africa, [7]Gabriel Toure Hospital, Bamako, Mali, [8]Fundaçao Manhiça, Maputo, Mozambique, [9]Penta Foundation, Padova, Italy, [10]Universidad Tor Vergata, Roma, Italy

Background: This study analyzed the total HIV reservoir, serially for 4 years, in African children who started ART early in life and identified factors associated with reservoir size dynamics.

Methods: Participants were infants from the EARTH-EPIICAL Cohort established in South Africa, Mozambique, and Mali where HIV was diagnosed shortly after birth followed by early ART initiation. Total HIV-1 DNA was analyzed longitudinally in all 208 participants, from ART initiation to 4 years (or death or loss to follow-up), from PBMCs by droplet digital PCR.

Results: 155/208 (74%) had a follow-up >12 months and were analyzed. ART was initiated at a median of 34 days [IQR, 26-73] with median follow-up time of 44.1 months [IQR 37.6-45.5]. A total of 19/155 (12%) children achieved undetectable HIV-1 DNA after 4 years of follow-up. Overall, total HIV DNA levels decreased over time from pre-ART to 4 years post-ART. The median decay slope was -0.020 [IQR:-0.042 to 0.00] log10 total HIV-1 DNA copies/mL per month (-0.212 [IQR:-0.503 to 0.077] per year). A total of 114/155 (73.6%) presented a negative slope, decreasing their HIV-DNA over time, and 38/155(24.5%) a positive slope. Determinants of faster HIV-1 DNA decay were lower pre-ART viral load (p<0.001) and region (Mali, p=0.001).

Children with who achieved sustained viral load undetectable for >12 months showed a faster virological decay (figure).Factors associated with a smaller reservoir after 3 years of ART were lower pre-ART viral load (p<0.01), faster rate of total HIV-1 DNA decay in the first year (p<0.05) and female sex (p<0.05).



Conclusions: Early virological parameters such as pre-ART viral load and initial HIV-1 DNA decay rate are important predictors of total viral reservoir size in early treated children living with HIV. A smaller reservoir in females highlights that sex differences should be explored to understand mechanisms of HIV reservoir control.

Novel treatment and prevention strategies, vaccines and immunotherapies

TUPEA014

Broadly neutralizing antibody VRC07-523LS persists at four months in mucosal tissue following intravenous administration at 10mg/kg and 30mg/kg (HVTN128)

M.P. Lemos[1], K. Seaton[2], J. Heptinstall[2], O. Hyrien[1], S. Chen[1], K. Chiong[2], A. Sharak[2], C. Paez[1], M.A. Anderson[1], J.A. Gwrira[3], L.L. Polakowski[3], J.A. Johnson[4], J.A. Gothing[4], J. Czartoski[1], J. Maenza[1], L.R. Baden[4], M.J. McElrath[1,5], G. Tomaras[2,6,7], S.R. Walsh[4]
[1]Fred Hutchinson Cancer Center, Vaccine and Infectious Disease Division, Seattle, United States, [2]Duke University, Center for Human Systems Immunology, Department of Surgery, Durham, United States, [3]National Institutes of Health, National Institute of Allergy and Infectious Diseases, Rockville, United States, [4]Brigham & Women's Hospital, Harvard Medical School, Division of Infectious Diseases, Boston MA, Harvard, United States, [5]University of Washington, Department of Medicine, Seattle, United States, [6]Duke University, Department of Immunology, Durham, United States, [7]Duke University, Department of Surgery and Department of Molecular Genetics and Microbiology, Durham, United States

Background: Effective concentrations of broadly neutralizing antibodies (bnAbs) are likely needed in mucosal tissues to protect against HIV-1 sexual exposure. VRC07-523LS, was infused intravenously (IV) every four months, and serum, rectal, seminal cervical, and vaginal VRC07-523LS levels were measured in male and female sex assigned at birth (MSAB and FSAB) individuals.
Methods: Twenty-four participants without HIV (13 MSAB and 11 FSAB,) from the US received VRC07-523LS (10mg/kg or 30mg/kg IV) at months 0, 4 and 8. Paired serum, rectal and cervicovaginal secretions, rectal, cervical and vaginal biopsies, and semen, were collected pre-infusion, 2 weeks after the first infusion, and 2 and 16 weeks post-third infusions.
VRC07-523LS levels were examined using SMCxPro (mucosal) and Binding Antibody Multiplex Assay (serum). VRC07-523LS concentrations were normalized to total IgG (Bioplex), to compare across compartments. Mucosal penetration percentages vs serum were calculated after total protein (Quant-it) normalization.
Results: VRC07-523LS was detectable in serum at all post-baseline timepoints (all p<0.001). In rectal, cervical and vaginal biopsies, semen and cervicovaginal secretions, VRC07-523LS was detectable 2 weeks and 16 weeks post-infusion in 80% of participants. VRC07-523LS was not detected above baseline levels in rectal secretions at any timepoint.
At 2 weeks post VRC07-523LS infusion, the 30mg/kg dose was 2.1-2.5 times higher in serum (p<0.001), 2.6-3 fold higher in rectal tissue (p<0.001) and 1.8-3.9 times higher in cervicovaginal secretions (p=0.014) than the 10mg/kg dose.
However, serum VRC07-523LS levels rarely correlated with those of mucosal compartments collected at the same timepoint.
Body weight-adjusted VRC07-523LS serum levels trended higher in FSAB than MSAB (p=0.052). VRC07-523LS levels in FSAB rectal biopsies were 1.9-fold higher than MSAB (p<0.001).
Rectal biopsy penetration was higher in FSAB (10mg/kg: 15.2%of serum; 30mg/kg: 22.3%; p=0.015) compared with MSAB (9.9% and 11.9% respectively).
Conclusions: Except for rectal secretions, both doses of VRC07-523LS reach mucosal compartments and persist four months post-third infusion in most participants, suggesting this dosing regimen provides detectable bnAb trough levels. In rectal biopsies, FSAB have higher VRC07-523LS than MSAB, suggesting a sex-specific difference in mAb penetration and accumulation.
Persistence of passively infused VRC07-523LS in the mucosa supports the use of this bnAb in HIV-1 prevention and treatment.

Emerging, re-emerging and neglected virus: epidemiology, pathogenesis, host immune responses, vaccines, immunotherapies and overlap with HIV acquisition

TUPEA016

SARS-CoV-2 infection induces pro-fibrotic and pro-thrombotic lipid-laden foam cell formation

A. Wahl[1], D. Battaglia[1], C. Post[2], W. Yao[2], J.V. Garcia[1]
[1]University of Alabama at Birmingham, Microbiology, Birmingham, United States, [2]University of North Carolina at Chapel Hill, Microbiology and Medicine/Infectious Diseases, Chapel Hill, United States

Background: COVID-19 and Long COVID are characterized by a dysregulated immune response and macrophages are an important aspect of this pathological immune response.
Methods: A clinical isolate of SARS-CoV-2 (2019-nCoV/USA-WA1/2020) was obtained from the US Centers for Disease Control and Prevention (GenBank accession MN985325.1) and passaged twice in Vero E6 cells to create a passage-5 working stock. Infectious virus clones were used to derive wild-type SARS-CoV, MERS-CoV (HCoV-EMC/2012),

SHC014-CoV, and WIV1-CoV. Viruses were titered on Vero E6 (SARS-CoV, SHC014-CoV, and WIV1-CoV) or Vero CCL81 cells (MERS-CoV). SARS-Cov-2 infected LoM human lung tissues analyzed at days 2, 6, and 14 post-exposure and analyzed following EIDD-2801 or vehicle. Human lung tissue collected from uninfected LoM and SARS-CoV-2 infected LoM at 2- and 6-days post exposure from previously published experiments were fixed, paraffin embedded, and sectioned (5µm). Tissue sections were deparaffined and stained overnight according to NanoString Technologies GeoMX Digital Spatial Profiler (DSP) Leica protocol.

Results: We demonstrate that SARS-CoV-2 infection induces macrophage proliferation and the extensive formation of enlarged lipid-laden macrophages or foam cells. These results were confirmed using three different *in vivo* models of SARS-CoV-2 infection: humanized mice implanted with human lung tissue, non-human primates, and post-mortem human lung tissue.

Notably, under our experimental conditions, this effect was not observed for the other coronaviruses tested. Infection by SARS-CoV-1, MERS-CoV, and two bat coronaviruses did not result in macrophage proliferation or the formation of foam cells. Foam cells in SARS-CoV-2 infected human lung tissue display a pro-fibrotic and pro-thrombotic phenotype. After viral clearance, macrophage numbers remain elevated, and lung fibrosis and thrombi persist.

Importantly, we show that pre-exposure prophylaxis or early treatment with a SARS-CoV-2 antiviral prevents SARS-CoV-2-induced macrophage proliferation, foam cell formation, collagen deposition, and smooth muscle actin production in lung tissue.

Conclusions: We postulate that SARS-CoV-2 infection induces the proliferation of lung macrophages and the production of foam cells with a pro-fibrotic and pro-thrombotic phenotype that populate alveolar spaces. These observations highlight the contribution of macrophages to the development of inflammation and tissue injury leading to the pulmonary fibrosis observed in COVID-19 patients.

Course of HIV disease

TUPEB017

Recurrent interruptions in treatment threaten the sustainability of gains in the third 95 in a country at 95-95-95

S. Matse[1], S. Haumba[1,2], L. Mamba[1], A. Mafukidze[1], F. Khumalo[1], R. Mapoana[1], N. Musarapasi[1], E. Nyandoro[1], R. Chekenyere[1], V. Williams[1,3], S. Matse[4], D. Bazira[2], S. Ojoo[2], P. Bongomin[1]

[1]Center for Global Health Practice and Impact, Georgetown University, Clinical Services, Mbabane, Eswatini, [2]Center for Global Health Practice and Impact, Georgetown University Medical Center, Washington, United States, [3]Utrecht University, Julius Global Health, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, the, [4]Ministry of Health, HIV Care and Treatment, Mbabane, Eswatini

Background: The Eswatini HIV program reports that interruption in treatment (IIT) has remained between 4-6% on a quarterly bases in Manzini and Lubombo regions over the last four years, regardless of introduction of new interventions to sustain the gains in the 95-95-95 targets. This could partly be due to recurrence in interruption by the same clients.

This study measured the rate of recurrent IIT among clients on antiretroviral therapy, its predictors, and its effect on viral load (VL) outcomes.

Methods: We conducted a prospective cohort study using programmatic data of clients who interrupted treatment between October 2020 and March 2021 in 84 facilities. The clients were followed for 36 months to March 2024 to observe if they reengaged in care and recurrently interrupted.

We collected VL results within the last 12 months prior to interruption and within 12 months by the end of the follow-up. Binary logistic regression analysis was used to identify predictors of recurrent IIT and unsuppressed VL.

Results: A cohort of 3928 clients who had interrupted treatment were followed, 16.7% (n=655) did not return to treatment. More than a fifth of the IIT clients recurrently interrupted treatment, an IIT recurrence rate of 22.7% (n=744) in 36 months.

Of the recurrent IIT clients, 63% (n=469) had interrupted treatment three times. The unsuppressed VL rate was higher (5.2%, n=18) among recurrent IIT clients than non-recurrent IIT clients (1.0%, n=17).

Clients likely to recurrently interrupt treatment are those receiving ART services in Public Health Units (facilities for maternal-child health services) (AOR:1.8 [95%CI:1.1-2.9], p=0.016); aged 15-29 years (AOR:1.5 [95%CI:1.1-2.0], p=0.007), or have switched ART-regimen (AOR:1.8 [95%CI:1.4-2.4], p<0.001).

Recurrent IIT clients were four folds more likely to be virally unsuppressed than non-recurrent IIT clients (AOR:4.1 [95%CI:1.8-9.4], p=0.001), and those who had an unsuppressed VL when they initially interrupted treatment[PM(1] were 10 folds more likely to have an unsuppressed VL (AOR:10.7 [95%CI:4.0-18.7], p=<0.001).

Conclusions: IIT recurrence is a challenge in the second 95, and recurrent IIT clients are more likely to be virally unsuppressed than non-recurrent IIT clients who reengage in care.

Cure interventions and other strategies and therapies

TUPEB018

Clinical outcomes 5 years after brief analytical treatment interruption among individuals who initiated antiretroviral therapy during acute HIV infection

P. Chan[1], S. Pinyakorn[2,3], C. Sacdalan[4,5], E. Kroon[4,6], P. Promsena[4], S. Sriplienchan[4], J. Intasan[4], N. Phanuphak[6], M. de Souza[4], T. Crowell[2,3], S. Vasan[2,3], R. Paul[7], S. Spudich[1], L. Trautmann[2,3], D. Colby[2,3], RV254 Research Group

[1]Yale University, New Haven, United States, [2]Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, United States, [4]SEARCH Research Foundation, Bangkok, Thailand, [5]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [6]Institute of HIV Research and Innovation (IHRI), Bangkok, Thailand, [7]Faculty of Psychological Sciences, Missouri Institute of Mental Health, University of Missouri-St. Louis, St. Louis, United States

Background: Understanding long-term outcomes after analytical treatment interruption (ATI) is crucial for designing safe HIV cure trials. We report long-term outcomes in Thai ATI participants.

Methods: We evaluated 212 adults who initiated ART during Fiebig I-V acute HIV infection (AHI) in Bangkok, Thailand. Seventy-two (34%) had undergone trials with brief ATI (median duration off-ART: 34 days) and ART resumption at plasma viral load (VL) >1000 copies/mL.

Their laboratory (CD4+ and CD8+ T-cell counts, plasma VL) and mood outcomes (Patient Health Questionnaire 9 [PHQ-9] score) at the first assessment following ART resumption with HIV re-suppression (T1), and five years later (T2) were compared to corresponding outcomes of control participants who met eligibility criteria but declined to participate in ATI, matched by ART duration since AHI.

Incidence density rates (IDRs) and 95% confidence intervals (CIs) of HIV blips (VL 20-999 copies/ml), viral failure (VL ≥1000 copies/ml), and Grade III or above adverse events (AEs) occurring between T1 and T2 were compared between groups.

Results: At T1, ATI participants trended towards younger age than control participants (p=0.054) but were similar in other characteristics *(Table)*.

Between T1 and T2, ATI participants exhibited no significant differences in changes in CD4+ and CD8+ T-cell counts, CD4/CD8 ratio, or PHQ-9 scores compared to controls (all p>0.05). They also demonstrated comparable IDRs of blips (3.87 [95%CI 2.33-6.04] vs. 4.02 [95%CI 2.80-5.58] per 100 years follow-up (/100YFU), p=0.931), viral failure (1.22 [95%CI 0.45–2.66] vs 1.95 (95%CI 1.14–3.12)/100YFU, p=0.522), and grade III or above AEs (IDR: 8.55 [95%CI 6.16-11.55] vs. 10.56 [95%CI 8.51-12.94]/100YFU, p=0.419) compared to controls. One participant succumbed to depression-related suicide 3.8 years after ATI.

	Control (n=140)	ATI Participants (n=72)	p-value
Age, year	31 (27-36)	28 (25-34)	0.054
Male, n (%)	133 (95)	70 (97)	0.721
T-cell Parameters			
CD4 T-cell count, cells/mm3	716 (575-863)	677 (547-739)	0.179
CD8 T-cell count, cells/mm3	608 (472-801)	570 (460-792)	0.819
CD4/CD8 ratio	1.15 (0.92-1.48)	1.18 (0.87-1.42)	0.494
Plasma HIV suppression (<20cps/ml), n (%)	136 (97)	72 (100)	0.302
Duration since Acute HIV Infection, years	3.2 (2.8 – 4.5)	3.4 (2.8 – 4.5)	0.572
Patient Health Questionnaire 9 Total Score (Range 0-27)	5 (2-8)	4 (2-6.5)	0.281
ART Regimen, n (%)			0.047
2NRTIs+DTG	89 (64)	33 (46)	
2NRTIs+EFV	41 (29)	31 (43)	
Others	10 (7)	8 (11)	

Median (Interquartile range) is presented unless specified.
Abbreviations: ART: Antiretroviral therapy; ATI: Analytical Treatment Interruption

Table. Participants Demographics upon Achieving HIV Resuppression Following ATI and ART Resumption (T1).

Conclusions: ATI participants in the RV254 study exhibited similar laboratory outcomes and AEs compared to controls five years after viral resuppression with ART, demonstrating the long-term safety of brief and closely monitored ATI trial participation.

ART resistance

TUPEB019

Three-years outcome after genotyping-guided switch in HIV multi-drug resistant clients in Cameroon: evidence-based strategies for achieving epidemic control in low-and middle-income countries

[1]Chantal Biya International Reference Center for Research on HIV/AIDS Management and Care, Yaounde, Cameroon, [2]National HIV Drug Resistance Working Group, Ministry of Public Health, Yaounde, Cameroon, [3]University of Buea, Faculty of Health Sciences, Buea, Cameroon, [4]University of Rome "Tor Vergata", Ph.D. Courses in Microbiology, Immunology, Infectious Diseases and Transplants (MIMIT), Faculty of Medicine and Surgery, Rome, Italy, [5]Regional Hospital Limbe, Limbe, Cameroon, [6]Regional Hospital Buea, Buea, Cameroon, [7]Baptist Hospital Mutengene, Mutengene, Cameroon, [8]University of Yaounde I, Faculty of Medicine and Biomedical Sciences, Yaounde, Cameroon, [9]Ministry of Public Health, Division of Health Operational Research, Yaounde, Cameroon, [10]Bambino Gesu' Children's Hospital, Rome, Italy, [11]Africa Centres for Disease Control and Prevention (Africa CDC), Addis Ababa, Ethiopia, [12]Ministry of Public Health, Central Technical Group, National AIDS Control Committee (NACC), Yaounde, Cameroon

Background: Monitoring of HIV-acquired clients with long-term treatment remains challenging in low- and middle-income countries (LMICs) due to risks of multi-class HIV drug resistance (HIVDR). Following a personalized strategy, we sought to evaluate the treatment response among clients with multi-class HIVDR following genotypic resistance guided switch in Cameroon.

Methods: A cohort-study was conducted in the South-West region of Cameroon among clients failing first- and second-line antiretroviral treatment (ART) (i.e. non-nucleoside reverse transcriptase inhibitors (NNRTI)- and protease inhibitor (PI)-based) from 2018-2023.

Following HIV-1 genotypic resistance testing (GRT), clients were switched to most-effective therapies and viral load (VL) was monitored after 3-, 6-, 12-, 24-, and 36-months. Data analysis used Epi Info v.7.2, with $p<0.05$ considered statistically significant.

Results: From the 336 clients failing ART in the region, 170 (50.6%) presented with GRT results; from these, 72 were further lost-to-follow-up, 12 died and 5 defaulted, giving 81 study-inclusions (57.5% females; 47/81). Before GRT, the median CD4 and VL were 232.5 [161.25–401.25] cells/µL and 54,480 [13,932.5–220,153] copies/mL respectively; with 65.4% (53/81) participants failing PI-based versus 34.6% (28/81) failing NNRTI- and dolutegravir (DTG)-based first-line ART. Overall HIVDR rate at failure was 60.5%, and prevailing mutations were M184I/V (26.1%), K103N/S (20.7%) and M46I/L (32.8%) for NRTI, NNRTI and PI respectively; with CRF02_AG as the prevailing viral clade (71.4%).

Following GRT, AZT+3TC+(LPV/r or ATV/r) (26.4%) was mostly recommended, followed by TDF+3TC+DTG+DRV/r (12.4%). Monitoring data revealed that 92.6% (75/81) of the participants respected the prescribed regimen.

Viral suppression (VL<1000copies/ml) post-GRT was 80% at 3-months, 84.8% at 6-months, 81.4% at 12-months, 93.7% at 24-months and 86.7% at 36-months. Prescription of DTG-based regimen was the only determinant of good virological response (p=0.04).

Furthermore, DTG-based regimens yielded significantly higher responses than DTG-sparing regimens up till 24-months (p=0.013, p=0.0015, p=0.0005, p=0.02 respectively).

Conclusions: Our findings highlight maintained viral suppression over three years, following GRT-guided switch in individuals with multi-class HIVDR, with DTG-based regimens yielding a higher outcome. This underscores the significance of personalizing ART management for difficult-to-treat people to achieve HIV control by 2030 in LMICs.

HIV and ageing

TUPEB020

Evaluation of differences in online drug-drug interaction tools among adults living with HIV

A. López Iñiguez[1], Y. Caro-Vega[1], P. Alarcón-Murra[1], G. Muñuzuri-Nájera[1], J. Castilho[2], F. Maruri[3], J.G. Sierra-Madero[1], B.E. Crabtree-Ramírez[1]

[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Infectious Diseases, Mexico City, Mexico, [2]Vanderbilt University Medical Center, Health Policy, Division of Infectious Diseases, Nashville, United States, [3]Vanderbilt University Medical Center, Vandebilt Tuberculosis Center, Nashville, United States

Background: To prevent harm, the identification of drug-drug interactions (DDI) is an important part of HIV care. Multiple databases for identifying DDI are available, there is scarce information in HIV treatment. This study aimed to compare the frequency of clinically significant DDI using two online DDI databases in a cohort of adults living with HIV (AHIV).

Methods: We evaluated all medications (use ≥30 days) self-reported at baseline visit by the Mexican participants included in the Sentinel Research Network (SRN) from IeDEA (International Epidemiology Databases to Evaluate AIDS). We described the frequency of DDI classified as: weak, potential and contraindicated by Liverpool HIV Drug Interactions®; and, as minor, moderate and major by Drugs.com®. Categories were considered equivalent between databases. Using Fleiss kappa statistics, we es-

timated the concordance of the results obtained. An ID physician evaluated the corresponding interactions levels, selected those clinically significant and reviewed the drugs and potential clinical effects reported.

Results: In 200 participants, 102 (51%) took concomitant medications besides ARVs. Most were male (n=91, 89.2%) with a median age of 54 years, and 94 (92.1%) had at least one comorbidity. With Liverpool®, there were 61 DDI: 19 weak interactions, 42 potential, and zero "contraindicated"; while with Drugs.com® there were 91 DDI: 9 minor, 61 moderate, and 21 majors. The concordance between databases was poor: κ of 0.08 (SE 0.06 95% IC: -0.03 – 0.21); there was no concordance in those classified as weak/minor or major/contraindicated; only 7 were similar in the moderate/potential DDI. From the clinically significant DDI, the more frequent clinical effects were risk of QT prolongation (n=17/28, 60.7%); acute kidney failure (n=4, 14.2%); rhabdomyolysis and reduction of ARV levels (n=2, 7.1%). The drugs more frequently related to major/contraindicated DDI were: efavirenz and psychiatric drugs.

Conclusions: In this cohort, the frequency of major/contraindicated DDI were different between databases (0 by Liverpool® and 21 by Drugs.com®) and, these were clinically significant, showing a poor concordance between databases. In the era of a growing number of AHIV and polypharmacy, identification of better tools to assess DDI is needed. A clinical evaluation of the DDI is important for intervention.

TUPEB021

Co-morbidities in HIV positive and HIV negative individuals aged ≥60 years: a comparative analysis

L.A. Ombajo[1,2], J. Penner[2,3], J. Nkuranga[1,2], V. Omodi[1,2], E. Otieno[1,2], S. Wahome[4], D. Nyakoe[5]

[1]University of Nairobi, Clinical Medicine and Therapeutics, Nairobi, Kenya, [2]University of Nairobi, Center for Epidemiological Modelling and Analysis, Nairobi, Kenya, [3]University of British Columbia, Family Practice, Vancouver, Canada, [4]Kenyatta National Hospital, Comprehensive Care Centre, Nairobi, Kenya, [5]Mbagathi Hospital, Radiology, Nairobi, Kenya

Background: Age-related co-morbidities are increasing among people living with HIV (PLWH)and impact treatment choices and outcomes. We report the prevalence of non-HIV co-morbidities in older PLWH (≥60 years) and age- and gender-matched HIV negative (HN) individuals.

Methods: Data from participants in the B/F/TAF Elderly Study (which enrolled virally suppressed PLWH ≥60 years on first line antiretroviral therapy and randomised them to continue their current regimen or switch to B/F/TAF) and an age- and gender-matched HN group were included. We assessed body mass index (BMI), blood pressure (BP), fasting blood sugar and lipids, estimated glomerular filtration rate (eGFR), lumbar and femoral neck bone mineral density (BMD), thoracolumbar vertebral fractures and Fried frailty phenotype. We compared the prevalence of co-morbidities and concomitant medications at enrolment into this 5-year study.

Results: Between February 2022 and 2024, 520 participants were enrolled into the B/T/TAF Elderly Study and a subset of 296 underwent DXA, vertebral X-rays and frailty assessment, along with 122 HN participants. All participants were black, the median age in both groups was 64 years (range 60-79), 267 (51.3%) PLWH and 61 (50%) HN were female. There was no difference in median BMI, hypertension, hyperglycaemia or frailty between groups (Table).

The median total cholesterol and LDL were higher in the HN group. Substantially more PLWH had eGFR <60mL/min/1.73m^3 (33% PLWH, 10% HN, p<0.001). Median lumbar spine BMD was lower in PLWH (0.87g/cm^2 PLWH, 0.95g/cm^2 HN, p<0.001) but there was no difference in thoracolumbar vertebral fractures (20% PLWH, 18% HN, p=0.635). More PLWH had ≥1 comorbidity (78% PLWH, 58% HN, p<0.001) and ≥1 non-ARV medication (99% PLWH, 28% HN, p<0.001).

Characteristic	PLWH N = 520	HIV Negative (HN) N = 122	Overall N = 642	P-Value
Body Mass Index, kg/m^2	26.4 (23.2, 30.1)	27.4 (24.6, 30.4)	26.6 (23.6, 30.1)	0.233
Hypertension	292 (56.2%)	46 (54.8%)	338 (56.0%)	0.812
Hyperglycemia	39 (7.5%)	13 (10.7%)	52 (8.1%)	0.239
Lipids				
LDL, mmol/L	2.8 (2.3, 3.5)	3.2 (2.7, 3.8)	2.90 (2.3, 3.5)	<0.001
Total cholesterol, mmol/L	4.5 (3.9, 5.3)	5.2 (4.6, 5.9)	4.63 (4.0, 5.4)	<0.001
Impaired kidney function (defined as eGFR < 60 mL/min/1.73m^2)	172 (33.1%)	12 (9.8%)	184 (28.7%)	<0.001
Bone (N=418)				
• BMD lumbar spine, g/cm^2	0.87 (0.78, 0.99)	0.95 (0.82, 1.08)	0.89 (0.80, 1.02)	<0.001
• Thoracolumbar vertebral fractures (≥1)	48 (20.3%)	15 (17.9%)	63 (19.6%)	0.635
• BMD category (using lumbar spine T-score)				
normal	91 (30.8%)	50 (46.7%)	148 (35.5%)	
Osteopenia	114 (38.6%)	41 (33.6%)	155 (37.2%)	0.005
Osteoporosis	90 (30.5%)	24 (19.7%)	114 (27.3%)	
Frail (≥ 3 frailty criteria) (N=418)	5 (1.7%)	2 (1.6%)	7 (1.7%)	>0.999
Number of comorbidities				
0	114 (21.9%)	51 (41.8%)	165 (25.7%)	
1	240 (46.2%)	37 (30.3%)	277 (43.1%)	
2	111 (21.3%)	26 (21.3%)	137 (21.3%)	<0.001
3	41 (7.9%)	6 (4.9%)	47 (7.3%)	
4	13 (2.5%)	2 (1.6%)	15 (2.3%)	
≥5	1 (0.2%)	0 (0.0%)	1 (0.2%)	
Number of concomitant medications (excluding ARVs)				
0	3 (0.6%)	88 (72.1%)	91 (14.2%)	
1	344 (66.2%)	20 (16.4%)	364 (56.7%)	<0.001
2	93 (17.9%)	9 (7.4%)	102 (15.9%)	
3	52 (10.0%)	4 (3.3%)	56 (8.7%)	
≥4	28 (5.4%)	1 (0.8%)	29 (4.5%)	

Table: comorbidities in PLWH compared to HIV negative individuals ≥60 years

Conclusions: PLWH compared to HN had more co-morbidities, medication burden and kidney impairment and osteoporosis. These findings highlight the burden of co-morbidities among older PLWH.

Diagnostic and monitoring tools

TUPEB022

Viral load monitoring during pregnancy and postpartum in the Western Cape province, South Africa, 2018-2021

K. Anderson (Melunsky)[1], E. Kalk[1], T. Phillips[1,2], N. Jacob[3], V. Mudaly[4], F. Phelanyane[1,5], J. Euvrard[1,5], A. Boulle[1,3,5], M.-A. Davies[1,3,5], On Behalf Of IeDEA Southern Africa, the International epidemiology Databases to Evaluate AIDS Southern Africa collaboration

[1]Centre for Integrated Data and Epidemiological Research, School of Public Health, Faculty of Health Sciences, University of Cape Town, Cape Town, South Africa, [2]Division of Epidemiology & Biostatistics, School of Public Health, University of Cape Town, Cape Town, South Africa, [3]Division of Public Health Medicine, School of Public Health, University of Cape Town, Cape Town, South Africa, [4]Service Priorities Coordination, Western Cape Department of Health and Wellness, Cape Town, South Africa, [5]Health Intelligence, Western Cape Department of Health and Wellness, Cape Town, South Africa

Background: Because sustained viral suppression is important in preventing vertical HIV transmission, adequate viral load (VL) monitoring during pregnancy and breastfeeding is crucial. Guidelines for improved VL monitoring were introduced in South Africa in early 2020, whereby, in addition to antenatal VL monitoring, mothers on antiretroviral therapy (ART) should have VL testing at delivery and 6 months thereafter.
Concurrently, dolutegravir-based regimens were introduced as preferred first-line ART (vs efavirenz-based), and strict national COVID-19 lockdown measures were implemented from March 2020.
Methods: We included mothers living with HIV in the Western Cape province, South Africa, who delivered live-born infants between May 2018 and April 2021, and initiated ART before/during pregnancy. We used logistic regression to compare differences in VL monitoring and proportion with unsuppressed VL (>1,000 copies/ml) among women who delivered before vs after guidelines changed (Era 1: 2018-2019 vs Era 2: 2020-2021), adjusted for maternal age and timing of maternal ART start relative to pregnancy.
Results: We included 46,860 deliveries (Era 1: 25,264; Era 2: 21,596). Mothers started ART before (72%) or during pregnancy (28%). Among mothers who started ART >3 months before delivery (n=43,555), late pregnancy testing was more likely during Era 2 than 1 (85% vs 75% coverage; aOR 1.93; 95%CI 1.83-2.03), and of those tested, unsuppressed VL was more likely in Era 2 than 1 (10% vs 9%; aOR 1.09; 95%CI 1.01-1.17).
Among all mothers, postpartum testing within 6 months of delivery was less likely among those delivering in Era 2 than 1 (44% vs 47%; aOR 0.92; 95%CI 0.89-0.96), and of those tested, unsuppressed VL was more likely in Era 2 than 1 (11% vs 9%; aOR 1.29; 95%CI 1.17-1.41).
Mothers aged <20 years (vs ≥20) at delivery and those who started ART before (vs during) pregnancy were less likely to have late pregnancy and postpartum VL testing.
Conclusions: After new VL monitoring guidelines were introduced, late pregnancy VL monitoring improved (due to delivery testing) but not postpartum VL monitoring.
National lockdown measures may have affected HIV service delivery, and may partially account for poorer implementation of postpartum VL monitoring and lack of improved viral suppression rates in Era 2.

Co-infections (including opportunistic infections)

TUPEB023

Improving HIV-associated meningitis outcomes: advancements through a Meningitis Diagnosis and Treatment Program in Northern Uganda

A. Link[1], M. Okwir[2,1], B. Nabongo[3], F. Okello[3,4], J. Alal[3], R. Nakato[4], B. Ocora[3,4], D. Meya[5,6], P. Bohjanen[1,7]

[1]University of Rochester, Department of Medicine, Division of Infectious Diseases, Rochester, United States, [2]Lira University, Lira, Uganda, [3]Lira Regional Referral Hospital, Lira, Uganda, [4]MARA Rural Health Consortium, Lira, Uganda, [5]Infectious Diseases Institute, Kampala, Uganda, [6]Makerere University, College of Health Sciences, Makerere University, Kampala, United States, [7]University of Minnesota, Division of Infectious Diseases and International Medicine, Minneapolis, United States

Background: Cryptococcal meningitis (CM) is an AIDS defining illness and is primarily found among people living with HIV (PLWH). Due to high baseline CM mortality (54.2%) at Lira Regional Referral Hospital in northern Uganda, efforts to improve early diagnosis and treatment were mobilized. In 2017, we implemented a CM diagnosis and treatment program and in 2021 we expanded the program to include all meningitis, providing molecular diagnostics and treatment for all etiologies. This study highlights the current meningitis burden and mortality among adult PLWH.
Methods: Patients admitted with clinical meningitis to Lira Regional Referral Hospital between 2021-24 were prospectively enrolled to evaluate meningitis etiologies and in-hospital mortality. Laboratory testing on CSF to evaluate meningitis etiologies included gram stain and culture, cell count and differential, cryptococcal antigen, India ink, BioFire, Pastorex, and TB GeneXpert Analysis was conducted using descriptive statistics utilizing data on underlying HIV infection, demographic information, HIV history, CD4 count, and mortality.
Results: Among 207 symptomatic meningitis PLWH, 101 had presumed bacterial meningitis (BM) or presumed viral meningitis (VM) based on CSF cell count and differential, 47 had unknown etiologies and, 126 had laboratory confirmed etiologies.
Among the confirmed cases, half had CM (n=64), followed by BM (n=33), tuberculosis meningitis (TBM, n=16), and VM (n=13), The mean age was similar between groups

ranging from 32.7 to 36.8 years and all groups were predominantly male (52-70%). Mean CD4 count was highest among patients with confirmed VM (171.3 cell/mm^3) with the lowest among CM (65.6 cell/mm^3). Patients with confirmed TBM had the highest mortality at 56.3%, followed by BM (42.4%), VM (30.8%) and CM (28.1%).

Conclusions: CM remains a common cause of meningitis among PLWH. However, our findings reveal that BM, VM, and TBM account for half the cases identified. CM mortality has greatly decreased since 2017, now representing the lowest mortality among the different etiologies.

This progress highlights the impact of targeted efforts and provides optimism for similar outcomes through the current meningitis program. Strong collaborations from host institutions and research initiatives, advancements in diagnosis and treatment can improve meningitis mortality in rural areas like northern Uganda and beyond.

TUPEB025

Tracking the Tuberculosis cascade among PLHIV accessing care in an ART Center in India: a 5-year analysis of outcomes

A. Subramanian[1], S. Kataria[2], K. Rajeshwari[3]
[1]Maulana Azad Medical College, Medicine, New Delhi, India, [2]Lok Nayak Hospital, ART Center, New Delhi, India, [3]Maulana Azad Medical College, Pediatrics, New Delhi, India

Background: Tuberculosis is the most common Opportunistic infection among PLHIV contributing significantly to mortality. Universal screening for TB using the WHO 4-symptom screen has been implemented in India to enhance TB detection and initiate early treatment. Despite this, TB diagnosis is often delayed and mortality rates remain high.

Methods: An analysis of PLHIV accessing care at an ART center from January 2018 – June 2024 was done. The analysis tracked all PLHIV who underwent a 4S screen.

The outcomes of TB diagnosis, type of TB, ART initiation, outcome (mortality or survival) and retention in care are discussed.

Results: Among the 3237 PLHIV registered in care, 1083 tested 4S positive i.e. were TB suspects- 33.5%. They underwent detailed clinical examination, Sputum CBNAAT, CXR (PA) and symptom-directed tests for diagnosis of TB- Ultrasonography and/or CECT of the abdomen and chest, lumbar puncture and CSF analysis, cytology / histopathology of appropriate biological samples as indicated.

498 / 1083 (45.98%) subjects, had a confirmed TB diagnosis. Among them, 289 had PTB and 209 had EPTB. The mortality rate was 10.6% (53 / 498). At the end of June 2024, 379/498 PLHIV with TB were retained in care.

Overall, 66/498 PLHIV were lost to follow up over the period of analysis. All PLHIV with TB were initiated on ART and anti TB treatment.

Conclusions: A routine 4S screen identified 33.5% PLHIV as TB suspects. Of these, 46% i.e. nearly half had a TB diagnosis. Though the 4S tool lacks sensitivity in detecting TB, it is a simple, remarkable tool for identifying TB suspects for further assessment. Almost 42% of PLHIV with TB had EPTB, highlighting the high prevalence of EPTB in this population. The mortality rate was 10.6%- despite diagnosis and initiation of both ATT and ART in these subjects. The study demonstrates that a significant proportion of subjects are not retained in care.

There must be consistent efforts to ensure that these very vulnerable subjects do not disengage from active care. A regular analysis of this TB cascade by programs is important to identify gaps in care and to formulate strategies to circumvent these gaps.

TUPEB026

Risk factors for hepatitis C (HCV) transmission in the Canadian Coinfection Cohort (CCC) before, during and after the COVID-19 pandemic

M. Hull[1,2], S. Wang[3], M. Knight[3], S. Walmsley[4], A. Wong[5], V. Martel-Laferriere[6], C. Cooper[7], J. Gill[8], B. Conway[9], M.-L. Vachon[10], M. Klein[3], J. Young[3]
[1]University of British Columbia, Vancouver, Canada, [2]BC Centre for Excellence in HIV/AIDS, VancouverCa, Canada, [3]Research Institute of the Mcgill University Health Centre, Montreal, Canada, [4]University of Toronto, Toronto, Canada, [5]Regina Qu'appelle Health Region, Regina, Canada, [6]Centre Hospitalier de l'Universite de Montreal, Departement de Microbiologie et Infectiologie, Montreal, Canada, [7]University of Ottawa, Ottawa, Canada, [8]University of Calgary, Calgary, Canada, [9]Vancouver Infectious Disease Centre, Vancouver, Canada, [10]Centre hospitalier universitaire de Québec-Université Laval, Laval, Canada

Background: Between 2018 and 2020, the number of new HCV infections reported in Canada fell by 41%. Disruptions to testing during the COVID-19 pandemic may influence this finding, however transmission risk may have been also altered.

We reviewed changes to risk factors for HCV transmission throughout the pandemic in participants in a long-standing HIV-HCV co-infection cohort.

Methods: We selected all participants enrolled prior to March 2018 with at least one follow up visit after March 2018. Participants were classified as: men reporting sex with men (gbMSM); injecting drugs at their last visit prior to March 2018 (active PWID); Indigenous individuals or in none of these groups ('Other').

We modelled the probability of injection drug use and of self-reported "unsafe" sex (either no, or intermittent condom use) from 2018 to 2024 using a generalised additive model, with covariate adjustment for age. The model included a random intercept allowing for repeated observations from the same individuals.

Results: Among 928 selected participants, the median age was 52; 31% were female and 30% were currently infected with HCV. Each subgroup was of a similar size (23% gbMSM, 35% active PWID, 26% Indigenous, 35% Other).

Overall the probability of reporting injection drug use declined among active PWID and Indigenous peoples, while the probability of reporting condomless sex increased in most subgroups (See Figure 1).

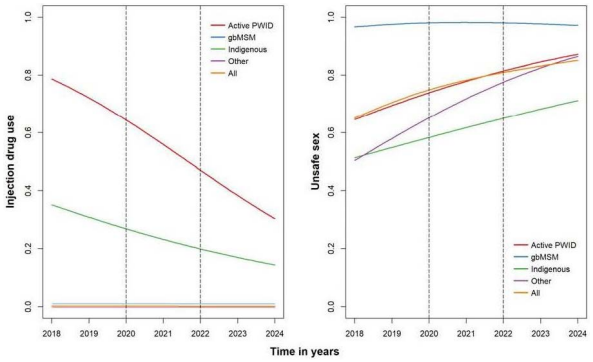

Figure 1.

Conclusions: Amongst individuals enrolled in a long-standing HIV/HCV co-infection cohort, self-reported injection drug use decreased despite the COVID-19 pandemic period, however sex with no or intermittent condom use increased. Given the differential contribution of these risks to HCV transmission, we might not expect large increases in HCV diagnoses as testing resumes post-pandemic if these changes are reflected in a general PWID population.

TUPEB027

Antifungal susceptibility of *Cryptococcus species* isolates in people diagnosed with HIV-associated cryptococcal meningitis in eastern and southern Africa

E. Nyirenda-Dziwani[1,2], D. Lawrence[3,4,5], A. Borman[6], S. McLachlan[6], E.M. Johnson[6], R. Doyle[3], K. Stott[7], C. Kanyama[8], D. Meya[9], M. Mosepele[10,4], H. Mwandumba[1,11], C. Muzoora[9,12], G. Meintjes[13,14], C. Ndhlovu[15], N. Youssouf[3], S.F. Molloy[16], T.S. Harrison[16], J.N. Jarvis[3,4]

[1]Malawi Liverpool Wellcome Program, Blantyre, Malawi, [2]Queen Elizabeth Central Hospital, Blantyre, Malawi, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Botswana Harvard Health Partnership, Gaborone, Botswana, [5]University of the Witwatersrand, Johannesburg, South Africa, [6]UKHSA National Mycology Reference Laboratory, Southmead Hospital, Bristol, United Kingdom, [7]University of Liverpool, Liverpool, United Kingdom, [8]University of North Carolina Project, Lilongwe, Malawi, [9]Infectious Disease Institute-Makerere University, Kampala, Uganda, [10]University of Botswana, Gaborone, Botswana, [11]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [12]Mbarara University, Mbarara, Uganda, [13]University of Capetown, Capetown, South Africa, [14]Queen Mary University of London, London, United Kingdom, [15]University of Zimbabwe, Harare, Zimbabwe, [16]City St George's, University of London, London, United Kingdom

Background: Cryptococcal meningitis is the second leading cause of AIDS-related mortality. Treatment in high-prevalence settings has historically been fluconazole monotherapy but WHO recommended combinations of amphotericin, flucytosine and/or fluconazole are increasingly used. We aimed to describe invitro susceptibility profiles of *Cryptococcus* to fluconazole, amphotericin and flucytosine for isolates collected during the AMBITION trial (ISRCTN72509687) and determine association with outcomes.

Methods: AMBITION recruited individuals with first episode of HIV-associated cryptococcal meningitis in Botswana, Malawi, South Africa, Uganda, and Zimbabwe. Baseline cerebrospinal fluid (CSF) was cultured and cryptococcal isolates were stored. Antifungal susceptibility testing was conducted using CLSI broth microdilution methodology at the National Mycology Reference Laboratory in Bristol, UK. We described MICs and the presence of resistance at pre-determined MIC thresholds and tested for association with ten-week mortality.

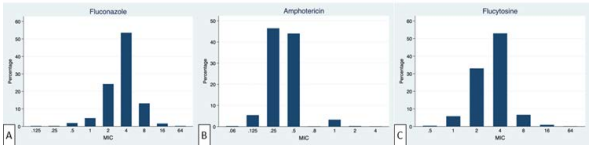
Results: Between January 2018 and February 2021, 844 participants were recruited and 738 grew *Cryptococcus* on baseline CSF for susceptibility testing: 285/738(38.6%) female; median age 37 years (IQR 32-43).

For fluconazole, geometric mean MIC was 4.17µg/mL, MIC_{50} was 4µg/mL and MIC_{90} was 8µg/mL with 17/738 (1.9%) resistant defined as MIC ≥16.

For amphotericin, geometric mean MIC was 0.39µg/mL, MIC_{50} was 0.5µg/mL and MIC_{90} was 0.5µg/mL with 3/738 (0.4%) resistant at MIC ≥2.

For flucytosine, geometric mean MIC was 3.61µg/mL, MIC_{50} was 4µg/mL and MIC_{90} was 4µg/mL, with 57/738 (7.7%) resistant at MIC ≥8.

There was no clustering. There was no association between ten-week mortality and individual antifungal resistance. Mortality was higher in those with any resistance (36.5% vs 25.6%, p=0.0447).



Conclusions: There is limited primary resistance to the three first-line antifungals for cryptococcal meningitis in eastern and southern Africa and no upward trend in fluconazole resistance compared to historical cohorts, suggesting the AMBITION regimen will be effective in these populations. Resistance may be associated with a higher risk of mortality, and ongoing monitoring of antifungal susceptibility and outcomes is required.

TUPEB028

Effect of TB preventive treatment on TB incidence and non-TB-related mortality: results from a large cohort of people living with HIV initiated on antiretroviral therapy in Cameroon, 2020-2022

Background: Tuberculosis (TB) remains a major cause of death among people living with HIV (PLHIV). Systematic screening for TB symptoms before antiretroviral therapy (ART) initiation and early initiation of TB preventive treatment (TPT) were identified as game changers to prevent TB disease and mortality among PLHIV.

We assessed the effect of TPT on TB incidence and non-TB related mortality and estimated the TB-free survival probability among PLHIV in Cameroon.

Description: This was a retrospective cohort study of PLHIV initiated on ART between October 2020 and September 2022 in the Littoral and South regions, where a six-month course of daily isoniazid (INH) was the available TPT regimen. TPT uptake categories included initiated and completed INH (TPT-completers), initiated but not completed INH (TPT-non-completers), and never initiated INH (TPT-non-initiators). For TB incidence and mortality (all causes excluding incident TB), we considered the time at risk started three months following ART initiation to exclude undiagnosed TB missed during ART initiation. We used the Poisson regression model to estimate TB incidence and Kaplan Meier method to estimate TB-free survival probabilities.

Lessons learned: Overall, 24,820 newly diagnosed PLHIV initiated ART, including 11,554 (46.5%) TPT-completers, 10,689 (43.1%) TPT-non-completers, and 2,577 (10.4%) TPT-non-initiators.

After a median follow up duration of 21 (IQR 10.7 - 29.3) months, 108 TB incident cases were reported (3.0/1,000-person-year), including 51 (2.4/1,000-person-year) among TPT-completers, 42 (3.5/1,000-person-year) among TPT-non-completers, and 15 (5.6/1,000-person-year) among TPT-non-initiators. During the same period, 1,401/24,820 (5.6%) deaths occurred, lower among TPT-completers (240/11,554; 2.1%) than TPT-non-completers (813/10,689; 7.6%) and TPT-non-initiators (348/2,577; 13.5%), p<0.001. The TB-free survival probability at 33 months following ART initiation was higher among TPT-completers (96.4%, 95%CI: [95.9-96.9]) compared with TPT-non-completers (91.7%, 95%CI: [90.9-92.4]) and TPT-non-initiators (84.5%, 95%CI: [82.1-86.5]), log-rank p-value <0.001.

Conclusions/Next steps: Initiating and completing TPT significantly decreased TB incidence and non-TB related mortality among PLHIV on ART, compared to initiating and not completing TPT or not initiating TPT. These programmatic results emphasized the importance of systematic TB screening, TPT initiation at the time of ART initiation, and effective TPT completion in accordance with national guidelines among PLHIV. Prioritizing interventions to improve TPT uptake and completion could help reducing non-TB-related mortality among PLHIV.

Co-morbidities and clinical complications of HIV and antiretroviral therapy

TUPEB029

Favorable lipid profile in people with HIV-1 switching to ainuovirine-based antiretroviral regimen: week 96 results from SPRINT, a randomized phase 3 trial

P. Ma[1], H. Wu[2], F. Zhang[3], W. Cai[4], Q. Zhao[5], H. Wei[6], H. Lu[7], H. Wang[7], S. He[8], Z. Chen[8], Y. Chen[9], M. Wang[10], H. Fu[11], H. Qin[11], X. Yun[11]

[1]Tianjin Second People's Hospital, Tianjin, China, [2]Beijing Youan Hospital, Capital Medical University, Beijing, China, [3]Beijing Ditan Hospital Capital Medical University, Beijing, China, [4]Guangzhou Eighth People's Hospital, Guangzhou Medical University, Guangzhou, China, [5]The Sixth People's Hospital of Zhengzhou, Zhengzhou, China, [6]The Second Hospital of Nanjing, Nanjing, China, [7]Shenzhen Third People's Hospital, Shenzhen, China, [8]Public Health Clinical Medical Center of Chengdu, Chengdu, China, [9]Chongqing Public Health Medical Center, Chongqing, China, [10]The First Hospital of Changsha, Changsha, China, [11]Jiangsu Aidea Pharmaceutical Co., Ltd, Yangzhou, China

Background: In SPRINT extensional study, people with HIV-1 (PWH) continued or switched to ainuovirine plus lamivudine and tenofovir DF (ANV/3TC/TDF) until 96 weeks. This secondary analysis aimed to evaluate the lipid profile of PWH switching to ANV/3TC/TDF through 48 to 96 weeks.

Methods: Out of 762 randomized participants, 376 participants originally assigned to ANV/3TC/TDF (376/381, 98.7%) and 371 participants originally to cobicistat-boosted elvitegravir with emtricitabine and tenofovir alafenamide (E/C/F/TAF) (371/381, 97.4%) completed the extensional study, respectively. The safety outcomes of special interest were absolute changes from 48 wk in LDL-C, non-HDL-C, total cholesterol (TC), triglyceride (TG), and HDL-C at 72 and 96 wk. Dyslipidemia severity was evaluated

using the atherosclerotic cardiovascular disease (ASCVD) risk stratification as per the primary prevention target for Chinese low-risk adults.

Results: Serum LDL-C remained unchanged in ANV/3TC/TDF arm from 48 wk, while a marked reduction was seen in E/C/F/TAF→ANV/3TC/TDF arm at both 72 wk (mean, -0.07 vs. -0.47 mmol/L) and 96 wk (0.01 vs. -0.37 mmol/L).

Similar trends were seen in the changes in non-HDL-C, TC, and TG: 72 wk, -0.04 vs. -0.71 mmol/L, -0.06 vs. -0.87 mmol/L, and 0.06 vs. -0.79 mmol/L, respectively; 96 wk, 0.08 vs. -0.60 mmol/L, 0.05 vs. -0.77 mmol/L, and 0.09 vs. -0.85 mmol/L, respectively. Modest decline was not observed in ANV/3TC/TDF arm but E/C/F/TAF→ANV/3TC/TDF arm (72 wk, -0.02 vs. -0.16 mmol/L; 96 wk, -0.03 vs. -0.17 mmol/L).

ASCVD risk-associated dyslipidemia stratifications showed comparable profiles between these two arms regarding LDL-C, non-HDL-C, TC, TG, an HDL-C. Marked improvement in LDL-C stratification was seen at both 72 wk and 96 wk for E/C/F/TAF→ANV/3TC/TDF arm (Figure 1).

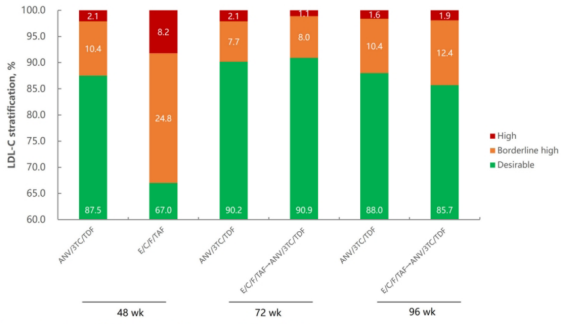

Figure 1. Change in LDL-C profiles at week 72 and 96
ANV/3TC/TDF, ainuovirine/lamivudine/ tenofovir disoproxil fumarate; E/C/F/TAF, elvitegravir/cobicistat/emtricitabine/tenofovir alafenamide; LDL-C, low-density-lipoprotein cholesterol.

Conclusions: Switch to ANV/3TC/TDF from E/C/F/TAF is favored for improved serum lipid profile and ASCVD risk-associated dyslipidemia in VS PWH.

TUPEB030

Preliminary impact of public health messaging on HPV vaccine uptake among adolescent girls and young women living with HIV in central Uganda

A. Kabarambi[1,2], S. Kizito[1,2], P. Nartey[1,2], P. Nabunya[1,2], F.M. Ssewamala[3,2], A. Girma[3]
[1]Washington University in St.Louis, St. Louis, United States, [2]International Center for Child Health and Development, Masaka, Uganda, [3]Washington University in St.Louis, St.Louis, United States

Background: In Uganda, HPV vaccine uptake remains low, with coverage for the full two-dose schedule reaching only 13% among the general population, largely due to limited awareness, misconceptions, and cultural barriers. We assessed the role of public health messaging on HPV vaccine uptake among adolescents and young women living with HIV in central Uganda.

Methods: We conducted a pilot randomized controlled trial among 100 adolescent girls and young women (10–24 years) living with HIV across four healthcare facilities in the Greater Masaka region, Uganda. Facilities were randomly assigned to either the treatment or control arm. Participants in the treatment arm received an hour-long educational session on cervical cancer and HPV vaccination, complemented by brochures and exposure to HPV vaccination posters.

The control arm participants were only exposed to HPV vaccination posters. Data were collected via interviewer-administered surveys assessing socio-demographics, HPV vaccine acceptability, perceived barriers, HPV and cervical cancer knowledge, and HPV vaccine uptake.

The primary outcome, HPV vaccine uptake, was assessed 6 months post-intervention. A mixed-effects logistic regression model was used to assess the intervention's effect on HPV vaccine uptake. The model included random effects for participants and study sites to handle between-participant and between-site variability.

Results: HPV vaccine uptake was 55% overall, with similar uptake rates across age groups and higher uptake among those with sufficient knowledge of the vaccine and cervical cancer and those with higher perceived susceptibility and vaccine acceptability.

The mixed-effects logistic regression model showed a significant effect of the intervention ($p < 0.001$), with participants in the intervention group having 99% higher odds of vaccination compared to the control group and a substantial positive interaction effect at the 6-month follow-up (OR = 56.57, $p < 0.001$).

The predicted probability of vaccine uptake increased significantly in the treatment arm over time, while the control arm remained unchanged, highlighting the intervention's effectiveness in promoting vaccine uptake.

Conclusions: This study highlights the importance of knowledge and targeted interventions in improving HPV vaccine uptake among girls and young women living with HIV. Tailored public health messaging, utilizing diverse communication strategies, can significantly enhance HPV vaccine uptake in this vulnerable group.

TUPEB031

Kidney dysfunction in adults living with HIV and HBV: a 10-year retrospective cohort study across seven Asia-Pacific countries

T.T. Vu[1], D. Rupasinghe[2], D.T.H. Nguyen[3], J.Y. Choi[4], S. Kiertiburanakul[5], N. Kumarasamy[6], S. Khusuwan[7], V. Khol[8], IK.A. Somia[9], M.P. Lee[10], S. Pujari[11], A. Avihingsanon[12,13], C.D. Do[14], J. Ross[15], A. Jiamsakul[2], on behalf of IeDEA Asia-Pacific

[1]Community Health and Social Sciences, CUNY Graduate School of Public Health and Health Policy, New York, United States, [2]Kirby Institute, UNSW Sydney, Sydney, Australia, [3]National Hospital for Tropical Diseases, Hanoi, Viet Nam, [4]Division of Infectious Diseases, Yonsei University College of Medicine, Seoul, Korea, the Republic of, [5]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, [6]VHS-Infectious Diseases Medical Centre, Chennai Antiviral Research and Treatment Clinical Research Site (CART CRS), Voluntary Health Services, Chennai, India, [7]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand, [8]National Centre for HIV/AIDS, Dermatology and STDs (NCHADS), Phnom Penh, Cambodia, [9]Faculty of Medicine Udayana University – Ngoerah Hospital, Bali, Indonesia, [10]Queen Elizabeth Hospital, Hong Kong SAR, Hong Kong, SAR of China, [11]Institute of Infectious Diseases, Pune, India, [12]HIV-NAT, Thai Red Cross AIDS and Infectious Diseases Research Centre, Bangkok, Thailand, [13]Center of Excellence in Tuberculosis, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [14]Bach Mai Hospital, Hanoi, Viet Nam, [15]TREAT Asia, amfAR - The Foundation for AIDS Research, Bangkok, Thailand

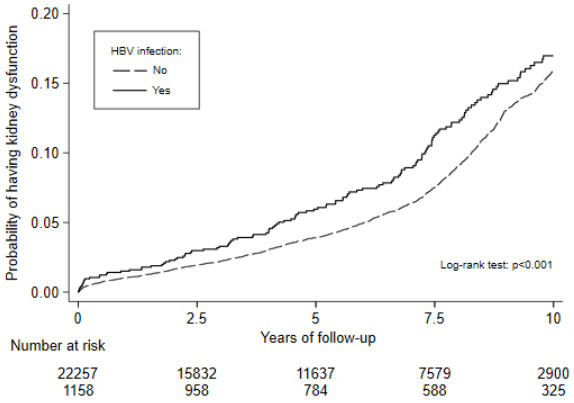
Background: This study investigated kidney dysfunction among people with HIV (PWH), comparing those with and without HBV co-infection. We also identified predictors of kidney dysfunction in PWH with HBV.

Methods: Adult PWH in the TREAT Asia Observational Database – Low Intensity TransfEr cohort, who were on antiretroviral therapy, with follow-up after 2010 were included. HBV co-infection was defined by positive hepatitis B surface antigen. Kidney dysfunction was determined as a single time estimated glomerular filtration rate <60ml/min/1.73m^2. Kaplan-Meier curves evaluated time to kidney dysfunction, and Cox proportional hazards model analyzed factors associated with kidney dysfunction in PWH with HBV.

Results: Among 23,415 participants (median age=37 years), most were male (62.2%), from lower-middle income countries (67.1%), and reported heterosexual HIV transmission (79.3%). The majority (83.6%) were prescribed NRTI+NNRTI, and 4.9% had HBV co-infection.

Overall, 8.0% had kidney dysfunction, with a higher prevalence among PWH with HBV (14.9%) than those without HBV (7.6%). Most cases of kidney dysfunction were stage 3 (84.2%).

Factors associated with higher risks of kidney dysfunction among PWH with HBV included older age (≥50: Hazard ratio [HR]=6.37, 95%CI: 2.28, 17.79; vs. 18-29), higher income (upper-middle income: HR=1.88, 95%CI: 1.23, 2.87; vs. lower-middle income), low platelet counts (HR=2.85, 95%CI: 1.86, 4.35; vs. normal), and ART regimens (NRTI+NNRTI: HR=0.40, 95%CI: 0.25, 0.64; NRTI+PI: HR=0.57, 95%CI: 0.35, 0.94; vs. NRTI+INSTI). Higher CD4 counts (200-349: HR=0.52, 95%CI: 0.30, 0.91; 350-499: HR=0.45, 95%CI: 0.26, 0.78; ≥500: HR=0.33, 95%CI: 0.20, 0.56; vs. <200) were associated with lower risk of renal dysfunction. We found no difference between TDF and TAF use with kidney dysfunction (HR=0.55, 95%CI: 0.25, 1.23; vs. TAF use).



Conclusions: A high prevalence of kidney dysfunction was observed among PWH in the Asia-Pacific, especially PWH with HBV. Renal screening and monitoring should prioritize older PWH with HBV, low platelets and CD4 counts in low-resource settings.

TUPEB032

Blood-based biomarkers – neurofilament light (NfL) and glial fibrillary acidic protein (GFAP) – and cognitive decline among older people with HIV with undetectable viral loads in Thailand

A. Hiransuthikul[1,2], P. Thanapornsangsuth[3], W. Luechaipanit[3], T. Haethaisong[3], S. Ubolyam[1,4], C. Wongvoranet[1], T. Apornpong[1], W.M. Han[1,5], H.M.S. Lwin[1], N. Hiranburana[1], S. Kerr[1,5,6], A. Avihingsanon[1,4]

[1]HIV-NAT, Thai Red Cross AIDS and Infectious Diseases Research Centre, Bangkok, Thailand, [2]Chulalongkorn University, Preventive and Social Medicine, Faculty of Medicine, Bangkok, Thailand, [3]King Chulalongkorn Memorial Hospital The Thai Red Cross Society, Thai Red Cross Emerging Infectious Diseases Health Science Centre, World Health Organization Collaborating Centre for Research and Training on Viral Zoonoses, Bangkok, Thailand, [4]Chulalongkorn University, Center of Excellence in Tuberculosis, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [5]Kirby Institute, UNSW Sydney, Sydney, Australia, [6]Chulalongkorn University, Biostatistics Excellence Centre, Faculty of Medicine, Bangkok, Thailand

Background: We previously reported that blood-based phosphorylated tau 217 (p-tau217) could predict distinct cognitive trajectories in older Thai people with HIV (PWH) with undetectable viral loads.

Given the limited data in PWH, this study aimed to assess the potential of neurofilament light (NfL) and glial fibrillary acidic protein (GFAP), emerging biomarkers for cognitive disorders, in predicting cognitive decline in this population.

Methods: Blood samples were collected from Thai PWH aged ≥50 years with plasma viral loads <50 copies/mL, who completed the Montreal Cognitive Assessment (MoCA) at baseline (2015–2017) and a follow-up visit (2021–2024). NfL and GFAP levels were measured at baseline and categorized into quartiles, with a binary comparison between quartile 4 (Q4) and quartiles 1–3 (Q1–Q3).
A multivariate linear mixed-effects model, adjusted for sex, education, baseline MoCA score, HIV duration, nadir CD4 levels, and efavirenz exposure, with an interaction term for biomarker quartiles and age, was used to estimate the effect of baseline NfL and GFAP levels on cognitive performance changes over time.
Results: A total of 255 PWH (63.1% male, median age 54.3 years [IQR: 51.8–59.1]) with a median follow-up of 5.9 years (IQR: 5.6–6.8) were included. In the adjusted model, no significant differences in overall MoCA score changes were observed between PWH in Q4 versus Q1–Q3 for either NfL or GFAP. However, PWH in Q4 of GFAP levels showed a significantly greater decline in visuospatial/executive function, with a score decrease of -2.1 (95% CI: -3.0 to -1.2) compared to -0.4 (95% CI: -1.1 to 0.2) for Q1–Q3 from age 50 to 80 years (*P*-interaction = 0.001) (*Figure*).

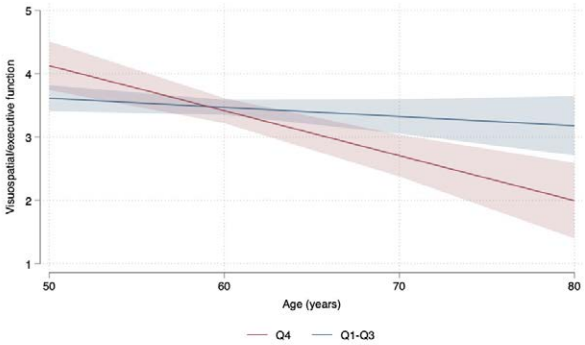


Figure. Modeled cognitive trajectories with 95% confidence intervals from age 50 to 80 years, comparing baseline blood-based GFAP levels between the highest quartile (Q4) and the lower three quartiles (Q1–Q3). Adjusted for sex, education level, baseline MoCA score, HIV duration, nadir CD4 levels, and exposure to efavirenz.

Conclusions: Baseline NfL and GFAP levels were not associated with overall MoCA performance, but higher GFAP predicted greater visuospatial/executive function decline. Domain-specific neuropsychiatric testing is needed to confirm this finding and explore its clinical utility.

Antiretroviral therapies and clinical issues in adults

TUPEB033

Continuity of pre-exposure prophylaxis service delivery among key populations in rural Teso region, North Eastern Uganda, before and after the Anti-homosexuality Act, 2022-2024

S. Ssentongo[1], D. Olweny[2], B. Oryokot[2], P. Sekiranda[2], E. Kutosi[2], J. Nalweyiso[2], C. Ninsiima[2], L. Byarugaba[2], T. Tumusiime[2], A. Munina[2], S. Ouma[3], B. Bakashaba[2]
[1]AIDS Information Center, Kampala, Uganda, [2]AIDS Information Center, Directorate of Program Management and Capacity Development, Kampala, Uganda, [3]The AIDS Support Organization, Kampala, Uganda

Background: The Anti-Homosexual Act (AHA), 2023 was enacted into law in Uganda on May 26, 2023. According to the Human Rights Awareness and Promotion Forum Report, violence, eviction, and arrests targeting key populations (KP) doubled to 1,085 in the year following the enactment of AHA, from 530 cases from June 2022 to May 2023. We examined how Pre-exposure prophylaxis (PrEP) service delivery among KPs in the Teso region changed after the implementation of AHA in May 2023.
Methods: We conducted a quasi-experimental design one year before the AHA (May 2022-April 2023) and one year after the AHA (June 2023-May 2024). We extracted routine program data on PrEP service from the national KP service tracker for 16 facilities in the Teso region, Uganda. We used STATA 18 to conduct an Interrupted time series analysis by Ordinary Least Squares and plotted the results to examine the change in PrEP service delivery with AHA. $p<0.05$ was considered statistically significant.
Results: A total of 7,841 records of clients were analyzed, with a median age of 27(interquartile range 22-35). Of these 35%(2,753) were involved in sex work, and 2.2%(170) men who have sex with men. There was an immediate decrease in PrEP initiations with the introduction of AHA (coefficient; -45.5, 95% Confidence Interval (CI);-83.15 to -7.92,P=0.018), and After AHA by 0.14 initiations per month (coefficient;-0.14, 95%CI; -0.268 to -0.126,P=0.031) as compared to before AHA (coefficient;0.117, 95% CI;-0.013 to 0.24). The PrEP refills before AHA were increasing by 2 refills per month (coefficient;2.06, 95% CI; 0.95-3.18, P=0.001), With the introduction of AHA there was a decrease in initiations (coefficient; -524.8, 95%CI; -820.33 to -229.23,P=0.001), and further decreased After AHA by 2 refills (coefficient;-1.6, 95%CI;-3.16 to −0.038,P=0.045). There was an increase in PrEP Stoppages (Coefficient;31.9, 95%CI;13.59 to 50.22,P=0.001) during AHA, followed by a decrease after AHA (Coefficient; -0.12, 95% CI;-0.2 to -0.038,P=0.004) as compared to before AHA (Coefficient; 0.015, 95% CI; -0.0024 to -0.32)
Conclusions: With the enactment of AHA, PrEP Refills decreased and Stoppages increased. Laws and policies that target people at risk of acquiring HIV especially key Populations undermine efforts to achieve HIV epidemic control by 2030.

TUPEB034

Rate of ART initiation in Ukraine under conditions of critical load on the health care system: results of a retrospective analysis of data from the electronic medical system MSSD

O. Samsonova[1], S. Riabokon[2], O. Klymova[2]
[1]Public Health Center of the MOH of Ukraine, department of HIV management and counteraction, Kyiv, Ukraine, [2]Public Health Center of the Ministry of Health of Ukraine, Department of HIV management and counteraction, Kyiv, Ukraine

Background: In the minds of war, apparently accelerated migration of the population, disrupted logistics, interruptions in electricity and the Internet. Early ART is one of the main supplies of support for PLHIV. The Public Health Center has changed regulatory acts (divided the Standards of medical care for HIV , implemented a new algorithm for testing for HIV , which makes it possible to recognize treatment on the day of screening), and conducted a number of seminars. Multidisciplinary teams have been created in the regions to coordinate assistance to PLHIV. Regular monitoring is carried out. Creation of a telemedicine office to provide remote medical assistance. To help PLHIV, a mobile app called "Care4you" has been created.
Methods: Data from the electronic medical system MSSD were analyzed to evaluate the effectiveness of the „Test and Start" strategy implementation. The recognition of ART in PLHIV throughout the history of ART in Ukraine since 2004 was analyzed.

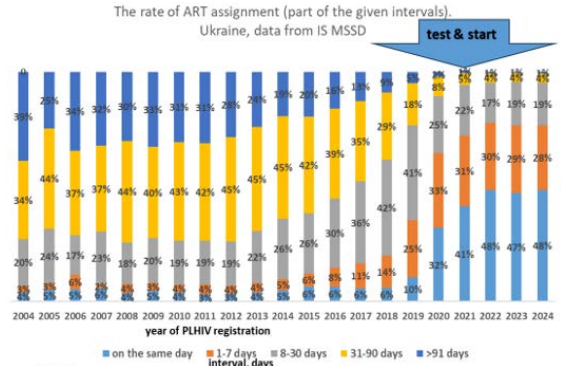

Figure 1.

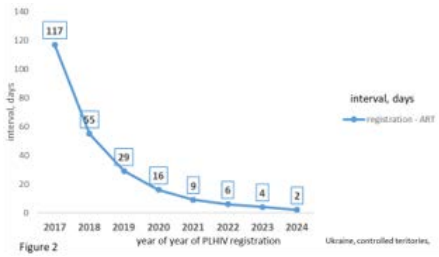

Figure 2.

The number of PLHIV registered in 2024 people by gender and age (total)								Tabel 1
	0-17 years	18-24 years	25-29 years	30-39 years	40-49 years	50-59 years	60 or >years	total

mail	30	107	221	1838	2294	885	256	5631
total	59	192	376	2664	3229	1542	504	8566

The number of PLHIV registered in 2024 people by gender and age (PLHIV initiating ART within 7 days)								Tabel 2
	0-17 years	18-24 years	25-29 years	30-39 years	40-49 years	50-59 years	60 or >years	total
femal	11	54	112	622	713	513	388	2210
mail	18	86	188	1487	1800	695	203	4477
total	29	140	300	2109	2513	1208	591	6687

Results: Data from the MSSD electronic medical system were analyzed to evaluate the effectiveness of the "Test and Start" strategy. Historical trends in ART initiation among PLHIV in Ukraine since 2004 were examined. Results showed that the percentage of PLHIV initiating ART within 7 days of an HIV diagnosis increased from 17% in 2017 to 68% in 2022. In 2024, despite ongoing challenges, 66% of PLHIV began ART within 7 days of diagnosis, and 48% started ART on the same day as diagnosis. The average time from diagnosis to ART initiation dropped dramatically, from 117 days in 2017 to just 2 days in 2024.
Conclusions: The substantial reduction in time from diagnosis to ART initiation highlights the resilience and adaptability of Ukraine's HIV care infrastructure. Maintaining these achievements requires ongoing support for innovative solutions, such as telemedicine and digital tools, alongside continuous training and evaluation.

TUPEB035

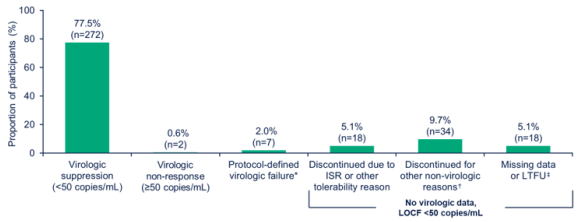
24-month outcomes of cabotegravir+rilpivirine long-acting every 2 months in a real-world setting: effectiveness, adherence to injections, and participant-reported outcomes from people with HIV-1 in the German CARLOS cohort

C. Wyen[1], S. Noe[2], C. Jonsson-Oldenbüttel[2], J. Borch[3], K. Ummard-Berger[4], E. Rodríguez[5], M. Lee[6], S. Scholten[7], M. Schneider[8], K.M. Dymek[9], B. Westermayer[10], J. Scherzer[9]
[1]Praxis am Ebertplatz, Cologne, Germany, [2]MVZ München am Goetheplatz, Munich, Germany, [3]Praxis Goldstein, Berlin, Germany, [4]UBN/Praxis, Berlin, Germany, [5]Praxis Dr. Rump, Freiburg, Germany, [6]MVZ München am Isartorplatz, Munich, Germany, [7]Praxis Hohenstaufenring, Cologne, Germany, [8]Institute of Virology, Helmholtz Zentrum München - GmbH, Neuherberg, Germany, [9]ViiV Healthcare, Munich, Germany, [10]GSK, Munich, Germany

Background: Injectable long-acting (LA) cabotegravir (CAB) plus rilpivirine (RPV) offers an alternative mode of administration with less frequent dosing than daily oral antiretroviral therapy (ART). CARLOS is a non-interventional, 3-year, multicenter cohort including people living with HIV-1 (PWH) on suppressive daily oral ART who switched to CAB+RPV LA dosed every 2 months in routine care in Germany. Here, we describe outcomes at Month (M) 24.
Methods: M24 effectiveness outcomes included virologic suppression (HIV-1 RNA <50 copies/mL), virologic non-response (HIV-1 RNA ≥50 copies/mL), and protocol-defined virologic failure (PDVF; two consecutive HIV-1 RNA ≥200 copies/mL, or a single HIV-1 RNA ≥200 copies/mL followed by discontinuation for any reason).
Additional outcomes included adherence to the injection window and change in HIV Treatment Satisfaction Questionnaire status version (HIVTSQs) score.
Results: In total, 351 PWH were included in the M24 analysis. Overall, 94.2% (n=3464/3676) of CAB+RPV LA injections were administered before/within the ±7-day injection window, and 5.8% (n=212/3676) occurred late. At M24, 77.5% (n=272/351) of participants maintained virologic suppression and 19.7% (n=69/351) discontinued while being virologically suppressed.

There were seven participants (2.0%) who met PDVF. Full virologic outcomes are shown in Figure 1.

For participants (n=233/351) completing the HIVTSQs at both baseline (mean score [standard deviation (SD)], 55.0/66 [10.0]) and M24 (mean score [SD], 61.0/66 [7.1]), a statistically significant (mean change, +6.0; p<0.001) and clinically important (greater than half of the baseline SD) improvement in treatment satisfaction was observed.



*Virologic failure (two consecutive HIV-1 RNA ≥200 copies/mL, or a single HIV-1 RNA ≥200 copies/mL followed by discontinuation for any reason): **Participant 1**: HIV-1 subtype unknown, BMI data not available, no data available for history of NNRTI or INSTI RAMs, on-time injections, NNRTI RAM (E138K) and INSTI RAM (Q148R) detected at PDVF; **Participant 2**: HIV-1 subtype B, BMI 23 kg/m², on-time injections, NNRTI RAM (Y181C), PI RAM (V82A), and INSTI RAMs (T97A, E138K, Q148R, N155H) detected at PDVF; **Participant 3**: HIV-1 subtype B, BMI 29 kg/m², injections 3 and 4 received outside of injection window, no RAMs detected at PDVF; **Participant 4**: HIV-1 subtype B, BMI 23 kg/m², injections 6 and 7 received outside of injection window, no RAMs detected at PDVF; **Participant 5**: HIV-1 subtype unknown, BMI 26 kg/m², on-time injections, NNRTI RAM (K101E) detected at PDVF; **Participant 6**: HIV-1 subtype B, BMI 20 kg/m², injection 8 received outside of injection window, NNRTI RAM (K101P) and INSTI RAMs (E138K, Q148R) detected at PDVF; **Participant 7**: HIV-1 subtype B, BMI 24 kg/m², NRTI RAM (K70R) detected at baseline, on-time injections, no RAMs detected at PDVF. PDVF classification was based upon two viral load measurements taken 2 days apart at injection 10. Participant subsequently resuppressed and was at injection 18 at the time of data cutoff.
†n=16 participants preferred oral ART.
‡Includes one participant on drug but missing viral load assessment in window.
ART, antiretroviral therapy; BMI, body mass index; INSTI, integrase strand transfer inhibitor; ISR, injection site reaction; LOCF, last observation carried forward; LTFU, lost to follow-up; NNRTI, non-nucleoside reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitor; PDVF, protocol-defined virologic failure; PI, protease inhibitor; RAM, resistance-associated mutation.

Figure 1. Intention-to-treat virologic outcomes at Month 24.

Conclusions: In this real-world cohort, CAB+RPV LA maintained high rates of virologic suppression, with 2.0% PDVFs, 2 years following switch. There was a low rate of discontinuation due to injection site reactions, and most injections were administered before or within the ±7-day injection window.

Despite high baseline scores on oral ART, the increase in treatment satisfaction for participants remaining on CAB+RPV LA met the threshold for minimum clinically important difference.

TUPEB036

Developing a prediction model for preterm birth for pregnant people living with HIV in British Columbia, Canada

J.M.H. Wong[1], T. Lee[2], G. Av-Gay[3], C. Elwood[1], J. van Schalkwyk[1], L. Sauvé[1], D. Money[1]

[1]University of British Columbia, Vancouver, Canada, [2]Centre for Advancing Health Outcomes, Vancouver, Canada, [3]Women's Health Research Institute, Vancouver, Canada

Background: Our study aims to identify independent risk modifiers of preterm birth and develop a prediction model for pregnant people living with HIV (PLWH).

Methods: Using the population-based cohort, British Columbia Perinatal HIV Surveillance Database, all singleton births among pregnant PLWH from January 1997 to December 2022 were analyzed. We identified univariate risk modifiers for preterm birth (< 37 weeks gestational age) through chi-squared tests, Fisher's exact tests, and Wilcoxon rank-sum tests. We then completed a multivariate logistic regression using clinically relevant risk modifiers with p-value < 0.1 in the univariate analysis.

Using stepwise regression with Akaike information criterion, the prediction model was developed. One hundred thousand bootstrap samples were conducted to assess the optimism-corrected estimate for the area under the ROC curve.

Results: Out of 578 singleton pregnancies in PLWH, 111 (19.2%) had preterm births. Adjusting for history of preterm birth, CD4 count at delivery, and antiretroviral regimens, independent risk factors include substance use in pregnancy (OR: 1.9; 95% CI: 1.03-3.50; p=0.041), Hepatitis C in pregnancy (OR: 1.98; 95% CI: 1.02-3.83; p=0.043), unsuppressed viral load at delivery (OR: 2.03; 95% CI: 1.09-3.79; p = 0.026) and sexually transmitted infections or bacterial vaginosis (STIBV) in pregnancy (OR: 2.06; 95% CI: 1.04 – 4.10; p = 0.039). A prediction model with substance use (score = 3), STIBV (score = 2), hepatitis C in pregnancy (score = 3), unsuppressed viral load (score = 3), and CD4 count < 350 cells/mm³ (score = 2) was developed (AUC = 0.73). For PLWH without any risk factors, the predicted probability of preterm birth is 9%.

Total Score	Predicted probability of preterm birth	Observed number of people living with HIV with preterm birth
0	9%	18/225 = 8%
2	14%	6/53 = 11.3%
3	18%	16/92 = 17.4%
4	23%	22/69 = 31.9%
5	28%	
6	34%	
7	42%	21/44 = 47.7%
8	48%	

Conclusions: Independent risk factors associated with preterm births in PLWH include substance use, unsuppressed viral load, Hepatitis C co-infection, and sexually transmitted infections or bacterial vaginosis. This prediction tool serves as a personalized counselling tool for preterm birth and identifies individuals at the highest risk for appropriate resource allocation.

TUPEB037

Comparative pharmacokinetics and safety of subcutaneous and intramuscular depot medroxyprogesterone acetate when used among women living with HIV on doravirine-containing antiretroviral therapy

N. Ndlovu[1], P. Maheria[2], R. Kgoa[1], L. Kew[1], L. Kapa[1], K. Reddy[1], N. Sigcu[1], M. Seedat[1], L. Shale[1], M. Govindasami[1], N. Matswake[1], N. Yongo[2], S.A. Hassan[2], T.L. Williams[2], D.W. Erikson[3], K.K. Scarsi[4], T. Palanee-Phillips[1,5], R.C. Patel[2]

[1]Wits RHI, Clinical Trials, Johannesburg, South Africa, [2]University of Alabama at Birmingham, Department of Medicine, Division of Infectious Diseases, Birmingham, United States, [3]Oregon Health & Science University, Endocrine Technologies Core, Oregon National Primate Research Center,, Beaverton, United States, [4]University of Nebraska Medical Center, Department of Pharmacy Practice and Science, Omaha, United States, [5]University of Washington, Department of Epidemiology; School of Public Health, Seattle, United States

Background: Injectable hormonal contraception is used globally among women living with HIV (WLWH). A formulation of subcutaneous depot medroxyprogesterone acetate (SC MPA, 104mg, i.e., Sayana Press), dosed lower than intramuscular (IM) DMPA (150mg), is available commercially.

Knowledge gaps exist with comparative assessments between SC MPA vs. IM DMPA and potential drug-drug interactions with antiretroviral therapy (ART).

Methods: We conducted a pharmacokinetic study between November 2021 and February 2024 with five parallel groups of WLWH aged 18-45 in Johannesburg, South Africa. Participants on doravirine-containing ART initiated SC MPA, IM DMPA, etonogestrel (ENG) implant, or non-hormonal copper intrauterine device. We report findings from the SC and IM DMPA groups compared to the non-hormonal group.

We measured serum MPA and plasma doravirine concentrations every two weeks using liquid chromatography – mass spectrometry (LC-MS/MS) assays. We used geometric mean ratios (GMRs) and multivariate models adjusted for age and body mass index (BMI) to analyze drug concentrations. We also evaluated safety, tolerability, and ART effectiveness.

Results: 21 participants each enrolled in the SC MPA and IM DMPA groups. SC MPA users showed significantly lower median MPA concentrations compared to IM DMPA users across all study visits (adjusted GMR range 0.37-0.61, *p*-values < 0.05), indicating that the MPA concentrations in the SC vs. IM DMPA groups were lower as expected. Doravirine concentrations were not significantly lower in the SC MPA vs. non-hormonal group (adjusted GMR range 1.64-2.37, *p*-values <0.15), indicating the SC MPA did not lower doravirine concentrations.

There was a total of 59 and 51 adverse events among SC MPA and IM DMPA users, respectively, with majority being categorized as minor/Grade 1. HIV suppression (<40 copies/mL) was similar between SC MPA, IM DMPA, and non-hormonal groups.

Study visits weeks	Original vs. censored sample2	SC MPA, median (range), number of samples	IM DMPA, median (range), number of samples	Unadjusted DOR + SC MPA: DOR + IM DMPA GMR3 (90% CI)	p-value	Adjusted DOR + SC MPA: DOR + IM DMPA GMR3 (90% CI) GMR4 (90% CI)
2	Original sample	542.0 (198.0-1067.0),n=21	1293.5 (2.0-2852.0), n=20	0.55 (0.37, 0.82)	0.013	0.51 (0.30, 0.88)
	Censored sample	557.5 (198.0 - 1067.0), n=20	1246.0 (2.0, 2642.0), n=15	0.64 (0.59, 0.68)	<0.001	0.61 (0.33, 1.13)
4	Original sample	412.0 (156.0-1091.0), n=22	1025.0 (514.0-3913.0), n=21	0.37 (0.31, 0.43)	<0.001	0.36 (0.28, 0.46)
	Censored sample	421.0 (156.0 - 1091.0), n=18	957.0 (514.0, 1969.0), n=14	0.39 (0.35, 0.45)	<0.001	0.39 (0.31, 0.52)
8	Original sample	321.0 (101.0 - 658.0), n=22	815.5 (222.0-2310.0), n=20	0.38 (0.29, 0.51)	<0.001	0.37 (0.27, 0.49)
	Censored sample	438.0 (125.0 - 658.0), n=17	815.5 (222.0, 2276.0), n=14	0.42 (0.32, 0.55)	<0.001	0.42 (0.31, 0.57)
12	Original sample	271.0 (116.0 - 523.0), n=19	542.0 (295.0-1439.0), n=21	0.44 (0.35, 0.54)	<0.001	0.44 (0.35, 0.54)
	Censored sample	301.0 (116.0 - 523.0), n=15	542.0 (318.0, 1439.0), n=11	0.47 (0.36, 0.63)	<0.001	0.48 (0.36, 0.64)

Conclusions: The data provides valuable insights into the pharmacokinetics and safety of SC MPA and IM DMPA in WLWH using and doravirine-containing ART. While MPA concentrations were lower in the SC MPA vs. IM DMPA groups, as expected, there was no significant impact on ART concentrations providing a signal of limited drug-drug interactions. Larger studies are critical to confirmation of these findings.

Antiretroviral therapies and clinical issues in adolescents and young adults

TUPEB038

Enhancing HIV disclosure rates among adolescents through continuous quality improvement (CQI) approach at Kisumu County Referral Hospital, Kenya

D. Oketch[1], M. Oloo[1], T. Otieno[1], A. Wasilwa[2], C. Mugo[3], T. Kamau[4]

[1]MOH County Government of Kisumu, Department of Health, Kisumu, Kenya, [2]CIHEB- KENYA, Department of Health, Kisumu, Kenya, [3]University of Washington, Reseach, Nairobi, Kenya, [4]KAHISA, Reseach, Eldoret, Kenya

Background: HIV remains a major public health challenge, particularly in Sub-Saharan Africa where 84% of adolescents with HIV live. Achieving the World Health Organization's 95% viral suppression target for adolescents is difficult, partly due to challenges in HIV status disclosure. Disclosure is crucial for ART adherence, psychosocial support, and improving viral suppression rates. However, the process is complex for both healthcare providers and caregivers. Kisumu County Referral Hospital, with a high HIV prevalence of 14.5%, serves 356 adolescents aged 10-19 living with HIV. Despite efforts, viral suppression rates remain below target, highlighting the need for improved disclosure practices to boost ART adherence and health outcomes.

Description: A Continuous Quality Improvement (CQI) approach was used to address barriers to HIV disclosure among 178 adolescents enrolled at the facility. A 50% disclosure gap was identified, and a Multi-Disciplinary Quality Improvement (QI) team conducted a root cause analysis using the Fishbone diagram, identifying barriers like knowledge gaps, poor documentation, and stigma. Interventions included sensitization sessions for 43 healthcare workers (HCWs) and 30 caregivers, focusing on best practices in disclosure and overcoming challenges. Pre- and post-training evaluations assessed the impact of the intervention.

Lessons learned: Disclosure monitoring from July to December 2022 showed a significant increase in full disclosure rates among adolescents, from 50% to 72%, and appointment keeping rates rose from 70% to 92%. HCWs and caregivers reported a 70% increase in knowledge and confidence after training. Continuous support and mentorship for caregivers and HCWs are critical for sustaining effective disclosure. Challenges included caregiver readiness, staff resistance due to workload, and inconsistent parental support.

Conclusions/Next steps: Training HCWs and caregivers on HIV disclosure processes improved disclosure rates, clinic adherence, and ART adherence. This emphasizes the importance of continuous education, caregiver and HCW support, and a multi-disciplinary approach in adolescent HIV care.

TUPEB039

High levels of mental distress among youth with HIV in southern Africa: a description of enrollment into IMPAACT 2016, a randomized controlled trial of a peer-led, group-based mental health intervention

D. Dow[1,2,3], J. Libous[4], P.L. Ponatshego[5], G. Masheto[6], T. Mvalo[7,8], C. Payesa[9], J. Buckley[10], L. Stranix-Chibanda[11], T.G. Nematadzira[11], T. Vhembo[11], A. Ace[12], M. Warshaw[13], E. Townley[14], S. Lee[15], O. Varechtchouk[14], G. Donenberg[16], the the International Maternal Pediatric Adolescent AIDS Clinical Trials (IMPAACT) 2016 Study Group

[1]Duke University Medical Center, Pediatrics, Durham, United States, [2]Duke Global Health Institute, Durham, United States, [3]Kilimanjaro Christian Medical Centre-Duke Collaboration, Moshi, Tanzania, the United Republic of, [4]FHI 360, Washington DC, United States, [5]Botswana Harvard Health Partnership, Molepolole, Botswana, [6]Botswana Harvard Health Partnership, Gaborone, Botswana, [7]University of North Carolina Project Malawi, Lilongwe, Malawi, [8]University of North Carolina at Chapel Hill School of Medicine, Pediatrics, Chapel Hill, United States, [9]Johns Hopkins Research Project-Kamuzu University of Health Sciences, Blantyre, Malawi, [10]Perinatal HIV Research Unit (PHRU), University of Witwatersrand, Johannesburg, South Africa, [11]University of Zimbabwe Clinical Trials Research Centre, Harare, Zimbabwe, [12]Frontier Science & Technology Research Foundation, Inc, Buffalo, United States, [13]Harvard T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [14]Division of AIDS, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, United States, [15]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, United States, [16]University of Illinois at Chicago, Center for Dissemination and Implementation Science, Chicago, United States

Background: Rates of mental distress for youth with HIV (YWH) are not well described for Southern Africa. Depression, anxiety, and post-traumatic stress symptoms can negatively impact antiretroviral therapy (ART) adherence, resulting in virologic failure, and contribute to poor quality of life.

This abstract presents rates of mental distress based on screening for the IMPAACT 2016 randomized controlled trial.

Methods: IMPAACT 2016 evaluates trauma-informed cognitive behavioral therapy adapted from the Kigali Imbereheza Project intervention developed in Rwanda. The intervention is delivered in six group sessions by trained peer leaders who receive weekly supervision. Enrollment criteria include YWH (15-19 years-old) who know their HIV status, have been prescribed ART for at least 6-months, are not co-enrolled in any other mental health intervention study, and have moderate to severe symptoms of depression (PHQ-9 ≥10), anxiety (GAD 7 ≥10), and/or post-traumatic stress (UCLA PTSD-RI ≥35) according to self-administered questionnaires. Recruitment occurred at adolescent HIV clinics and teen clubs. Screening and

enrollment occurred from March to September 2024 across eight IMPAACT network sites in four Southern African countries.

Results: Of the 366 youth screened, 276 (75%) self-reported elevated symptoms of mental distress, and 254 (69%) enrolled in the trial (Table 1). Reasons for non-enrollment (n=22) were primarily school conflicts with attending weekly group sessions and family emergencies preventing return for enrollment. Most youth (71%) reported symptoms on more than one questionnaire; 39% met criteria on all three (Figure 1).

Country	Screened (N=366)	Enrolled (N=254)	% youth reporting symptoms of mental distress
Botswana	70	50	71%
Malawi	87	66	75%
South Africa	29	20	69%
Zimbabwe	180	118	65%

Table 1.

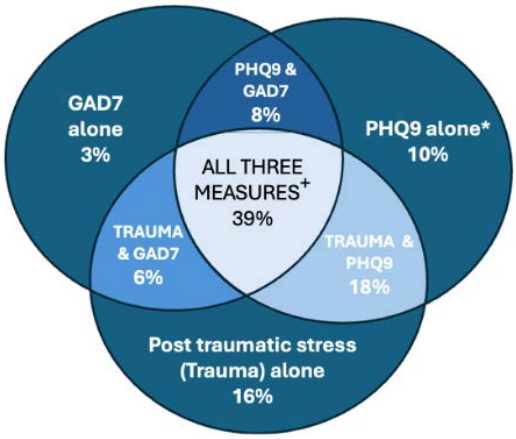


Figure 1. Mental distress symptoms on screening questionnaires.
**includes 6 youth inadvertently enrolled with a PHQ9 score of 9*
+size of the shaded area is not to scale

Conclusions: Successful enrollment into IMPAACT 2016 underscores the high rate of mental distress among YWH and their desire for care. These data amplify the urgent need to integrate mental health screening and services into HIV care and treatment programs for youth in Southern Africa.

TUPEB040

Effectiveness of layered interventions in improving viral load suppression among children and adolescents (0-19years) living with HIV in western Kenya, 2021-2023

A. Wasilwa[1], E. Amadi[1], M. Mumbi[1], R. Oyuga[1], S. Wafula[1], S. Gachau[2], L. Omotto Nyabiage[2], I. Mutisya[2], E. Koech[1], A. Bisera[1]

[1]Center for International Health, Education, and Biosecurity (CIHEB), Nairobi, Kenya, [2]Division of Global HIV&TB (DGHT), U.S. Centers for Disease Control and Prevention (CDC), Nairobi, Kenya

Background: Despite Kenya's progress towards the UNAIDS' 95-95-95 targets for epidemic control, viral load suppression (VLS) among children and adolescents living with HIV (CALHIV) on antiretroviral treatment (ART) remains low at 84% compared to 94% among adults. We implemented layered interventions and assessed its impact on VLS among CALHIV within CIHEB supported sites in western Kenya.

Methods: We conducted a retrospective cohort analysis of data from electronic medical records of CALHIV (0-19yrs) on ART between October 2021 and September 2023 in 93 facilities. The layering approach included five multiple interventions such as expert parent-led sessions during family clinic days, adolescent peer support, Papa-Mama (PAMA) club meetings with fun days, linking orphans and vulnerable children to community support programs and expressive art therapy during enhanced adherence counseling. Full layering was defined as receiving all eligible interventions, while missing at least one was categorized as not fully layered. VLS was defined as viral load <200cp/ml. Descriptive summary statistics described outcomes and covariates. Chi-square tests assessed VLS differences at baseline and end-term. A multivariable logistic regression model, adjusted for sex, age, and facility clustering, was used to evaluate association between layering status and VLS.

Results: The analysis included 7,291 CALHIV with a median age of 13 years [interquartile range (IQR) 10-16], 3,841 (53%) were female, 5,646 (77%) being on ART for 5+ years and 6,234 (86%) were on a dolutegravir based regimen. Overall, 4,174 (57%) received all the eligible interventions while 3,117 (43%) missed at least 1 intervention. CALHIV with VLS improved from 5,569 (76%) to 6,386 (88%) at the end of the period (p<0.001). CALHIV who received full layered interventions had a VLS of 88%, compared with 86% among those not fully layered (p=0.82). After adjusting for age, sex, time on ART, type of regimen and VL results at baseline, CALHIV who received all interventions they were eligible for were more likely to achieve VLS (adjusted Odds Ratio 1.18, 95% CI: 1.02-1.37) compared with those who did not.

Conclusions: Full uptake of layered interventions was associated with improved VLS among CALHIV. Implementing structured multiple interventions could enhance treatment outcomes and support efforts towards epidemic control.

Antiretroviral therapies and clinical issues in neonates, infants and children

TUPEB041

Efficacy and safety of emtricitabine/tenofovir alafenamide (F/TAF) plus cobicistat-boosted protease inhibitors in children with HIV-1 aged 2-<12 years and weighing 14-<40 kg: Week 48 outcomes

H.A. Mujuru[1], R. Strehlau[2], P. Kosalaraksa[3], J.G. Deville[4], M. Pan[5], B. Okware[5], V.A. Vieira[5], N. Rakhmanina[6]
[1]University of Zimbabwe, Harare, Zimbabwe, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Khon Kaen University, Faculty of Medicine, Khon Kaen, Thailand, [4]UCLA Mattel Children's Hospital, University of California, Los Angeles, United States, [5]Gilead Sciences, Inc., Foster City, CA, United States, [6]Children's National Hospital, The George Washington University, Washington, DC, United States

Background: TAF is a nucleoside reverse transcriptase inhibitor with improved renal and bone safety compared with tenofovir disoproxil fumarate. F/TAF is approved in Europe and the US for use with boosted protease inhibitors in adults and older children, and is being evaluated with cobicistat-boosted atazanavir (ATV/co) or darunavir (DRV/co) in younger children in an ongoing open-label Phase 2/3 trial (NCT02016924).
Here, we report efficacy and safety outcomes through 48 weeks in children with HIV aged 2-<12 years and weighing 14-<40 kg.
Methods: Participants aged 6-<12 years, weighing 25-<40 kg, received 200/25 mg F/TAF + ATV/co or DRV/co (Cohort 2). Participants aged ≥2 years and weighing 14-<25 kg received 120/15 mg F/TAF + ATV/co or DRV/co (Cohort 3). Baseline characteristics, virologic suppression, changes in clinical parameters, and changes in bone mineral density (assessed by dual-energy X-ray absorptiometry) are reported.
Results: Twenty-three (Cohort 2) and 26 (Cohort 3) participants were enrolled. At baseline, in Cohort 2/Cohort 3, 61%/54% of participants were female, 91%/92% were Black, median (range) age was 10 (8-12)/6 (3-10) years, and 96%/92% had HIV-1 RNA <50 copies/mL. At Week 48, 100% (23/23) of participants in Cohort 2 and 96% (25/26) in Cohort 3 had HIV-1 RNA <50 copies/mL. Two participants, both in Cohort 3, each experienced two Grade 3/4 study drug–related treatment-emergent adverse events (TEAEs). All four TEAEs were of elevated bilirubin/hyperbilirubinemia (Grade 3) and were considered related to ATV; one was classified as a serious TEAE. Changes in clinical parameters reported in the *Table (following page)* were not clinically significant.
Conclusions: Over 48 weeks of treatment, F/TAF + ATV/co or DRV/co in children aged 2-<12 years and weighing 14-<40 kg maintained high rates of virologic suppression, with an acceptable safety profile. There were no renal, bone, or weight gain/loss concerns, supporting further evaluation of these drug combinations in pediatric populations.

TUPEB042

Risk of neural tube defects in births periconceptionally exposed to antiretroviral therapy in Malawi

N. Wadonda[1], J. Mkungudza[2,3], M.Y. Simkonda[2], D. Williamson[4], A.N. Kabaghe[1], D. Valencia[5], L. Chiwala[2], C. Moore[6], E. Rabold[4], C. Mai[6], I. Namakhoma[2], H. Katengeza[7], A. Mwale[3], F. Thaulo[8], G. O'Malley[9], G. Bello[2,3]
[1]U.S. Centers for Disease Control and Prevention, Malawi, Division of HIV and TB, Lilongwe, Malawi, [2]I-TECH, University of Washington, Lilongwe, Malawi, [3]Ministry of Health, Malawi, Public Health Institute of Malawi, Lilongwe, Malawi, [4]U.S. Centers for Disease Control and Prevention, Division of HIV and TB, Atlanta, United States, [5]U.S. Centers for Disease Control and Prevention, National Center for Emerging and Zoonotic Infectious Diseases, Atlanta, United States, [6]U.S. Centers for Disease Control and Prevention, National Center on Birth Defects and Developmental Disabilities, Atlanta, United States, [7]Ministry of Health, Malawi, Reproductive Health Department, Lilongwe, Malawi, [8]Kamuzu University of Health Sciences, Obstetrics and Gynecology, Blantyre, Malawi, [9]University of Washington, Seattle, United States

Background: Antiretroviral therapy (ART) has significantly reduced vertical transmission of HIV. However, there have been concerns of birth defects, including neural tube defects (NTDs), associated with periconceptional exposure to ART. We assessed the risk of NTDs among births periconceptionally exposed to ART from pregnant women living with HIV (WLHIV).
Methods: We analysed data collected between December 2016 and December 2023 from four high-volume delivery hospitals in Malawi implementing active birth defects surveillance. All informative live births, stillbirths, and spontaneous abortions, regardless of gestational age, were included. Periconceptional ART exposure was defined as ART use from one month before estimated date of conception through the first trimester based on last menstrual period or estimated gestational age from

ultrasound scan. We used adjusted binomial regression (adjusted for maternal age, number of prior pregnancies, and antenatal care attendance) to compare prevalence of NTDs in births exposed to ART periconceptionally and births from women without HIV.

Results: Of 271,981 informative births, 25,614 (9.4%) were from WLHIV, of whom 25,146 (98.2%) were on ART. Of the births from WLHIV on ART, 13,439 (53.4%) were periconceptionally exposed to ART (6,509 [48.4%] on efavirenz-based ART and 6,855 [51.0%] on dolutegravir-based ART).

The overall prevalence of NTDs per 10,000 informative births was 6.3 (95% CI=5.4-7.3, n=172) among all births, 13.8 (95% CI=7.3-26.3, n=9) among those with periconceptional exposure to efavirenz, and 11.7 (95% CI=5.9-23.0, n=8) among those with periconceptional exposure to dolutegravir.

Periconceptional exposure to efavirenz-based ART was significantly associated with an increased risk of NTDs (aPR = 2.2, 95% CI=1.1-4.4, p=0.02), but there was no statistically significant association between periconceptional exposure to dolutegravir-based ART and NTDs (aPR=1.9, 95% CI=0.9–3.9, p=0.08).

Conclusions: Our findings suggest that periconceptional exposure to efavirenz was associated with an increased risk of NTDs. However, as NTDs are a rare outcome, the small number of cases may have influenced the precision of the point estimates. Ensuring adequate folic acid uptake periconceptionally may mitigate potential risk of an NTD-affected pregnancy for women on ART. Active surveillance of birth defects remains an important strategy to identify potential associated risk factors of NTDs.

Epidemiology of HIV

TUPEC043

Spatial trends and predictive factors of detectable HIV viremia in people on dolutegravir-based antiretroviral therapy in Botswana

O.T. Choga[1,2], Z. Matsena-Zingoni[3], R. Musonda[1], J. Makhema[1,4], B. Nkomo[5], D. Ramaabya[5], T. Chebani[5], P. Makuruetsa[5], S. Moyo[1,4], S. Blower[3], S. Gaseitsiwe[1,4]
[1]Botswana Harvard Health Partnership, Research Lab, Gaborone, Botswana, [2]University of Botswana, Departments of Medical Sciences, Gaborone, Botswana, [3]University of California, Center for Biomedical Modeling, Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, Los Angeles, United States, [4]Harvard T.H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [5]Botswana Ministry of Health, Gaborone, Botswana

Background: Botswana has achieved the UNAIDS 95-95-95 targets in 2022, however, the rate of new HIV cases remains concerningly high. The study aims to assess the predictors of detectable HIV viremia in the era of dolutegravir (DTG)-based first-line antiretroviral therapy (ART) in Botswana, utilizing logistic regression and spatial mapping to pinpoint regions with high rates of detectable viremia that are likely to experience new HIV cases.

Methods: This was a longitudinal observational cohort utilizing a dataset of 42,545 people living with HIV (aged≥18 years) on DTG-based first-line ART from June 2016 to December 2022 who were enrolled in the Botswana National Treatment Program. Detectable viremia was defined as viral load (VL)>50 copies/mL and further classified into low-level viremia (LLV) (VL: 50-1000 copies/mL) and virologic failure (VF) (VL≥1000 copies/mL). The rates of detectable viremia were stratified by year from 2017-2022 and mapped by 28 administration districts in Botswana. Univariate logistic regression models were utilized to identify predictors of detectable viremia.

Results: There is an overall trend of increasing detectable viremia: 6.7% (2017), 5.6% (2018), 4.7% (2019), 7.1% (2020), 13.5% (2021) and 11.2% (2022). LLV increased from 2.3% in 2017 to 8.0% in 2022, however, rates of VF declined from 4.4% to 3.2% over the same period.

Among 28 districts, Ghanzi experienced the highest increased rates of LLV from 1.2% (2017) to 11.2% (2022). Ngamiland West also reported notable increased LLV rates from 3.7% to 8.8% over the same period.

Being a male (unadjusted odd ratio (OR): 1.31 95% Confidence intervals (CI);1.25-1.37), residing in a rural area (OR: 1.14 95% CI;1.09-1.20) or being a young adult (18-21 years) (OR: 1.97 95% CI:1.72-2.26) were associated with increased odds of experiencing detectable viremia (p-values for all variables <0.01).

Conclusions: The study shows that the annual rate of viral failure is decreasing, however, detectable viremia is increasing, and LLV is the primary driver of unsuppressed VLs. This suggests that intensified targeted interventions are recommended to reduce rates of detectable viremia in men, young adults, rural areas and districts with increasing trends of LLV. Strengthening these efforts is critical to reducing detectable viremia and prevent new HIV cases.

TUPEC044

Comparative prevalence of premature cognitive aging in adult Ugandans living with HIV and demographically matched HIV-negative controls

A. Ezeamama[1], A. Sikorskii[1], S.K. Zalwango[2], N. Nakasujja[3], B. Giordani[4]
[1]Michigan State University, Psychiatry, East Lansing, United States, [2]Kampala Capital City Authority, HIV Services, Kampala, Uganda, [3]Makerere University, Psychiatry, Kampala, Uganda, [4]University of Michigan / Michigan Alzheimer's Disease Research Center, Psychiatry, Ann Arbor, United States

Background: The prevalence rates of mild cognitive impairment (MCI) and Alzheimer's dementia (AD) in cART-treated people living with HIV (PWH) compared to age-matched HIV-negative peers remain unclear. The global demographic shift towards aging populations highlights the importance of this data for health system planning.

Methods: A total of 471 adults aged 20–87 years (277 PWH and 189 HIV-negative controls), matched by age, sex, and residence, underwent neuropsychological evaluation in Kampala, Uganda. Seven cognitive domains, including recall, memory, language, processing speed, executive function, attention/working memory, and motor function, were assessed.

Cognitive status was classified (not impaired, ANI, MND, HAD if HIV+), and age-related dysfunction (AD subtype) was defined per Bondi et al. (2014). MCI was identified as moderate (≥1 SD worse in ≥2 tests) or pronounced (>2 SD worse in ≥1 test) cognitive impairment without functional limitation, with amnestic MCI involving memory deficits. AD was defined by ≥1 pronounced memory-related impairment (e.g., delayed recall) with functional limitation.

Differences in MCI/AD by HIV status were analyzed using chi-square tests and odds ratios (OR) with 95% confidence intervals (CI), stratified by age (<60 vs. ≥60 years).

Results: Of participants, 26.1% (n=123) were cognitively normal, 17.2% (n=81) had amnestic MCI, 27.8% (n=131) non-amnestic MCI, 9.1% (n=43) AD, and 10.8% (n=93) other dementia. Among cognitively unimpaired/ANI individuals, amnestic MCI prevalence was 28.9% (60/204) in PWH vs. 14.7% (21/133) in HIV- controls (OR=2.18, 95% CI:1.25, 3.84). Among MND/HAD individuals, AD prevalence was 38.7% (29/75) in PWH vs. 23% (14/61) in HIV- controls (OR=2.11, 95% CI:0.99, 4.50).

For unimpaired/ANI individuals <60, amnestic MCI prevalence was 30.3% in PWH vs. 16.2% in controls (OR=1.9, 95% CI:1.02, 3.60). Among MND/HAD individuals, AD prevalence was 38.6% in PWH vs. 16.3% in controls (OR=3.23, 95% CI:1.23, 8.52). For those ≥60 with ANI/no impairment, amnestic MCI prevalence was 41.9% in PWH vs. 14.7% in controls (OR=4.04, 95% CI:1.23, 13.40), but AD prevalence was identical at 38.9% in both groups.

Conclusions: PWH face higher risks of MCI/AD diagnosis, potentially at younger ages compared to HIV-negative peers. These findings emphasize the need for MCI/AD screening and interventions to mitigate risks in PWH.

Monitoring and population-level interventions for non-HIV outcomes

TUPEC045

Radiology report of hepatic steatosis is associated with increased risk of hepatocellular carcinoma or hepatic decompensation in people with and without HIV

J. Torgersen[1,2], J.P. Tate[3,4], C. Mezzacappa[3,4], Y.C. Ilagan-Ying[3,4], M. Skanderson[3,4], R. Mehta[3,4], L. Buchwalder[3,4], D.M. Carbonari[2], T.H. Taddei[3,4], V. Lo Re, III[1,2], A.C. Justice[3,4,5]

[1]University of Pennsylvania Perelman School of Medicine, Department of Medicine, Philadelphia, United States, [2]University of Pennsylvania Perelman School of Medicine, Department of Biostatistics, Epidemiology, and Informatics, Center for Clinical Epidemiology and Biostatistics, Philadelphia, United States, [3]Yale School of Medicine, New Haven, United States, [4]VA Connecticut Healthcare System, West Haven, United States, [5]Yale School of Public Health, Division of Health Policy and Management, New Haven, United States

Background: While rates of chronic viral hepatitis are decreasing globally, rates of hepatocellular carcinoma (HCC) in people with HIV (PWH) have tripled, parallelling the rise in obesity and diabetes. Steatotic liver disease (SLD), the hepatic manifestation of metabolic syndrome, may lead to HCC or hepatic decompensation (HD); however, it is unclear if SLD, independent of metabolic factors and HIV status, contributes to increased risk of HCC or HD.

Methods: We applied a validated HCC risk score to PWH and people without HIV (PWoH) in the Veterans Aging Cohort Study-HIV between 2001-2017; people with hepatitis B or C were excluded. The HCC risk score uses age, sex, race, ethnicity, Fibrosis-4 Index, body mass index, smoking, and diabetes status to quantify risk of HCC on a 0-100 scale among people without viral hepatitis or prevalent HCC/HD. SLD was identified using natural language processing on radiology reports from the first computed tomography, magnetic resonance, or ultrasound. Incident HCC and HD were defined by cancer registry or validated International Classification of Disease-9/-10 codes. Cox regression was used to estimate 10-year risk of the composite of first HCC/HD event associated with SLD, independent of HCC risk score or HIV.

Results: Of 56,731 included (96% male; median age, 53 years; 6.5% Hispanic, 44% Black; 24% PWH), SLD was identified in 23% of radiology reports. 89 incident HCC (incidence rate [IR]: 2.0/10,000 person-years) and 831 HD events (IR: 18.3/10,000 person-years) were identified. SLD was associated with significantly increased risk of HCC/HD (hazards ratio: 2.25; 95% confidence interval: 1.97-2.56), independent of HCC risk score and HIV (*Table*).

Model discrimination improved with addition of SLD (c-statistic without SLD: 0.76, with SLD: 0.78). PWH had a 15% increased risk of HCC/HD. Risk of HCC/HD increased 9% for every 1-point increase in HCC risk score, independent of SLD status.

Variables	Unadjusted Hazards (95% CI)	Adjusted Hazards (95% CI)
HCC risk score	1.09 (1.09-1.10)	1.09 (1.08-1.09)
HIV	1.16 (1.00-1.34)	1.15 (0.99-1.34)
SLD	3.02 (2.65-3.43)	2.25 (1.97-2.56)

Table. Unadjusted and Adjusted Hazards Ratio of Hepatocellular Carcinoma or Hepatic Decompensation in People with and without HIV.

Conclusions: SLD is independently associated with greater risk of HCC/HD in PWH and PWoH who underwent radiology studies. Interventions to ameliorate metabolic factors contributing to SLD and HCC/HD are urgently needed.

TUPEC046

Is life expectancy "Near Normal" for people aging with HIV in the United States?

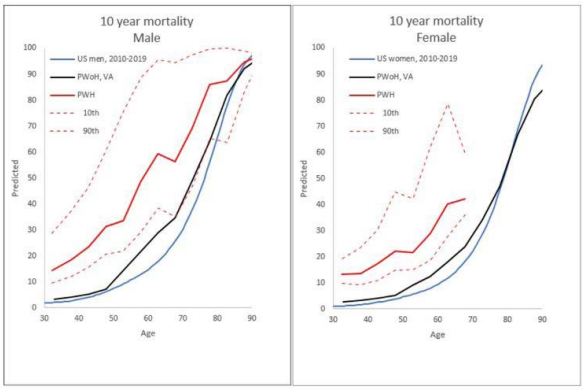
J. Tate[1,2], K. McGinnis[2], V. Marconi[3,4], M. Rodriguez-Baradas[5,6], S. Brown[7], A. Justice[2,1], J. Torgersen[8]
[1]Yale University School of Medicine, New Haven, United States, [2]VA Connecticut Healthcare System, West Haven, United States, [3]Emory University School of Medicine and Rollins School of Public Health, Atlanta, United States, [4]Atlanta VA Medical Center, Atlanta, United States, [5]Baylor College of Medicine, Houston, United States, [6]Michael E. DeBakey Department of Veterans Affairs Medical Center, HoustonUnite, United States, [7]James J. Peters VA Medical Center, Bronx, United States, [8]University of Pennsylvania, Center for Viral Hepatitis, Philadelphia, United States

Background: Claims that life expectancy is "near normal" for people with HIV infection (PWH) on antiretroviral therapy fail to consider HIV-associated risk for physiologic injury and comorbid disease. Applying a validated mortality index (Veterans Aging Cohort Study-Charlson Comorbidity Index, VACS-CCI) in the United States (US) Veterans Healthcare Administration (VA), we asked whether 10-year mortality by age and self-reported sex differs by HIV status. We compare with "population mortality" based upon US life table data.

Methods: Using (VA) electronic health record data, we randomly selected one outpatient visit date per person at least 18 months after the first outpatient diagnosis. PWH were required to have visited at least one year after the date of the first ART prescription. We obtained laboratory data on the closest date prior to 18 months before and all diagnoses comprising the CCI two years before visit date.

We calculated VACS-CCI, using age, albumin, creatinine, platelets, alanine and aspartate transaminases, white blood cell count, body mass index, and these comorbid conditions. For population estimates, we used US death rates by age and year stratified by sex.

Results: The VA sample had 6,588,688 people without HIV (PWoH) and 30,539 PWH. The figure illustrates median expected mortality by age, for PWH and PWoH in VA and life table-based US population estimates (red, black, and blue lines respectively) for men and women. The dotted red lines illustrate the 10th and 90th percentiles among PWH. PWH in VA are expected to have substantially higher mortality than PWoH in VA and compared to US general population. Differences were greater for women than men.



Conclusions: Using a validated risk index incorporating laboratory measures and comorbid diagnoses, PWH are likely to have substantially higher mortality than PWoH. Disparities were even greater for women than for men. We see no evidence that PWH have a "near normal" life expectancy.

Surveillance: Measuring the HIV pandemic

TUPEC047

Quantifying interruptions in sexual and reproductive health programmatic outputs in Malawi following cyclone Freddy- an interrupted time-series analysis using routine health information system and satellite imagery data

M. Niwa[1], R. Haggard[2], B. Klyn[2], T. Smith[1], H. Cooper[2], D. Green[2], P. Khomani[1]
[1]Cooper/Smith, Lilongwe, Malawi, [2]Cooper/Smith, Austin, United States

Background: Cyclone Freddy, the longest-lasting tropical cyclone worldwide, may have disrupted access, availability, and demand for HIV and related health services in Malawi. We quantified its impact across health facilities using routine programmatic data and satellite imagery.

Methods: Our analysis included data from 356 urban and rural facilities across the 15 Southern districts in Malawi in the cyclone path. We defined February 2020 to February 2023 as the pre-cyclone period and February 2023 to December 2023 as the post-cyclone period with February 2023 as the month Cyclone Freddy took place.

We defined our exposure of interest using satellite imagery and machine learning building detection algorithms to quantify health facility building damage into categories of least, medium, and most damage.

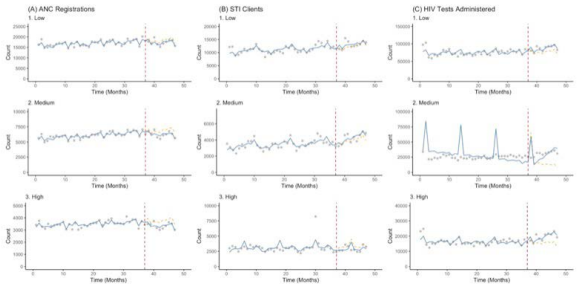
Our outcomes of interest were drawn from DHIS2 monthly for each facility and included the number of HIV tests, STI clients, and ANC registrations.

We then conducted an interrupted time series analysis of our outcomes across satellite-derived damage levels adjusting for seasonality.

Results: Most facilities (246) had low damage, with 21% (76) categorized as medium damage, and 10% (32) as high damage. While Blantyre had the most facilities overall (n=62), Machinga had the most high-damage facilities (n=10).

Across the full period, facilities saw a median of 271 total HIV tests (IQR: 134-434), 32 total STI clients (IQR: 17-52), and 68 ANC Registrations (IQR: 37-109) per month. Post-cyclone, on average, high-damage facilities administered 59,060 (SE: 3,843) fewer HIV tests, saw 8,146 (SE: 213) fewer STI clients, and had 13,409 (SE: 156) fewer ANC registrations compared to low-damage facilities post-cyclone.

Figure 1. ANC Registrations, STI Clients, and HIV Test Administered counts by facilities that had low, medium, and high damage across February 2020 (month 1) to December 2023 (month 46). Grey dots indicate average facility output levels, the solid blue line represents the fitted regression, the red line indicates Cyclone Freddy (Feb 2023), and the orange dotted line indicates the estimated counterfactual.



Conclusions: Cyclone Freddy was associated with notable trends in sexual and reproductive health service-seeking behavior. Layering geospatial data with causal inference methods can provide insights into informing and planning the health system's resource allocation efforts during natural disasters.

TUPEC048

Population-level coverage and correlates of enrollment in community-based antiretroviral therapy (ART) refill models in Africa: a multi-country study

L. Lukose[1], R. Kairania[2], F. Nalugoda[2], G. Nakigozi[2], G. Kigozi[2], R. Ssekubugu[2], S.J. Reynolds[3,2,4], L.W. Chang[4,5], C.E. Kennedy[5], M.K. Grabowski[6,1], J.G. Rosen[7,8]

[1]Johns Hopkins University, Department of Epidemiology, Bloomberg School of Public Health, Baltimore, United States, [2]Rakai Health Sciences Program, Kalisizo, Uganda, [3]National Institute of Health, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, Bethesda, United States, [4]Johns Hopkins University, Division of Infectious Diseases, School of Medicine, Baltimore, United States, [5]Johns Hopkins University, Department of International Health, Bloomberg School of Public Health, Baltimore, United States, [6]Johns Hopkins University, Department of Pathology, School of Medicine, Baltimore, United States, [7]Brown University, Department of Medicine, The Warren Alpert Medical School, Providence, United States, [8]Rhode Island Hospital, Division of General Internal Medicine, Providence, United States

Background: Community-based antiretroviral therapy (ART) distribution, through models like out-of-facility drug distribution points and peer-/provider-led home ART delivery, has emerged as a promising strategy to increase HIV treatment accessibility and achieve HIV epidemic control in Africa. While these community-based models are increasingly implemented across Africa, especially to mitigate service disruptions during the COVID-19 pandemic, coverage and factors associated with service enrollment, specifically at the population level, remain understudied.

Methods: We pooled data from six Population-based HIV Impact Assessment (PHIA) surveys (Eswatini, Lesotho, Malawi, Mozambique, Uganda, Zimbabwe), conducted in 2020-2021—yielding a household-based, multistage probability sample of virally suppressed (<1000 RNA copies/ml) persons living with HIV initiating ART 12+ months prior who were eligible for community-based ART distribution. Survey-weighted multivariable logistic regression with jackknife variance estimation identified correlates of enrollment in community-based, relative to facility-based, ART distribution models.

Separately, sex-stratified negative-binomial regression quantified mean viral load differences (number of RNA copies/ml) by ART refill model, reported as adjusted incidence rate ratios (adjIRR) with 95% confidence intervals (CI).

Results: Across countries, 10391 virally suppressed persons living with HIV on ART for 12+ months (mean age: 42.1 years, 67.0% female) self-reported their assigned ART refill model, 3.5% of whom received ART from a community-based pickup point (*range*: 0.5% in Mozambique to 7.6% in Zimbabwe). Factors independently associated with enrollment in a community-based ART refill model included rural residence (adjusted odds ratio [adjOR]=2.15, 95% CI: 1.11-4.17, *p*=0.025), past-year mobility (adjOR=1.57, 95% CI: 1.05-2.34, *p*=0.028), ART use for 5+ years (adjOR=1.48, 95%

CI: 1.00-2.18, *p*=0.049), and transportation-related barriers to facility-based HIV care (adjOR=1.52, 95% CI: 1.08-2.14, *p*=0.019). Enrollment in a community-based ART refill model was associated with superior virologic control (i.e., lower mean viral load) among males (adjIRR=0.61, 95% CI: 0.40-0.93, *p*=0.022) but not females (adjIRR=1.04, 95% CI: 0.74-1.47, *p*=0.811).

Conclusions: Findings reveal that community-based ART refill models can reach populations at increased risk for HIV care attrition (i.e., mobile persons, individuals experiencing transportation-related barriers to care), but coverage estimates fall well below national programmatic targets—suggesting the presence of constraints hindering implementation. Continued scale-up of community-based ART refill models may be needed to optimize population-level impact.

TUPEC049

Trajectory and correlates of viral load suppression at individual and geospatial levels in Malawi: a descriptive nation-wide study of laboratory information management system data

L. Metz[1], R. Haggard[1], B. Klyn[1], T. Smith[2], H. Cooper[1], C. Mwase[2], P. Khomani[3], D. Green[1]
[1]Cooper/Smith, Austin, United States, [2]Cooper/Smith, Lilongwe, Malawi, [3]Cooper/Smith, Blantyre, Malawi

Background: Treatment as prevention is a key strategy of HIV programmes. Monitoring viral load is an important indicator of effective HIV management and has epidemiological implications for epidemic control.

Methods: We used Malawi's laboratory information management system (LIMS) data on viral load test results from all 28 districts in 2022 and 2023. Our primary outcome was viral load suppression (VLS), defined as a viral load below 1,000 copies/mL.

We examined the change in VLS between an individual's first and second test. This change was then classified into four categories: durable VLS, where viral load remained below 1,000 copies/mL for both tests; viral rebound, where viral load increased from below to above 1,000 copies/mL; persistent viremia, where viral load remained above 1,000 copies/mL; and new/renewed VLS, where viral load decreased from above to below 1,000 copies/mL.

We describe patterns of these trajectories across districts and health facilities, and perform generalized mixed effects models to identify factors associated with viral rebound.

Results: Our analysis includes 188,361 ART clients with at least two viral load tests, of whom 128,077 (68%) were female, 115,379 (61%) were aged 24-49, mean time on ART was 6.9 years, 126,930 (67.4%) were on first-line therapy, and there was an average of 45.6 weeks between tests. Among included clients, 159,351 (85%) had durable VLS, 13,089 (7%) had new/renewed VLS, 10,255 (5.5%) experienced viral rebound, and 5,666 (2.5%) had persistent viremia. Trajectories across districts were heterogeneous with 17 of 28 districts seeing increases in average VLS between tests.

Males had 1.15 times greater odds of viral rebound compared to females, those on second-line therapy had 0.71 lower odds of viral rebound compared to those on first-line, and those aged under age 15 had 3.79 times greater odds of viral rebound compared to those aged 25-49 (all after adjusting for time on ART, and district).

Conclusions: VLS trajectories are highly heterogeneous in Malawi at district, facility, and individual level. Careful monitoring is recommended to understand reservoirs of viremia and correlates of persistent and rebound viremia.

TUPEC050

Comparative study on substance use and HIV risk among PWUD/PWID in the city of Kigali

N. Kabanyana[1], S. Murindanyi[1], J.P. Ayingoma[1], D. Ndagijimana[1], L. Ngabonzima[1], C. Ndinda[2], B. Ikuzo[2]
[1]Rwanda NGOs Forum on HIV/AIDS & Health Promotion (RNGOF on HIV/AIDS & HP), Kigali, Rwanda, [2]Rwanda Biomedical Centre, Kigali, Rwanda

Background: In Rwanda, data on the prevalence and incidence of Human Immunodeficiency Virus (HIV) among People Who Use or Inject Drugs (PWUD/PWID) is lacking. This study, conducted in 2019 and 2024 in collaboration with the Rwanda NGOs Forum on HIV/AIDS and Health Promotion and Rwanda Biomedical Center (RBC), aimed to assess injection drug use (IDU) and its associated risk factors for HIV and other transmissible infections among PWUD/PWID in Nyarugenge, Kicukiro, and Gasabo districts in Kigali.

Methods: A comparative descriptive study with a quantitative approach was employed. Participants were recruited using convenience and respondent-driven sampling. Data were collected through structured questionnaires administered by trained data collectors. HIV testing was conducted, and socio-demographic profiles of participants were documented. Data analysis was performed using SPSS version 21.0.

Results: In 2019, 529 PWUD/PWIDs were identified, while in 2024, 482 were identified. HIV prevalence among self-reported substance users was 12.8% in 2019, compared to 8.9% (95% CI: 7.4-10.4) in 2024. Regarding substance use, heroin use was 45.3% in 2019 and 99.06% (95% CI: 98.87-99.25) in 2024, and opium use was 35.9% in 2019 and 0.67% (95% CI: 0.51-0.83) in 2024. Alarmingly, in 2019, 56.9% of respondents reported no access to HIV services, including HIV testing and counselling (HTC), care and treatment, family planning (FP), or condom distribution, compared to 29.1% (95% CI: 26.8–31.5), in 2024.

Conclusions: >The findings indicate that the use of heroin has increased among PWID while opium use has reduced. However, HIV prevalence among self-reported was decreased due to the increase in access to HIV services. Targeted interventions are urgently needed to address the health needs of PWUD/PWID, including integrating this group into national health policies and programming. Future research should explore extended geographical sites and the size of PWID to inform further interventions and strategies.

Modelling the HIV pandemic

TUPEC051

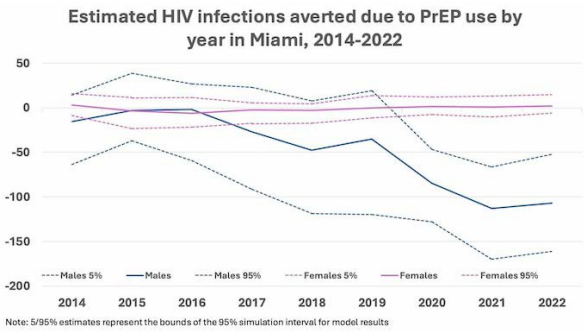
The estimated impact of pre-exposure prophylaxis (PrEP) use on new HIV infections in Miami, USA, from 2014-2022

D. Escudero[1], N. Maldonado Rueda[1], S. Seifi[1], A. Johnson[2]
[1]Vanderbilt University Medical Center, Nashville, United States, [2]University of Miami, Miami, United States

Background: Miami has had the highest rate of new HIV diagnosis in the United States (US) for decades. Miami has also experienced a significant rise in pre-exposure prophylaxis (PrEP) use over the last decade. To inform HIV elimination strategies, we sought to estimate the total preventive impact of observed PrEP use in Miami from 2014-2022.

Methods: We constructed an agent-based model of the Miami population, incorporating important local factors: demographics, sexual risk behavior, HIV treatment, condom use, among others. We obtained PrEP enrollment, adherence, and retention estimates by subpopulation of interest (sex, race/ethnicity) from published empirical research in Miami and the US. We calculated the HIV incidence rate and total new HIV infections for two scenarios: a "baseline" using empirical data from 2014-2022, and a scenario in which there was no PrEP availability. We used these estimates to calculate infections averted due to PrEP use by subpopulation.

Results: We estimated that between 2014-2022, 441 HIV infections (95% simulation interval [SI]: 31-999) were averted within the total population of Miami (49 per year), which typically has a total incidence of about 1,200 cases per year, in a county of 2.7 million. Almost all these infections averted, 434 (SI: 35-949), were among men. In 2022, the largest single-year reduction in the rate of HIV infection was among Hispanics: 6.7/100,000 (SI: 0.8-13.9/100,000). Hispanics also had the largest relative reduction in HIV incidence due to PrEP use: 20% (SI: 2%-43%), followed by Whites, 17% (SI: 2%-33%), and Blacks, 10% (SI: -4%-26%).



Conclusions: PrEP use has increased steadily in Miami, contributing towards HIV elimination goals. This progress, however, was not equally experienced by males and females, nor by race/ethnicity. More complete data on PrEP use, retention, and adherence may enhance such estimates for the future, including on data on emerging PrEP formulations (e.g., long-acting injectables).

HIV prevention research

TUPEC052

Real-world utilization and adherence of cabotegravir long-acting for HIV pre-exposure prophylaxis in the United States: results from the PrEPFACTS study using healthcare administrative claims data

A. Metzner[1], G. Herman[2], S. Walko[2], D. Martinez[2], C. Nguyen[3], R. Desai[4], S. Shi[5], L. Young-Xu[4], M. DerSarkissian[3]
[1]ViiV Healthcare, Health Outcomes, Durham, United States, [2]ViiV Healthcare, Durham, United States, [3]Analysis Group, Inc., Los Angeles, United States, [4]Analysis Group, Inc., Boston, United States, [5]Groupe d'Analyse, Ltée, Montréal, Canada

Background: APRETUDE (cabotegravir long-acting [CAB-LA]) was approved for human immunodeficiency virus (HIV) pre-exposure prophylaxis (PrEP) in the United States (US) in December 2021. The PrEPFACTS study evaluated real-world utilization patterns and adherence to CAB-LA.

Methods: PrEPFACTS was a retrospective US cohort study using data from the Komodo Research Database (01/Dec/2020-30/Sept/2023). Individuals ≥12 years old who received ≥1 CAB-LA injection (first injection defined as index date), had ≥12 months of continuous insurance eligibility before the index (i.e. baseline), and ≥6 months after were included.

Individuals with HIV-1 or HIV-2 diagnosis or receiving ≥60 days of non-PrEP antiretroviral therapy during baseline were excluded. Individuals were followed from index to the earliest of either end of continuous enrollment, death, or end of data availability (i.e. follow-up).

Utilization and adherence (proportion of days covered [PDC] from index to earliest therapy discontinuation [i.e., gap of ≥91 or ≥121 days during initiation or continuation phase, respectively] or end of follow-up) to CAB-LA were described.

Results: Among 1,202 eligible individuals (Table 1) with median follow-up of 325 days (interquartile range [IQR] 242, 423), 85.2% received >1 CAB-LA injection, and median number of injections per individual per year was 6. Of 2,048 initiation and 3,715 continuation injections, the median interval between first and second injection was 29 days (IQR 24, 42) and was 56 days (IQR 49, 63) for continuation injections (Table 2).

	OVERALL N=1,202	COMMERCIAL N=709	MEDICARE N=48	MEDICAID N=444
Age at index (years), mean ±SD	36.5 ± 11.7	37.2 ± 10.7	52.5 ± 17.3	33.8 ± 10.9
Male sex recorded by payer, n (%)	992 (82.5)	661 (93.2)	38 (79.2)	292 (65.8)
Transgender men, n (%)[1]	55 (4.6)	12 (1.7)	0 (0.0)	43 (9.7)

White race, n (%)	368 (30.6)	222 (31.3)	26 (54.2)	120 (27.0)
Black or African American race, n (%)	263 (21.9)	85 (12.0)	9 (18.8)	169 (38.1)
Hispanic or Latino ethnicity, n (%)	214 (17.8)	109 (15.4)	8 (16.7)	97 (21.8)
New PrEP starters, n (%)[2]	331 (27.5)	164 (23.1)	11 (22.9)	156 (35.1)

SD, standard deviation
1. Evidence of transgender experience was based on a diagnosis code-based algorithm incorporating history of gender dysphoria and gender-affirming surgery or hormone therapy.
2. New PrEP starters defined as no evidence of oral PrEP during baseline

Table 1. Baseline Characteristics.

	OVERALL	COMMERCIAL	MEDICARE	MEDICAID
2nd initiation injection within 37 days, n/N (%)[1]	732/1,024 (71.5)	-	-	-
2nd initiation injection within 60 days, n/N (%)[2]	886/1,024 (86.5)	-	-	-
Duration of interval between two continuation injections within 67 days, n/N (%)[3]	3,196/3,715 (86.0)	-	-	-
Duration of interval between two continuation injections within 90 days, n/N (%)[4]	3,577/3,715 (96.3)	-	-	-
Adherence: PDC, median (IQR)	1.00 (0.96, 1.00)	1.00 (0.96 , 1.00)	1.00 (0.96 , 1.00)	1.00 (0.96 , 1.00)
Individuals with PDC ≥0.9, n/N (%)	1,048/1,202 (87.2)	617/709 (87.0)	44/48 (91.7)	386/444 (86.9)
Individuals with PDC ≥0.8, n/N (%)	1,161/1,202 (96.6)	685/709 (96.6)	48/48 (100.0)	427/444 (96.2)

IQR, interquartile range; PDC, proportion of days covered
1. Initiation injections should be given 1 month apart for 2 consecutive months. Individuals may be given CAB-LA up to 7 days before or after the date the individual is scheduled to receive the injections
2. For initiation injections, if the time since last injection was ≤2 months, administer CAB-LA as soon as possible, then continue to follow the every-2-month injection dosing schedule
3. Continuation injections should be given every 2 months. Individuals may be given CAB-LA up to 7 days before or after the date the individual is scheduled to receive the injections.
4. For continuation injections, if the time since last injection was ≤3 months, administer CAB-LA as soon as possible, then continue to follow the every-2-month injection dosing schedule

Table 2. CAB-LA Utilization and Adherence.

Conclusions: PrEPFACTS reports real-world high adherence to CAB-LA's dosing schedule, which is an important factor for ensuring effectiveness of HIV PrEP. Most injections occurred within allowable timeframes before reinitiation as required per label.

TUPEC053

Differential HIV incidence and PrEP-to-need ratio among a large, diverse cohort of people with Mental Illnesses in the U.S.

S. Bunting[1], M. Hyman[2], A. Hazra[3]
[1]University of Chicago, Dept. of Psychiatry & Behavioral Science, Chicago, United States, [2]University of Chicago, Center for Health and the Social Sciences, Chicago, United States, [3]University of Chicago, Section of Infectious Disease, Dept. of Medicine, Chicago, United States

Background: Mental illnesses (MI) like depression, schizophrenia, and bipolar disorder (BD) have been broadly associated with increased incidence of HIV. However, use of highly-effective pre-exposure prophylaxis (PrEP) for HIV prevention among people with MI is not well understood and data describing PrEP use are absent from the literature.

Methods: We utilized data from the Merative MarketScan® Commercial Claims Database between years 2010-2022 to identify patients with a diagnosis of: depression, BD, Schizophrenia/Schizoaffective disorder (schizophrenia).

We determined the number of new HIV diagnoses (defined as a two outpatient claims on different dates or one inpatient claim with an HIV-associated diagnosis code) and prescriptions for PrEP (defined as at least 28 days of TDF/FTC or TAF/FTC without prescription of another antiretroviral). The PrEP-to-Need ratio (PnR), representing the ratio of PrEP prescription and HIV incidence (per 100,000) was calculated as a measure of PrEP scale-up. National PnR data (available beginning 2012; publicly-available) was taken from AIDSVu.

Results: The cohort consisted of 3,105,922 people with depression, 333,851 with BD, and 45,070 with schizophrenia. HIV incidence (Fig. 1A) increased between 2010-2022 for people with depression (18.5 vs. 23.2), BD (18.9 vs. 47.2), schizophrenia (23.1 vs. 58.0) while the national HIV rate decreased (15.4 vs. 11.3). PnR (Fig. 1B) increased for all diagnosis groups between 2010-2022 including depression (0.3 vs. 11.3), BD (0.4 vs. 8.5), schizophrenia (0 vs. 3.7) and the national PnR also increased (0.24 vs. 11.6).

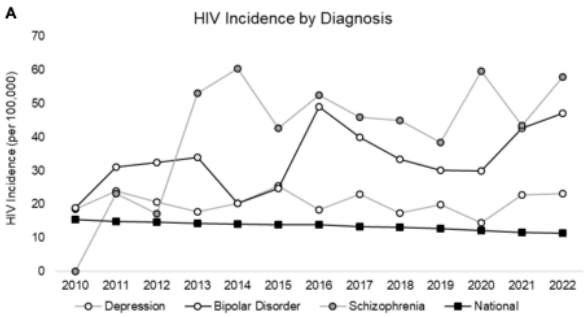

Fig. 1A

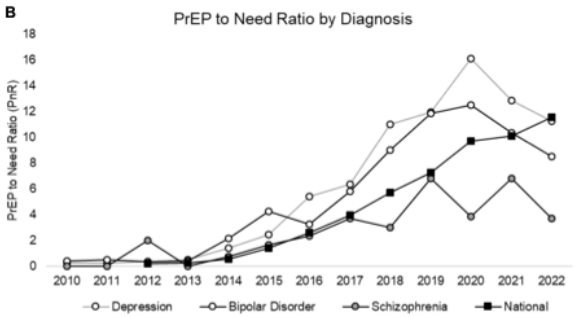

Fig. 1B

Conclusions: In this large, national analysis, commercially-insured people with schizophrenia experienced the highest HIV incidence and lowest PrEP use. While the PnR for all groups increased during the period of analysis, HIV incidence remained relatively constant or increased for all groups despite national decrease. Targeted efforts are needed to accurately identify people with MI who may benefit from PrEP and to include in the PrEP care continuum.

TUPEC054

Who wants PrEP? Factors related to PrEP interest among sexually active adolescents in urban and suburban pediatric primary care settings in the US

S. Jelinek[1,2,3], A. Gzesh[4,3], J. Whelihan[5,6], G. DiFiore[6], M. Powell[6], A. Fiks[2,6,3], B. Jenssen[3,6,3], R. Arrington-Sanders[5,2]
[1]Children's Hopsital of Philadelphia, Craig-Dalsimer Division of Adolescent Medicine, Philadelphia, United States, [2]University of Pennsylvania, Perelman School of Medicine, Pediatrics, Philadelphia, United States, [3]University of Pennsylvania, Leonard Davis Institute for Health Economics, Philadelphia, United States, [4]Univeristy of Pennsylvania, School of Social Policy & Practice, Philadelphia, United States, [5]Children's Hopsital of Philadelphia, Adolescent Medicine, Philadelphia, United States, [6]Children's Hospital of Philadelphia, Clinical Futures and PolicyLab, Philadelphia, United States

Background: Adolescents aged 13–24 remain at high risk for HIV, yet pre-exposure prophylaxis (PrEP) uptake remains low. The CDC's 2021 guidelines recommend informing all sexually active adolescents about PrEP; however, data on PrEP interest and eligibility in pediatric primary care remain scarce.
This study aimed to identify demographic and behavioral correlates of PrEP interest among sexually active adolescents.
Methods: We analyzed cross-sectional data from adolescents (aged 13–21) who completed an Adolescent Health Questionnaire (AHQ), a tablet-based screener, during preventive visits from January 2021 to December 2024 at 32 primary care clinics in urban and suburban southeastern Pennsylvania and New Jersey in the US. Eligible participants reported sexual activity.
Our primary outcome was PrEP interest, defined as responding "yes" or "maybe" to "Would you like to speak with someone about PrEP today?" Using multivariable logistic regression, we examined associations between PrEP interest and variables such as sexual behavior, LGBTQ+ identity, race/ethnicity, STI testing history, and condom use.
Results: Among 24,415 sexually active adolescents, 8.9% (2,172) expressed interest in PrEP. The sample was diverse; 19.3% (4,705) identified as LGBTQ+, including 3.4% (829) as transgender or gender-diverse. The mean age was 17.2. In adjusted analyses, interest was higher among LGBTQ+ adolescents (aOR=1.82, 95% CI: 1.58–2.10), those interested in HIV/STI testing (aOR=14.63, 95% CI: 12.80–16.73), those with a history of STI (aOR=1.42, 95% CI: 1.21–1.67), and those with multiple sexual partners in the past 3 months (aOR=1.31, 95% CI: 1.07–1.60). Non-White adolescents had nearly twice the odds of PrEP interest compared to non-Hispanic Whites (aOR=1.89, 95% CI: 1.59–2.24). Condom non-use (aOR=1.26, 95% CI: 1.11–1.42) and attending a primary care clinic located in an urban area (aOR=1.24, 95% CI: 1.09–1.42) were also significantly associated with PrEP interest.
Conclusions: Although adolescents expressing interest in PrEP exhibited higher HIV risk, 91% of eligible adolescents did not express interest. Understanding why many eligible adolescents are not interested in PrEP is critical to addressing this gap. Future efforts should target public health messaging, sexual education, and strategies to engage eligible adolescents in PrEP counseling and prescribing within pediatric primary care.

TUPEC055

Acceptability and adherence to daily oral PrEP among adolescent girls and young women in sub-Saharan Africa: a randomized clinical trial comparing F/TAF and F/TDF

H. Hanif[1], K. Dominguez[1], M. Beksinska[2], J. Smit[2], N. Mgodi[3], D. Potloane[4], A. Martinez[5], E.E. Tolley[5], J. Rooney[6], G.F. Doncel[1]
[1]CONRAD, Eastern Virginia Medical School, Macon & Joan Brock Virginia Health Sciences at Old Dominion University, Norfolk, United States, [2]Wits MRU, University of the Witwatersrand, Dept of Obstetrics and Gynaecology, Durban, South Africa, [3]Harare Health and Research Consortium (HHRC), Harare, Zimbabwe, [4]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [5]FHI 360, Durham, United States, [6]Gilead Sciences, Inc., Foster City, United States

Background: Adolescent girls and young women (AGYW) in sub-Saharan Africa face disproportionately high HIV infection rates and show low adherence to approved HIV prevention methods like F/TDF (Truvada®). F/TAF (Descovy®)-based regimens may offer advantages over F/TDF through higher intracellular levels of active metabolite at lower tenofovir doses (25mg vs 300mg), potentially improving efficacy, adherence and safety, while reducing costs and pill size.
Methods: We conducted a two-arm, randomized clinical trial among 330 AGYW without HIV aged 15-24 years across three sites (two in South Africa, one in Zimbabwe), comparing acceptability of and adherence to daily oral F/TAF (200mg/25mg) versus F/TDF (200mg/300mg). Participants, including pregnant and breastfeeding women, were randomized 1:1 to take either product for 24 weeks with local standard of care counseling. Acceptability was assessed through voluntary discontinuation rates and questionnaires at months 1, 3 and 6. Adherence was measured using dried blood spot (DBS) analysis.
We also examined individual, partner-related, clinical and cultural context variables, including HIV risk perception, self-efficacy and PrEP use stigma.
Results: Overall, participants reported high acceptability, with low voluntary product discontinuation rates (5% at month 3, 8% at month 6) that did not differ by PrEP product. However, DBS analysis revealed suboptimal adherence: fewer than 25% of participants showed protective drug levels equivalent to 4 or more pills per week at month 3, declining to 10% at month 6, when 52.1% of participants had drug levels below the level of quantification, suggesting no product use. The F/TAF arm demonstrated significantly higher adherence at month 3 compared to F/TDF (28% vs 17% taking ≥4 pills/week).
Multivariate regression analysis controlling for factors like age, education, and adverse events showed F/TAF was associated with higher odds of adherence than F/TDF (OR

1.54 [95% CI 0.97 - 2.43]). Qualitative data suggest that the smaller pill size and reduced antiretroviral-associated stigma of F/TAF may have contributed to better adherence.
Conclusions: While both oral PrEP products were acceptable, F/TAF characteristics appeared to support better adherence. However, with only a quarter of participants taking the products consistently, additional strategies to support adherence remain crucial for effective HIV prevention in AGYW.

TUPEC056

Characteristics of early non-persistors on Cabotegravir long-acting (injectable PrEP) compared to persistent users in the PrEPared to Choose study in Cape Town, South Africa

C. Pike[1], K. Lebelo[1], E. Rousseau[1], P. Macdonald[1], P. Mapukata[1], O. Vanto[1], L.-G. Bekker[1]
[1]Desmond Tutu Health Foundation, Woodstock, South Africa

Background: Long-acting injectable HIV pre-exposure prophylaxis (PrEP) options, including Cabotegravir long-acting (CAB-LA), are anticipated to mitigate persistence challenges seen with oral formulations. Few studies have delivered injectable PrEP in a real-world context, without research-related reimbursement.
People that seroconvert after stopping injectable PrEP are at risk of developing antiretroviral drug resistance, potentially complicating HIV treatment. The challenge is to optimise CAB-LA access, while curtailing delivery to users less likely to persist.
Methods: PrEPared to Choose (PtC) delivers CAB-LA as an option alongside oral PrEP and the vaginal PrEP ring to 1164 adolescents and young people (15-29 years) and their intimate male partners in Cape Town, South Africa. PrEP is offered from:
a. a mobile clinic, and;
b. a government primary healthcare facility.
Visits are noted on appointment cards with text reminders sent one week prior. Participants that do not return within 7 days are messaged, phoned, or visited at home. Information on how to stop CAB-LA safely is provided. We report baseline characteristics of PrEP users associated with their odds of returning vs not returning at month 1.
Results: Of 862 participants initiated on CAB-LA, 254 (29%) did not return at month 1 for their second injection. Of those that returned, 11% returned >28 days from their scheduled visit and were required to restart the CAB-LA regimen. Participants >19 years (OR 1.5, CI 1.09-2.30), that were PrEP experienced (OR 2.4, CI 1.53-4.09), had disclosed PrEP use (OR 2.59, CI 1.48-3.69), or that access CAB-LA through the mobile clinic (OR 1.42, CI 1.04-1.95) were more likely to return. Likelihood of return was similar amongst male and female participants (OR 1.12, CI 0.80-1.56) and not influenced by employment status (OR 1.03 CI 0.76-1.40). Participant return was not influenced by reason for PrEP use, HIV risk perception, number of sexual partners, having a sexually transmitted infection, mental health score, or alcohol misuse.
Conclusions: Early results from PtC, a real-world, minimal retention implementation science trial, show a high proportion of injectable PrEP users (71%) returning to continue PrEP. Older CAB LA users with PrEP-experience and those who accessed PrEP from community mobile clinic sites were more likely to return.

TUPEC057

Predictors of HIV pre-exposure prophylaxis preferences using the Health Belief Model: twice-yearly subcutaneous lenacapavir versus daily pills in the PURPOSE 1 trial

L.E. Mansoor[1], L. Lebina[2], P. Makhoba[3], L. Naidoo[4], G. Nair[5], D. Mezzio[6], G. Leung[6], X. Li[6], A. Kintu[6], M. Das[6], Q. Abdool Karim[1]
[1]Centre for the AIDS Programme of Research in South Africa, University of KwaZulu Natal, Durban, South Africa, [2]Africa Health Research Institute, Somkhele Research Campus, Durban, South Africa, [3]Qhakaza Mbokodo Research Clinic, Ladysmith, Durban, South Africa, [4]HIV and Other Infectious Diseases Research Unit, South African Medical Research Council, Durban, South Africa, [5]Desmond Tutu Health Foundation, University of Cape Town, Cape Town, South Africa, [6]Gilead Sciences, Inc., Foster City, United States

Background: Twice-yearly subcutaneous (SC) lenacapavir demonstrated 100% efficacy in preventing HIV and superiority to daily oral emtricitabine-tenofovir disoproxil fumarate (F/TDF) in cisgender women in South Africa and Uganda with no safety concerns (PURPOSE 1 trial; NCT04994509). The majority of participants reported a preference for twice-yearly injections over daily pills. We analyzed factors that may predict preference for twice-yearly SC lenacapavir.
Methods: We utilized the Health Belief Model (HBM) to identify predictors of twice-yearly injection preference. The HBM is based on the idea that beliefs about health conditions influence health behaviors. Participants who received pre-exposure prophylaxis (PrEP) injections and daily pills at baseline, week (W) 26 and W52 visits were included (randomized, double-blind approach with active drug and SC/oral placebo). During visits, participants completed electronic surveys, which included Likert scale and multiple-choice questions about preference for twice-yearly injections or daily pills. Selected variables included baseline demographics, sexually transmitted infections, prior HIV testing and PrEP use, sexual behaviors, self-reported injection pain at W52, stigma-related concerns, and other reported feelings about PrEP by type. A logistic regression model was specified and fitted to explore covariates predicting twice-yearly injection preference. Standard-fit statistics were used; a two-tailed *P* value <0.05 was considered statistically significant.
Results: A total of 1997 participants met the preference study criteria; mean age was 21 years. Before trial entry, 82% (n=1638) received an HIV test and 95% (n=1895) had not taken any PrEP. At W52, 71% (n=1422) preferred twice-yearly injections over daily pills. Those who expected greater adherence with twice-yearly injections or who

felt more protected from HIV with twice-yearly injections were significantly more likely to prefer injections over daily pills (odds ratios: 52.3 and 9.8, respectively; both *P*<0.0001). Model-fit statistics indicated a good fit of the HBM to the data. No other variables were significantly associated with reported preferences.

Conclusions: Feelings of increased confidence in maintaining adherence on PrEP and of increased protection from HIV were significantly associated with twice-yearly PrEP injection preference. As PrEP modality options expand beyond daily pills, identifying factors that may predict PrEP preference will help PrEP users and their providers choose the optimal PrEP option for them.

TUPEC058

Early learnings from CAB-LA implementation in Zimbabwe

B. Chingombe[1], T. Hove[1], P. Chida[1], P. Matambanadzo[1]
[1]CeSHHAR Zimbabwe, Key Populations, Harare, Zimbabwe

Background: Despite existing HIV prevention options, UNAIDS reported approximately 17000 new HIV acquisitions in Zimbabwe during 2023,with approximately 25% contributed by key populations (KPs). To effectively address their diverse HIV prevention needs, there is a critical need to expand the range of available prevention options beyond existing methods.

Description: CeSHHAR rolled out long-acting injectable Cabotegravir (CAB-LA) among KPs in Zimbabwe at three sites. We initiated 944 persons between April and December 2024. Data from MoHCC registers and RedCap was analyzed for CAB-LA enrollment and continuation.

We used Kaplan-Meir method to analyze time until discontinuation for persons who received at least one injection, with discontinuation defined as missing more than 60 days from Initial Injection or over 90 days for subsequent injections.

Additionally, we utilized Cox Proportional Hazard models to explore the relationship between independent variables and CAB-LA discontinuation.

Lessons learned: Survival analysis revealed that highest risk of discontinuation occurs 60 days after the initial injection, with 16% probability, compared to subsequent injections that had lower risks: 5% for Injection 2, 11% for Reinjection 1,8% for Reinjection 2.Discontinuations were notably higher among younger persons (<25 years) at 28%, compared to 13% for older individuals (≥25 years) – see Figure 1.

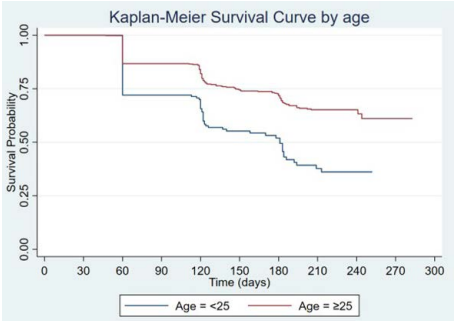

Figure 1.

PrEP naïve persons had higher discontinuation rates than those transitioning from oral PrEP(HR=1.62, 95% CI: 0.66 – 3.99). Participants in Harare and Hwange had a lower relative risk of discontinuation compared to Gweru, (HR=0.52, 95% C1: 0.27 – 0.98) and (HR=0.83, 95% CI: 0.64 – 1.07) respectively.

Conclusions/Next steps: CAB-LA has the potential for rapid integration into key populations programmes. The higher discontinuation rates among CAB-naïve participants after the initial injection highlight the need for intensifying person-centered support to improve early adherence. Younger KPs and those newly starting PrEP are particularly vulnerable, requiring tailored support to ensure sustained and effective use of CAB-LA.

Integration of HIV services with other services, including sexual and reproductive health services

TUPEC059

Correlates of objective doxycycline post-exposure prophylaxis adherence among cisgender women on daily HIV PrEP in Kenya

L. Violette[1,2,3], V. Kwach[4], B. Rono[4], V. Omollo[4], K. Oware[4], J. Odoyo[4], D. Donnell[5], M. Hearst[6], E. Bukusi[4], J. Baeten[1], J. Stewart[6,7], dPEP Kenya Study Team
[1]University of Washington, Seatte, United States, [2]Harvard Medical School, Department of Population Medicine, Boston, United States, [3]Harvard Pilgrim Health Care Institute, Boston, United States, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]Fred Hutchinson Cancer Center, Seattle, United States, [6]University of Minnesota, Minneapolis, United States, [7]Hennepin Healthcare Research Institute, Minneapolis, United States

Background: The use of event-driven post-exposure prophylaxis with doxycycline (doxyPEP), an antibiotic which is usually prescribed for sexually transmitted infections (STIs), is rising as a promising strategy to prevent STI transmission. Population characteristics associated with confirmed use of doxyPEP, especially in relationship with confirmed HIV pre-exposure prophylaxis (PrEP) use, are not well described. We describe the correlates of confirmed doxyPEP use among cisgender women taking HIV PrEP.

Methods: An open-label 1:1 randomized trial among 449 cisgender women taking oral PrEP in Kisumu, Kenya included participants randomized to take 200 mg of doxycycline PEP within 72 hours of condomless sex, or to standard of care, for 12 months. Quarterly, vaginal swabs were collected, STI testing conducted, and participants taking doxyPEP completed sexual activity and doxyPEP adherence diaries.

Plasma was collected at study exit. Among participants who reported taking doxyPEP following sex within five days of their quarterly visit, doxycycline and TFV/FTC con-

centrations in vaginal fluid and/or plasma were measured following standard methods and detection defined as >1.0 ng/swab and >10 ng/mL respectively.
We used generalizing estimating equation methods to assess baseline participant characteristics associated with doxyPEP detection, in addition to time-varying assessment of detectable TFV/FTC at that visit.
Results: Among 224 participants assigned to doxyPEP, 169 reported condomless sex in the six days preceding 401 quarterly visits and 161/169 (95%) reported taking doxyPEP. Among 123/161 participants, 240 samples were available and tested (61 plasma specimens and 179 vaginal fluid specimens). Doxycycline and TFV/FTC were detected in 20% (47/240) and 15% (36/240) of samples, respectively.
Age, not having a primary sex partner, transactional sex, hormonal contraceptive and having an STI diagnosis at baseline were not significantly associated with doxycycline detection. Participants with TFV/FTC detection at the same visit were more than 2 times more likely to have doxycycline detected (RR=2.66, 95% CI=1.63-4.32) compared to those where TFV/FTC was not detected.
Conclusions: Among cisgender women with a high prevalence of STIs, the use of doxyPEP was low but objective adherence was associated with concurrent detection of HIV PrEP. Our findings suggest that doxyPEP might have a greater impact among women adherent to PrEP.

TUPEC060

Implementing an MMR vaccination programme for adults living with HIV in response to a measles outbreak in London, UK

H. Lamden[1,2], D. Marinopoulos[2], E. Cheserem[2], A.M. Geretti[2,3,4]
[1]Botswana Sexual Reproductive Health Initiative, Gaborone, Botswana, [2]North Middlesex University Hospital, Department of Infection, London, United Kingdom, [3]Fondazione PTV, University of Rome Tor Vergata, Department of Infectious Diseases, Rome, Italy, [4]King's College London, School of Immunity and Microbial Sciences, London, United Kingdom

Background: An outbreak of measles virus in the UK has resulted in 2,918 cases since January 2024. The British HIV association recommends that all adults living with HIV be screened for serological evidence of measles immunity and offered MMR vaccination if susceptible, provided they are clinically stable with CD4 counts >200 cells/mm^3.
Given falling MMR vaccination rates in the community and difficulty accessing vaccination through primary care for this group, we aimed to integrate measles immunity screening and vaccination into routine HIV care.
Description: Commencing in January 2024, the ongoing programme is based at the Alexander Pringle Centre in North London, a clinic providing HIV care to 1,450 adults. Testing for measles IgG targets all individuals entering or already engaged in routine care. Measles IgG seronegative individuals are screened by physicians for vaccine eligibility and counselled using agreed pathways. MMR vaccination is administered by nursing staff and recorded on the individual's national health record.
Lessons learned: A total of 1461 measles IgG tests were completed in January – November 2024, of which 77/1461 (5.3%; 95% CI 4.1-6.4%) were negative. Of these, 44/77 (57.1%) were male, median age 40 (IQR 19). Most (72/77, 93.5%) were eligible for vaccination, with contra-indications present in five (four had CD4 counts <200 cells/mm^3, one was receiving immunosuppressive therapy).
Of those eligible, 26/72 (36.1%) received a full course (two doses 1 month apart), 11/72 (15.3%) received one dose, 10/72 (13.9%) declined vaccination, 12/72 (16.7%) are pending physician discussion, 9/72 (12.5%) were out of care and 4/72 (5.6%) were vaccinated elsewhere.
Vaccine hesitancy was common and required careful counselling to address concerns and promote the benefits of vaccination. The key to success for our programme was flexibility. We offered both the MMRVAXPRO and PRIORIX vaccines to provide an alternative for clients who declined porcine gelatine.
Additionally, vaccination was offered opportunistically and at designated appointments. One client commented 'It was easy to book a convenient time and it was quick'.
Conclusions/Next steps: Integrating measles immunity testing and MMR vaccination into routine HIV care is feasible. It ensures ease of access to vaccination and promotes vaccine uptake, improving health outcomes for people living with HIV.

TUPEC061

Integrating PrEP and contraceptive services for adolescent girls and young women: lessons from DREAMS program implementation in five HIV high-prevalence districts in South Africa

P. Potsane[1], C. Sokhela[1], R. Makiwa[1], N. Mtshali[1]
[1]Shout-It-Now, Centurion, South Africa

Background: The DREAMS program aims to reduce HIV acquisition and improve sexual and reproductive health (SRH) outcomes among adolescent girls and young women (AGYW) in high burden districts in South Africa, where the epidemic disproportionately affects AGYW.
The 6th South African National HIV Prevalence, Incidence, Behaviour and Communication Survey reports an HIV prevalence of 6.9% among AGYW aged 15-24 years compared to 3.5% among males of the same age group.
Additionally, recent data from Stats SA indicate that over 105,000 girls aged 10 to 19 gave birth between April 2022 and March 2023, underscoring the urgent need for integrated HIV prevention and SRH services.
Description: The study utilized programmatic data from Shout-It-Now's DREAMS program to assess the integration of PrEP and contraceptives services for AGYW living in two urban and three rural districts of South Africa. Data of AGYW's different PrEP dispense dates was collected through Shout's electronic Clinical Management System and stored in a structed SQL database.
Quantitative descriptive analysis compared PrEP uptake and refill rates for four months before (Apr – Jul 2021) and after (Feb – May 2022) the launch of contraceptives services. Outcomes included the percentage increase in PrEP

initiations and refills and the proportion of clients receiving both PrEP and contraceptives services on the same day.

Lessons learned: PrEP uptake increased by 169% (6,187 vs. 2,297) after integrating PrEP and contraceptive services. Similarly, refill rates rose by 94% (1,723 vs. 889). Among those served, 29% of clients initiated on PrEP received contraceptives on the same day, while 24% received PrEP refills and contraceptives simultaneously.

These findings demonstrate the effectiveness of service integration in improving access to PrEP among AGYW, highlighting the potential of integrated delivery models to enhance comprehensive sexual and reproductive health services.

Conclusions/Next steps: The DREAMS program's integrated PrEP and contraceptives service approach demonstrates enhanced uptake and continuation of PrEP services in addition to improved access to contraceptives that prevent teenage pregnancy among AGYW in high-burden districts. This approach provides a scalable and impactful framework for reducing HIV incidence and improving SRH outcomes in similar high prevalence settings.

TUPEC062

Women's preferences for embedding PrEP delivery within STI and reproductive health services in Uganda – results from a discrete choice experiment

B. Kamusiime[1], P. M. Smith[2], A. Nalumansi[1], G. Eram[1], V. Kasiita[1], P. Ssendiwala[1], F. Bambia[1], T. Wood[2], T. R. Muwonge[1], A. Nakyanzi[1], A. Mujugira[1,3], E. T. Montgomery[4,5], R. Heffron[2]

[1]Infectious Diseases Institute, Kampala, Uganda, [2]University of Alabama at Birmingham, Department of Medicine, Birmingham, United States, [3]University of Washington, Department of Global Health, Seattle, United States, [4]RTI International, Women's Global Health Imperative, Berkeley, United States, [5]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States

Background: HIV prevention is paramount for adolescent girls and young women (AGYW) in Uganda and oral PrEP is not always a suitable option. With emerging novel HIV prevention products (e.g. ring, injectables), there are opportunities to explore AGYW preferences to inform strategies for expanding PrEP programs and launching new multi-product PrEP programs.

Methods: From January–September 2024, we recruited AGYW aged ≥18-25 years from community sites in Kampala, Uganda for a cross-sectional discrete choice experiment (DCE) to determine the most preferred attributes and levels of multi-product PrEP programs.

Choices for PrEP programming were described as they currently exist for Ugandan oral PrEP provision. The DCE was developed via literature review, informal conversations with AGYW, and cognitive interviewing among AGYW using a prototype. In the final iteration, attributes (and levels) included: method of PrEP information dissemination (WhatsApp, brochure, in-person consultations), PrEP counseling delivery (virtual, group, in-person counselling), proximity of PrEP location (nearer to or far from work, school, home), type of facilities offering PrEP (private or government clinic, pharmacy), availability of additional services (STI testing and treatment, family planning, no additional services), client wait times (5, 30, 90 minutes), and associated costs (small cost, no cost for PrEP). Participants responded to 9 randomly-assigned choices of 2 scenarios when asked, "Which PrEP program would encourage you to use PrEP?" We used multinomial logit modeling to estimate preference weights and importance scores.

Results: Of 343 screened, 300 AGYW consented to participate (median age: 21 years, IQR: 20-23) with 38.3 % having oral PrEP experience and 71.7% reporting recent condomless sex. "Access to other services" in conjunction with PrEP dispensing had the greatest influence on PrEP program choice (importance score: 27%) with preference for STI testing and treatment (preference weight: 0.39, 95% CI: 0.32, 0.47) and family planning (PW: 0.14, 95% CI: 0.07, 0.21). Type of facility offering PrEP (9.7%), method used for PrEP information dissemination (10.2%), and proximity of the PrEP location (6.9%) were not influential on program choice.

Conclusions: Young women's preference for co-located STI and reproductive health and PrEP services indicates an opportunity to embed current and future PrEP delivery within these existing services.

Population-specific interventions for HIV prevention

TUPEC063

A cluster randomized trial of multi-disease vs HIV-focused recruitment strategies to promote biomedical HIV prevention uptake among adults at alcohol-serving venues in rural Kenya and Uganda

G. Chamie[1], L. Balzer[2], J. Litunya[3], B. Beesiga[4], K. Marson[1], J. Nakato[2], J. Mwango[3], E. Mugoma[3], P. Agaba[4], J. Temple[1], J. Schwab[2], S. Shade[5], C. Camlin[5], J. Hahn[1], E. Kakande[4], J. Kabami[4], M. Petersen[2], D. Havlir[1], J. Ayieko[3], M. Kamya[6], OPAL-East Africa study team

[1]University of California San Francisco, Division of HIV, Infectious Diseases & Global Medicine, San Francisco, United States, [2]University of California Berkeley, Berkeley, United States, [3]Kenya Medical Research Institute, Kisumu, Kenya, [4]Infectious Diseases Research Collaboration, Mbarara, Uganda, [5]University of California San Francisco, San Francisco, United States, [6]Infectious Diseases Research Collaboration, Kampala, Uganda

Background: Alcohol-serving venues are sites of increased HIV transmission risk in sub-Saharan Africa. Optimal strategies to engage persons in pre-/post-exposure prophylaxis (PrEP/PEP) from these venues are unknown.

Methods: In 2023-2024, we conducted a cluster-randomized trial to compare recruitment strategies for adults (≥18 years, patrons and workers) at alcohol-serving venues for PrEP/PEP in rural Kenya and Uganda (NCT05862857). In eight communities (~10,000 persons/community), we mapped all alcohol-serving venues and created venue-clusters based on geographic co-location.
We randomized venue-clusters to:
a. Multi-disease mobilization and distribution of recruitment cards offering free screening/referral for broad services (hypertension, diabetes, tuberculosis, malaria, HIV); or;
b. HIV-focused mobilization and cards offering free screening/referral for HIV services only.
Both strategies offered transport reimbursement upon linkage to clinic-based screening. We hypothesized that multi-disease recruitment would increase PrEP/PEP uptake by mitigating HIV stigma and inaccurate risk perceptions. We compared new PrEP/PEP initiations among persons without HIV (primary endpoint) by recruitment strategy, accounting for clustering and missing data.
Results: We randomized 64 venue-clusters to multi-disease (N=32) or HIV-focused (N=32) arms: 2 clusters (1/arm) were excluded due to low numbers of cards distributed. Baseline characteristics were balanced by arm, with 242 multi-disease venues (88% informal; 81% Uganda; 14% with rooms for sex work) and 235 HIV-focused venues (89% informal; 82% Uganda; 12% with rooms for sex work). Of 9,348 cards distributed (4916 multi-disease, 4432 HIV-focused), 36% were to women and 83% to patrons; median age=32 (IQR:26-42).
Overall, 7727 (83%) persons linked for clinic-based screening. Of the 6111 (79%) testing HIV-negative, 1739 (28%) newly initiated PrEP/PEP; 101 (2%) were already taking PrEP/PEP. There was no difference in the primary endpoint by venue-based recruitment strategy; irrespective of linkage, 24% of recruited persons without HIV initiated PrEP/PEP in both arms (p=0.918). Results were similar by country and gender.
Conclusions: We found no difference in multi-disease vs. HIV-focused recruitment strategies on PrEP/PEP uptake among >9000 adults at >450 alcohol-serving venues. Both strategies resulted in high linkage (>80%) for screening, with over one-quarter of persons testing HIV-negative initiating PrEP/PEP, demonstrating that card-based recruitment with transport reimbursement is an effective strategy for engaging adults at alcohol-serving venues in biomedical HIV prevention.

TUPEC064

Satellite OST model for scaling up of opioid substitution therapy as part of harm reduction strategy for people who inject drugs under the National AIDS Control Program, India

G. Ngaihte[1], S. Rajan[1], S.P. Bhavsar[1], S. Purohit[1], S. Verma[1]
[1]*National AIDS Control Organization, Ministry of Health and Family Welfare, New Delhi, India*

Background: National AIDS Control Programme (NACP) provides Opioid Substitution Therapy (OST) as a key harm reduction strategy for reducing HIV transmission and other drug use related harms among people who inject drugs (PWIDs) in India. The HIV prevalence continues to be highest among the People Who Inject Drugs (PWID) at 9.03 %, and injection route accounts for the majority of new HIV infections for 11 states in 2023-24.
Description: National AIDS Control Program (NACP) Phase V (FY 2022-26) has planned for scaling up of the OST program to cover fifty percent of the estimated PWIDs which is about 0.15 million. However, setting up new OST centres often has multiple challenges of human resource and infrastructure. To overcome these barriers, a no- cost satellite OST model was designed to be set up in existing health facilities such as primary health centres, health and wellness centres, prisons, community-faith based settings or TI-NGOs. The satellites serve as additional dispensing sites and are linked to a parent or full-fledged centre. In 2024-25 the satellite model has been scaled up effectively to 190 centres to enable coverage of 58,648 PWIDs with satellite centres accounting for over 21 percent coverage.

Year	Coverage of PWID on OST	No. of OST Centres	No. of Satellite Centres	% of PWID coverage by Satellite Centres
2021-22	42274	265	126	12
2022-23	50408	251	134	12
2023-24	54210	263	174	18
2024-25	58648	286	190	21

Lessons learned: Satellite OST centres increase accessibility by expanding service delivery points to PWIDs residing at far away locations, decongest OST centers with high client load and alleviate the burden on resources required for setting up full-fledged OST centres with a rational use of available health workforce.
Satellite OST model is able to integrate the often compartmentalised health system particularly at the primary levels for delivery of HIV prevention and treatment for opioid use disorders to PWIDs.
Conclusions/Next steps: The satellite OST model can be replicated to increase access to prevention and treatment services with addition of digital technology and tele-medicine. The larger health system can take up the satellite OST model for cost – efficient delivery of prevention and treatment services for substance use disorders and co-morbidities at the primary and secondary levels in resource constraint settings.

HIV testing

TUPEC065

Diagnostic outcomes among women with detectable HIV RNA after starting injectable cabotegravir within a multi-method PrEP market implementation study

R.N. Adams[1], D. Marwanga[2], V. Fonner[2], A.L. Heaps[3], A. Mayo[2], E. Livant[3], E. Gwavava[4], T. Taleng[5], E. Bosek[6], H. Subedar[7], R. Kahariri[6], C. Akello[8], K. Torjesen[2], U.M. Parikh[3], C. Martin[9]

[1]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]FHI 360, Durham, United States, [3]University of Pittsburg, Pittsburgh, United States, [4]Pangaea Zimbabwe, Harare, Zimbabwe, [5]Jhpiego, Maseru, Lesotho, [6]LVCT Health, Nairobi, Kenya, [7]National Department of Health, Pretoria, South Africa, [8]FHI 360, Kampala, Uganda, [9]Wits Reproductive Health and HIV Institute, Implementation Science, Johannesburg, South Africa

Background: Most countries use national testing algorithms with point-of-care (POC) rapid antibody tests to determine HIV status before starting pre-exposure prophylaxis (PrEP). Using cabotegravir (CAB) PrEP during undetected acute HIV infection could delay HIV seroconversion and increase risk of drug resistance. We examined diagnostic outcomes in women starting CAB PrEP with negative POC rapid tests and detectable HIV RNA.

Methods: CATALYST, a study implemented by the PEPFAR/USAID-supported MOSAIC project is currently offering oral PrEP, PrEP ring and CAB PrEP in Lesotho, South Africa, Uganda, and Zimbabwe. Consenting participants with a negative POC rapid test starting CAB PrEP as their first method or switching to CAB PrEP from another PrEP method had blood collected before CAB injection and sent to a local lab for HIV RNA. Testing after detectable RNA included repeat rapids, HIV RNA, qualitative DNA PCR and/or ELISA. Clients' CAB injections were paused pending repeat testing outcomes. Final HIV status and medication management were assessed from clinical records.

Results: During April–October 2024, 1,295/1,407 (92%) participants starting CAB PrEP had blood collected for RNA testing, and 1,261 (97%) had results returned. Five participants (0.6%) had detectable RNA. Three of the five participants had used oral or Ring PrEP within 30 days of starting CAB. Two participants with HIV RNA >10,000 c/mL had repeat positive rapid tests eight- and 21-days post initiation injection and were referred to start antiretroviral therapy (ART). Two participants with HIV RNA <1,000 c/mL had negative repeat HIV rapid tests and undetectable RNA levels five- and seven-days post-injection, followed by undetectable repeat RNA, negative ELISA and DNA PCR one-month post-injection. They received their second CAB injections 41- and 43 days after initial detectable RNA levels. The fifth participant had 694 HIV RNA c/mL; no follow-up was available.

Conclusions: In four cases of detectable HIV RNA at CAB PrEP initiation with follow-up test results, two continued CAB PrEP and two were referred for ART, indicating that RNA results did not clarify HIV status for individuals starting CAB PrEP. The utility of HIV RNA in HIV testing algorithms for PrEP initiation/ continuation should be further evaluated in programmatic settings.

TUPEC066

Strategic efforts to enhance HIV testing and case Identification among youths: leveraging index testing with integration of social network strategy (SNS) in the Tanzania's southern highlands regions

A. Msomba[1], O. Nzoutchoum[2,3], R. Gervas[1], E. Bahemana[1], D. Nicholaus[4], M. Ndolichimpa[1], S. Chalamila[1]

[1]HJF Medical Research International, Clinical, Mbeya, Tanzania, the United Republic of, [2]The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc., Medical, Bethseda, United States, [3]U.S. Military HIV Research Program, CIDR, Walter Reed Army Institute of Research, Clinical, Silver Spring, United States, [4]Walter Reed Army Institute of Research-Africa, Clinical, Dar es salaam, Tanzania, the United Republic of

Background: Tanzania has significantly improved HIV status awareness, from 61% in 2017 to 83% in 2023 (THIS 2023). However, adolescents and young people (AYP) aged 15–24 remain disproportionately affected, contributing to 42% of new acquisition and achieving only a marginal increase in case identification (52% to 54%) during the same period. Addressing this gap requires innovative, youth-specific strategies.

Description: From October 2023-September 2024, a youth-focused index re-elicitation approach was implemented at 171 high-volume sites in the Southern Highlands Regions. HIV-positive youths aged 15-24 enrolled in care were line-listed, and their close contacts were comprehensively re-elicited and integrated with Social Network Strategy coupons distribution at health facilities and community sites, enabling AYP to recruit high-risk peers for HIV testing using unique referral codes for tracking. Peer support systems were integrated to create a stigma-free environment that encouraged disclosure and participation. Data were collected through routine monitoring systems, focusing on HIV case identification and linkage to care outcomes.

Lessons learned: Integrating index testing and SNS led to notable increases in testing coverage and case identification. Among 15-19-year-olds, HIV testing rose by 76% (809 to 1,422), with positives identified more than doubling (47 to 96). HIV testing for 20-24-year-olds increased by 8% (1,504 to 1,628), with a 33% increase in positives identified (169 to 225). Results from SNS yielded a 265% increase in testing (189 to 689) among 15-19-year-olds, and 229% for 20-24-year-olds (573 to 1,887). Positives identified through SNS rose by 450% (2 to 11) and 95% (19 to 37), respectively. Peer support facilitated proxy linkage (number enrolled divided by number newly tested positive), improving rates from 107% to 121% for 15-19-year-olds and from 91% to 97% for 20-24-year-olds. High-risk HIV-negative AYP were successfully linked to appropriate prevention services.

Conclusions/Next steps: Incorporating SNS and peer support into the youth-focused re-elicitation approach effectively bridged critical gaps in HIV testing, case iden-

tification, and linkage to care. This youth friendly, socially integrated model demonstrates scalable potential for high-burden areas to achieve UNAIDS first 95 targets.

Cascades of HIV prevention, treatment and care

TUPEC067

Spatiotemporal trends and progress toward UNAIDS 95-95-95 targets in Zimbabwe: insights from ZIMPHIA 2015 and 2020

D. Cuadros[1], T. Chowdhury[1], S. Nyimbili[2], H.-Y. Kim[2], T. Apollo[3], O. Mugurungi[3], J. Justman[4], A. Bershteyn[2]
[1]University of Cincinnati, Digital Epidemiology Laboratory, Cincinnati, United States, [2]New York University, Department of Population Health, New York, United States, [3]Ministry of Health and Child Care, Harare, Zimbabwe, [4]Columbia University, Mailman School of Public Health, New York, United States

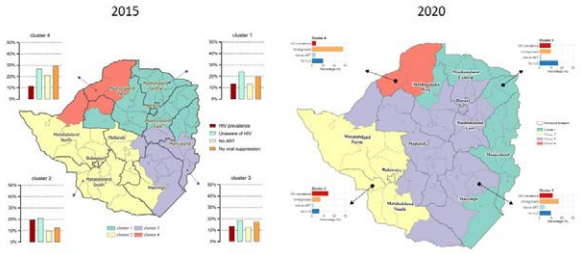
Background: Zimbabwe has made substantial progress toward achieving UNAIDS 95-95-95 targets. However, geographic and demographic disparities persist. Using Zimbabwe's 2015-16 and 2020 Population-Based HIV Impact Assessments (ZIMPHIAs), we compared and forecasted spatiotemporal trends in HIV prevalence, diagnosis, treatment, and viral suppression (VLS) to evaluate progress and identify persistent gaps delaying epidemic control.

Methods: We conducted a comparative analysis of ZIMPHIA 2015-16 and 2020 data using spatial and statistical modeling. Geographic disparities were identified using Getis-Ord hotspot analysis and K-means clustering. Temporal projections incorporated logistic growth models, accounting for diminishing returns, resource constraints, and demographic shifts. Data were stratified by age and gender to assess subgroup-specific gaps.

Results: Between 2015 and 2020, diagnosis (awareness) improved from 76% to 87%, ART coverage increased from 88% to 97%, and VLS rose from 85% to 90%. Geographic disparities decreased, with ART coverage gaps shrinking from >15% in 2015 to <3% in 2020.

However, clusters of undiagnosed PLHIV (>14%) persisted in Mashonaland Central and northern Midlands, while hotspots of non-suppression (>11%) remained in Mashonaland Central, Mashonaland West, and Matabeleland North. K-means analysis revealed distinct trends across four clusters, with Cluster 4 (Mashonaland West) showing the highest burden of undiagnosed PLHIV and non-suppression in both years (Figure).

Temporal projections estimate that Zimbabwe could achieve 95-95-95 by 2030 under current trends, but resource-constrained scenarios could delay target achievement beyond 2030. Gender disparities persisted, with men aged 25-34 showing lower awareness (62% vs. 81%) and viral suppression in younger age groups (15-24 years; 71% vs. 84%) compared to women.



Conclusions: Zimbabwe has achieved significant progress, particularly in reducing regional disparities in ART coverage. However, undiagnosed clusters and viral load non-suppression persist in several sub-regions and demographic subgroups. This study's comparative spatiotemporal projections underscore the importance of targeted testing, adherence programs, and male-focused interventions to address care continuum.

TUPEC068

Optimizing strategies to integrate Latino community stakeholders from the United States to promote HIV services in their communities

M. Garcia[1], L. Geronimo[2], F. Amaya[2], N. Leon[2], R. Alegre[2], R. Abbott[2], A. Zavaleta[3], C. Marquez[2]
[1]San Jose State University, social work, San Jose, United States, [2]University of California San Francisco, San Francisco, United States, [3]Latino Task Force, San Francisco, United States

Background: HIV incidence overall has dropped in the United States, but continues to increase among Latinos. In California, Latinos comprise the largest number of people newly diagnosed with HIV. Increasing HIV services with status-neutral linkage among Latinos is crucial to ending the epidemic, but few studies have leveraged their perceptions about optimal strategies to increase HIV services, especially among immigrants.

This study aims to identify culturally and linguistically appropriate strategies to improve HIV services for Latino immigrant cisgender male sexual minorities.

Methods: An exploratory-descriptive qualitative study design was administered to explore perspectives from HIV service providers on how to enhance HIV interventions for Latino immigrant cisgender male sexual minorities in San Francisco. Service providers were recruited to participate in focus groups administered in English (n=8) and Spanish (n=6). Focus group recordings were transcribed verbatim, cleaned, and prepared for data analysis. Rapid qualitative data analysis was used to identify prominent themes based on the original language of the focus group; research findings were translated from Spanish to English.

Results: Overall, 14 service providers (5 cisgender males, 5 cisgender females, and 2 transgender females) participated in the study; the majority identified as Latino (n=13) and heterosexual (n=8). Five themes emerged, all with a shared emphasis on healthy communities:

1. Establ[mg1] ishing a Sense of Community – promoting collectivistic cultural beliefs and values that encourage healthy communities through social activities;

2. Peer-Based Interventions – training people in the community to develop culturally informed approaches by peers sharing their lived experience;
3. HIV Stigma – emphasizing that everyone is susceptible to HIV and informing the general Latino community that HIV is preventable (Undetectable=Untransmittable and PrEP);
4. Holistic Wellness - offering HIV testing during routine medical screenings, and;
5. PrEP – developing culturally and linguistically appropriate campaigns addressing concerns and benefits associated with PrEP.

Conclusions: Findings suggest that peers are more influential in engaging people from their social networks by demonstrating and articulating the effectiveness of HIV services. Service providers can facilitate peer-based interventions by providing spaces to congregate, trainings to be certified health promoters, and formal collaborations with community stakeholders to develop culturally and linguistically appropriate peer-based HIV interventions.

TUPEC069

Using machine learning to personalize HIV care and reduce treatment interruptions for people living with HIV: results from an 11-month implementation study in Nigeria

T. Mnguni[1], S. Parrot[1], K. Sharpey-Schafer[1]
[1]Palindrome Data, Cape Town, South Africa

Background: Interruption in treatment (IIT) among people living with HIV (PLHIV) in Nigeria significantly impacts viral suppression and health outcomes. IIT rates can reach 49%, as current care models struggle to identify and address at-risk clients, leading to preventable setbacks and drug resistance.
This study evaluates how leveraging electronic medical record system (EMR) data, machine learning (ML)-driven risk scores, and digital tools empowered healthcare workers (HCWs) in Nigeria to shift IIT management from reactive to proactive, reducing IIT rates.
Methods: This quasi-experimental study assessed the effectiveness of an ML-based IIT risk scoring model integrated with an EMR-linked client management (CM) mobile application. The model predicted IIT risk and enabled HCWs to deliver personalized, risk-based interventions. Health facilities were randomized into 30 intervention sites using the IIT risk score-enabled CM app and 19 control sites with the standard app. A total of 66,308 clients were included. Quantitative and qualitative data from December 2023 to November 2024 assessed feasibility, acceptability, and effectiveness, focusing on adoption, user experience, and client outcomes.
Results: Between December 2023 and November 2024, 167,193 visits were recorded for 66,308 clients. The app classified 9% of clients as high-risk, 49% as medium-risk, and 42% as low-risk for IIT. HCWs spent 76% more time on high-risk lists (12.4 seconds) than on low-risk lists (7.0 seconds). Enrolled clients achieved a fourfold greater IIT reduction compared to control facilities. ML-driven scores reliably identified client risks, although HCWs overruled AI recommendations in 5% of high-risk cases.
Multi-month dispensing (MMD6) reduced IIT for low-risk clients (22%) but was less effective for medium- and high-risk groups (26% and 31%). MMD3 demonstrated consistent performance across all risk levels.
Conclusions: The ML-driven IIT risk scoring model significantly reduced IIT by enabling proactive, personalized care. Enrolled clients saw a fourfold IIT reduction compared to the control group, demonstrating the effectiveness of risk-based interventions. Integrating AI tools into routine care enhances HCW efficiency and client outcomes, with targeted approaches recommended for high-risk groups.

TUPEC070

Characteristics and clinical outcomes of mother-infant pairs with HIV exposure and breastfeeding experience: observational cohort in the United States

J. Unternaher[1], E. Alpin[2], L. Anderson[1,3,4], O. Awofeso[1], T. Williams[1], N. Rakhmanina[1,4,5]
[1]Children's National Hospital, Infectious Diseases, Washington, DC, United States, [2]George Washington University School of Medicine & Health Sciences, Washington, DC, United States, [3]Children's National Hospital, Adolescent and Young Adult Medicine, Washington, DC, United States, [4]George Washington University School of Medicine & Health Sciences, Pediatrics, Washington, DC, United States, [5]Elizabeth Glaser Pediatric AIDS Foundation, Washington, DC, United States

Background: Infant feeding guidelines for mother-infant pairs with perinatal HIV exposure (MIPHE) in the United States (US) significantly evolved in recent years. National data on breastfeeding outcomes among MIPHE remains limited. We aimed to evaluate the characteristics and clinical outcomes of MIPHE cared for at Children's National Hospital (CNH) in Washington, DC.
Methods: A retrospective cohort of MIPHE in care at CNH from January 2018 through July 2024 was analyzed. Data were extracted from mothers' referral forms (maternal demographics, HIV diagnosis duration, HIV viral load before delivery, and antiretroviral treatment information) and infants' medical records (infant demographics, birth parameters, antiretroviral prophylactic drugs, breastfeeding duration and complications, and HIV testing results). Infants were deemed definitively HIV negative after two negative HIV RNA tests following breastfeeding cessation.
Results: Twenty-one mothers with HIV (median age=33 years [IQR:29-37]; 95.2% African American/Black or African; median HIV diagnosis duration=8 years [IQR:4-12]) breastfed 22 infants (54.5% female, 86.4% with low-risk HIV exposure, 68.2% prescribed zidovudine only).
Known maternal regimens (n=20) before delivery were 2NRTI+1NNRTI (13.6%), 2NRTI+1PI (13.6%), and 2NRTI+1INSTI (63.6%). Majority (77.3%) of MIPHE attended their first postnatal appointment within 4.5 weeks (range:2-64.9).
Median breastfeeding duration was 11 weeks (IQR:5-36), and 13 (59.1%) MIPHE mixed breastfeeding with formula feeding (n=11, 84.6%) and/or solid oral feeding (n=3, 23.1%).

Nine (42.9%) mothers reported complications (low milk supply (n=4), viral blips (n=3), difficulty latching (n=2), sore nipples (n=1), and clogged milk duct (n=1)) while breastfeeding.
Among three mothers who experienced viremia while breastfeeding (range: 30-1,700 copies/mL), two continued breastfeeding and one stopped after a single viral load of 60 copies/mL.
Eleven infants were lost to care while breastfeeding (n=4) or after one HIV test (n=7); one MIPHE transferred care. Only 10 (45.4%) infants were deemed definitively HIV negative.
Conclusions: Our cohort of MIPHE in the US had a relatively short median breastfeeding period with over half mixing breastfeeding with formula and/or oral solid feeding. A high proportion of MIPHE was lost to care; less than half completed recommended HIV testing after discontinuing breastfeeding. More data on infant feeding practices are needed to design optimal clinical and support services for MIPHE in the US.

TUPEC071

Low HIV pre-exposure prophylaxis use despite high interest among individuals with behavioral vulnerability to HIV in Uganda

R. Ying[1,2], N. Burns[1,2], J. Tonzel[1,2], J. Kasule[3,4], B. Mwesigwa[3,4], G. Mirembe[3,4], H. Kibuuka[3], I. Nakabuye[3], M. Yacovone[5], T.A. Crowell[1,2], for the Multinational Observational Cohort of HIV and other Infections (MOCHI) Study Group
[1]U.S. Military HIV Research Program, CIDR, Walter Reed Army Institute of Research, Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]Makerere University Walter Reed Project, Kampala, Uganda, [4]U.S. Military HIV Research Program, Walter Reed Army Institute of Research - Africa, Kampala, Uganda, [5]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, United States

Background: Pre-exposure prophylaxis (PrEP) is effective for preventing HIV, but global uptake is suboptimal. We assessed factors associated with PrEP use and preferences in a Ugandan cohort.
Methods: From October 2022 to September 2024, we enrolled individuals aged 14-55 years without HIV in Kampala, Uganda, who reported recent sexually transmitted infection (STI), injection drug use (IDU), transactional sex, condomless sex, and/or anal/neovaginal sex with male/transgender partners.
Participants were asked about PrEP knowledge, PrEP use, and interest in various types of PrEP. We used robust Poisson regression with purposeful variable selection to estimate adjusted prevalence ratios (aPRs) and 95% confidence intervals (CIs) for variables associated with ever taking PrEP and currently taking PrEP.
Results: Among 415 participants, 57.1% were female, 32.5% were men who have sex with men, and 81.2% were aged <24 years. While 95.9% of participants had ever heard of PrEP, only 41.9% were currently taking PrEP (Figure).
Most participants who had ever heard of PrEP reported interest in PrEP (96.0%), with greater interest in daily pills (80.0%) than on-demand pills or monthly injections (67.4% and 65.0%, respectively, McNemar's p<0.001 for each comparison to daily pills).
Among participants who had ever heard of PrEP, ever taking PrEP was associated with living near a medical facility (≤3km vs. >3km, aPR 1.25 [95%-CI 1.00-1.56]) and having taken multiple courses of post-exposure prophylaxis (>1 vs. ≤1, aPR 1.50 [1.23-1.83]).
Among those who had ever taken PrEP, current use was lower among participants assigned male at birth (aPR 0.78 [0.61-1.00]) and greater among younger participants (<24 vs. ≥24 years, aPR 1.49 [1.08-2.06]).

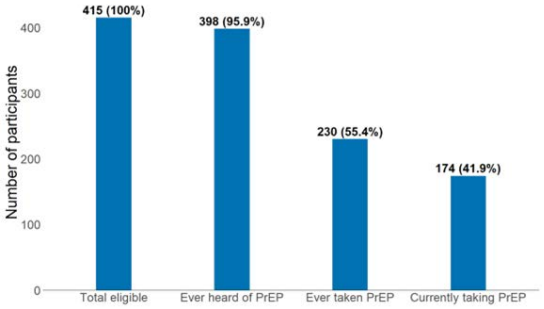


Figure. Cascade of PrEP knowledge and persistent usage among individuals with behavioral vulnerability to HIV in Uganda.

Conclusions: Despite high interest in PrEP, uptake and persistence among participants in our study remain suboptimal. Increasing PrEP options and improving access to facilities may increase PrEP initiation. Interventions to improve PrEP persistence are needed for older males with behavioral vulnerability to HIV.

TUPEC072

Tailored interventions to enhance ART adherence and viral suppression in children: insights from Niger State, North-Central Nigeria

A. Amusan[1]
[1]Centre for clinical care and Clinical Research, Program, Ilorin, Nigeria

Background: Children living with HIV (CLHIV) aged 0-14 face significant challenges in achieving viral suppression and improved health outcomes due to unique barriers they face.
Despite conventional Enhanced Adherence Counseling (EAC) support and the availability of pediatric antiretroviral (ARV) formulations and dosing which is "child-friendly", only 17% of unsuppressed CLHIV in Niger State achieved suppressed viral load results after post-EAC sample collection between January to March.
Key barriers to adherence include orphanhood, limited caregiver oversight, lack of targeted support, and self-stigmatization.
The study evaluates the impact of tailored ART adherence support on viral re-suppression among virally unsuppressed CLHIV in Niger State.

Methods: A total of 71 virally unsuppressed CLHIV post EAC were identified between April and October 2024 from 18 facilities in 18 LGAs and were enrolled in a tailored intervention program.

The interventions are as follows:

- v Family Therapy: Creating supportive environments by integrating ARV intake into daily routines, such as family prayer times, to serve as reminders and a family member is assigned to monitor compliance and report on WhatsApp platform,
- v Linkage to OVC Case Managers: Facilitating comprehensive care for orphans and vulnerable children (OVC),
- v Organized OTZ Meetings: Peer-led gatherings where children were motivated by success stories shared by others, fostering a sense of hope and possibility,
- v Intensified ART Adherence Counseling: Conducted by trained ESM Nurses emphasized the importance of adherence while nurturing a hopeful vision for the child's future.
- v Self-Stigmatization Mitigation: Individualized counseling addressed personal challenges,

Results: 57 (80%) completed the tailored intervention and underwent re-bleeding. The intervention led to a significant improvement, with 77% of the participants achieving viral re-suppression rate. Additionally, there was a reduction of 69% in relapse rates among the participants.

Conclusions: The findings underscore the effectiveness of tailored and sustainable ART adherence support via Family therapy, caregiver engagement, and focused individualized counseling in overcoming barriers to viral suppression among CLHIV.

Monitoring the epidemiology, impact and prevention of new or resurgent pathogens

Safety, efficacy, and immunogenicity of mpox vaccines: a living systematic review and meta-analysis

J. Ballivian[1], J.M. Sambade[1], A. Bardach[1], M. Brizuela[1], J. Caravario[1], N. Castellana[2], E. Couto[1], A. Mazzoni[3], V. Ortega[3], A.P. Perez Oyola[2], F. Salva[1], F. Scarafia[2], J. Smutny[1], K. Stegelmann[1], A. Ciapponi[1], M. Berrueta[3], E. Parker[4], A. Stergachis[5], X. Xiong[6], F. Muñoz[7]

[1]Institute for Clinical Effectiveness and Health Policy, Health Technology Assessment (HTA), health economics and systematic reviews., Buenos Aires, Argentina, [2]Institute for Clinical Effectiveness and Health Policy, Statistics, data management and information systems, Buenos Aires, Argentina, [3]Institute for Clinical Effectiveness and Health Policy, Maternal and Child Health Research Department, Buenos Aires, Argentina, [4]4Department for Infectious Disease Epidemiology and International Health, London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]5School of Pharmacy and School of Public Health, University of Washington, Seattle, United States, [6]6Celia Scott Weatherhead School of Public Health and Tropical Medicine, Tulane University, New Orleans, United States, [7]Baylor College of Medicine, Texas Children's Hospital, Houston, United States

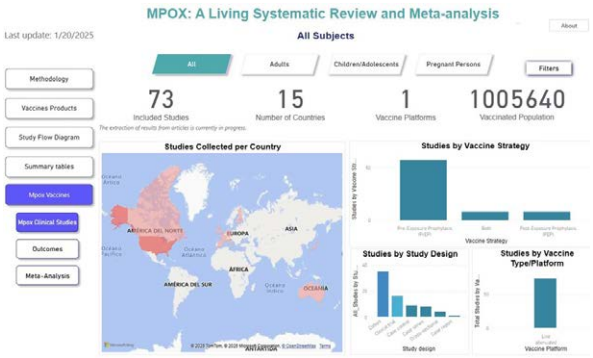
Background: Mpox became a global health concern after the 2022 outbreak, posing a significant threat to vulnerable populations, including children, pregnant individuals, and immunocompromised persons. To address the evolving evidence on mpox vaccines, we developed a living systematic review (LSR) to continuously evaluate their safety, efficacy, and immunogenicity, informing public health strategies and improving outcomes for affected populations.

Methods: We conducted a LSR and meta-analysis to evaluate the safety, efficacy, and immunogenicity of mpox vaccines in the general population, children, and pregnant individuals. The review adhered to PRISMA guidelines and was registered in PROSPERO (CRD42024586205, CRD42024591322). Eligible studies included randomized controlled trials and observational studies. Two reviewers performed data extraction independently, and the risk of bias was assessed using established tools.

Meta-analyses were performed using a random-effects model to calculate pooled estimates and 95% confidence intervals (CIs) for primary outcomes. The vaccine effectiveness (VE) was calculated using the formula VE=(1−RR)×100, where RR represents the risk ratio derived from the data.

Results: 73 studies, including clinical trials and observational studies with 1,005,640 vaccinated individuals, met the inclusion criteria. Of these, 65 studies focused on adult and adolescent populations, 9 on children, and 6 on pregnant individuals. The pooled vaccine effectiveness estimate for the MVA-BN vaccine in adults was 64% (95% CI: 34–81%).

Adverse events were reported at varying rates, with fever occurring in 7 per 100 observations (95%CI: 3–11%) and rash in 3 per 100 observations (95%CI: 0–14%). Substantial heterogeneity was observed across studies, driven by differences in study populations, vaccines, and outcome reporting.



Conclusions: Mpox vaccines demonstrate promising efficacy and a safety profile in adult populations. However, significant data gaps remain regarding their use in pediatric and pregnant populations.
Addressing these gaps through targeted research is critical to support vaccine implementation and optimize public health outcomes.

Social science theories, frameworks, concepts and methods

TUPED073

Using qualitative data to design a discrete choice experiment for measuring preferences for differentiated HIV care in western Kenya

H.-Y. Kim[1], K. Kadede[2], S. Amboka[2], H. Osese[2], D. Osodo[2], E. Koech[3], A. Nyabiage[3], S. Wafula[3], E. Geng[4], E. Bukusi[2], S. Baral[5], RS. Braithwaite[1], C. Berry[1], J.F.P. Bridges[6], A. Bershteyn[1]
[1]New York University Grossman School of Medicine, New York, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Center for International Health, Education, and Biosecurity, Nairobi, Kenya, [4]Washington University School of Medicine in St. Louis, St. Louis, United States, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [6]College of Medicine, The Ohio State University, Columbus, United States

Background: Differentiated service delivery (DSD) models aim to improve HIV treatment outcomes by tailoring services to client needs. While discrete choice experiments (DCEs) are a robust method to quantify preferences for health services, their validity depends on identifying attributes that matter to clients.
We report how qualitative data were systematically translated into a DCE instrument to assess preferences for current and emerging DSD models in Kisumu, Kenya.

Methods: Attributes influencing client preferences were explored through a literature review, 32 in-depth interviews (16 with healthcare workers and 16 with clients), and 7 focus group discussions (FGDs) across eight clinics. Twenty key attributes were identified, achieving saturation of themes and ensuring coverage of relevant constructs.
A dot voting exercise was subsequently conducted during three FGDs (8 participants per FGD). Each participant was allowed 20 points to allocate across 20 attributes for each of two rounds of voting, with discussion following each round.
The most prioritized attributes, combined with qualitative findings, informed the initial DCE design. Attributes and levels were further refined through pilot testing and think-aloud interviews (n=12). Data from the pilot test were used to finalize the DCE instrument, optimizing for statistical efficiency.
Results: In-depth interviews and FGDs identified a spectrum of constructs shaping client preferences, including confidentiality, convenience, and social support. Attributes such as reduced opportunity costs (e.g., travel time and costs) and concerns on confidentiality were well understood and commonly discussed, while engagement in shared decision-making required additional exploration to ensure comprehension.
The dot voting exercise helped to quantitatively prioritize 20 attributes, bridging qualitative insights into the DCE design.
Think-aloud interviews refined these attributes and confirmed the instrument's clarity and relevance to clients.
The final DCE instrument included the six attributes: location, frequency of medication pick-up, total time of clinic visit, availability of additional health services, adherence support and counseling, and confidentiality.
Conclusions: A comprehensive approach involving qualitative interviews, a prioritization exercise, and think-aloud interviews helped systematically identify and refine the attributes and levels for the DCE, providing a robust framework for developing a tool that is relevant and meaningful to client preferences.

Social and behavioural aspects and approaches to HIV prevention and living with HIV

TUPED074

Peer-led adolescent-friendly service delivery models for fast-tracking viral load suppression and overall well-being among adolescents living with HIV

N. Roshan[1], S. Ghosh[1], P. Majhumdar[1], A. Singh[2], R. Baba[2]
[1]YRG CARE, Chennai, India, [2]Johns Hopkins University School of Medicine, Infectious Disease, Baltimore, United States

Background: Project ACCELERATE, supported by PEPFAR/USAID, aims to improve the health and well-being of adolescents living with and affected by HIV/AIDS (ALHIV) through innovative, adolescent-friendly health centres (AFHC). The services integrate value-added, non-HIV entry points such as martial arts classes, music sessions, and casual makeup courses, fostering adolescent participation while addressing sexual and reproductive health (SRH), mental health, and HIV prevention in a peer-led model.

Description: The AFHCs serve as platforms offering individualised peer led support and leadership skill development alongside HIV-related services. ALHIV are categorized into two groups—cases requiring intensive or routine services—based on six indicators: recent antiretroviral therapy (ART) initiation, unsuppressed viral load, ART adherence <95%, opportunistic infections, incomplete tuberculosis preventive therapy, and loss to follow-up.

Tailored interventions, guided by an ART adherence barrier assessment tool, address individual challenges, such as stigma, emotional issues, and treatment side effects.

Support groups led by 20 trained treatment champions provide peer support and role modeling, significantly influencing ART adherence and health-seeking behaviors. Peer norms are reinforced through community events and targeted support group meetings, especially for virally unsuppressed adolescents.

Lessons learned: Acceptance of HIV status emerged as a critical factor for improving ART adherence and viral suppression. Peer-led approaches fostered better treatment outcomes and well-being by addressing barriers beyond clinical issues. Support groups for virally unsuppressed cases proved transformative, promoting peer-driven solutions and strengthening adherence behavior.

As of December 2024, the AFHC established in Imphal, Manipur, served 206 ALHIV, achieving 100% ART initiation, 99.5% viral testing eligibility, and 98.05% viral suppression from 70% VL suppression as compared to the baseline in January 2021.

Conclusions/Next steps: The peer-led AFHC model demonstrates a scalable and sustainable strategy for fast-tracking viral load suppression among ALHIV.

Standard operating procedures developed through this initiative are being adapted for scale-up within government programs, highlighting the potential for national implementation.

TUPED075

Urban gardens and peer nutritional counseling for improving HIV clinical outcomes: scaling and evaluating the *ProMeSA* intervention among people with HIV in the Dominican Republic

K.P. Derose[1], K. Palar[2], A. Then-Paulino[3], G. Jimenez-Paulino[3], L.A. Sheira[2], C. Tavares[3], R. Acevedo[4], G.J. Wagner[5], T.B. Neilands[2], S. Khan[2], G. Puerto[1], M. Alvarez[6], M.A. Fulcar[7], L.E. Pena[8], A. Gomez[9], P.C. Tien[2], E.A. Frongillo[10]
[1]University of Massachusetts Amherst, Health Promotion and Policy, Amherst, United States, [2]University of California, San Francisco, San Francisco, United States, [3]Universidad Autonoma de Santo Domingo, Santo Domingo, Dominican Republic, the, [4]Consejo Nacional de VIH/Sida, Santo Domingo, Dominican Republic, the, [5]RAND, Santa Monica, United States, [6]Ministerio de Salud Publica, Santo Domingo, Dominican Republic, the, [7]World Food Programme, Santo Domingo, Dominican Republic, the, [8]Ministerio de Agricultura, Santo Domingo, Dominican Republic, the, [9]Servicio Nacional de Salud, Santo Domingo, Dominican Republic, the, [10]Unversity of South Carolina, Columbia, United States

Background: HIV and food insecurity pose severe and interrelated problems in Latin America and the Caribbean, including in the Dominican Republic (DR), where HIV is one of the top 5 causes of death and our prior studies have found nearly 70% of people with HIV (PWH) have moderate or severe food insecurity. Despite the established, detrimental role of food insecurity on poor HIV treatment outcomes, evidence on sustainable interventions that address the cycle of food insecurity and poor HIV health is scarce.

Previously, we developed and rigorously piloted an intervention integrating urban gardens and peer nutritional counseling [*ProMeSA (Project to Improve Food Security)]* in the DR and found it feasible and acceptable, and it improved food security and HIV virologic suppression at 6 and 12 months.

Description: We are now conducting a fully powered cluster randomized controlled trial to assess *ProMeSA's* efficacy evaluated over a longer period (18 months).

Our design will determine ProMeSA's impact on the primary outcome of HIV viral suppression [undetectable HIV viral load (VL)] and secondary outcomes of ART adherence and HIV care retention among adults with food insecurity across diverse regions in the DR.

We will also assess intermediate outcomes and potential mediation based on our conceptual framework, as well as barriers and facilitators to intervention uptake, implementation, and sustainability. The trial will include up to 20 HIV clinics randomized to intervention or usual care control (with up to 25 participants per clinic and 500 total study participants).

Lessons learned: Urban gardening is a promising upstream intervention to improve food security and health of PWH across nutritional statuses. Given the high prevalence of food insecurity among PWH in the DR and other low-resource settings and its consistently negative effects on HIV-related outcomes, research is urgently needed to

assess the efficacy, causal pathways, and factors affecting intervention scale-up of sustainable food security interventions for PWH across diverse settings.

Conclusions/Next steps: *ProMeSA* will be the first full-scale trial to integrate peer nutritional counseling with food-generating activities among PWH and food insecurity, in support of national and international goals to achieve viral suppression and reduce the disease- and economic burden of HIV.

TUPED076

Adverse childhood experiences among young women accessing contraception and HIV PrEP at retail pharmacies in Kisumu, Kenya

C. Otachi[1], B. Rono[2], F.O. Mogaka[1], B. Nyerere[2], G. Rota[3], E. Harrington[4], H. Lagat[5], J. Odoyo[1], K.F. Ortblad[5], M. Lenn[5], M. Mugambi[5], M. Sharma[6], V. Omollo[1], Z. Kwena[5], E. Bukusi[7], J. Pintye[5]

[1]Kenya Medical Research Institute, Research, Kisumu, Kenya, [2]Kenya Medical Research Institute, Data, Kisumu, Kenya, [3]Kenya Medical Research Institute, Pharmacy, Kisumu, Kenya, [4]Fred Hutchinson Cancer Research Centre, Global Health, Seattle, United States, [5]University of Washington, Global Health, Seattle, United States, [6]Kenya Medical Research Institute, Global Health, Seattle, United States, [7]Kenya Medical Research Institute, Research, Nairobi, Kenya

Background: Adverse childhood experiences (ACEs) negatively impact lifelong health behaviors, including behaviors associated with HIV acquisition. Adolescent girls and young women (AGYW) in Kenya face disproportionately high HIV incidence and are a priority population for HIV pre-exposure prophylaxis (PrEP). Understanding ACEs and PrEP use among AGYW in Kenya is key to improving PrEP uptake and reducing HIV incidence.

Methods: We analyzed data from an ongoing cluster randomized controlled trial (NCT05467306) assessing pharmacy-based PrEP delivery among AGYW (aged 15–24 years) seeking contraception at 20 retail pharmacies in Kisumu, Kenya. Data on adverse childhood experiences (ACEs), sociodemographic factors, and sexual behaviors were collected. ACEs were measured using the ACEs International Questionnaire (ACE-IQ; 10 items), assessing abuse (physical, emotional, sexual), neglect (physical, emotional), and household dysfunction. ACE-IQ scores ranged from 0 to 10 points; scores <4 were defined as low, and scores ≥4 as high based on established cut-points. Poisson regression identified cofactors associated with high ACE scores.

Results: Between May 2023 and December 2024, 1531 AGYW enrolled in the trial; the median age was 21 years (IQR 19–23). The majority were unmarried (83%, 1234/1531), reported having casual sexual partner(s) (59%, 903/1531), had experienced a prior pregnancy (54%, 827/1531), and reported ever experiencing intimate partner violence (41%, 628/1531). Overall, 82% (1255/1531) took up oral PrEP or DPV-VR at enrollment. Most AGYW, 85% (1301/1531), experienced at least one ACE (score ≥1), and roughly 42% (643/1531) had experienced high ACE (score ≥4). High ACE scores were associated with engagement in transactional sex (11% vs. 3%, PR=3.57, 95% CI 2.17–5.89, p<0.001) and having a prior pregnancy (50% vs. 38%, PR=1.32, 95% CI 1.17–1.50, p<0.001) compared to those with low ACE. PrEP acceptance was similar among AGYW with high and low ACE scores (82% vs. 81%, p=0.696).

Conclusions: AGYW accessing contraception at retail pharmacies in Kenya had high ACE scores, particularly among those with characteristics associated with HIV acquisition. Scaling up pharmacy-based sexual and reproductive health services, such as HIV PrEP, can effectively reach AGYW at high HIV risk, including those with ACEs, reducing incidence and improving health outcomes in this vulnerable population.

TUPED077

Perceptions of changes in risk factors and adherence as a result of engaging in a packaged intervention during the early ART initiation period

L.L. Sabin[1], J. Kaiser[1], E. Trowbridge[1], L. Jennings[2], N. Halim[1], W. MacLeod[1], J.E. Haberer[3], A.L. Gifford[4], C. Orrell[2]

[1]Boston University School of Public Health, Global Health, Boston, United States, [2]Desmond Tutu HIV Centre, Institute of Infectious Diseases and Molecular Medicine and the Department of Medicine, University of Cape Town, Cape Town, South Africa, [3]Massachusetts General Hospital, Center for Global Health, Boston, United States, [4]Boston University School of Medicine, Department of Medicine, Boston, United States

Background: People living with HIV often struggle to be adherent to antiretroviral therapy (ART) medications after initiation, particularly if they experience risk factors such as depression, substance use, and HIV stigma. In community clinics in Cape Town, South Africa, the SUSTAIN trial is assessing whether combinations of adherence monitoring (via electronic monitoning using Wisepill, pharmacy refill, and Viral Load test) and support interventions (weekly text messages, counseling using motivational interviewing) improve adherence post-initiation. Serial interviews explore the influence of interventions on risk factors and adherence over time. Here we describe participants' perceptions of changes after one year on treatment.

Methods: 512 individuals were enrolled in SUSTAIN between March 2022 and March 24. At enrollment, we administered a questionnaire assessing six self-reported risk factors using validated scales. Among participants who screened positive for 1+ risk factors, we identified 60 for serial interviews (baseline, months 12 and 24), selected for a range of risk factors, genders, and ages. IDI guides queried experiences with risk factors, recent changes, and influence of interventions on motivation and capacity to be adherent. IDIs were repeated one year later with participants who attended month 12 clinic visits. We conducted content analysis in Nvivo®.

Results: A total of 27 (45%) participants engaged in a month 12 IDI. Among them, 74% had screened positive at enrollment for depression, 59% for food insecurity, 44% for substance use, 30% for transport/clinic issues, 22% for HIV

stigma, and 22% for gender inequity. Before month 12, 16 (59%) were identified as non-adherent. A key theme in IDIs was the positive impact of enhanced counseling on several risk factors, including substance use, mental health challenges, and food insecurity.
Following counseling and strategizing on managing/reducing substance use, food consumption (not required with medication), and seeking support, including disclosure, participants described increased ability to take their medications. Some participants also believed Wisepill use for monitoring improved their attention to adherence.
Conclusions: Monitoring and support interventions such as enhanced counseling may improve adherence over time by ameliorating known risk factors. More research to better understand the mediating role of risk factors in adherence behavior is urgently needed.

TUPED078

"With a year's supply of medication, I feel secure and in control of my health": experiences of multi-month dispensing models among migrant populations in Mozambique (january-April 2024)

A. Chissaque[1], N. Bhatt[2], N. Herrera[2], M. Songane[1], H. Inguane[3], C. Chambe[1], A. Muteerwa[4], A. Louvado[5], S. Chilundo[5], A. Sucá[1], C. Alons[1], M. Bonou[6], C. Cuinhane[7]
[1]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Research, Maputo, Mozambique, [2]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Research, Washington D.C., USA, United States, [3]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Research, Maputo, United States, [4]U.S. Centers For Disease Control and Prevention, Division of Science, Maputo, Mozambique, [5]U.S. Centers For Disease Control and Prevention, Division of Global HIV & TB, Maputo, Mozambique, [6]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Technical, Maputo, Mozambique, [7]Universidade Eduardo Mondlane, Research, Maputo, Mozambique

Background: In 2019, health authorities in Gaza Province, Mozambique, started a pilot program for 6 and 12 multi-month dispensing (MMD) of antiretroviral therapy (ART) in selected health facilities for migrant clients living with HIV. However, there is limited understanding of how these clients and the healthcare providers' perceive these dispensing models. We aimed to explore both groups' perceptions regarding the 6MMD and 12MMD ART models in Gaza Province, Mozambique.
Methods: We conducted a qualitative study to assess the implementation and perceived impact of 6MMD and 12MMD between February and April 2024. Data were collected through 44 semi-structured interviews with 25 migrant clients living with HIV and 19 healthcare providers across 11 health facilities that are implementing the MMD dispensing in Gaza Province. Thematic analysis was used to identify key facilitators, barriers, and outcomes of MMD. Data were coded and managed using NVIVO QSR International (version 13).
Results: Both 6MMD and 12MMD models were widely regarded as effective by clients and healthcare providers. Clients cited reduced transportation costs, fewer clinic visits, and better alignment with work schedules as key benefits, improving their adherence and retention in care. Healthcare providers reported reduced patient volume, enabling them to deliver more personalized care and manage other clinic responsibilities effectively. They also perceived that these models enabled clients to take their medication without missing out on access to care at the facilities. Critical facilitators included awareness campaigns, professional training, and the availability of ART supplies.
Challenges reported included: migrants often missed viral load testing due to travel or insufficient follow-up mechanisms; women faced limited integration of MMD with family planning and cervical cancer screening services; and some clients expressed concerns about extended intervals between clinical evaluations, highlighting the need for enhanced support systems.
Conclusions: The 6MMD and 12MMD models have shown the potential to improve HIV treatment access in high-mobility populations by reducing financial and logistical barriers while maintaining adherence.
Addressing challenges such as follow-up systems, service integration, and resource constraints (costs) plays a crucial role in maximizing the potential benefits of MMD. These findings provide valuable insights for scaling differentiated HIV care in similar high-burden settings of Mozambique.

TUPED079

Acceptability and experiences of adolescent girls and young women with genital sampling procedures in an HIV vaccine preparedness study in Uganda

C. Ssekyewa[1], D. Kibuuka[1], G. Nanyonjo[1], I. Kitabye[1], M. Wambuzi[1], M. Namuleme[1], A. Nanvubya[1], J. Mpendo[1], B. Okech[1], A. Ssetaala[1], K. Ondeng'e[2], Y. Wangui Machira[2], M. Price[3,4], P. Maenetje[5], M. Kuteesa[2]
[1]UVRI-IAVI HIV Vaccine Program, Entebbe, Uganda, [2]IAVI, Nirobi, Kenya, [3]IAVI, New York, United States, [4]UCSF, San Francisco, United States, [5]Aurum Institute, Rustenburg, South Africa

Background: Engaging Adolescent Girls and Young Women (AGYW) in trial design is key towards supporting product development tailored to their needs. Genital sample collection procedures essential for STI monitoring and immunological research may impact study adherence.
We explored AGYW's acceptability and experiences with genital sampling procedures in the Multi-site Adolescent Girls Young Women study (MAGY) in Uganda to understand acceptability and participation.
Methods: This qualitative study was conducted among AGYW who had undergone genital sampling with Softcup, Cytobrush, and vaginal swabs, and parents/guardians of AGYW living in fishing communities around Lake Victoria, Uganda.
30 AGYW,15 parents/guardians of AGYW were purposively selected for participation considering age, occupation, and residence. AGYW and parents/guardians were sensitized before collection on the types of samples needed,

and their importance to study goals. Genital sampling for AGYW was conducted at month 0 and every three months. Parent and AGYW in-depth interviews were conducted in Luganda after screening, at month 0 and month 6. Data were transcribed verbatim and thematically analyzed using Nvivo 14.

Results: Neither AGYW nor parents/guardians had prior knowledge or experience with the SoftCup, CytoBrush, or vaginal swabs.

AGYW found procedures acceptable though some reported discomfort with the size of the SoftCup, the vaginal speculum, and CytoBrush as well as mild abdominal pains or tickling. Perceived fear of the Cytobrush damaging the uterus was also reported by the AGYW. Female clinicians were preferred for sample collection. Self-sample collection was perceived to be uncomfortable.

Parents/Guardians highlighted the need for detailed explanations to address concerns about pain and tool size. They had mixed preferences on the clinician's gender. They recommended involving sexual partners, local, and religious leaders to foster community acceptance.

Conclusions: Genital sampling is generally acceptable among AGYW. Addressing procedural concerns, and preferences is key. Involving partners and key stakeholders might foster broader acceptance and trust.

TUPED080

Factors influencing adherence to daily oral PrEP during pregnancy and postpartum: qualitative findings from Malawi, South Africa, Uganda and Zimbabwe

P. Musara[1], L. Stranix-Chibanda[1,2], P. Slutzker[3], J. Etima[4], R. Nabukenya[5], F. Mathebula[6], L. Seyama[7], M.N. Tichareva[8], O. Munaiwa[8], T. Mutasa[8], E. Brown[9], H.M. Spiegel[10], D. Kacanek[11], B. Chi[12], K.R. Amico[13]

[1]Clinical Trials Research Centre, University of Zimbabwe, Harare, Zimbabwe, [2]UZ FMHS, Harare, Zimbabwe, [3]University of Michigan School of Public Health, Ann Arbor, United States, [4]Makerere University-Johns Hopkins University Research Collaboration, Kampala, Uganda, [5]Baylor College of Medicine Children's Foundation, Kampala, Uganda, [6]Wits RHI, University of Witwatersrand, Faculty of Health Sciences, Johannesburg, South Africa, [7]Johns Hopkins University, University of Malawi, Blantyre, Malawi, [8]Clinical Trials Research Centre, University of Zimbabwe, Harare, Zimbabwe, [9]FHI 360, Durham, United States, [10]Kelly Government Solutions, Contractor to DAIDS, NIAID, NIH, Rockville, United States, [11]Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [12]University of North Carolina, Chapel Hill, United States, [13]University of Michigan, School of Public Health, Ann Arbor, United States

Background: Oral PrEP is recommended in pregnant and breastfeeding women (PBFW) at risk for HIV. However, data about peripartum use is limited. Through in-depth interviews with PBFW who initiated daily oral PrEP (DO-PrEP) in the IMPAACT 2009 study, we explored factors influencing DO-PrEP use.

Methods: In this multi-center clinical study, 350 PrEP-eligible pregnant women aged 16-24 years were enrolled between March and December 2022. All participants were offered daily oral TDF/FTC and followed through 26 weeks postpartum.

Among the 229 PBFW who initiated DO-PrEP, 20 antepartum and 20 postpartum women were purposively selected for an in-depth interview. Within each period, we interviewed 10 women with optimal (6-7 doses/week) and 10 with sub-optimal adherence (<6 doses/week) based on TDF/FTC drug levels in dried blood spots at two consecutive visits.

Interviewers asked women about facilitators and challenges to DO-PrEP use. Interview transcripts were thematically coded and analyzed, focusing on experiences with DO-PrEP during and immediately following pregnancy.

Results: In both ante- and postpartum groups, a strong desire to prevent HIV for self and baby was reported to promote consistent DO-PrEP use. Common facilitators of DO-PrEP use included dosing reminders, adherence counselling and routine dosing schedules. Concerns about side effects and male partner disapproval were stronger during pregnancy compared to postpartum, prompting inconsistent dosing and nondisclosure of DO-PrEP use until after delivery. Good experiences with DO-PrEP during pregnancy influenced a positive attitude
about its use during breastfeeding. Other pregnancy-related barriers to DO-PrEP use included labor and concomitant pregnancy symptoms/sickness, adding to the pill burden of routine pregnancy supplements. Overall, women described their experience with DO-PrEP use during breastfeeding as better compared to pregnancy.

Conclusions: PBFW receiving DO-PrEP were aware of HIV risk and motivated to protect themselves and their infants; however challenges unique to pregnancy including side effects to the baby, were reported. Tailor-made counselling is needed for peripartum DO-PrEP use.

TUPED081

Correlates of network- and non-network – based HIV testing strategies among female sex workers and men having sex with men in lower eastern, Kenya

V. Booko[1], P. Eshikumo[1], C. Onyango[1], F. Makori[1], D. Muli[1], S. Wafula[1], P. Kyalo[1], E. Koech[1]

[1]CIHEB Kenya, Pact Imara, Nairobi, Kenya

Background: Female sex workers (FSWs) and men who have sex with men (MSM) are disproportionately affected by HIV. Testing for HIIV is critical for accessing prevention and treatment services, yet the impact of testing strategies on linkage to services remains under studied.

This evaluation compared network-based and non-network-based HIV testing strategies to understand their correlates and influence on linkage to HIV prevention and treatment services among key populations in Lower Eastern Kenya.

Description: We conducted retrospective analysis of data from nine key population drop-in centers (DICEs) in Lower Eastern Kenya was conducted. Data from the last HIV

test between October 2023 and September 2024 was extracted, including testing strategies, test settings, HIV risk scores, test results, and linkage to prevention and treatment services.

Lessons learned: A total of 17,870 key population (KP) clients were tested, including 9,894 (55.4%) FSWs. The median age was 30 years (IQR: 25–37), with 43.5% aged 25–34. Most clients (88.6%) were tested using non-network-based strategies, and 94.7% were unaware of their HIV status. Among those tested, 93.5% had documented HIV risk scores, with 50.8% classified as medium risk. Testing primarily occurred in community settings (77.8%), and the overall test positivity rate was 1.2% (218 clients). Ninety percent of clients were linked to prevention services, with 40.1% linked to ARV-based prevention or treatment.

Network-based testing was more likely among MSM (AOR = 1.12, 95% CI: [1.02–1.25], p = 0.024), clients with very high risk scores (AOR = 2.56, 95% CI: [1.99–3.28], p < 0.001), and those testing HIV-positive (AOR = 8.21, 95% CI: [6.01–11.26], p < 0.001).

Repeat testers and those not linked to prevention services were less likely to use network-based strategies (AOR = 0.74, 95% CI: [0.70–0.79], p < 0.001; AOR = 0.33, 95% CI: [0.26–0.43], p < 0.001, respectively).

Conclusions/Next steps: Network-based testing was strongly associated with higher HIV positivity, very high risk scores, and improved linkage to ARV-based prevention and treatment, particularly among MSM. Tailored testing strategies are vital for effective HIV prevention and control.

TUPED082

Efficacy testing of a stigma reduction intervention clinical trial among urban and rural women with HIV

D. Kisamo[1], M. Kilonzo[1], W. Pan[2], R. Mtei[1], L. Nyblade[3], M. Relf[2]

[1]Muhimbili University of Health and Allied Sciences, Psychiatry and Mental Health, Dar-es-salaam, Tanzania, the United Republic of, [2]Duke University, School of Nursing, Durham, United States, [3]RTI International, Washington, United States

Background: In Tanzania, HIV is a leading cause of death and an estimated 1,000,000 women are living with HIV (WLWH). Stigma is a barrier to testing, prevention, treatment, and well-being for WLWH, yet few evidence-based interventions exist to address it.

This study tested preliminary efficacy of a theoretically-based, culturally relevant, linguistically sensitive, sex-specific stigma-reduction intervention, Labda Siku Moja (Maybe Someday) through a pilot randomized clinical trial.

Methods: The stigma-reduction intervention consisted of five video stories comprised of personalized stigma coping messages acted by and relevant to Tanzanian WLWH, and guided by the Theory of Narrative Transportation. WLWH watched the videos in groups of 9 to 12 organized by age groups (18 to 24, and 25+). Motivational Interviewing was used as the mechanism of debriefing each of the five stories. To test preliminary efficacy and determine effect sizes of this intervention, a 2 (treatments) x 4 (time points [baseline, 30, 90, 180 days]) repeated-measures RCT was used. Participants were recruited from one urban and one rural health center.

Results: Of the 192 WLWH screened for study participation, 167 met enrollment criteria; 87 were randomized to the intervention and 80 to the control, stratified by age (18-24/25+). Retention was high; 154 (97.5%) completed the 30-day, 155 (98.1%) completed the 90-day and 152 (96.2%) completed the 180-day follow-up surveys.

From baseline through 180-days, participants in the intervention arm significantly reduced scores more than the control arm for overall stigma (p<.0001) and subscales: perceived (p=.001), anticipated (p<.0001),internalized (p<.0001), and disclosure related stigma (p<.0001).

There was a significant increase on coping self-efficacy (p=.0095), self-esteem (p=.0310), resilience (p=.0268) among women in the intervention arm more than the control arm over the same follow-up period.

Conclusions: These findings suggest that it is possible to mitigate the negative effects of stigma among WLWH. Further research is necessary to determine how to scale the intervention for widespread dissemination.

Similarly, as stigma experiences differ among men and women, additional research is also needed to develop and test a stigma reduction intervention for men living with HIV.

TUPED083

Group by time analysis of forming an explicit sexual agreement: results from a digital HIV serostatus neutral intervention trial with adult, cisgender male couples

J. Mitchell[1], A. Sophus[1], C. Rodriguez[1], Z. Bursac[1]

[1]Florida International University, Stempel College of Public Health and Social Work, Miami, United States

Background: Few HIV serostatus neutral interventions exist in the US that are efficacious, couples-based, and delivered digitally for adult, sexual minority male couples. LuvHub is a couples-based, digital HIV serostatus neutral intervention (DHI) that is currently being evaluated via a nation-wide, digital randomized controlled trial (RCT). LuvHub teaches couples essential skills, including forming an explicit sexual agreement.

Methods: We enrolled 389 eligible and consented adult, cisgender sexual minority male couples across the US to participate in a 16-month, digital RCT to assess the efficacy of LuvHub over time. Post baseline, couples were randomized to immediate intervention condition (G1) to use LuvHub for 16 months or 8-month delayed control condition (G2) to use LuvHub began for the last 8 months of the trial.

Assessments occurred every 4 months. Present analyses examined differences in forming an explicit sexual agreement (categorical outcomes) from baseline to month 4 between G1 and G2. Generalized estimating equation (GEE) mixed models were conducted to test for group (G), time (T), and group by time (GxT) interaction effects.

Results: At baseline, there were no significant differences in sex agreement formation between groups (p=0.07). At 4m, there were significant differences between groups (p<0.0001). For G1, all agreement categories increased while not having any agreement decreased to 4.5% and G2 remained about the same as baseline. GEE model showed significant GxT interactions for all sexual agreements compared to no agreement. G1 had 70% increase in odds of closed agreement relative to no agreement when compared to G2, and 2.1 increase in odds of open with rules agreement relative to no agreement compared to G2. For GxT, there were no group differences at baseline; at 4m, G1 had >3 fold increase in odds of closed agreement (p=0.0041), 2 fold increase in odds of open with no rules (p=0.0678), and 3.8 fold increase in odds of open with rules (p<0.0001), relative to no agreement, compared to G2.
Conclusions: Findings show potential promise of LuvHub for encouraging couples to form an explicit sexual agreement over time. Analyses of remaining assessment data, once available, are needed to reveal longitudinal trends in these outcomes.

Social, cultural, political, legal, environmental and structural determinants of health in different contexts

TUPED084

Impact of stigma and discrimination on HIV prevalence and cascade of care among female sex workers: a global systematic review and meta-analysis

B. J. Njiro[1], J. Dawe[1], K. Anam Mazhar[1], S. Aijaz Khan[1], J. Ambia[1], A. Trickey[1], L. Barass[1], A. Asgharzadeh[1], M. Hickman[1,2], J. Stone[1], P. Vickerman[1,2], A. Artenie[1]
[1]University of Bristol, Bristol Population Health Science Institute, Bristol Medical School, Bristol, United Kingdom, [2]University of Bristol, Health Protection Research Unit, Bristol Medical School, Bristol, United Kingdom

Background: Female sex workers (FSW) face an increased risk of HIV transmission due to risky sexual practices resulting from their work and economic constraints. HIV research and interventions have predominantly focused on individual-level risk behaviours and biomedical approaches. This global systematic review evaluated the impact of stigma and discrimination on HIV care cascade outcomes among FSW.
Methods: We systematically reviewed studies from MEDLINE, Embase, and PsycINFO databases published over 01/012010-25/03/2024 assessing associations between stigma or discrimination and HIV outcomes (HIV testing, HIV incident or prevalent status, ART use, ART adherence, or viral load suppression) among FSW. We extracted and pooled associations (adjusted estimates when available, otherwise unadjusted estimates) from the included studies using random-effects meta-analyses. We applied a multi-level approach as multiple estimates were available from some studies (e.g., associations with different stigma types). We conducted subgroup analyses for HIV-related and sex-work related stigma.
Results: Thirty-six studies including 35,634 participants from 24 countries (22 (92%) from low and middle-income countries with 13 (54%) from Africa) were analysed, contributing 104 associations between stigma or discrimination and HIV outcomes.
Overall, 34% of FSW reported experiencing stigma or discrimination; either ever (34%) or recent (28%). We found a positive association between stigma/discrimination and HIV positive status (pooled OR:1.10; 95%CI:1.00–1.21; I^2:49.6%, n=28 estimates) and a negative association with ever or recent HIV testing (pooled OR:0.75; 95%CI:0.58–0.96; I^2:80.2%, n=21 estimates). Stigma or discrimination showed no association with ART use, adherence, and viral load suppression.
In subgroup analyses, HIV-related stigma/discrimination was associated with lower HIV testing among FSW (OR:0.72; 95%CI:0.53–0.97; I^2:67.5%, n=7 estimates), whereas sex-work stigma showed no association (OR:0.85; 95%CI:0.64–1.13; I^2:81.5%, n=15 estimates).
Conclusions: Stigma and discrimination may increase the risk of HIV transmission and reduce HIV testing among FSW, but evidence suggesting an impact on other HIV care outcomes is insufficient. There is a need for tailored interventions focusing on stigma and discrimination to reduce structural barriers and inequalities in HIV care among FSW, with these being accompanied by political commitment and sex work friendly policies. Additional evidence is also needed on the causal pathways linking stigma and discrimination to HIV outcomes.

TUPED085

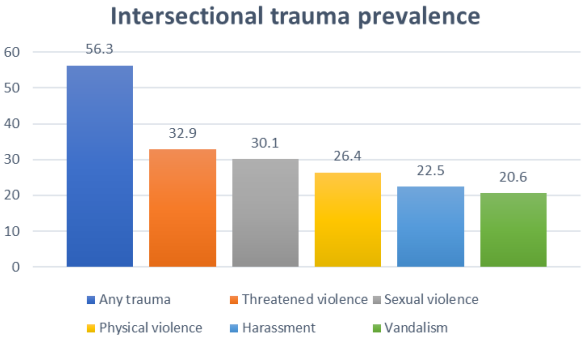
Intersectional trauma exposure, posttraumatic stress, and PrEP engagement among sexually minoritized cisgender men in the United States

J.M. Wiginton[1], S. Baral[2], T. Sanchez[3]
[1]Johns Hopkins University Bloomberg School of Public Health, Mental Health, Baltimore, United States, [2]Johns Hopkins University Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Emory University, Epidemiology, Atlanta, United States

Background: Sexually minoritized men (SMM) in the United States (US) are disproportionately burdened by HIV, trauma exposure, and posttraumatic stress disorder (PTSD). Minimal research has examined how trauma shapes PrEP engagement, which remains suboptimal. We determined intersectional trauma and PTSD burden and assessed PTSD/PrEP engagement associations.
Methods: Using online, cross-sectional, nationwide data from HIV-negative and status-unknown participants (N=2144) in the American Men's Internet Survey (2022-2023), we calculated prevalence of intersectional trauma (harassment, vandalism, threatened violence, actual physical or sexual violence) and PTSD, and performed logistic and ordinal logistic regressions to assess intersectional trauma/PTSD associations and PTSD/PrEP engage-

ment associations. We used stratification to assess effect measure modification of PTSD/PrEP engagement associations by race.

Results: Mean age was 43 years; 70% of participants were non-Hispanic white (n=1501), with roughly 10% each of Black (n=213), Hispanic (n=205), and another race or multiracial participants (n=207). More than a third (n=741) reported current PrEP use. More than half (n=1206) endorsed ≥1 trauma, the most prevalent being threatened violence (Figure).



Roughly 7% (n=152) screened positive for PTSD. All traumatic events were positively associated with PTSD (p≤0.001). Among ever-PrEP users (n=960), PTSD was negatively associated with current PrEP use (OR=0.48, 95% CI=0.29-0.80). Among current PrEP users, PTSD was negatively associated with PrEP persistence (OR=0.55, 95% CI=0.31-0.99) but not adherence (OR=0.81, 95% CI=0.39-1.68). Stratified by race, PTSD was negatively associated with current PrEP use among Black (OR=0.17, 95% CI=0.04-0.72) and Hispanic ever-PrEP users (OR=0.23, 95% CI=0.05-1.10; p=0.066) only.

Conclusions: Trauma and PTSD are potential intervention targets that may optimize PrEP engagement and promote psychosocial wellness among SMM. PrEP programming that is both trauma-informed (i.e., creates safe, supportive, empowering environments that avoid re-traumatization) and trauma-focused (i.e., specifically addresses and aims to treat trauma's effects) is needed. As vulnerabilities may vary by race, tailoring and cultural adaptation may be warranted.

TUPED086

Risks and vulnerabilities among adolescents livings with visual disabilities enrolled in the DREAMS initiative in Monze and Mongu districts in Zambia

A. Mweemba[1], S. Sipulila[1], L.K. Mwango[1], K. Nalungwe[1], M. Mujansi[1], P. Makasa[1], S. Tembo[1], D. Zulu[1], M. Mweemba[2], M. Mwansa[3], O.N. Chilyabanyama[3], A. Adebayo[3], C. Baumhart[4,5], C. Claassen[3,4,5], L. Hachaambwa[1,4,5]

[1]Ciheb Zambia, Lusaka, Zambia, [2]Young Women Christian Association, Lusaka, Zambia, [3]Maryland Global Initiative Corporation Zambia, Lusaka, Zambia, [4]Center for International Health, Education, and Biosecurity, Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [5]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States

Background: Adolescents with disabilities (AWD) in Zambia are at increased risk of HIV due to limited access to inclusive health services, pervasive stigma, and social barriers. While the Determined, Resilient, Empowered, AIDS-free, and Mentors (DREAMS) program has reduced HIV risk among adolescents, further assessment is needed to ensure it effectively meets the unique needs of those with disabilities. Ciheb-Zambia examined the specific risks and vulnerabilities faced by visually impaired AWD enrolled in DREAMS to identify opportunities for enhanced inclusivity and support

Methods: From October 2023 to September 2024, AWD presenting at DREAMS centers were screened for eligibility, risk, and vulnerability by trained mentors in Monze and Mongu districts. Mapping covered 9 communities, including schools, with collaboration from the Ministry of Education and community gatekeepers to reach adolescent girls and young women (AGYW). AWD underwent structured risk assessments, enrolling only AGYW identified with multiple risks. De-identified data were analyzed in R using descriptive and inferential statistics to assess risk factors and program outcomes.

Results: A total of 213 AGYW with visual impairments were screened for risks and vulnerabilities with 65 (31%) aged 10-14, 128 (60%) aged 15-19, and 20 (9%) aged 20-24 years-old. Of those screened, 98.5% (210/213) with multiple risk factors were enrolled in DREAMS. Over half (53%) reported irregular condom use, and 32% reported multiple sexual partners in the last year.

Additionally, 28% engaged in transactional sex. Experiences of violence were prevalent, with 24% reporting emotional or physical abuse or neglect and 13% reporting lifetime sexual violence. Substance use disorders were present in 18%, and 3% reported an STI diagnosis.

Furthermore, 14% were out of school, and 9% have been pregnant or were already mothers.

Conclusions: Our findings in two districts reveal complex vulnerabilities among visually impaired AGYW in the DREAMS program, with high rates of irregular condom use, transactional sex, multiple partners, and violence exposure underscoring critical gaps in support. The low STI diagnosis rate may reflect limited healthcare access rather than reduced exposure. These insights underscore

the urgent need for DREAMS to adopt more inclusive, disability-specific strategies to address the unique challenges faced by AWD.

TUPED087

Assessing health-related social needs among people living with HIV in the Bronx, New York

D. Watnick[1], L. Bauman[1], M. Campo[2], A. Lewis[1], R. Kouvatas[1], E. Chambers[1], U. Felsen[3], D. Hanna[1]
[1]Albert Einstein College of Medicine, 10461, United States, [2]New York Institute of Technology College of Osteopathic Medicine, Westbury, United States, [3]Montefiore Medical Center/Albert Einstein College of Medicine, 10461, United States

Background: Health-related social needs (HRSN) such as housing instability and food insecurity pose significant barriers worldwide to HIV treatment adherence and viral suppression, which are key targets to limit disease transmission and progression among people living with HIV (PLWH).
To address these barriers valid assessment tools are necessary to first identify HRSN, particularly among PLWH in underserved communities, and then offer targeted support.
Methods: We convened an advisory panel including PLWH, providers and researchers to establish acceptability and content validity of a 9-item HRSN clinical tool designed for general clinical settings, to be adapted for HIV clinic implementation in the Bronx, New York.
The first 8 items identified recently experienced HRSN (housing instability, housing quality, hunger, economic insecurity, transportation access, healthcare affordability, caregiver support, legal services access). Item 9 captured interest in receiving help.
Next, we recruited PLWH from an HIV clinic to participate in cognitive interviews (CIs), probing for conceptual coverage and cognitive domains (item comprehension/interpretation, information retrieval, judgment, response process). We conducted 3 rounds of CIs (8-10 PLWH per round, n=28). We used analytic memos and data matrices to identify patterns across participants and items.
Results: The panel:
1. concluded that clinical implementation was acceptable and conveyed provider empathy, and
2. identified content gaps to subsequently address in CIs.
CI participants were 57% women, 79% diagnosed with HIV >10 years ago, and 79% reporting ≥1 HRSN. Mean age was 54 years.
We identified challenges to conceptual coverage (e.g., tool excluded need for 'home health care') and to cognitive domains:
1. unheeded temporality: disregarding varying recall periods (e.g., "past 2 months", "past 12 months");
2. conflation of referent groups: non-systematic inclusion of individual vs. household/family HRSN;
3. judgment and self-censorship:
a. internalizing personal responsibility rhetoric reduced help-seeking,
b. selectively reporting *prioritized* vs. *all* HRSNs;
4. limited response options: 'Yes' or 'No' may capture current HRSN, disregarding reality of chronic, intermittent or anticipated needs.
Conclusions: Findings led to significant revisions to the HRSN assessment tool for PLWH. As HRSN identification expands into clinical settings, tools designed for the general population may require significant revision to ensure validity if used with PLWH.

Community-engaged/participatory social science-based interventions

TUPED088

Moving beyond mere community engagement to community leadership by young women to prevent HIV and gender-based violence in Ngqushwa, South Africa: Ubomi Bethu (it's our lives) Programme

P. Gola[1], L. Namba[1], K. Pepper[2], B. Ganca[1], L. Nkanyana[3]
[1]Ubunye Foundation, Ubomi Bethu Programme, Makhanda, South Africa, [2]Ubunye Foundation, Director, Makhanda, South Africa, [3]Ubunye Foundation, Senior M&E Manager, Makhanda, South Africa

Background: The Ubunye Foundation pushes boundaries focussing only on community-led programmes. Ubomi Bethu (It's our life) programme is designed, managed, evaluated and presented by young women from rural areas. These women, living with HIV, wanted to address young women (aged 10-24) who exchange sex for food/luxury items with 'umalabane' (sugar daddies) who are often school taxi drivers. Parents support the relationships since they bring food/resources into otherwise impoverished households. Yet, these women experience violence and GBV risking themselves to HIV and unplanned pregnancies.
Description: 150 young women learners in eight high schools volunteer as Youth HIV Ambassadors (YHAs) covering 3400 learners. YHAs are mentored in passing on accurate information on HIV prevention in informal chats with other learners. They link those needing immediate professional help to counsellors, teachers, police, nurses - local public sector employees trained to help young people. YHAs also refer those in relationships with umlambane to Life Skills groups. Here, they create alternative life plans with financial, training, psycho-social, and study support. A mobile app gives all people access to Ubomi Bethu resources, project feedback, local assistance, and supportive chat platform. YHAs now also have a bi-annual youth-led summit where young women and men talk and pledge on building happy healthy supportive relationships.
Lessons learned: Ubunye uses community-led M&E systems. YHAs and learners use participatory action M&E, allowing them to speak directly. They collate analyse, review and ultimately present data. They identify and measure their own indicators of success, progress and change.

Some indicators focus on young people's increased use of clinics, (up 52% in two years). Yet other indicators report on supportive conversations; outomes after advice on relationship challenges; links to professionals in times of crisis. Their findings show (his)tories of support given, impressions of courage, individual programme impact; images of extreme life challenges.

Conclusions/Next steps: Ubomi bethu shows community leadership working in HIV prevention. It is an alternative to Global North imposed methodologies that merely engage communities. It shows young women working together to change their futures in ways that are locally managed by them. HIV prevention is shown to be about rights, education, access to essential resources, not only health care.

TUPED089

Transforming care: integrating afrocentric principles, symbolism, and community-based research to address IPV and HIV among african, caribbean, and black women in Ontario Canada

W. Gichuki[1], A. Joseph[1], M. Carranza[1], I. Waldron[1], T. John[2], W. Tharao[2], A. Dawe[3], D. Johnson[4], C. Leonard[5], M. Muchenje[6], A.-B. Manji[7], T. Bryan[8], C. Campbell[8], D. Joyette[9], L. Samuels[10], S. Joseph[3]

[1]McMaster University, Global Health, Hamilton, Canada, [2]Women's Health in Women's Hands Community Health Centre, Toronto, Canada, [3]Roots Community Services Inc, Brampton, Canada, [4]Agapé Lens Consulting and Therapy, Toronto, Canada, [5]CAL Consulting, Toronto, Canada, [6]University of Toronto, Toronto, Canada, [7]University of Ottawa, Ottawa, Canada, [8]Community, Brampton, Canada, [9]Joyette Consulting, Brampton, Canada, [10]Sheridan College, Brampton, Canada

Background: African, Caribbean, and Black (ACB) women face unique and intersecting challenges when navigating intimate partner violence (IPV) and HIV. These challenges are shaped by systemic barriers such as anti-Black racism, colonization, and stigma which discourages vulnerability and help-seeking.

This study explores these intersections in the Greater Toronto Area (GTA) in Ontario, Canada, focusing on the lived experiences of ACB IPV survivors women and the systemic and cultural factors influencing their access to care. Drawing on Afrocentric theory, Black feminist thought, and the Intersectionality concept, the research seeks to advance culturally informed, community-driven solutions that foster healing and resilience.

Methods: The study employed a community-based research (CBR) approach to prioritize the voices of ACB women and engage stakeholders at every stage using a qualitative design and was conducted between May-Aug 2023. Participants included ACB women aged 18–64 who are IPV survivors with lived experiences of HIV, healthcare, and social service providers with expertise in IPV and HIV in ACB communities.

Recruitment was facilitated through convenience and snowball sampling using social media and community networks. Data collection involved six talking circles and 18 semi-structured interviews. Thematic analysis was applied to identify patterns and themes, while ethical protocols, including informed consent and confidentiality, were observed.

Results: Findings revealed pervasive systemic barriers, including stigma, fear of disclosure, and a lack of culturally relevant services. Participants expressed frustration with mainstream healthcare and social services that failed to address their unique needs and the intersectionality of IPV and HIV. The Strong Black Woman schema emerged as a significant barrier, perpetuating silence and isolation by stigmatizing vulnerability.

Conversely, protective factors such as spirituality, culturally informed therapy, and community support networks were identified as critical to resilience. The principles of Ujima collective work and responsibility were central to creating inclusive, culturally safe spaces that prioritized communal healing and empowerment.

Conclusions: The research underscores the need for culturally informed, community-driven approaches to support ACB women experiencing IPV and HIV. Afrocentric principles and CBR provide pathways for sustainable, inclusive care.

Future work should integrate these frameworks into policy and practice to foster systemic change, improve access to services, and promote holistic healing.

TUPED091

Community based viral load sample collection through community cadres is possible among vulnerable subpopulations with limited mobility: lessons learnt from Mwami Rural Hospital, Hurungwe, Zimbabwe

T. Makoni[1], C. Mademutsa[1], S. Mukungwa[1], T. Mwareka[1]

[1]Zimbabwe National Network of People Living with HIV, Harare, Zimbabwe

Background: Viral load monitoring establishes whether a client has achieved viral load suppression. In rural areas in Mashonaland West health care workers at Mwami Rural Hospital identified long distances hinder access to viral load monitoring annually as expected.

When recipients of care are elderly or living with disabilities, access is limited. Recipients volume and clinical responsibilities provide challenges for healthcare professionals to dedicate time for outreach or household services.

Description: The health care workers, to enhance access to viral load monitoring, approached Community Health Agents (CHAs) and proposed to extend community viral load monitoring on the existing Differentiated Services Delivery of ART medicines conducted at community level and capacitated them through one-day sessions on collecting finger-prick dried blood samples for viral load monitoring. The community health agent visits the community and collects dried blood samples for the elderly and other vulnerable populations so that they do not miss out on viral load monitoring. Commcare was used to collect Client Satisfaction Sentiments (CSS) and referral data by the CHAs.

Lessons learned: Community cadres collecting viral load samples has proven to be effective and client-centered, ensuring no one is left behind in accessing care and treatment services. Over the 9-month period the program has managed to facilitate 185 viral load monitoring referrals for defaulters and elderly recipients of care ensuring 100 % clients have valid viral load results.
CSS data collected over the period has shown steady progression of valid viral loads reported by recipients of care from 88% Q2, 86% Q3 and 100% Q4. Identifying challenges and receiving training for sample collection and result delivery, community cadres demonstrate that local communities can lead the HIV response. This approach allows recipients to receive customized services, which motivates adherence to medication.
Conclusions/Next steps: Viewed as complex procedure requiring trained professionals, this novel practice offers a new, scalable model in similar settings. It highlights the potential for community involvement to enhance healthcare accessibility and improve health outcomes for people living with HIV. The practice addresses human resource shortages in the provision of healthcare services.

A community-engaged social media campaign addressing HIV-related stigma in Peru: results from the "DiME" campaign

M. Curtis[1], A. Nunez[1], M. Wong[2], K. Kosyluk[3], R. Errea[2], M. Franke[1]
[1]Harvard Medical School, Global Health and Social Medicine, Boston, United States, [2]Socios en Salud, Lima, Peru, [3]University of South Florida, Mental Health Law & Policy, Tampa, United States

Background: Mitigating HIV-related stigma is crucial to improving outcomes for people living with HIV (PLWH) and reaching global HIV targets. We designed and implemented a community-engaged social marketing campaign to address HIV-related stigma among young people in Peru, and examined the feasibility of working with influencers to disseminate campaign content.
Methods: We conducted formative community-engaged research with young PLWH in Lima, Peru to identify key campaign messages and change targets. Based on findings, we developed social media content addressing common myths and stereotypes regarding HIV, encouraging empathy for PLWH, and normalizing conversations around testing, prevention and treatment. Content was reviewed and approved by a community advisory board.
Additionally, seven top Peruvian influencers (four lifestyle influencers, one physician, one reality television star, and one newscaster) were paid to create and post content from their accounts. 85 local (unpaid) micro-influencers were invited to disseminate content. Social media metrics were documented.
Results: The campaign occurred over three months in 2024. We created and posted 49 videos to campaign Instagram and TikTok accounts, yielding 1,666,250 views, 2,686 comments, and 72,200 likes. The campaign generated 1,767 Instagram followers and 11,275 TikTok followers, 53.6% of whom were in Peru. The five top posts created by the DiME marketing team received 143,462 views, 322 comments, and 9,583 likes, while the five top influencer posts had a total of 502,520 views, 277 comments, and 23,023 likes. 37 unpaid micro-influencers (43.5%) reposted content.
There was a positive correlation between influencer dissemination and content reach. We received 639 direct messages inquiring about HIV services, requesting HIV-related information, or sharing personal experiences (Graphic).

Conclusions: Social media is a powerful tool for disseminating anti-stigma messaging, and collaboration with influencers to disseminate content was feasible and effective in expanding reach. Analyses examining the content's and campaign's ability to reduce HIV-related stigma are ongoing.

TUPED093

Evaluating strategies for STI partner notification and treatment in adolescent populations in Cape Town, South Africa

L. Fynn[1], M. Wallace[1], P. Fuzile[1], S. Sindelo[1], P. Vundhla[1], M. Mngqibisa[1], F. Bennin[1], A. Buttenheim[2], B. Maughan-Brown[3], L.-G. Bekker[1], E. Rousseau[1]
[1]Desmond Tutu Health Foundation, Cape Town, South Africa, [2]Penn Nursing and Perelman School of Medicine, Philadelphia, United States, [3]SALDRU, University of Cape Town, Cape Town, South Africa

Background: Adolescents in sub-Saharan Africa face significant barriers to STI prevention and treatment, including limited education on curable STIs and cultural taboos around discussing sexual health. These challenges result in low rates of STI testing, treatment, and partner notification among this vulnerable population. With the aim to obtain insights to improve STI notification options and

communication strategies, thereby reducing STI transmission and improving sexual health outcomes, we conducted research to understand communication practices, barriers, and facilitators in young people.

Methods: This study used focus group discussions (FGDs) with Youth Community Advisory Board (YCAB) members in Cape Town, South Africa, as part of the FastPrEP implementation science project. Six FGDs, each with 8–10 participants, explored communication practices, barriers, and facilitators related to STI partner notification and treatment. A rapid thematic analysis, supported by Dedoose software, was conducted to identify actionable insights. Feedback was obtained from participants on existing partner notification intervention prototypes as well as recommendations for alternative intervention options to improve communication. The FGDs were audio-recorded and subsequently transcribed for qualitative analysis.

Results: Participants emphasized the need for discretion, autonomy, and strategies to reduce stigma in interventions focused on partner notification and STI communication. Participants suggested offering couples' STI/HIV testing framed as a relationship-strengthening option rather than solely STI-focused. Educational approaches such as brief videos and role-playing were appreciated for their engaging format but required a careful balance of relatability and seriousness.

Alternative STI notification slips are effective with clear information, QR codes, and a focus on love and joint testing. Insights also indicated that delivering testing kits with neutral packaging or pharmacy pick-up options was viewed as a practical, stigma-reducing solution that facilitates private, safe conversations about testing.

Conclusions: Tailored interventions addressing communication, stigma, and privacy concerns are essential for STI prevention among adolescents and young people (AYP), according to the expert opinion from YCAB members. Incorporating community-driven feedback into partner notification and treatment strategies can enhance their acceptability and engagement.

This research will be used to develop an intervention aiming to address the identified barriers and communication gaps, ultimately enhancing sexual health outcomes and reducing STI transmission among adolescents.

TUPED094

Leveraging media advocacy for HIV testing and treatment: insights from young key populations in Nigeria

V. Thompson[1], R. Oyeniyi[1], O. Olajubu[1], K. Usoro[2]
[1]The Momentum Support Initiative, Lagos, Nigeria, [2]The Colored Space, Lagos, Nigeria

Background: In Nigeria, young key populations (KPs) living with HIV including LGBTQ+ individuals, people who use drugs, and sex workers are suffocated by layers of systemic stigma, media misrepresentation, and cultural invisibility fueled by the same-sex marriage prohibition act. These destructive narratives not only dehumanize but also isolate young KPs from life-saving HIV services, perpetuating cycles of fear and discrimination.

Recognizing the media's dual power to perpetuate harm or catalyze change, a strategy session funded by Y+ engaged young Key Populations (KP) living with/affected by HIV to address gaps in media representation and create actionable solutions for stigma reduction.

Description: The session engaged 15 young KP activists living with/affected by HIV aged 18-27 from diverse backgrounds over two days in Lagos State. The goal was to co-develop strategies for leveraging media to reshape public perceptions of young KPs living with HIV.

During this intensive session, participants dissected real-life examples of stigmatizing coverage, brainstormed approaches to amplify authentic KP narratives and foster allyship within the media industry, co-developed journalist training guides and ethical storytelling frameworks to promote accurate portrayals of young KPs living with HIV, and proposed innovative media campaign strategies tailored to highlight the lived experiences and resilience of young KPs living with/affected by HIV.

Lessons learned:

1. Value of KP-Led Insights: The session revealed the nuanced challenges young KPs face in media engagement, emphasizing the importance of community-led solutions.
2. Barriers to Change: Entrenched cultural biases and a lack of KP representation in decision-making roles within the media sector were identified as major hurdles.
3. Transformative Potential of Media: Thoughtfully crafted campaigns showcasing KP stories have the power to shift public attitudes, as evidenced by successful examples discussed during the session.

Conclusions/Next steps: Media advocacy, rooted in KP-led strategies, is essential for challenging stigma and fostering inclusivity. Recommendations from the session include scaling up young KP living with HIV involvement in media content creation, establishing partnerships with journalists for capacity-building, and launching nationwide campaigns to normalize KP narratives. This approach can drive systemic change, reduce stigma, and improve health outcomes for young KPs living with HIV.

TUPED095

Strengthening capacity of cooperatives for accelerating HIV impact reduction in Rwanda

O. Nyiramucyo[1], D. Mutambuka[1], J.B. Tugirimana[1], J. Mukantwari[2], G. Rwibasira[3], P. Mutesi[1]
[1]Rwanda Network of People Living with HIV/AIDS (RRP+), Kigali, Rwanda, [2]UNWOMEN, Kigali, Rwanda, [3]Rwanda Biomedical Center (RBC), Kigali, Rwanda

Background: To encourage People Living with HIV (PLHIV) to get involved in HIV prevention, care, and treatment as well as impact mitigation, Rwanda Network of People Living with HIV/AIDS (RRP+) was founded in 2003 and established 500 associations, 300 cooperatives, and 12 NGOs whose members are people living with or affected by HIV. Cooperatives provide financial resources, vocational training, and psychosocial counseling to PLHIV members, fostering resilience, reducing stigma, and promoting prevention and treatment awareness.

Description: From 2019 to 2022, RRP+ with the support of Rwanda Biomedical Center (RBC) and the United Nations Entity for Gender Equality and the Empowerment of Women (UNWOMEN), and Rwanda Cooperative Agency (RCA), 138 cooperatives benefited from financial and capacity building support to enhance their income generating activities as a way to promote independence and social economic inclusion.
RCA trained them on cooperative management and governance. 67% female and 33% male benefited doing small businesses, animal breeding, handicrafts, and agriculture, which help them to share experiences, enhance community education and create safe spaces.
Lessons learned: The members of the supported cooperatives have shown changes benefited from the cooperative income generating activities by exchanging information on HIV status and coping strategies to the community on HIV that they also have transformational potential in decreasing the negative effects of HIV.
The diverse range of income within PLHIV demonstrates the power of community-led approaches; they improved life condition as well as nutrition on 58%, school education facilitation of their kids on 59%, health insurance on 81% and other needs on 54%, through their generated income.
Also, 99% of members in our cooperative reached viral load suppression, which was partly attributable to routine health education during their activities. They have shown that working together in organizations can be an effective way of meeting HIV-related needs through resource sharing, knowledge sharing and creating an enabling environment.
Conclusions/Next steps: It can be concluded that establishing and running PLHIV cooperatives contribute to their well-being and social and economic situation.
RRP+ plans to continue educating and training cooperative members in order to encourage more cooperatives. It will focus efforts on building cooperatives for youth and engaging with other partners.

TUPED096

"*I'm not ready to go back to the clinic*": a photovoice study exploring the perceptions and apprehension of ALHIV to transition to adult care at a supportive transition facility

C. Petinger[1], T. Crowley[2], B. van Wyk[1]
[1]University of the Western Cape, School of Public Health, Cape Town, South Africa, [2]University of the Western Cape, School of Nursing, Cape Town, South Africa

Background: In South Africa, adolescents living with HIV (ALHIV) between the ages of 10-19 years make up approximately 4.2% (320,000) of people living with HIV. As they mature, ALHIV are expected to transition to adult care, where they have to assume greater responsibility for managing their condition and care pathway.
The aim of this research was to explore the experiences and needs of ALHIV with respect to the transition to adult HIV care.
Methods: We used the participatory action research method, photovoice methodology, to explore the transition experiences of ALHIV on ART who were on ART at an NGO-supported primary health care facility providing care in the form of youth clubs prioritizing peer support and individualized care.
Participants for this study were recruited from a public primary healthcare facility in an urban community. Adolescent participants (N=24) were given camera phones and instructed to take pictures how they feel about adult services and to describe their experience of living with HIV. Data was collected from the pictures and the focus group discussions around their chosen pictures. Audio data was digitally recorded and transcribed verbatim and subjected to thematic analysis using Atlas.Ti version 24.
Results: Five themes emerged from the analysis, namely, "'feelings' about transitioning to adult care", "self-management", "challenges to adherence", "psychosocial support", and "adolescent-friendly services: filling the gap".
The results of this study highlighted how the participants received unfavorable care in local clinics prior to joining the youth clubs. The clubs fostered resilience, adherence, and psychological well-being through creating a safe, supportive space. Within group sessions, the participants developed trusted relationships, practical experiences to remain adherent, confidence, and independence.
Conclusions: The findings of this study highlight the importance of holistic care for ALHIV, wherein peer support and guidance, individualized care to support adherence, and psychosocial support are prioritized.
Therefore, we recommend the development of similar services as it will ensure that adolescents are equipped with the necessary skills to remain in care post-transition and empower them with the confidence to maintain their overall well-being into adulthood.

TUPED097

Advancing cervical cancer literacy for WLHIV: Case based evaluation of a community led advocacy and literacy tool

M. Dukashe[1], A. Footman[2]
[1]HIV Survivors and Partners Network, Public Health, The Reeds, South Africa, [2]AIDS Vaccine Advocacy Coalition, STI, New York, United States

Background: In 2018, approximately 63% of women with cervical cancer were HIV positive, with 53% of those cases attributable to HIV in South Africa. HPV can lead to precancerous lesions and eventually cervical cancer. Cervical cancer (CC) can be prevented through Human Papilloma Virus (HPV) vaccination, screening and treatment of precancerous lesions.
Limited knowledge on the above subject for women living with HIV (WLHIV) may impede efforts to prevent cervical cancer in this population.
Description: We conducted an online survey with 210 WLHIV in September 2024 to assess WLHIV HPV, Pap smear (PS) and CC literacy levels and documented the results. The following month, we disseminated an online literacy

booklet as a tool to enhance their literacy levels, intending to create demand for CC screening and strengthen their advocacy efforts for HPV vaccination.
Finally, we conducted a case based evaluation and post-implementation review to assess the impact of the intervention in improving their literacy levels and in creating demand for CC and HPV screening services.
Out of the 210 WLHIV, only 47 % knew that HPV may eventually cause CC, 43% were aware that they can access or request a pap smear at local clinics, 37% ever accessed pap smear since their HIV diagnosis. In December 2024, we conducted a post intervention evaluation and discovered that their HPV, PS benefits and CC literacy improved to 91%, 100% were aware they have a right to request pap smear, 86% went to the clinic to do a pap smear and out of this number 14% had abnormal pap smear and were referred for further investigations.
Lessons learned: We have learned that lack of urgency or delayed actions and inadequate cervical cancer screening and prevention opportunities for women living with HIV will hinder efforts to eliminate cervical cancer and the reduction of HIV-related death. Communities have a power to change their environment and bring change.
Conclusions/Next steps: The program demonstrated a missed opportunity, and that the rights of WLHIV are neglected. We will disseminate the tool to ensure it reaches more WLHIV, introduce it to the government. We are hoping to see it integrated in HIV services.

TUPED098

A peer support approach to client management is not inferior to traditional case management: a study among young persons living with HIV in Nigeria

E. Nwanja[1], O. Onwah[1], U. Akpan[1], O. Toyo[1], C. Nwangeneh[2], C. Okolo[1], D. Ogundehin[3], M. Katbi[3], C. Obiora-Okafo[3], A. Idemudia[3], A. Aikhomokhor[4], R. Agulu[5], E. James[3], J. Pius[3], O. Oyelaran[3], O. Onyedinachi[1], A. Adegboye[3], A. Eyo[1]
[1]Excellence Community Education Welfare Scheme, Uyo, Nigeria, [2]FHI360, Abuja, Nigeria, [3]United States Agency for International Development (USAID), Office of HIV and TB, Abuja, Nigeria, [4]National AIDS, STI and Viral Hepatitis Control Program, Abuja, Nigeria, [5]National Agency for the Control of AIDS, Abuja, Nigeria

Background: Peer supporters have effectively provided psychosocial support to young persons living with HIV (YLHIV), but this has not been well documented in Southern Nigeria. In 2023, the PEPFAR/USAID-funded ECEWS ACE-5 project trained and integrated peer supporters into clinical teams to support the management of YLHIV.
This study compared HIV treatment outcomes between YLHIV managed by peer supporters and those managed by traditional case managers in Southern Nigeria.
Methods: This retrospective cohort study analysed data from electronic medical records of YLHIV aged 15-24 years receiving antiretroviral therapy (ART) as of September 2023 at 24 health facilities in Akwa Ibom and Cross River States. These facilities implemented both traditional and peer-based case management for YLHIV.
Data extracted included age (15-19 years, 20-24 years), sex, case manager type (peer supporter or traditional case manager), duration on ART, ART status, and viral load (VL) results with dates, as of September 2024. In the peer-based approach, YLHIV were randomly assigned to peer-supporters, to a maximum of 150 YLHIV per peer-supporter, with the remaining YLHIV assigned to traditional case managers.
Retention was determined by "active" ART status as of September 2024), while viral suppression was categorised into undetectable (<50 copies/ml), and suppressed (51-1000 copies/ml). Chi-square was used to compare retention and viral suppression as of September 2024 between clients managed by traditional case management (YLHIV assigned to case managers who also managed adults) and those managed via the peer-based approach between September 2023 and September 2024.
Results: A total of 4,979 YLHIV were included: 79.0% (3,932) were female, 75.7% (3,768) were aged 20-24 years, 23.4% (1,169) were managed by peer supporters, with a median duration on ART of 4.1 years (IQR=2.8-4.9).
Retention was comparable between YLHIV managed by peer supporters and those managed by traditional case managers (93.4% (1092/1169, vs 94.9% [3617/3810]; p=0.411, respectively).
Undetectable viremia was 88.5% (969/1095) among those managed by peer supporters compared to 93.6% (3,408/3,640) and those managed by traditional case managers (p<0.001), while suppressed VL was 96.9% (1,061/1095) vs 98.9% (3,599/3,640) (p<0.001), respectively.
Conclusions: Peer-based approaches are comparable in clinical outcomes to traditional case management and offer additional psychosocial support advantages for YLHIV.

Key populations and other vulnerable populations: Behavioural, social, cultural, structural and multilevel issues, contexts and interventions

TUPED100

Factors associated with PrEP awareness and demand amongst migrants in Europe

A. Flaherty-Gupta[1], D. Onyango[1], H. Majdoub[1], E. Sesange[1], T. Kouadio[2], G.R. Freeman Browne[3], E. Erevbenagie-Johnbull[4], J.P. Ngueya[5], J.P. Nkuibo[6], R.I.K.O. Babu[7], A. Ajomale[8], P. Lawson[8], W. Gomes[9]
[1]Africa Advocacy Foundation, London, United Kingdom, [2]Plateforme Prevention Sida, Brussels, Belgium, [3]GRN Europe, Barcelona, Spain, [4]Generation for Change CY, Nicosia, Cyprus, [5]Youth of the World in Action, Paris, France, [6]Unaffiliated, Berlin, Germany, [7]Open Paths Athens, Athens, Greece, [8]Noaks Ark Mosaik, Malmo, Sweden, [9]GAT, Lisbon, Portugal

Background: The ECDC reported data on migrant PrEP uptake is scarce and that the medication remains inaccessible for undocumented migrants, despite finding that migrants accounted for 48% of all new HIV diagnoses in Europe in 2022. We sought to understand PrEP awareness and demand rates amongst migrants.
Methods: Between October 2024 – January 2025 we conducted a PrEP awareness and demand study amongst migrants in 14 European countries (Belgium, Cyprus, Finland, France, Germany, Greece, Malta, Netherlands, Poland, Portugal, Spain, Sweden, Switzerland, UK). Study variables were collected through peer-led outreach in a community-based survey of all participants.
Results: Preliminary analysis of responses from 439 migrants (average age of 34 years, 41% male) shows 33% reported asylum seeker migration status, 20% reported holding a visa and 8% reported refugee status.
Substantially higher levels reported knowing their own HIV status as compared to their partner(s)' (75% aware of their status versus 48% aware of partner(s)'s). Roughly similar levels reported having ever discussed PrEP with a healthcare provider or community worker (28%) as reported an accurate understanding of PrEP (29%), as assessed by correctly answering follow-up questions describing the medication.
Despite condoms being the most reported HIV prevention method amongst our sample (reported by 33%, n=145 of sample), the most commonly reported risk factor (n=100) was condomless sex with partner(s) with unknown HIV status in the past year. The most common barrier to PrEP access (n=85) was lack of knowledge about where to get it and the most common reason (n=60) to not use PrEP was lack of knowledge about PrEP. Though only 10% reported current PrEP usage, 48% of our sample indicated they would use PrEP if offered.
Conclusions: PrEP uptake and awareness rates are low amongst migrants in Europe. Community-led, culturally-sensitive PrEP messaging is needed to increase HIV prevention method knowledge and linkage to PrEP services amongst migrants.

TUPED103

Prioritization of holistic care by pregnant women and mothers of infants when considering HIV research engagement

G. White[1], E.R. Masese[2], D. Kinyanjui[3], E. Were[4], C. Halverson[5], M.A. Ott[6], J.G. Carlucci[1,7], J. Humphrey[1,7], E. Wahome[7], D. Munyoro[7], A. Nafiseh[1], K. Cunningham[1], M. Cory[1], M. Nyalumbe[7], R.A. Ombitsa[7], M.S. McHenry[1,7]
[1]Indiana University School of Medicine, Department of Pediatrics, Indianapolis, United States, [2]Moi University, Department of Sociology, Psychology, and Anthropology, Eldoret, Kenya, [3]Moi University School of Medicine, Department of Mental Health and Behavioral Sciences, Eldoret, Kenya, [4]Moi University School of Medicine, Department of Reproductive Health, Eldoret, Kenya, [5]Indiana University School of Medicine, Center for Bioethics, Indianapolis, United States, [6]Icahn School of Medicine at Mount Sinai, Arnhold Institute for Global Health, Department of Global Health, New York City, United States, [7]Academic Model Providing Access to Healthcare Kenya, Eldoret, Kenya

Background: The ethical principle of respect for persons requires that investigators design research that is responsive to participants' preferences and concerns. This is especially important when engaging vulnerable populations such as mothers of infants and pregnant women living with HIV (MIPWLHIV).
This qualitative study was designed to characterize the understanding and prioritization of holistic care by MIPWLHIV when considering HIV research engagement.
Methods: This qualitative study was conducted within the Academic Model Providing Access to Healthcare in Eldoret, Kenya. We performed 45 semi-structured interviews between January and September 2024.
Interviews were conducted with 30 MIPWLHIV and 15 mothers without HIV who were actively or recently participating in research with their infants. Interviews were audio-recorded, transcribed, translated, and analyzed by multiple coders using a priori coding, constant comparison, axial coding, and triangulation.
Results: Holistic care emerged as a major factor facilitating longitudinal research participation. Dimensions of holistic care that motivated participants to remain engaged included observation of their child's health and development, increased access to referrals and healthcare, reimbursement, and education about topics including parenting, living with HIV, preventing vertical transmission, and their child's health.
The participants often viewed contact and visits with the research team as opportunities for positive interactions without stigma where MIPWLHIV reported feeling cared for, free to ask questions, accepted, and empowered.
Participants identified ways investigators engage MIPWLHIV that promote respect for participants and accommodate their desire for holistic care. These include the return and explanation of all tests results, dynamic reimbursement based on the burden of participation, providing a supportive visit environment, checking on participants between visits, and offering educational resources, re-

ferrals, and guidance when needed. Participants also reported concerns surrounding how they and their children navigate the potential loss of support when their research participation ends. For this reason, they emphasized the need for clear communication about the ongoing relationship between research and participants after the study period.

Conclusions: Holistic engagement and understanding of the factors affecting participation enable researchers to honor participants' dignity and prevent harm while uplifting MIPWLHIV and their children in their health journeys.

TUPED104

The perception of HIV pre-exposure prophylaxis amongst sex workers in Buea, Cameroon

F. Emilia Nde[1], M.L. Akeh[2], Y. Peter Nshiom[3]

[1]School of Health and Medical Sciences, Kesmonds International University, Public Health, Ngaoundere, Cameroon, [2]Clinical Research Education Networking and Consultancy, Yaounde, Cameroon, [3]School of Health and Medical Sciences, Kesmonds International University, Ngaoundere, Cameroon

Background: Pre-exposure prophylaxis or "PrEP" is the use of antiretroviral medication by HIV negative people to reduce the risk of HIV acquisition. Despite its proven efficacy, the uptake of PrEP among sex workers in Cameroon remains low, hindered by various factors including lack of awareness, biased attitude, stigma, and limited access to healthcare services.

The aim of this research is to assess the knowledge, attitude, and perceptions of sex workers on HIV pre-exposure prophylaxis for HIV prevention in Buea, Cameroon.

Methods: A cross-sectional community-based study was conducted on sex workers in Buea from September 2024 to October 2024 using multistage sampling. A structured questionnaire was used for data collection. A scoring method was used and participants who scored above average were classified as having good knowledge, attitude, and perception.

Multivariate logistic regression was used to determine factors associated with the uptake of PrEP with a 95% confidence interval in the final model.

Results: All sex workers were female with 20% having no formal education, 27.3% earned below 50,000frs, 22.7% stayed in rural areas and relocated as a result of the crisis. 94% had a good knowledge, attitude, and perception of PrEP. Despite the huge percentage, 8.7% were not currently on PrEP due to stigma, 66.7% was due to unavailability, 71.3% have never been offered PrEP by a health provider while 76.7% have never used PrEP. This was because, 24.7% were afraid of the side effects while 6.7% did not trust it. When asked what will encourage their use of PrEP, 28.7% said free access, 35% said easy availability, 20.7% said more information about PrEP while 6.7% said fewer side effects.

Multivariate analysis revealed the following factors were associated with the knowledge, attitude and perception of PrEP. Sex workers who had primary (AOR=0.012 95%CI: 0.000-0.800) and secondary education (AOR=0.017 95%CI:0.000-0.677) respectively, participants with poor attitude towards PrEP(AOR=55.833 95% CI: 3.432- 908.230).

Conclusions: While there is a generally high level of knowledge, attitude and perception toward PrEP, economic, accessibility and availability, challenges remain barriers. Therefore, making PrEP free, available and accessible to sex workers will increase their usage.

TUPED107

Acceptability of telehealth for PrEP care among Latine sexual minority men

E.A. Andrade[1,2], G. Morales[3], L. Marrero[4], S. Rivera[5], D. Watnick[6], J. Rojas Antigua[2], M. Akiyama[2], V.V. Patel[2], J. Ross[2]

[1]University of Pittsburgh, Behavioral and Community Health Sciences, Pittsburgh, United States, [2]Albert Einstein College of Medicine, Division of General Internal Medicine, Bronx, United States, [3]Latino Commission on AIDS, New York, United States, [4]Voces Latinas, Queens, United States, [5]Destination Tomorrow, Bronx, United States, [6]Albert Einstein College of Medicine, Division of Pediatrics, Bronx, United States

Background: Latine sexual minority men (LSMM) are disproportionally impacted by HIV in the United States and are experiencing increasing incidence rates. Despite the elevated risk among LSMM, pre-exposure prophylaxis (PrEP) uptake has remained low. LSMM face unique multilevel barriers to access PrEP, telehealth has been shown to be an effective strategy for PrEP implementation, but whether this modality is of interest and acceptable to LSMM remains unclear.

Methods: We conducted a mixed-methods study during 2023-2024 to assess interest in and acceptability of telehealth for PrEP among LSMM in New York City, in collaboration with three community-based organizations (CBO) that provide HIV prevention services. CBO clients were recruited to an online cross-sectional survey assessing experience with, interest in, and acceptability of telehealth. Bivariate tests were conducted to identify factors associated with telehealth interest and acceptability. We conducted qualitative interviews with LSMM referred by CBOs to telehealth (n=14) or in-office (n=10) PrEP care; transcripts were analyzed thematically to identify social conditions shaping preference for telehealth.

Results: Among 145 LSMM who completed the survey, median age was 29 years, 76% (n=111) were immigrants, and 73% (n=106) had health insurance. While most (80%, n=117) had no previous telehealth PrEP experience, a majority 59% (n=69) endorsed interest in this modality. Common motivations for using telehealth included saving time (68%), convenience of not traveling to appointment (58%), and feeling it was more private than a provider's office (32%).

Qualitative themes that emerged among participants with telehealth experience included saving time required for in person care, having flexibility to be at work or home, and feeling comfortable talking about sexual health on video. Participants who chose in-office care felt that this

modality provided them with a more personal connection to their provider, and the opportunity to care for other health concerns.

Conclusions: Among LSMM clients of CBOs in NYC, interest and acceptability of telehealth was high, driven by a desire for flexibility and ease of access. However, some LSMM preferred in-office care, valuing connectedness with their providers over convenience. Telehealth-based PrEP delivery can meet the needs of LSMM and should be offered as a care option to this population.

TUPED108

"This is about someone's life; everyone is responsible for their own life": views on research consent among adolescents and guardians within Uganda's Rakai community cohort study

P. Kreniske[1], N. Haba[2], H. Isenberg[1], F. Nalugoda[3], M.A. Ott[4], T. Lutalo[3], N. Nakyanjo[3], W. Ddaaki[3], D. Isabirye[3], R. Nakubulwa[3], R. Ssekebugu[3], E. Spindler[5], B.X.J. Chan[1], K. Sievwright[5], G. Kigozi[3], D. Serwadda[6], N. Sewankambo[6], S. Hoffman[5], J. Santelli[5]

[1]City University of New York, Graduate School of Public Health and Health Policy, New York, United States, [2]Weill Cornell Medical College, New York, United States, [3]Rakai Health Sciences Program, Rakai, Uganda, [4]Icahn School of Medicine at Mount Sinai, New York, United States, [5]Columbia University Irving Medical Center, New York, United States, [6]Makerere University, Kampala, Uganda

Background: Most countries allow minors (<18years) to consent for some sexual and reproductive healthcare, but many require parent/guardian (hereafter guardian) permission to participate in research. Guardian permission is an important barrier to adolescent inclusion in biomedical prevention research on sensitive topics like HIV and sexual and reproductive health (SRH), as it is a disclosure risk for sensitive information to guardians.

Globally, adolescents as young as 14 demonstrate the cognitive capacity to consent, yet sociocultural perspectives on decision making may differ. Thus, our analysis examined adolescent and guardian perspectives on decision-making for adolescent research participation.

Methods: Adolescents were recruited from the Rakai Community Cohort Study in Uganda. Participants > 18 years consented, < 18 years assented with guardian permission. A systematic decision-making analysis was conducted using semi-structured interviews from 80 adolescents (early (10-14yrs), n=40; middle (15-17yrs), n=20; and late (18-19yrs), n=20) with guardians (n=24) completing in-depth interviews.

Results: Most adolescents reported making their own decisions to participate in research. This increased by age (early adolescents 18/40; middle 13/20; older 14/20). As a 16-year-old girl explained: "because this is about someone's life, everyone is responsible for their own life,".

Many also reported that participation in research was their guardian's decision (early 11/40; middle 6/20; older 6/20), "because [parents] have nurtured them up to where they are, and paid school fees" (14-year-old girl).

Among early adolescents, a subset (8/40) reported that the decision was made jointly: "Adolescents should seek parent's advice…because parents are more experienced than an adolescent who…may not be aware of the benefits and risks associated with participating in the study," said a 15-year-old girl.

Over half of guardians of early (n=5/10), middle (n=4/8) and late adolescents (n=5/6) believed it was the adolescents' decision: "because they tend to get engaged in certain practices without our knowledge, more especially having sex" (36 years, woman).

Conclusions: Most adolescents and guardians agreed that the decision to participate in research should be made by the adolescent. Findings underscore the importance of developing consent policies that prioritize adolescent autonomy while maintaining appropriate safeguards, ensuring inclusion of adolescents in biomedical trials and advancing HIV prevention efforts.

Key populations and other vulnerable populations: Behavioural, social, cultural, structural and multilevel issues, contexts and interventions

TUPED101

Female sex worker preferences for HIV pre-exposure prophylaxis delivery in Uganda: a discrete choice experiment

R. Mpirirwe[1], A. Mujugira[2], K. Moses[3], A. Katahoire[1]

[1]Makerere University, Clinical Epidemiology and Biostatistics, Kampala, Uganda, [2]Infectious Diseases Institute College of Health Sciences Makerere University, Research, Kampala, Uganda, [3]Makerere University, Family Medicine, Kampala, Uganda

Background: Cisgender female sex workers (FSWs) in sub-Saharan Africa have a high risk of HIV acquisition, highlighting the need for innovative approaches to expand coverage of evidence-based HIV prevention methods, including oral pre-exposure prophylaxis (PrEP). Our study aimed to identify FSWs' preferences for a PrEP delivery model with structured choices for delivery location, services offered, and adherence support.

Methods: We conducted a discrete choice experiment (DCE) among cisgender FSWs ≥18 years recruited from the Most At-Risk Population Initiative (MARPI) clinic in Kampala, Uganda, between October and November 2023. FSWs were recruited using consecutive sampling. To determine the most effective PrEP delivery method for FSWs, we created eight choice sets, each with three alternative combinations of PrEP service attributes and an opt-out using a D-efficient experimental design.

Participants were presented with three alternatives, plus an opt-out (no model selected), and asked to make selections based on four distinct attributes: the PrEP provider, place of delivery, delivery channel, and support services. We analyzed FSW preferences and attribute trade-offs

using a panel data mixed model and identified the preferred PrEP delivery model using the highest median utility score.

Results: Overall, 203 participants completed the DCE. The median age was 24 years (interquartile range [IQR] 20-32). Most FSWs preferred receiving PrEP from a healthcare worker at the clinic with short message service (SMS) reminders for adherence support (median utility score 0.87; interquartile range [IQR] 0.82, 0.94). This preference remained consistent across all age groups, with a median utility score of 0.88 for ages 15-19, 0.87 for ages 20-24, and 0.85 for ages ≥25.

Conclusions: FSWs preferred to receive PrEP care directly from providers at healthcare facilities. They highlighted the need for additional support, such as SMS reminders, to improve adherence and prevent HIV acquisition.

If implemented, this preferred model could increase prevention coverage and inform future approaches to delivering PrEP through the Uganda National PrEP Program.

TUPED102

Advancing HIV care for blind and deaf women in Kampala District, Uganda: lessons from a community-centred, gender-responsive approach

R.M. Kemigisha[1], T. Christine[1]

[1]Clarke International University, Public Health, Kampala, Uganda

Background: Blind and deaf women in Kampala, Uganda, face significant challenges in accessing HIV prevention, treatment, and care services due to the intersecting impacts of disability, stigma, and gender inequality.

This project aimed to design, implement, and evaluate a community-centred, gender-responsive model to address these barriers and improve health outcomes for this marginalized group.

Description: The programme was conducted over 18 months in Kampala District, integrating HIV services with accessible tools such as Braille and sign language resources, peer-led support groups, and tailored mental health interventions.

A participatory approach was adopted, involving affected women, local organizations, and healthcare providers in co-developing interventions. Key activities included mobile clinics, community-led awareness campaigns, economic empowerment initiatives, and training sessions for healthcare workers on disability inclusion. The target population included blind and deaf women aged 18-45 living with or at high risk of HIV.

Lessons learned: The programme achieved a 48% increase in HIV testing and a 32% improvement in treatment adherence among participants. Peer-led initiatives and economic empowerment activities were pivotal in fostering trust and increasing engagement.

However, challenges such as limited transportation options and caregiver stigma highlighted the need for sustained support. The participatory approach ensured interventions were well-tailored to the needs of the community, underscoring the value of inclusive practices in addressing intersectional vulnerabilities.

Conclusions/Next steps: This project demonstrates the effectiveness of community-centred, gender-responsive HIV care models in Kampala. Scaling these initiatives, addressing structural challenges, and leveraging technology for accessibility will be key to sustaining progress. These lessons provide a blueprint for advancing equitable HIV care for marginalized populations in Uganda and beyond.

TUPED105

Using coordinated care mechanisms to improve treatment outcomes for hidden and hard-to-reach sex workers in Marsabit, Kenya

D. Kwala[1], A. Abdullahi[1], M. Rasugu[1], J. Achieng'[1], P. Mwangi[1]

[1]Bar Hostess Empowerment and Support Programme, Health, Nairobi, Kenya

Background: Bar Hostess Empowerment and Support Programme (BHESP) has been implementing HIV prevention and care interventions tailored to female sex workers in Kenya's arid and semi-arid lands (ASAL) since 2021. Hidden and hard-to-reach populations, such as Muslim and migrant sex workers, face barriers to accessing care due to cultural, religious, and geographic challenges. In November 2023, BHESP adopted a Person-Centred Care (PCC) approach to address these barriers and strengthen coordinated care mechanisms aimed at improving HIV treatment outcomes for these marginalized groups.

Description: Between November 2023 and January 2024, BHESP reached 614 clients through interventions targeting both those living with HIV to support retention in care and those vulnerable to HIV acquisition. The approach leveraged healthcare providers and peer navigators to foster strong client-provider relationships while ensuring cultural and religious sensitivity in care delivery.

Empowerment sessions integrated into community engagements provided education, emotional support, and socioeconomic and mental health support. These sessions were held at hotspots accessible to Muslim and migrant sex workers. A coordinated care mechanism involving healthcare providers, peer navigators, and community leaders facilitated continuous follow-up, adherence support, and tailored referrals. Exit interviews were conducted to assess the acceptability and impact of the interventions.

Lessons learned: Exit interviews with 216 female sex workers revealed that 179 (82.9%) preferred care that was culturally sensitive and allowed for their active involvement in health decisions. The number of hidden sex workers accessing services increased by 37%, with clients reporting improved trust and satisfaction. Coordinated care enabled early identification of clinical challenges, such as a suspected treatment failure in a Muslim sex worker, who achieved viral suppression by February 2024 following intensive adherence support

Conclusions/Next steps: Coordinated care mechanisms significantly improved access to HIV care for hidden and hard-to-reach sex workers in Marsabit. These interventions, addressing cultural and religious dynamics, empowered clients to take responsibility for their health.

BHESP recommends scaling up coordinated care models for all key populations in ASAL regions to achieve equitable and sustainable health outcomes.

TUPED106

Lessons learned from deploying the PrEP Uganda mobile application for HIV prevention

I. Kagolo[1], L.H. Kamulegeya[1], J. Ssenkumba[1]
[1]Africa Center for Applied Digital health, Kampala, Uganda

Background: Digital health innovations are transforming HIV prevention, particularly in resource-limited settings like Uganda, where structural barriers, stigma, and non-adherence hinder pre-exposure prophylaxis (PrEP) uptake and retention. The PrEP Uganda app, developed under the USAID Social and Behavior Change Activity (2020–2024), aimed to address these barriers through an integrated digital platform. The app was designed to improve PrEP access, adherence, and education, targeting individuals at high risk of HIV infection, including key populations such as men who have sex with men (MSM) and female sex workers (FSWs).
Description: The PrEP Uganda app combined a PrEP site locator, live chat with healthcare providers, medication reminders, and multimedia educational content. The app was accessible via Google Play for Android devices and supported by robust backend infrastructure. It featured offline geolocation to over 290 PrEP service sites across Uganda, confidential live chat capabilities, and customizable medication reminders. Educational resources included videos, infographics, and interactive content addressing HIV prevention myths and adherence strategies. Between 2022 and 2024, the app was downloaded 1,128 times, with 1,110 active monthly users. User demographics highlighted high adoption among younger populations and urban regions like Kampala and Masaka.
Lessons learned: The app demonstrated its ability to bridge critical gaps in HIV prevention. The PrEP site locator enabled equitable access to services, while the live chat feature reduced stigma and provided confidential support, facilitating 2,098 interactions with healthcare providers. Customizable reminders improved adherence for 72.3% of users who enabled this feature, and multimedia content boosted engagement, with 76% of users reporting increased confidence in managing PrEP. However, challenges included limited adoption in rural areas due to low smartphone penetration and internet connectivity, as well as a lack of local language support.
Conclusions/Next steps: The PrEP Uganda app highlights the transformative potential of digital health tools in HIV prevention. Iterative improvements, such as expanding offline functionality and incorporating local languages, are needed to enhance inclusivity. The app serves as a scalable model for leveraging mobile technology to address HIV prevention barriers in resource-limited settings, with significant implications for broader global health strategies.

Mental health and well-being interventions, programmes and models

TUPED109

The impact of COVID-19 changes and disruptions on generalized anxiety disorder among young adults living with HIV (YLHIV) in Uganda

A.Z. Girma[1], R. Brathwaite[1], Y. Karamagi[2], N. Nakasujja[3], P. Nabunya[1], O.S. Bahar[1], F. Ssewamala[1]
[1]Washington University in St. Louis, Brown School, St. Louis, United States, [2]Mildmay Uganda, Kampala, Uganda, [3]Makerere University, Department of Psychiatry, College of Health Sciences, Kampala, Uganda

Background: The COVID-19 pandemic has posed unique mental health challenges, particularly for young adults living with HIV (YALHIV) in low-resource settings like Uganda. This population already faces compounded vulnerabilities due to stigma, limited resources, and chronic illness. Using the Social Determinants of Health framework, this study investigates the association between COVID-19-related disruptions and generalized anxiety disorder (GAD) levels among YALHIV.
Methods: Data were drawn from 500 YALHIV (aged 19–25) participating in the Suubi+Adherence R2 COVID-19 Supplement. Anxiety was assessed using the GAD-7 questionnaire, while COVID-19-related disruptions were measured via an 8-item Coronavirus Impact Scale. Hierarchical logistic regression and multivariate linear regression were employed to analyze the relationships between specific disruptions and anxiety levels, controlling for key demographic variables and intervention group assignment.
Results: Severe disruptions in routines and family stress were strongly associated with increased GAD levels ($p < 0.01$). Female participants showed higher susceptibility to GAD compared to males. Additional contributors to anxiety included financial instability, stress due to the pandemic, and reduced access to mental health services. Sensitivity analyses confirmed these findings, emphasizing the significance of routine and familial stability in mitigating anxiety.
Conclusions: This study highlights the exacerbation of anxiety among YALHIV due to pandemic-induced disruptions, underscoring the need for tailored interventions. Strategies to stabilize routines, support family dynamics, and ensure mental health service accessibility could mitigate anxiety impacts during future crises. These findings are pivotal for designing resilient mental health interventions in similar low-resource contexts.

TUPED110

Mental health integration in routine service delivery to Adolescent Girls and Young Women (AGYW) in Uganda

I. Sebuliba[1], A. Namale[1], S. Nantume[2], J. Cheptoris[3]
[1]Makerere University, School of Public Health, Kampala, Uganda, [2]Cennters for Disease Control and Prevention, Division of Global HIV and TB, Kampala, Uganda, [3]Ministry of Health, AIDS Control Program, Kampala, Uganda

Background: Globally, 14% of 10-19-year-olds experience a mental disorder, a global burden of disease in this age group. Anxiety, depression, substance use disorders, post-traumatic stress disorder and psychotic illness are commonly associated with decreased testing for HIV, reduced likelihood of initiating ART & retention care. Worldwide prevalence of child and adolescent mental disorders of approximately 20% and access to mental health services is hindered by limited knowledge and awareness on mental health plus inadequate availability to such services. UNAIDS and WHO emphasize the need for mental health assessment, diagnosis and psychotherapy integration in HIV prevention and treatment services. HIV prevalence among Ugandan AGYW aged 10–24 years is four times higher than in their male counterparts while depressive disorders are 22.2% and 21.2% in children and adults respectively. PEPFAR Uganda, integrated mental health services into the DREAMS program for adolescent girls and young women 10-24 years of age in 2022.
Description: The program adopted the WHO self-reporting questionnaire (SRQ20) as screening tool for anxiety and depression. Experienced peers in the program and social workers were trained in mental health psycho education, screening, and psychotherapy to support the roll out. An individual with a total score of 6 and above is deemed to have anxiety and depression and any report of having thought of ending your life is addressed immediately. The assessments are done every six months as part of the DREAMS program in the country.
Lessons learned: In the period of 18 months since program inception on the DREAMS program 270,824 AGYW have been assessed of which 9.6% were found to have symptoms of anxiety and depression, 3.9% of these has suicidal tendencies and 1% were at risk of alcohol and substance abuse. Anxiety and depression are mainly experienced by AGYW above 14 years and 92% of the AGYW that received psychotherapy interventions had symptoms address.
Conclusions/Next steps: Longitudinal tracking of individual to monitor anxiety and depression status change for AGYW on the program is being done to monitor any possible relapses and new cases that previously showed no symptoms. Expand mental health services to Adolescent Boys and Young Men met though the program.

Gender, sexuality and sexual cultures: Meanings, identities, norms and interventions

TUPED111

Assessing the state of peer-reviewed published HIV research concerning sexual minority women globally: a scoping review

J.L. Glick[1,2], M. Schor[1], F.M. Wolf[3], M. Nguyen[4], L. Rosman[5]
[1]School of Public Health, Louisiana State University Health Sciences Center (LSUHSC), Community Health Science & Policy (CHSP), New Orleans, United States, [2]Johns Hopkins Bloomberg School of Public Health, Department of Health, Behavior and Society, Baltimore, United States, [3]University of California San Francisco, Department of Epidemiology & Biostatistics, San Francisco, United States, [4]Herbert Wertheim School of Public Health & Human Longevity Sciences, University of California San Diego, La Jolla, United States, [5]Johns Hopkins School of Medicine, Welch Medical Library, Baltimore, United States

Background: Sexual minority women (SMW) face unique and exacerbated HIV risks compared to their heterosexual counterparts. However, to date, no systematic methods have been utilized to assess the breadth of current knowledge on the topic.
Therefore, to assess the current landscape of relevant literature, we conducted a scoping review of studies published in English before May 2023 reporting HIV-related outcomes among SMW.
Methods: Following PRISMA-ScR guidelines, we conducted a scoping review of peer-reviewed health literature on sexual minority women and HIV. We searched PubMed (PubMed.gov), Embase (Elsevier), PsycInfo (EBSCO), Sociological Abstracts (ProQuest), and CINAHL (EBSCO).
Eligibility criteria included studies published in English containing disaggregated data on SMW and reported any findings related to HIV and conceptualized by the study authors as in the context of HIV. Findings were summarized using systematic narrative synthesis.
Results: Our search identified 7,615 deduplicated studies; 187 met eligibility requirements. Most studies were conducted in the US (n=122; 65%) and utilized quantitative methods (n=154; 82%), most commonly cross-sectional (n=139; 74%), using survey data (n=150; 80%), and obtained via convenience sampling (n=114; 61%).
Overwhelmingly, studies did not utilize community-engaged methods (n=173; 93%). Publication numbers show an upward trend over time. Forty-eight studies (26%) focused exclusively on SMW. Inclusion of demographic data on SMW (sub)samples varied; about half of studies reported on age (n=99; 53%) and race (n=97; 52%); about two thirds reported on sexual orientation (n=127; 68%).
The included studies covered a range of HIV-related outcomes including: sexual risk behaviors (n=110; 59%), substance use (n=78, 42%), sexually transmitted infections (n=55, 29%), healthcare access and service utilization (n=38, 20%), intimate partner violence (n=28, 15%), mental health (n=27, 14%), stigma (n=18, 10%), and incarceration (n=15, 8%).

Conclusions: To our knowledge, this is the first review to systematically identify and synthesize scientific literature regarding the state of HIV research inclusive of SMW. Our review offers insights on a range of key methodological and topical gaps in the current literature related to SMW and HIV, which can inform future research and practice efforts to improve HIV-related outcomes among SMW.

TUPED112

No Means No Worldwide (NMNW): a sustainable approach in achieving HIV prevention among adolescent boys and girls aged 9-14 years in Benue State

G. Ezekwe[1], S. Oyibo[1], A. Ejideh[2], C. Shiche[1], I. Teryima[1], O. Onyezue[1], J. Ibiloye[1], E. Ejimkaraonye[1], E. Achimugu[1], K. Ngwoke[1], B. Amoo[1], M. Obaje[1], U. Okezie[1], I. Onwuatuelo[1], P. Okonkwo[1]
[1]APIN Public Health Initiative, Abuja, Nigeria, [2]Benue State University Teaching Hospital, Paediatrics, Makurdi, Nigeria

Background: Gender-based violence (GBV) is both a cause and consequence of HIV, significantly affecting clinical outcomes and posing a barrier to epidemic control. Addressing GBV and gender inequality is critical for ending the AIDS epidemic and protecting human rights. In Benue State, high rates of GBV emphasize the urgent need for evidence-based interventions. No Means No Worldwide (NMNW) program is a dual gender intervention aimed at preventing gender based violence by educating adolescents aged 9-14years. The program delivers 10 transformative modules in either five 2-hour or ten 1-hour sessions across schools, communities, and religious centers.
This study evaluates the impact of the NMNW intervention on the knowledge of GBV among boys and girls aged 9-14 years in Benue state.
Methods: In Benue state, 4,404 adolescent boys and 4,270 adolescent girls were enrolled into the program between October 2023 and September 2024, with 2,526 boys and 2,788 girls voluntarily selected for pre and post-intervention assessments after completion of the five 2-hour classes or ten 1-hour classes to evaluate their knowledge of GBV. A pre and post study was used to measure the program's impact on GBV knowledge. Microsoft Excel was used to compute test scores. Statistical analysis was conducted using SPSS, to assess the significance of the changes in knowledge scores between the pre- and post-intervention.
Results: A total of 5314 participants, 2526 boys and 2788 girls completed both pre-and post-intervention questionnaires. An improvement in knowledge was found in both with statistical significance at (P<0.05). Receiving the intervention improved the awareness and prevention of GBV from 18% to 86% (boys) and 21% to 92% (girls) with statistical significance (P<0.05). These results demonstrates that the intervention was effective in improving knowledge of GBV among the study population.
Conclusions: Findings from this study highlight the significant impact of the NMNW program in improving knowledge of GBV among adolescent boys and girls aged 9-14 years.
These results emphasize the program's potential as an effective, scalable, and adaptable model for GBV prevention and *as* a tool for advancing HIV prevention and control efforts in this subpopulation. We recommend further research on leveraging GBV knowledge to combat GBV

TUPED119

Exploring gender disparities in viral load suppression among people with HIV: insights from a cohort study at the University Teaching Hospital of Kigali

J.J. Irakiza[1,2], C. Ntagungira[3], N. Umuhoza[4], R. Mukantegeye[5], M. Cyiza[5], T. Mpunga[5]
[1]University Teaching Hospital, HIV/AIDS, STIs and Viral Heapatitis, Kigali, Rwanda, [2]Infection Prevention and Control Rwanda Organization (IPCRO), Musanze, Rwanda, [3]University Teaching Hospital of Kigali, HIV/AIDS, STIs and Viral Heapatitis, Kigali, Rwanda, [4]University Teaching Hospital of Kigali, Kigali, Rwanda, [5]University Teaching Hospital of Kigali, Kigali, Rwanda

Background: Gender disparities in HIV treatment outcomes present a major obstacle to achieving sustained viral load suppression (VLD < 1000 copies/ml), a key indicator of effective HIV care. In Rwanda, where the national goal is to end HIV by 2030, understanding gender-based differences in antiretroviral therapy (ART) outcomes is essential. This study examines the 2023-2024 cohort of people living with HIV (PLHIV) at the University Teaching Hospital of Kigali (CHUK) to evaluate viral load suppression rates by gender and age.
The objective is to explore how gender norms influence ART outcomes and provide data to support the development of targeted interventions aimed at improving HIV care in Rwanda.
Methods: This retrospective cohort study analyzed routine clinical data of PLHIV at CHUK during the 2023-2024 period. Participants were stratified by gender and categorized into six age groups: under 10 years, 10-14 years, 15-19 years, 20-24 years, 25-49 years, and 50+ years. Viral load suppression (suppressed vs. unsuppressed) was the primary outcome. A Chi-Square test was used to assess the association between gender and viral suppression rates.
Results: Significant gender-based differences in viral suppression were observed in the 15-19 years and 20-24 years age groups. In the 15-19 years group, 93% of males (28/30) achieved suppression compared to 57% of females (31/54), with a statistically significant difference ($p = 0.00056$). In the 20-24 years group, 84% of males (52/62) suppressed viral load, while 76% of females (71/93) did, but the difference was not statistically significant ($p = 0.257$).
Female suppression rates were generally lower than males in most age groups, except for under-10 and 10-14 years, where no significant gender differences were observed. The Chi-Square test showed a statistically significant association between gender and viral suppression ($\chi^2 = 89.09$, $p = 1.47 \times 10^{-12}$).
Conclusions: This study highlights gender disparities in viral load suppression among PLHIV, with significant differences observed in younger age groups.

The findings suggest that gender-sensitive interventions are essential to address these disparities and optimize HIV care. Targeted strategies focusing on ART adherence and gender-transformative approaches could help reduce these gaps, contributing to Rwanda's goal of ending HIV by 2030.

TUPED120

Gender-responsive interventions for HIV prevention and care: lessons from Rwanda

D. Ndagijimana[1], N. Kabanyana[1], R. Mugisha[1], I.L. Ntawunga[2], J.P. Ayingoma[1], L. Ngabonzima[1], Z. Nzeyimana[2], C. Ndinda[2]

[1]Rwanda NGOs Forum on HIV/AIDS and Health Promotion, Kigali, Rwanda, [2]Rwanda Biomedical Center, Kigali, Rwanda

Background: In Rwanda, Key and vulnarable populations, including female sex workers (FSWs), men who have sex with men (MSM), and adolescent girls and young women (AGYW), face disproportionate HIV risks due to structural, social, and economic vulnerabilities.

This study evaluates the effectiveness of gender-responsive interventions in reducing HIV incidence and improving care engagement among these key and vulnarable populations.

Methods: A mixed-methods approach was used, combining program data analysis (2023-2024) with (4,661 MSM, 2,541 FSW and 457 AGYW) structured interviews from key and vulnarable populations. Multilevel logistic regression and propensity score matching assessed intervention impacts on HIV testing, PrEP uptake, and ART adherence, with interaction terms exploring urban-rural disparities. Descriptive statistics and thematic analysis provided insights into quantitative outcomes and barriers to accessing HIV services.

Results: HIV testing rates increased significantly across all groups: FSWs (67%), MSM (59%), and AGYW (70.3%) ($p < 0.001$). PrEP uptake was highest among AGYW (aOR 3.45, 95% CI: 2.98-4.01) compared to FSWs (aOR 2.87, 95% CI: 2.32-3.42) and MSM (aOR 2.15, 95% CI: 1.78-2.62). ART adherence improved among MSM (33%) and FSWs (28%) ($p < 0.05$). Urban participants demonstrated greater benefits than their rural counterparts (interaction $p = 0.02$).

The findings highlighted reduced stigma, trust in healthcare providers, and the role of peer support networks as key facilitators of intervention success.

Conclusions: Gender-responsive interventions have demonstrated significant impact in improving HIV prevention and care outcomes among FSWs, MSM, and AGYW in Rwanda.

Tailored data-driven approaches addressing gender-specific risks and barriers are essential for achieving equitable health outcomes. Future research should focus on long-term outcomes to further inform policy and programming.

Implementation research to scale up HIV testing

TUPEE113

Impact of AP3 strategy on the diagnosis of HIV in children in selected health facilities in Malawi: a comparative analysis of pre and post-intervention

L. Phiri[1], K. Mwitiwa[1], A. Ngambi[2], P. Damiano[3], K. Namachapa[1], I. Mataya[1], J. Khunga[4], P. Mbulaje[1], C. Udedi[5]

[1]Malawi AIDS Counselling and Resource Organisation, Programs, Lilongwe, Malawi, [2]Malawi AIDS Counselling and Resource Organisation, Programs, Blantyre, Malawi, [3]Malawi AIDS Counselling and Resource Organisation, Monitoring and Evaluation - Biostatistics, Lilongwe, Malawi, [4]Ministry of Health, Programs, Lilongwe, Malawi, [5]Malawi AIDS Counselling and Resource Organisation, Management, Lilongwe, Malawi

Background: Malawi has made strides in achieving UNAIDS 95-95-95 targets however, early diagnosis of HIV in children remains a great challenge. Approximately 46,600 children aged 0-14 years in Malawi are living with HIV yet only 34,000 (73.1%) are aware of their status. This leaves 12,500 children (26.9%) undiagnosed falling short of the 95% UNAIDS targets. To address this gap, Malawi AIDS Counselling and Resource Organisation (MACRO) adopted and implemented the Accelerating Progress in Pediatrics/PMTCT (AP3 strategy). This study compares data pre and post implementation of the AP3 strategy to evaluate its impact on the diagnosis of HIV in children.

Methods: A cohort study was conducted in seven healthcare facilities in Malawi, comparing data from 7 months pre-intervention (August 2023–February 2024) to 7 months post-intervention (March–September 2024). The AP3 strategy involved comprehensive interventions, including healthcare provider orientation, index testing, under-five testing, family testing days, youth-friendly health services, peer-led HIV self-test kit distribution, and active follow-up of postnatal mothers for HIV testing.

Data analysis was performed using descriptive and inferential statistics, including t-tests, in MS excel.

Results: Pre-intervention, 14175 children were tested for HIV, with 83 diagnosed as HIV positive (0.5%). During post-intervention, 61468 children were tested and 987 were diagnosed HIV positive (1.6%). There was a significant increase in both diagnostic yield and testing coverage ($p<0.001$) and ($p <0.05$) respectively. Linkage to care and treatment improved from 79% to 92% ($p <0.01$). Qualitative findings from healthcare providers and caregivers emphasized increased awareness contributing to the strategy's success.

Conclusions: The AP3 strategy significantly improved pediatric HIV diagnosis and linkage to care in Malawi, emphasizing the value of integrating services, provider orientation, and strengthened community partnerships. These findings suggest that scaling up the AP3 strategy could strengthen pediatric HIV programs in resource-limited settings, contributing to achieving the UNAIDS 95-95-95 targets.

TUPEE114

Acceptability and feasibility of HIV self-testing among adolescent girls and young women in rural Northern Uganda: a baseline formative study

R. Olum[1], M. Okello[1,2], F. Kitutu[3,4], E. Geng[5], P. Musoke[6,7]
[1]Makerere University, School of Public Health, Kampala, Uganda, [2]Gulu University, Faculty of Medicine, Gulu, Uganda, [3]Makerere University, Department of Pharmacy, Kampala, Uganda, [4]Uppsala University, Department of Women's and Children's Health, International Child Health and Migration, Uppsala, Sweden, [5]Washington University in St Louis, Division of Infectious Diseases, St Louis, United States, [6]Makerere University, Department of Paediatrics and Child Health, Kampala, Uganda, [7]MU-JHU Care Ltd, Kampala, Uganda

Background: Adolescent girls and young women (AGYW) in Uganda bear a significant HIV burden, accounting for 25% of new diagnoses. Despite improved HIV testing services, AGYW in rural areas face barriers to facility-based testing due to stigma, physical access barriers, and confidentiality concerns.
This study assessed the acceptability and feasibility of HIV self-testing (HIVST) among AGYW in rural Northern Uganda.
Methods: This cross-sectional study was part of a baseline assessment for a quasi-experimental trial evaluating community-led HIVST among AGYW aged 15–24 years in 5 sub-counties in Omoro District. Data were collected using systematic random sampling of households, with trained research assistants administering structured questionnaires on tablets.
The survey captured demographic characteristics, sexual history, HIV knowledge, prior testing practices, and attitudes toward HIVST. Factors influencing HIVST acceptability were analyzed using simple logistic regression in Stata 18.0.
Results: We enrolled 415 AGYW (median age: 19 years; IQR 17–22); 51.8% were adolescents, 23.1% had secondary education, and 41.4% were married/cohabiting. Sexual activity was reported by 74.2%, and 12.7% had multiple sexual partners in the past year. While 75.6% had ever tested for HIV, only 28.0% had heard of HIVST, and 6.0% had used it. Acceptability of HIVST was 93.0%, with 53.3% preferring blood-based tests.
Acceptability was associated with older age (odds ratio (OR): 1.19, 95% confidence interval (CI): 1.03–1.37, p=0.017), prior sexual activity (OR: 2.67, 95%CI: 1.25–5.71, p=0.011), and previous HIV testing (OR: 2.32, 95%CI: 1.07–5.04, p=0.033). Preferred access points included government health facilities (64.8%), community hotspots (57.8%), and friends (33.3%). HIVST support was desired by 61.0%, preferring health workers (69.6%) and friends (26.1%). Key anticipated challenges included result interpretation (57.1%), insufficient information (53.7%), and performing HIVST (52.3%).
Conclusions: Our findings indicate high acceptability of HIVST among AGYW in rural northern Uganda, influenced by age, sexual activity, and prior HIV testing experience. Targeted implementation strategies addressing knowledge gaps, providing beneficiary support, and leveraging existing community structures could further optimize HIVST uptake. Research on optimal models of HIVST will be critical to reaching underserved AGYW, reducing persons undiagnosed with HIV, and strengthening HIV prevention and care outcomes in this key population.

Implementation research to scale up prevention

TUPEE115

Designing a community of practice for healthcare workers to adopt integrated PrEP delivery in maternal and child health clinics

B. Odhiambo[1], K. List[2], M. Awuor[1], A. Dollah[1], M. Okombo[1], N. Oyugi[1], F. Abuna[1], K. Sharrock[2], J. Sila[1], J. Dettinger[2], F. Owuor[1], E. Sifuna[1], G. Oketch[1], N. Ngumbau[1], J. Onentiah[3], G. John-Stewart[2], A.D. Wagner[2], J. Kinuthia[1], A.R. Means[2]
[1]Kenyatta National Hospital, Nairobi, Kenya, Medical Research, Nairobi, Kenya, [2]University of Washington, Department of Global Health, Seattle, United States, [3]Ministry of Health, NASCOP, Nairobi, Kenya

Background: This study aims to test a scale-up package to expand the delivery of pre-exposure prophylaxis (PrEP) for pregnant and postpartum women in Kenya. This analysis seeks to support healthcare workers (HCWs) in integrating PrEP within maternal and child health (MCH) services by identifying preferences for designing and implementing a community of practice (CoP). CoPs have been used in low- and middle-income countries (LMICs) to disseminate best practices and provide a space for group problem-solving. We are piloting a CoP for healthcare workers to facilitate interaction and co-learning based on the findings from this analysis.
Methods: We conducted 12 focus group discussions (FGDs) with 94 participants, including HCWs, facility leadership from MCH clinics, and county and national-level representatives in Kisumu, Siaya, and Homa Bay counties between July and September 2024. Data were transcribed verbatim and analyzed using matrix-based rapid qualitative analysis. Two reviewers identified key themes related to the design, content, and implementation of CoPs for adopting integrated PrEP delivery in MCH clinics.
Results: Three main themes were identified regarding factors affecting the design and launch of a CoP for integrated PrEP delivery in MCH.
First, CoPs require early and thorough stakeholder engagement to reflect member preferences. There was a strong preference for WhatsApp as a space for CoP member interaction, given its familiarity. Participants also emphasized the importance of accessing updated PrEP guidelines and practical guidance for counseling on eligibility, side effects, pill burden, and partner stigma through the CoP.
Second, CoPs should provide ongoing capacity building for all levels of HCWs, not just direct service providers. Participants preferred a single CoP for all cadres rather than separate spaces by level.

Third, capacity building should be integrated into existing health systems, using models like the national training of trainers and regular continuing medical education sessions

Conclusions: CoPs to facilitate PrEP in MCH are likely feasible with WhatsApp and would enable providers to keep up with guideline changes and learn innovative program implementation strategies from fellow providers. Effective COPs could include varied MCH topics with tight integration within the health system

TUPEE116

One-year implementation outcomes of cabotegravir long-acting injectable PrEP in men who have sex with men (MSM) & transgender men (TGM): findings from the PILLAR study

D. Dandachi[1], L. Mercado[2], M. Whitehead[3], J. White[4], A. Liu[5], A. Gaudion[6], R. Moodley[6], B. Li[7], T. Ibbotson[7], P. Daniele[8], A. Herbst[8], D. Merrill[9], H. Swygard[9], P. Budnik[6], M. Aboud[9], K. Brown[9], M. Czarnogorski[9], N. Pilgrim[9]

[1]University of Missouri-Columbia, Columbia, United States, [2]Valley AIDS Council, Harlingen, United States, [3]AHF Healthcare Center, Pensacola, United States, [4]Peter Shalit MD & Associates, Seattle, United States, [5]San Francisco Department of Public Health, San Francisco, United States, [6]ViiV Healthcare, London, United Kingdom, [7]GlaxoSmithKline, Collegeville, United States, [8]Evidera, Wilmington, United States, [9]ViiV Healthcare, Durham, United States

Background: Long-acting cabotegravir (CAB-LA) is the first and only approved LA medication for HIV-1 PrEP, addressing barriers to daily oral PrEP. PILLAR (NCT05374525) is a Phase IV implementation science study evaluating strategies for integrating CAB-LA into care at US PrEP clinics. We present 12-month implementation outcomes and experiences of MSM and TGM receiving CAB-LA.

Methods: Seventeen clinics were randomized 2:1 into dynamic (treatment) and routine (control) implementation. From May 2022 to August 2023, 201 participants initiated CAB-LA and were followed through Month 12 (M12). Baseline (BL) and M12 surveys assessed implementation outcomes (i.e., acceptability and feasibility) and CAB-LA experiences, and were completed by 186 and 142 participants, respectively. Differences in implementation outcome by arm were assessed using t-tests. Interviews with 44 participants at M12 were analyzed.

Results: At BL, 6% were TGM, median age (interquartile range) was 35 (29–44) years, 26% were Black, and 38% were Hispanic. Based on a maximum scale score of 5, participants found CAB-LA highly acceptable (BL: mean=4.4 [SD=0.69]; M12: mean=4.6 [SD=0.64]), and feasible (BL: mean=4.4 [SD=0.74]; M12: mean=4.4 [SD=0.76]) at BL and M12. Changes in acceptability and feasibility between BL and M12 were not statistically significant by arm.

At M12, most participants (94%) reported no difficulty with getting to the clinic every 2-months or scheduling CAB-LA appointments. Offering flexible appointments (e.g., injection only appointments, advance appointment booking, injection without appointments) were useful to >90% of participants in supporting their CAB LA journey. Injection reminders were used by 83%, with 89% finding them useful. Implementation support, including education brochures, expectation videos, and digital platforms, were helpful to 70%-80% of participants. Use of supports were relatively similar across arms.

Conclusions: CAB-LA is highly acceptable, feasible, and favored over oral PrEP among diverse MSM and TGM. Flexible scheduling, reminders, and educational tools effectively support CAB-LA use to enhance PrEP uptake and adherence.

TUPEE117

Trends in the HIV prevention continuum among *travestis* and transgender women following PrEP implementation: findings from a large Brazilian cohort

C. Coutinho[1], C. Arsolino[1], E. Peixoto[1], B. Fernandes[1], T. Vianna[1], M. Derrico[1], R. Friedman[1], L. Ferreira[1], B. Hoagland[1], M. Silva[1], S. Cardoso[1], L. Monteiro[1], V. Veloso[1], B. Grinsztejn[1], E. Jalil[1]

[1]FIOCRUZ, Evandro Chagas National Institute of Infectious Diseases, Rio de Janeiro, Brazil

Background: Daily oral PrEP is available in Brazil since 2018 for all individuals under high vulnerability, including *travestis* and transgender women (TGW). We aimed to describe trends in HIV prevention behaviors in a large Brazilian TGW cohort and to compare HIV pre-exposure prophylaxis (PrEP) outcomes before and after PrEP implementation.

Methods: *Transcendendo* is an open, status-neutral, clinic-based cohort of TGW established in 2015 in Rio de Janeiro, Brazil. At baseline, participants answer structured questionnaires and perform laboratory tests. We calculated prevalences of PrEP and post-exposure prophylaxis (PEP) awareness, interest, and use, as well as HIV prevention preferences and compared outcomes between pre- (2015-2017) and post-(2018-2023) implementation periods. PEP was available in Brazil throughout the entire study period.

Results: Between 2015-2023, 508 HIV-negative TGW were enrolled (pre-PrEP:210[41.3%], post-PrEP:298[58.7%]), with a median age of 27 years (interquartile range:22-36), 73.7% Black/Mixed. Overall, 73.8% knew about PrEP, 89.1% were interested in using it, and 40.5% had used it before.

Comparing the pre- to post-PrEP implementation periods, PrEP awareness increased from 40.8% to 96.6%, interest in oral PrEP decreased from 96.0% to 85.0%, and ever PrEP use increased from 11.3% to 60.6%. The most common PrEP-related concerns were side effects (61.3%), long-term effects (61.0%), and interactions with gender-affirming hormones (56.8%).

Strategies most frequently reported as extremely/very useful for supporting PrEP included increasing HIV prevention literacy both individually (82.0%) and within the community (81.4%). Receiving PrEP information or support through text messages was highly accepted (68.5%). When asked about PrEP modalities, 48.5% would prefer long-acting PrEP options. PEP awareness, interest, and ever

use were 72.5%, 76.9%, and 16.8%, respectively. Although PEP interest decreased from 89.9% to 68.1% between pre- and post-PrEP implementation, PEP awareness (53.0% vs. 87.4%) and ever use (8.8% vs. 22.8%) increased.

Conclusions: The substantial PrEP adoption among Brazilian TGW after its implementation in the country underscores its high acceptability within this community, highlighting its potential to reduce HIV incidence and improve overall sexual health outcomes.

Tailored interventions are needed to further enhance HIV prevention and support PrEP uptake, adherence, and persistence among TGW.

TUPEE118

Community-led approaches to PrEP implementation: insights from community consultations to enhance HIV prevention in Andhra Pradesh, India, 2024

C. Kechamada Uthappa[1], J. Williams[2], V. Armugam[2], C. Subramaniam[2], V. Pakkela[2], R. Pampana[2], R. Bhatia[3], P. Nadol[1]

[1]U.S. Centers for Disease Control and Prevention (CDC), India office, U.S. Department of Health and Human Services (HHS), Delhi, India, [2]Voluntary Health Services (VHS), Chennai, India, [3]U.S. Centers for Disease Control and Prevention (CDC), U.S. Department of Health and Human Services (HHS), Atlanta, United States

Background: The HIV epidemic in India is concentrated among key populations (KP). Despite WHO's recommendation of PrEP as a critical HIV prevention tool, uptake in India is hindered by low awareness, affordability, and access. To address this, we implemented a phased PrEP implementation program in Andhra Pradesh, focusing on community engagement, demand creation, and tailored person-centered service delivery models.

Description: The PrEP-UP Andhra program was implemented in three phases from June 2022 to March 2024. Phase I involved listening exercises among 79 KPs (Female Sex Workers and Men who have Sex with Men) to understand PrEP perceptions, barriers, and preferences. Phase II used these findings to develop demand-creation materials, designed PrEP dispensation models, and consult with stakeholders for subsidized PrEP. Phase III involved rolling out PrEP in collaboration with the stakeholders. The consultations were instrumental in shaping effective PrEP implementation strategies. We designed three PrEP dispensation models: One-Stop Centers (OSC), Preferred Private Providers, and Tele-PrEP. Subsidized PrEP at $5 against market value of $25 was provided.

Lessons learned: Findings highlighted low baseline awareness (5%), strong interest (97%), and preferences for Tele-PrEP and OSC based delivery due to convenience and confidentiality. Over 95% KPs suggested $5-$6 for a bottle of PrEP to make it generally accessible. While regular follow-ups and periodic testing were widely accepted, affordability and difficulties in maintaining regular adherence were identified as key barriers for discontinuation. Community-driven education materials and engagement fostered trust and ownership. Key phase III activities included sensitizing1,688 healthcare providers and providing outreach to 70,901 communities through context-appropriate information and education materials to create demand for PrEP services.

Conclusions/Next steps: The phased implementation of community-centered PrEP delivery models demonstrated feasibility and acceptability, particularly through OSCs. Engaging communities early in the process increased ownership and played a pivotal role in designing community-centered models. PrEP outcomes for KPs can be increased by addressing discontinuation rates through enhanced adherence support, offering flexible PrEP delivery options, and maintaining affordability.

There is a clear demand for PrEP, and scaling these models, supported by policies and programs that prioritize making PrEP accessible to those most in need can further augment HIV preventions efforts in India.

TUPEE121

Advancing comprehensive community care: integrating hepatitis screening and testing into PrEP services for MSM/MSW in Kenya

A. Onyango[1], J. Kamau[2], J. Maina[3], P. Macharia[4], J. Mathenge[3], K. Mwangi[3]

[1]HOYMAS Kenya, Grant writring and Reearch, Nairobi, Kenya, [2]HOYMAS Kenya, Clinical, Nairobi, Kenya, [3]HOYMAS Kenya, Nairobi, Kenya, [4]HOYMAS Kenya, Monitoring, Evaluation, Research and Learning, Nairobi, Kenya

Background: Pre-exposure prophylaxis (PrEP) has reduced HIV acquisition among high-risk populations, yet the integration of hepatitis B (HBV) and C (HCV) screening remains limited, particularly for men who have sex with men (MSM) and male sex workers (MSW), who face elevated risks of acquiring hepatitis alongside HIV. The Kenya ART Guidelines (2022) advocate for client-centered PrEP delivery, including HBV and HCV testing, to improve care outcomes.

This program aimed to enhance health equity by integrating hepatitis screening, prevention, and management into PrEP services to address the dual risks of HIV and hepatitis acquisition.

Description: Between January 2023 and December 2024, HOYMAS Kenya, a community-led organization, implemented an integrated program to address the dual risks of acquiring HIV and hepatitis B (HBV) and C (HCV) among MSM and MSW in Nairobi, Nyeri, and Kajiado counties. The initiative integrated HBV and HCV screening, prevention, and management into pre-exposure prophylaxis (PrEP) services, including baseline testing, routine follow-up, HBV vaccination, and linkage to care. Community sensitization and peer-led education reduced stigma and increased service uptake by 61%, while data from 876 MSM/MSW provided insights into screening coverage, care linkage, and PrEP adherence. This model highlights the feasibility and impact of integrating hepatitis screening into PrEP to advance health equity for key populations.

Lessons learned: Integrating hepatitis screening into PrEP services plays a vital role in addressing both HIV and hepatitis risks among MSM/MSW. Among 876 clients, 13.2%

were diagnosed for HBV, while 7.1% were diagnosed with HCV, with comorbidity rates of 28.4% and 32.8%, respectively. Following community sensitization, screening uptake increased by 61%, emphasizing the effectiveness of targeted outreach. Routine screening further enhanced early detection, vaccination, and linkage to care, demonstrating the potential for scaling this approach to promote health equity among key populations

Conclusions/Next steps: Integrating hepatitis screening into PrEP services is essential in addressing HIV and hepatitis comorbidities among MSM and MSW. To scale this impact, full implementation of the Kenya ART Guidelines 2022, increased funding for HBV and HCV testing, expanded HBV vaccination, and enhanced education on PrEP and hepatitis are pivotal in advancing health equity and reducing the burden of comorbidity.

TUPEE122

Acceptability and feasibility of integrating enhanced HIV pre-exposure prophylaxis into a sexually transmitted infection clinic in Lilongwe, Malawi

G. Lukhanda[1], J. Chen[2], E. Jere[1], M. Tsidya[1], L. Limarzi-Klyn[2], T. Munthali[1], Z. Mphande[3], J. Mbendera[1], E. Mathiya[1], B. Ndalama[1], N. Nyirenda[1], N. Bonongwe[1], G. Banda[1], A. Bula[1], C. Pedersen[2], G. Mulholland[2], M. Hosseinipour[1,2], I. Hoffman[2,1], S. Rutstein[2], M. Matoga[1]

[1]University of North Carolina (UNC) Project Malawi, Lilongwe, Malawi, [2]University of North Carolina (UNC) at Chapel Hill, Chapel Hill, United States, [3]Lighthouse Trust, Lilongwe, Malawi

Background: Oral Pre-Exposure Prophylaxis (PrEP) is a proven HIV prevention tool, yet its integration with sexually transmitted infection (STI) services in sub-Saharan Africa remains underexplored. We assessed the acceptability and feasibility of integrating an enhanced PrEP (ePrEP) delivery program, which included etiologic STI testing and assisted partner notification, at an urban STI clinic in Lilongwe, Malawi.

Methods: We enrolled a cohort of men and women eligible for PrEP and seeking STI services. Participants were classified as index participants (initiated on PrEP), PrEP decliners (eligible but declined) and referred partners (referred by index participants and initiated on PrEP). Index participants completed surveys and HIV/STI testing at baseline and quarterly visits, alongside baseline in-depth interviews. PrEP providers aged ≥18 were also enrolled and completed surveys and interviews at study launch and approximately 6 months after implementation of the enhanced program.

Results: Between March and December 2022, we enrolled 238 clients (174 index participants, 37 PrEP decliners and 27 referred partners; median age 27 [Interquartile Range (IQR): 22, 31], 58% male). There was high acceptability among PrEP-taking participants as most strongly agreed that PrEP-STI integration (98%), assisted partner notification (97%) and etiologic STI testing (99%) were appealing. Among decliners, reasons for declining PrEP were pill burden and concern for side effects. Ten PrEP providers (median age 43 [IQR: 38, 47]) were also enrolled. Acceptability and feasibility were high among providers, with most (≥90%) strongly agreeing that all ePrEP components were likeable, appealing, implementable and easy to implement.

In-depth interviews highlighted convenience and reduced cost burden for participants, and an STI clinic being a strategic entry point for PrEP demand-creation and engagement, as some of the reasons for the high acceptability and feasibility. Lack of space and inadequate staff were cited as barriers.

Conclusions: Integrating PrEP with STI services, including assisted partner notification and etiologic STI testing, was both acceptable and feasible in this study. These findings support the adoption of integrated PrEP and STI care models in sub-Saharan Africa.

TUPEE123

From early adopter to blazing the trail in PrEP service provision: the case of Zambia's successful PrEP scale up

C. Mutila[1], M. Musonda[2]

[1]PEPFAR Coordination Office, U.S Government Department of State, Lusaka, Zambia, [2]Health Office, United States Agency for International Development, Lusaka, Zambia

Background: The 2021 ZAMPHIA reported 28,000 new infections which declined to 23,000 in 2023 according to UNAIDS. Critical to this success has been the introduction and scale-up of pre-exposure prophylaxis (PrEP) in 2018, beginning with service provision in 4 sites. In September 2024, access to PrEP expanded to over 2,000 public health facilities, with Zambia surpassing 1 million individuals initiated on PrEP.

Description: Initial PrEP introduction targeted AGYW and key populations and saw low uptake driven by myths, misconceptions and stigma. In 2019, a PrEP demand generation strategy, Zambia Ending AIDS (ZEA), was developed. ZEA aimed to provide accurate information on HIV prevention, through various platforms including social media, which emphasized taking control of one's sexual health by choosing the preferred HIV prevention to avert HIV acquisition.

This was done in conjunction with an aggressive scale-up plan to increase the number of sites providing PrEP, while capacitating healthcare workers (HCWs) to provide supportive and non-judgmental services.

Lessons learned: In 2018, PEPFAR Zambia initiated 3,311 individuals on PrEP through implementation in 4 pilot sites. In 2019, with service provision expanded to 184 sites, with 23,352 individuals initiated on PrEP. The program saw exponential growth in 2021, where 131,260 clients were initiated through 1,286 sites.

Continued investments in capacity building of HCWs and ensuring equity by expanding access to more rural communities increased the number of sites to 1,605 in 2023, with 273,628 individuals initiated on PrEP.

In 2024, Zambia initiated the largest number of individuals on PrEP in one year, with 368,689 individuals initiated through 2,107 facility and community-based sites.

Conclusions/Next steps: Successful scale-up of PrEP has played a critical role in reducing the number of new infections in Zambia. Key to this success has been the use of a modern demand generation strategy, coupled with capacity building and onsite mentorship of HCWs. Strong collaboration between various stakeholders, including PEPFAR, civil society and implementing partners, under the strong leadership of the Ministry of Health, have catapulted Zambia from an early adopter to global leader.

TUPEE124

Integrating the ShangRing device method to increase options, access and uptake of VMMC services among adult clients in five regions of Tanzania

P. Mwakipesile[1], M. Makokha[1], C. Kiame[1], G. Mwanjali[1], J. Anthony[1], M. Msabilla[1], N. Rweyemamu[1], S. Tesha[1], A. Christensen[2], S. Mmbando[3], N. Fida[4], Y. Mlawa[4], I. Udo[4], Z. Mwandi[5], V. Kiggundu[6,7]

[1]Jhpiego, Reaching Impact, Saturation, and Epidemic Control, Dar Es Salaam, Tanzania, the United Republic of, [2]Jhpiego, Dar Es Salaam, Tanzania, the United Republic of, [3]Ministry of Health, National AIDS, STIs, Hepatitis Control Program (NASHCoP), Dar Es Salaam, Tanzania, the United Republic of, [4]U.S. Agency for International Development (USAID) Tanzania, Health Office, Dar Es Salaam, Tanzania, the United Republic of, [5]Jhpiego Kenya, RISE, Nairobi, Kenya, [6]USAID, Office of HIV/AIDS (OHA), Washington DC USA, United States, [7]GHTASC - Credence Management Solutions, LLC., Washington DC, United States

Background: With support from the U.S. President's Emergency Plan for AIDS Relief (PEPFAR) through USAID, the Reaching Impact, Saturation, and Epidemic Control (RISE) project supports VMMC services in 5 regions of Tanzania. Historical delivery of VMMC services uses the dorsal slit (DS) method.

The World Health Organization (WHO) approved the ShangRing device (SR) as an additional method for conducting VMMC. The Tanzania Ministry of Health (MOH) approved SR use in routine services in 2023.

Description: RISE supported the Tanzania MOH to train 20 providers and equipped 5 sites to integrate SR circumcision. The SR target for the 5 sites was 3,000 circumcisions from October 2023 to September 2024. SR usage data from the sites and national health management information system (DHIS2) were reviewed and analyzed to determine:

a. SR target achievement by site,

b. User age distribution for the two methods,

c. Average procedure time reported by providers trained to perform both methods.

Analysis incorporated insights from VMMC providers and promoters.

Lessons learned: RISE surpassed the SR target by achieving 120% (3,594 circumcisions) equivalent to 3% of all 130,263 circumcisions supported by the project during this period. Four of the five SR sites averaged 140% against target (122%-156%), suggesting that SR can be integrated and was effective to meet targets.

The site that did not achieve its target (39%) had unresolved misconceptions about the SR device left in place, pain during device removal and secondary intention healing. 85% of all SR users compared to 93% of DS users were aged 15-24 years while the rest were users aged 25 years and older. The average SR procedure time was shorter, 9 minutes (7-10 minutes) than DS procedure time which averaged 27 minutes (25-30 minutes) conforming to its value proposition as a time-efficient method.

Conclusions/Next steps: Integration of SR in routine VMMC services is feasible and scalable. SR expands choice for men concerned about injection pain, suturing and procedure time associated with the DS method, which deters adult clients from using VMMC services. RISE will involve communities to address persisting misconceptions and barriers to increase access and improve efficiency in SR delivery for men.

TUPEE125

Mentors transforming lives: empowering Zambian adolescent girls and young women (AGYW) to thrive and prevent HIV through the DREAMS initiative

M. Zimba-Chisashi[1], A. Shiku[2]

[1]USAID Controlling the HIV Epidemic among Key and Underserved Populations II (CHEKUPII), Strategic Information, Lusaka, Zambia, [2]USAID Controlling the HIV Epidemic among Key and Underserved Populations II (CHEKUPII), Priority Populations, Lusaka, Zambia

Background: The PEPFAR DREAMS initiative aims to reduce HIV incidence among adolescent girls and young women (AGYW) by addressing structural, behavioral, and biomedical vulnerabilities. In Zambia, AGYW face risks such as gender-based violence, economic dependency, and limited access to sexual and reproductive health (SRH) services.

This abstract highlights the pivotal role of mentors, functioning as case managers, in the USAID-funded CHEKUP II Project, which operates across seven DREAMS centers to empower AGYW and improve HIV prevention outcomes through a layered service delivery model.

Description: CHEKUP II implemented a mentor-driven case management framework that paired each AGYW with a mentor. Mentors identified vulnerabilities during enrollment, developed individualized intervention plans, and coordinated tailored services.

A service layering matrix combined biomedical services (HIV testing, PrEP, family planning, STI treatment) with psychosocial and structural interventions (mental health support, economic empowerment). Safe spaces fostered mentor-AGYW relationships, enabling AGYW to share challenges openly. Comprehensive care was delivered directly or through external referrals.

Lessons learned: Between 2023 and 2024, 54,874 AGYW were enrolled, with screening highlighting key vulnerabilities: 12% engaged in transactional sex, 42% reported inconsistent condom use, and 74% experienced violence. Mentors facilitated access to biomedical services, initiating 11,349 AGYW on PrEP and conducting HIV testing for

15,925. Structural interventions supported socio-economic needs, with 607 AGYW receiving school subsidies and vocational training. Mentors also connected 9,897 AGYW to mental health services, addressing emotional well-being and fostering resilience. The proactive engagement of mentors was instrumental in linking AGYW to services, building trust, and addressing multifaceted vulnerabilities.

Conclusions/Next steps: The mentor-driven case management approach effectively tailored interventions to AGYW's unique needs, reducing HIV risks and addressing structural and gender-related barriers. Mentors played a critical role in fostering resilience and ensuring access to comprehensive services. Future initiatives should enhance mentor capacity, expand economic empowerment efforts, and leverage multisectoral partnerships to improve outcomes for AGYW in Zambia.

TUPEE126

Experiences with HIV testing among clients initiating CAB-LA: a case series from South Africa

C.E. Martin[1], N. Mngomezulu[1], P. Nongena[1], L. Hans[2], K. Steegen[2], M. Monametsi[1], N. Koloane[1], V. Butler[1], S. Mullick[1]

[1]University of the Witwatersrand, Wits RHI, Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Molecular Medicine and Haematology, Johannesburg, South Africa

Background: The introduction of long-acting pre-exposure prophylaxis (PrEP) has raised discussions about HIV testing approaches, and the challenges that may be encountered if PrEP is initiated in individuals with early HIV, undetected through antibody-based rapid point of care (POC) tests.

We aimed to describe the proportion of participants initiating cabotegravir long-acting (CAB-LA) who may have HIV missed when applying standard HIV testing algorithms, and to describe the consequent testing undertaken to confirm an HIV diagnosis.

Methods: This is a sub-analysis of data collected through an implementation study among HIV-negative men and women ≥15 years, offered an option of oral, ring or CAB-LA PrEP in six department of health clinics and three linked mobiles in three districts in South Africa between April and November 2024. All participants were tested using a single, rapid, third-generation POC HIV test in line with national guidelines, at the time of PrEP provision. Test kits used varied by district, depending on local procurement, and were either One Step Anti-HIV (1&2) or Toyo Anti-HIV 1/2.

Further, we conducted laboratory-based HIV viral load testing (Abbott Alinity m HIV-1) among participants initiating CAB-LA. We describe those who had a detectable viral load (VL) at the time of CAB-LA initiation.

Results: Of the 2845 participants initiated on CAB-LA, 2731 had a viral load sample processed in the laboratory, of which 2695 had valid results. Of these, 9/2695 (0.3%) had detectable virus, ranging from 3365 to 7423963 copies/ml. Participants with detectable virus were all female; aged between 19 and 22 years; 3/9 (33%) had prior oral PrEP use but were not using oral PrEP at the time of CAB-LA initiation. Subsequent point of care testing confirmed HIV in 7/9 participants, with the remaining two confirmed either through laboratory-based 4th-generation antibody test and or repeated detectable viral load results.

Conclusions: There were few participants initiated on CAB-LA who were mis-identified as HIV-negative at initiation using rapid POC HIV tests. Of these, most were confirmed HIV-positive using subsequent POC antibody tests. This data provides reassurance for programmes introducing long-acting PrEP methods at scale.

TUPEE127

Acceptability of HIV prevention and sexual health services for men in South African barbershops: owner, barber and client views

S. Govere[1,2], J. Jarolimova[3,4,5], J. Yan[6], M. Nzuza[1], A. Khumalo[1], P.-g. Zwane[1], D.L. Zionts[4], S. Sagar[4], L.S. Johnson[4], R.A. Parker[6,5,7], I.V. Bassett[3,7,8]

[1]Aids Healthcare Foundation, Durban, South Africa, [2]University of KwaZulu Natal, Durban, South Africa, [3]Massachusetts General Hospital, Infectious Disease, Boston, United States, [4]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States, [5]Harvard Medical School, Boston, United States, [6]Massachusetts General Hospital, Biostatistics Center, Boston, United States, [7]Harvard University Center for AIDS Research, Boston, South Africa, [8]Africa Health Research Institute, Durban, South Africa

Background: Men in South Africa are less likely to undergo HIV testing, utilise PrEP, or initiate antiretroviral therapy. Community-based barbershops may be useful venues for offering HIV prevention and sexual health services.

We assessed the perceived acceptability and feasibility of barbershop-based HIV prevention and sexual health services in South Africa.

Methods: We surveyed barbershop owners, barbers, and male clients (≥18y) at barbershops in Umlazi township and Durban about the acceptability and feasibility of offering health services, including HIV testing, PrEP, and sexually transmitted infection (STI) management. We asked clients their perceptions of receiving health services in barbershops and barbers and owners about including health service provision in barbershops.

We assessed the association (Chi-Square test) between barbershop location and client age with clients' attitudes towards receiving health services.

Results: We surveyed 8 owners, 27 barbers, and 332 clients at 8 barbershops: 5 township and 3 Durban; median 110 unique clients/month (IQR 85-150). Seven owners (88%) and 24 barbers (89%) were comfortable with clients receiving health services in their barbershops. Twenty-five barbers (93%) were comfortable talking to clients about health topics if given proper training; however, 15 (57%) reported lack of privacy as a potential barrier.

Clients had median age 28y. The majority (201, 61%) visit the barbershop at least twice/month and attend the same barbershop for most visits (229, 69%); 205 (62%)

reported they would be comfortable receiving sexual health services at the barbershop, specifically, 141 (43%) HIV testing, 161 (48%) oral and 152 (46%) injectable PrEP, and 152 (46%) STI testing. Among those comfortable receiving services, 153/203 (75%) had no service provider gender preference.

Clients from barbershops in the township, compared to Durban, were more willing to receive health education (p=0.009), health services (p=0.01), oral PrEP (p=0.018) and injectable PrEP (p=0.019) in the barbershop. Men <30y were more willing to receive oral PrEP (p=0.002) compared to those ≥30y.

Conclusions: Most owners, barbers, and clients were comfortable with the delivery and receipt of HIV prevention and sexual health services in barbershops. Barbershops are a novel, male-centred, community-based venue for reaching men with HIV prevention and sexual health services.

TUPEE128

PrEP awareness and uptake among high school learners in the context of school-based SRH/HIV prevention: findings from the Safer Choices baseline survey in rural KwaZulu-Natal, South Africa

N. Chimbindi[1,2,3], F. Magut[1], U. Ngema[1], B. Zulu[1], A. Gibbs[4,5], A. Davies[6], A. Harrison[7], C. Herbst[1], J. Dreyer[1], A. Jalazi[1], N. Okesola[1], J. Seeley[1,3,8], M. Shahmanesh[1,2,3]
[1]Africa Health Research Institute, KwaZulu-Natal, South Africa, [2]University College London, Institute of Global Health, London, United Kingdom, [3]University of KwaZulu-Natal, South, South Africa, [4]University of Exeter, Department of Psychology, Exeter, United Kingdom, [5]South Africa Medical Research Council, Gender and Health Research Unit,, Durban, South Africa, [6]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, [7]Brown University, Department of Behavioral and Social Sciences, International Health Institute, Providence, United States, [8]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom

Background: Despite the free availability of HIV pre-exposure prophylaxis (PrEP), uptake of PrEP remains low among young people. We investigate PrEP awareness and uptake among high school learners prior to roll-out of a multi-component whole-school health-promotion intervention, Safer Choices, in a rural area with high HIV prevalence in KwaZulu-Natal (KZN), South Africa.

Methods: Between January 2023–December 2024, we conducted a pilot study to assess acceptability of Safer Choices optimised with HIV/SRH service delivery through a randomized cluster trial Thetha Nami (Trial #xxx) in KwaZulu-Natal.

We conducted a pre-intervention baseline survey recruiting n=361 randomly selected learners in Grade 9-10 aged 15-19, from five purposively selected high schools to represent rural/urban schools. Survey was tablet-based with self-completed sections to measure exposure and changes in self-reported SRH and HIV-risk behaviors. Descriptive analysis Pearson's Chi-squared test and Fisher's exact test was conducted to determine factors associated with uptake of PrEP.

Results: Half of the learners 52.4%(189/361) were male, and overall median age was 16 years (interquartile range (15.0-17.0). Most learners were in Grade 10 (70.4%), 24.9% from food insecure households and almost all (98.3%) benefitted from the school-feeding scheme.

About a quarter (80/355 22.5%) of learners reported ever having sex, with a higher proportion (31.0% vs 13.5% p<0.001) being boys.

Of these, 30.0% had condomless sex in the last 12months, 43.5% being girls p=0.236, but just over half of learners (54.3%) didn't know their partners' HIV status.

Overall, PrEP awareness was high 57.9% (209/361), but offer and uptake was low 3.3% (7/209). Among those who used PrEP, 4/7 (57.1%) took oral PrEP daily. PrEP uptake was higher 6 (85.7%) in older learners (18-19 vs 15-17 p<0.001) and those having condomless sex 5 (71.4%) p<0.001.

The majority 353/361 (97.8%) of learners self-reported being HIV negative, no difference between boys and girls p=0.265. Regarding PrEP preference, 54.8% (198/361) preferred a two-monthly injection.

Conclusions: Although many learners were aware of PrEP in this rural setting, there is need develop strategies to deliver PrEP including injectable PrEP to learners. A multi-component whole-school intervention Safer Choices offers an opportunity to increase PrEP awareness and support PrEP uptake in this rural area with high sexual risk and vulnerability.

TUPEE129

Survival of individuals on long-acting cabotegravir for HIV pre-exposure prophylaxis and associated discontinuation factors in Zambia: a 10 months retrospective cohort analysis

L. Kawanga[1], A. Ndhlovu[1], D. Mwamba[2], M. Musonda[2], J. Musangulule[1]
[1]JSI, USAID DISCOVER Health Project, Lusaka, Zambia, [2]USAID, Health, Lusaka, Zambia

Background: Long-acting Cabotegravir (CAB-LA) is a promising injectable option for HIV pre-exposure prophylaxis (PrEP). Despite its potential to improve adherence, limited literature exists on survival on CAB-LA among users. USAID DISCOVER-Health, implemented by JSI, has been supporting CAB-LA implementation in Zambia since February 2024. This study assessed the survival of individuals on CAB-LA and identified factors associated with discontinuation.

Methods: A retrospective cohort analysis was conducted using electronic health records data from clients who initiated CAB-LA between February and September 2024 in Kitwe and Chibombo districts over 10 months.

Survival analysis, including Kaplan-Meier estimates and Cox regression, were employed to determine survival and identify associated discontinuation factors. Discontinuation was defined as missing a scheduled injection appointment for 30 days or more.

Results: The cohort had 1,308 individuals with a mean age of 29 years ranging from 17 to 67 years, 785 (60%) females and 523 (40%) males. Population category included 536 (41%) general population, 366 (28%) adolescent girls and young women (AGYW), 353 (27%) young men, and 52 (4%) key populations. They contributed 6,386 person-months of follow-up, median survival time of 7 months, with 823 discontinuations making 0.129 per person-month (95% CI: 0.120–0.138) incidence rate. Oral PrEP-experienced individuals had a 33% lower hazard of discontinuation compared to naive clients. Males had a 20% higher hazard compared to females. Age was protective, with each additional year associated with 1% reduction in the hazard of discontinuation. Kaplan-Meier survival estimates revealed significant differences in survival probabilities by oral PrEP experience, with experienced individuals demonstrating better retention (log-rank p<0.0001). AGYW (HR=1.24, p=0.014), Key Populations (HR=1.35, p=0.052), and Young Men (HR=1.46, p<0.001) exhibited higher hazards of discontinuation compared to the general population, although these associations did not persist after adjusting for other variables.

Conclusions: Survival on CAB-LA for PrEP was moderate, with higher discontinuation risks among males, younger people, and PrEP-naive clients, while prior oral PrEP experience and increasing age were protective. Targeted interventions, including enhanced counselling and differentiated services, are recommended to support these more at-risk groups. Further research is needed to establish a standard median risk period for accurately assessing PrEP retention

Implementation research to scale up treatment

TUPEE130

Improving viral load coverage initiative among children 0-14 yrs living with HIV on treatment through intensified site support in Zimbabwe 2024: lesson learnt through implementation

M. Mhangara[1], S. Mukungunugwa[1], T. Tapera[1]
[1]USAID, Harare, Zimbabwe

Background: Zimbabwe has approximately 69,000 children aged 0-14 living with HIV (CLHIV). The country's progress toward achieving the global 95:95:95 targets for children lags behind adults, with coverage rates of 82:81:88 compared to 97:98:96 among adults, according to 2023 UNAIDS estimates. National viral load testing and suppression coverage among children remain suboptimal at 93% and 64%, respectively, with geographic and age-related variability.

This abstract discusses the lessons learned from a PEPFAR initiative aimed at improving viral load coverage in 24 USAID-supported districts in Zimbabwe.

Description: To address viral load testing gaps, USAID supported 24 of Zimbabwe's 44 PEPFAR districts with an intensified improvement plan. This involved reviewing HIV case management files and creating a line list of children missing viral load tests. Follow-ups were conducted through SMS, phone calls, and community visits. Dedicated teams managed appointments, follow-ups, and data entry, ensuring testing in health facilities or communities based on caregiver preference. High viral load clinics were established to address suppression gaps, with monthly audits guiding program adjustments.

Lessons learned: Viral load coverage improved across age groups, with children under 1 year increasing from 25% in FY23 Q4 to 44% in FY24 Q4 (Fig 1).

Figure 1. Improved viral load coverage among children 0-14 yrs in the USAID Zimbabwe support districts, FY23-FY24.

Coverage in the 1-4-year age group rose from 45% to 70%, and in the 5-9 and 10-14 age groups, coverage increased from 64% to 74% and from 76% to 83%, respectively. Despite these gains, viral load suppression remained suboptimal (<95%) for children under 1 year and those in the 1-4-year group (Fig 1).

Conclusions/Next steps: Viral load monitoring is essential to ending HIV/AIDS in children by 2030. This case study demonstrates the feasibility of improving viral load coverage and suppression through community and facility collaboration. Further efforts are needed to scale these initiatives across all ART sites for continuous improvement.

TUPEE131

Can a one-time economic incentive enhance the effectiveness of community-based tracing to re-engage people who have disengaged from HIV care? Rudi Kundini: a cluster randomized trial in Tanzania

S. Winters[1], J. Kadota[2], M. Mlowe[3], H. Maila[3], B. Joseph[3], J. Hu[1], L. Packel[2], N. Ulenga[4], W. Dow[1], P. Njau[5], R. Hémono[1], J. Wang[1], A. Sabasaba[3], S. McCoy[1]
[1]University of California, Berkeley, Berkeley, United States, [2]University of California, San Francisco, San Francisco, United States, [3]Health for a Prosperous Nation, Dar Es Salaam, Tanzania, the United Republic of, [4]Management and Development for Health, Dar Es Salaam, Tanzania, the United Republic of, [5]Ministry of Health, Dodoma, Tanzania, the United Republic of

Background: Out-of-care people living with HIV (PLHIV) play a disproportionately large role in onward HIV transmission. Innovative interventions are needed to support this important subgroup.

Methods: We conducted a Type 1 hybrid implementation-effectiveness trial among out-of-care PLHIV (lost-to-follow-up or missed appointment by ≥28 days) at 32

health facilities in Lake Zone, Tanzania to examine the effectiveness of home-based care (HBC) counseling and a one-time economic incentive on HIV care engagement. Facilities were randomized 1:1 to standard HBC counseling or HBC counseling plus a one-time incentive (~$10 USD; half provided at enrollment and half provided conditional on returning to care within 90 days).

The primary outcome was care re-engagement with viral suppression (<1000 copies/mL) at 6 months.

Secondary outcomes included retention in care with viral suppression at 12 months, 6-month and 12-month retention, and viral suppression using an alternative <50 copies/mL threshold.

Generalized estimating equations and a cluster-based permutation test were used to estimate adjusted risk differences (aRD) and 95% confidence intervals (CI).

Results: Between July 25, 2022 and October 19, 2023, 567 PLHIV were enrolled (62% female, mean age 36.9 years, mean time out-of-care 4 months), of which nearly 99% returned to care within 90 days. At 6 months, 82% of intervention participants were in care and virally suppressed vs. 76% of comparison participants (aRD = 4.3, 95% CI: -3.6, 12.2; p-value=0.84). At 12 months, 69% of intervention participants were in care and virally suppressed vs. 62% of comparison participants (aRD = 6.4, 95% CI: -4.7, 17.6, p-value=0.42). Risk differences using a <50 copies/mL threshold for viral suppression were larger; however, based on the width of the CI we cannot rule out the possibility of no effect.

Conclusions: We found unexpectedly high rates of re-engagement in HIV care for out-of-care PLHIV receiving standard HBC counseling. Adding a one-time economic incentive demonstrated modest but statistically insignificant improvements in retention and viral suppression at 6 and 12 months. Nevertheless, in both groups, approximately ⅓ were not achieving traditional metrics of success in HIV care at 12 months, suggesting that more substantial support to overcome persistent barriers is needed for this subgroup.

Advancing HIV epidemic control: reducing treatment interruptions through continuous quality improvement in Niger State, North-Central Nigeria

O. Olufemi[1], S. Idris[2], A. Olutola[3], P. Gado[4], A. Etsetowaghan[5], A. Amusan[6], M. Onyilo[7], C. Aka-Okeke[8], U. Nwanchor[9], P. Anjov[10], V. Obiukwu[11], O. Nwankwo[11], D. Tsado[11], O. Atibioke[12]

[1]Center for Clinical Care and Clinical Research, Continuous Quality Improvement, Jahi District, Nigeria, [2]Center for Clinical Care and Clinical Research, Technical Director, Jahi District, Nigeria, [3]Center for Clinical Care and Clinical Research, CEO, Jahi District, Nigeria, [4]USAID, AOR, Central District, Nigeria, [5]Center for Clinical Care and Clinical Research, Chief of Party, Jahi District, Nigeria, [6]Center for Clinical Care and Clinical Research, Care and Support Associate, Jahi District, Nigeria, [7]National Ministry of Health, National Clinical Mentor, Central Area, Nigeria, [8]Center for Clinical Care and Clinical Research, Laboratory, Minna, Nigeria, [9]Center for Clinical Care and Clinical Research, Clinical Services, Minna, Nigeria, [10]Center for Clinical Care and Clinical Research, Care and Support, Minna, Nigeria, [11]Center for Clinical Care and Clinical Research, Continuous Quality Improvement, Minna, Nigeria, [12]Center for Clinical Care and Clinical Research, TB / HIV, Minna, Nigeria

Background: Interruption in Treatment (IIT) among people living with HIV (PLHIV) presents a critical barrier to achieving viral suppression and advancing HIV Epidemic control. Niger State has faced persistent challenges with heightened insecurity amongst other issues such as stigma, socio-economic barriers and data quality gap with consequent high IIT rates, necessitating innovative and context-specific interventions.

This study highlights the application of continuous quality improvement (CQI) methodologies to address IIT and enhance treatment continuity in resource-constraint and security-ravaged settings.

Methods: A CQI-driven approach was implemented across 12 high-volume facilities in Niger State between July – September 2024. Root Cause Analysis identified key barriers: service disruptions due to incessant banditry, sub-optimal documentation, client stigma, and prevailing economic hardships. Interventions included establishing multidisciplinary quality improvement teams, regular data reviews to identify IIT trends, and developing client-centered retention strategies. Key activities included community engagement with security personnel for safe drug delivery in conflict zones, CBO-driven service delivery in the community, psychosocial support through support group empowerment, healthcare worker training on effective counseling skills, client tracking, real-time records updates and appointment scheduling.

Results: The intervention achieved a 63.2% reduction in the cumulative IIT rate, dropping from 3.8% during the pre-intervention period (April–June 2024) to 1.4% during the intervention period (July–September 2024), demonstrating the significant impact of targeted CQI interventions over the three months.

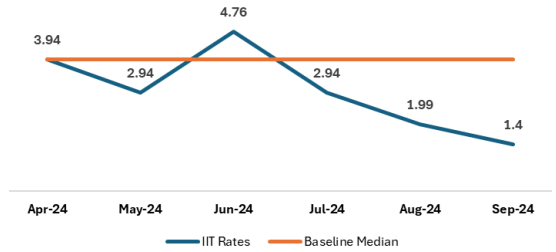

Figure. Cumulative monthly IIT rate.

Conclusions: CQI interventions, using Root Cause Analysis and PDSA cycles, significantly reduced IIT rates across Niger State facilities. These results highlight the effectiveness of Continuous Quality Improvement (CQI) strategies, through targeted, data-driven approaches and client-centered CQI strategies in improving treatment continuity and retention, with the potential for scaling across regions.

Global and national financing, economic evaluation and sustainability

Incentivizing PrEP investment: analysis of PrEP budgets in countries accessing PrEP matching funds in Global Fund Grant Cycle 7

D. Resar[1], A.J. Mwamelo[2], B. Longwe[2], M. Honu[3], C. Obermeyer[3], C.C. Igbomezie[3], H. Ingold[4], M. Rodolph[4], R. Borain[5], E. Otobo[5], T. Vernon[6], K. Hatzold[7], S. Jenkins[1]
[1]Clinton Health Access Initiative, Boston, United States, [2]Clinton Health Access Initiative, Lusaka, Zambia, [3]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland, [4]World Health Organization, Geneva, Switzerland, [5]Children's Investment Fund Foundation, London, United Kingdom, [6]Population Services International, Washington DC, United States, [7]Population Services International, Cape Town, South Africa

Background: In 2023, Kenya, Mozambique, Nigeria, South Africa, Uganda, and Zambia accounted for 64% of all people receiving pre-exposure prophylaxis (PrEP) but saw >380,000 HIV acquisitions. To catalyze PrEP and post-exposure prophylaxis (PEP) scale-up, the Children's Investment Fund Foundation (CIFF) and the Global Fund (GF) established a Matching Fund (MF), incentivizing increased PrEP investment in these countries in Grant Cycle 7 (GC7).
We analyzed publicly available GF budgets to evaluate impact on funding allocated towards PrEP.
Methods: We extracted budgets from GF's financial insights dashboard for GC5-GC7 across 5 countries accessing PrEP MFs. While eligible for MFs, South Africa was excluded as their GC7 budget was not available at the time of analysis.
Results: In aggregate, countries accessing MFs increased PrEP budgets 46-fold GC6-GC7, while non-MF countries saw a 3-fold increase (Figure 1). Allocation of PrEP budget by population varied (Figure 2), with greatest overall investments in adolescent girls and young women, sex workers, and men who have sex with men. All 5 countries allocated PrEP budget towards prisoners and people who use drugs for the first time in GC7.

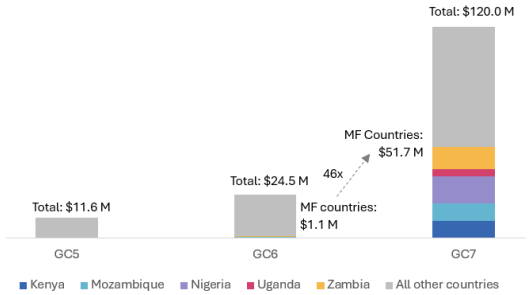

Figure 1. Total budget for PrEP by country, GC5-GC7

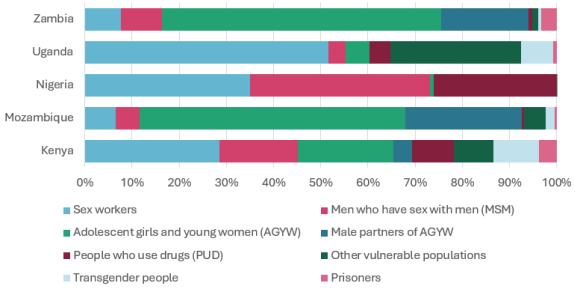

Figure 2. GC7 PrEP budget by country and population.

Conclusions: GF PrEP budgets grew rapidly since GC5. Significant increases from GC6-GC7 in MF countries compared to all others suggest the MF incentivized increased investment. While this represents a critical investment objective, analysis is needed to assess epidemiological impact, quality of services, PrEP/PEP uptake, and choice. Further financial analysis is also recommended given limitations of budget analysis (some PrEP funding falls outside of PrEP-specific modules and budgets do not translate to spend, among others).

Health systems, health systems strengthening and partnerships

Advancing cervical cancer screening and treatment for women living with HIV in Northern Zambia: lessons learnt from the "Screen and Treat" approach

P. Mwala[1], M.-C. Umuhoza[1,1], G. Mutaawe[1], T. Jere[1], A. Mwango[1], B. Chirwa[1], C. Wose Kinge[2], C. Chasela[3], E. Mothibi[4], S. Kunda[5], N. Mambo[5], G. Lingenda[6], K. Kapembwa[6], C. Kanene[7], B. Nkula[5]
[1]Right to Care Zambia, Lusaka, Zambia, [2]Right to Care Zambia, Centurion, South Africa, [3]Right to Care South Africa, Centurion, South Africa, [4]Right to Care South Africa, Lusaka, Zambia, [5]Ministry of Health, Mansa, Zambia, [6]USAID Lusaka, Lusaka, Zambia, [7]USAID Mansa, Mansa, Zambia

Background: Cervical cancer is the leading cause of cancer-related morbidity and mortality among women in Zambia. Women living with HIV (WLHIV) are four to five times more likely to develop cervical cancer. Screening and prompt treatment helps to prevent and cure cervical cancer but remains a major challenge especially for women living in rural areas.
The USAID Action HIV Project, in collaboration with Zambia's Ministry of Health, implemented an enhanced cervical cancer screening and treatment program in Luapula, Muchinga, and Northern provinces. We analyzed the outcomes of this initiative in 2023 and 2024.
Methods: In 2024, the Project expanded an intensive training program for healthcare staff in screening and treatment of precancerous lesions and procured additional equipment to facilitate a "screen and treat" approach. WLHIV aged 15-49 years were screened using visual inspection with acetic acid (VIA) or Human Papilloma Virus (HPV) DNA collection kits, with HPV-positive cases undergoing confirmatory VIA screening as per national algorithm.
Treatment options included cryotherapy, thermocoagulation, and loop electrosurgical excision procedure (LEEP). A two-sample test of proportion (α=0.05) was used to compare treatment coverage between 2023 and 2024.
Results: The Project screened 31,479 WLHIV in 2023 and 30,448 in 2024. VIA-positive rates were 8.6% (2,708) in 2023 and 8.2% (2,508) in 2024. Treatment coverage for VIA-positive cases significantly increased from 57.9% (1,568) in 2023 to 92.7% (2,326) in 2024 ($z=28.90$, $p<0.001$).
Luapula province consistently reported the highest proportion of VIA-positive cases (77.4% in 2023 and 71.2% in 2024). HPV positivity rates increased from 11.8% (1,009/8,519) in 2023 to 20.3% (257/1,269) in 2024, while VIA positivity among HPV-positive WLHIV decreased from 22% to 11.7%.
Conclusions: The implementation of the „screen and treat" approach dramatically improved treatment coverage for WLHIV with VIA-positive results, increasing from 57.9% to 92.7%. This strategy is highly effective in enhancing access to cervical cancer prevention and treatment services for WLHIV in resource-limited settings. We further recommend research to elucidate the possible causes of the high VIA-positive rates in Luapula province.

TUPEE135

Potential policy implications and scalability of PMTCT through community HIV testing for pregnant women in unconventional delivery settings

F. Muse[1], D. Oyewole[1], O. Kolade[1], O. Ogwa[1], E. Vincent[2], A. Akinyole[3], L. Abass[4]
[1]Damien Foundation Belgium (Nigeria Project), Programme, Ibadan, Nigeria, [2]Institute of Human Virology, Programme, Abuja, Nigeria, [3]State AIDS, Viral Hepatitis and STIs Control Programme, Ibadan, Nigeria, [4]State Agency for the Control of AIDS, Programme, Ibadan, Nigeria

Background: Unconventional delivery settings, such as traditional birth attendants (TBA) centers and spiritual healing homes, serve as primary care providers for pregnant women in many resource-limited settings. Integrating community-based HIV testing and Prevention of Mother-to-Child Transmission (PMTCT) services in these settings is critical for eliminating pediatric HIV infections.
This abstract explores the potential policy implications and scalability of this approach, drawing from implementation experiences in high-burden regions.
Methods: A PMTCT intervention was designed to integrate community HIV testing services into unconventional delivery settings. Women who are pregnant and accessing care in unconventional delivery settings were offered HIV testing, counseling, and linkage to antiretroviral therapy (ART) if diagnosed positive.
Stakeholders, including TBAs and community leaders, were trained on PMTCT protocols and referral systems. Program data on service uptake, maternal ART initiation, and infant HIV testing were analyzed to assess outcomes and scalability.
Results: The intervention reached over 25,821 pregnant women across unconventional settings, with an HIV testing uptake of 98%. Among those tested, 72 were diagnosed with HIV, and all individuals who tested positive were successfully linked to care.
The model demonstrated cost-effectiveness by leveraging existing community structures and reducing the need for additional infrastructure. However, challenges included stigma and limited regulatory oversight in unconventional settings.
Policy Implications: The integration of PMTCT services into unconventional delivery settings requires policy frameworks to formalize partnerships with TBAs and other informal providers. Recommendations include:
1. Establishing standardized PMTCT training and certification programs for TBAs and spiritual healers.
2. Strengthening referral networks between unconventional settings and formal health facilities.
3. Incorporating community HIV testing in national PMTCT guidelines and scaling up funding for such programs.

Scalability: This model is scalable across resource-limited settings with high reliance on unconventional delivery systems. Success depends on stakeholder engagement and integration into national health strategies.
Conclusions: PMTCT through community HIV testing in unconventional delivery settings has the potential to bridge gaps in maternal and child health services. Policymakers should prioritize this approach to achieve EMTCT and address inequities in access to care in resource-limited settings.

TUPEE136

Integrated management of hepatitis B among pregnant women with HIV as a part of routine care at antiretroviral therapy clinics, Andhra Pradesh, India- 2024

M. Thogarucheeti[1], S. Attada[1], N. Surapaneni[2], K.P. Prasad[1], R. Allam[3], N. Chava[4], R. Agarwal[5], G. Ramesam[4], R. Praveen[4], P. Ajit[4], J. Kurada[4], V. Yeldandi[4], P. Turaka[4], P. Rajendra Prasad[4], S. Chakravarthy[1], P. Nadol[3]
[1]Andhra Pradesh State AIDS Control Society, Vijayawada, India, [2]Viral Hepatitis Control Program, Vijayawada, India, [3]U.S Centres for Disease Control and Prevention, DGHT, Delhi, India, [4]Society for Health Allied Research & Education India, Hyderabad, India, [5]WHO, Division of HIV, Hepatitis and STI, Delhi, India

Background: India is one among three countries contributing to ~50% of the global burden of hepatitis B. Most of the global burden of chronic hepatitis B is attributed to vertical transmission from mother to infant with a risk of ~90% for progression to chronic infection among exposed infants.
We describe the package of care provided to all pregnant women living with HIV (PWLHIV) and determine pregnancy outcomes among those accessing care at antiretroviral therapy (ART) clinics in Andhra Pradesh (AP).
Methods: During January 2022-November 2024 at 54 ART clinics we integrated hepatitis B testing using hepatitis B surface antigen (HBsAg) rapid tests for all people living with HIV on ART, providing hepatitis B vaccination for PWLHIV who test negative, and initiating rapid start of a tenofovir containing ART regimen for PWLHIV with hepatitis B co-infection. We analyzed data from routine program records to calculate the HBsAg positivity and estimated the difference in the pregnancy outcome (live birth) among those with and without hepatitis B post-delivery using chi-square test for proportions.
Results: Of the 2,864 PWLHIV, 2,472 (86.3%) were tested for HBsAg. The median age was 24 years (IQR 21–28). Among these, 1,388 (56.1%) were ART naïve at screening and 83% initiated ART on the same day. HBsAg positivity was 1.1% (28/2,472) and 96.3% were continued/transitioned to tenofovir based regimen. Hepatitis B vaccination was offered to 88.7% (2,168/2,444) of those testing negative and 72% completed three doses. All live infants received a monovalent dose of hepatitis B vaccine within the first 24 hours after birth. There was no statistical difference (p>.05) in pregnancy outcomes among PWLHIV with (82.1%) and without hepatitis B (87.4%).
Conclusions: The intervention demonstrated access to an integrated person-centred package of hepatitis B services for PWLHIV as a public health approach within routine ART care. The pregnancy outcomes did not differ among PWLHIV with and without hepatitis B coinfection.

TUPEE137

Client-centered quality improvement: implementing digital feedback systems in Nigerian HIV care settings

H. Bello Raji[1], O. Adebayo[1], O. Adetola[2], U. Ugwoke[1], C. Oga-Omenka[3], M. Bathnna[4], E. Vincent[1], E. Kwasi Armah-Ansah[3], O. Adeagbo[5], O. Ajayi[2], V. Nnamani[2], L. Ekpere[2], K. Nzeadibe[1], U. Atoi[1], E. Okpokoro[4], O. Olupitan[1], A. Agbaje[6], C. Mensah[7], P. Dakum[6], N. Workneh[8], J. Kimeu[8], K. Tsujii[8], M. Zamzu[8], J.-. Nouboussi[8]
[1]Institute of Human Virology Nigeria (IHVN), Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [2]Seamhealth Innovations, Abuja, Nigeria, [3]School of Public Health Sciences, University of Waterloo, Waterloo, Canada, [4]Institute of Human Virology, Nigeria IHVN, International Research Centre of Excellence,, Abuja, Nigeria, [5]College of Public Health, University of Iowa, Iowa, United States, [6]Institute of Human Virology Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [7]Institute of Human Virology Nigeria (IHVN), Office of the COO, Abuja, Nigeria, [8]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Switzerland

Background: Client satisfaction is crucial for healthcare quality and Anti-Retroviral Therapy (ART) adherence. In Nigeria, home to 1.9 million Persons Living-with HIV (PLHIV), understanding client experiences is vital for addressing service delivery gaps and achieving the UNAIDS third „95" target.
To address this gap, the Institute of Human Virology Nigeria (IHVN) piloted a novel digital feedback system, using a mobile application and web platform to evaluate Client satisfaction across critical service points in HIV care to identify areas requiring improvement, and ultimately enhance service delivery to support viral suppression among PLHIV.
Methods: The Clientshot Continuous Quality Improvement initiative was conducted for three months (September-November 2024) in 40 high-volume healthcare facilities across Kwara, Gombe, Anambra, and Ebonyi states Nigeria. A custom mobile application with offline capabilities and automated data synchronization was used to collect client feedback via a structured questionnaire. All PLHIV visiting the health facilities were invited to participate.
Feedback was categorized into complaints and commendations across key service points: adherence counseling, medical records, pharmacy, medical review/consultation, and laboratory services.
Data validation was performed using quality checks and verification before analysis using simple frequencies and percentages.

Results: Of the 24,346 PLHIV visiting the facilities during the reporting period, 14,625 provided feedback, resulting in a 60% response rate. Client satisfaction was high, with 96.5% (14,114) commendations and 3.5% (511) complaints. Adherence counseling received the highest proportions of both complaints (32%) and commendations (30%). Other service points, including medical review, pharmacy, medical records, and laboratory services, followed similar patterns. Of 511 complaints, 61% (309) were unresolved, 6% (32) were in progress, and only 33% (170) were fully resolved, at the end of the pilot highlighting gaps in issue resolution.
Conclusions: The Clientshot CQI pilot demonstrated the effectiveness of digital tools for client feedback and emphasized integrating this feedback into quality improvement efforts.
While satisfaction levels were high, the 61% unresolved complaints highlight critical gaps in responsiveness and follow-up, risking care quality and outcomes. A robust complaint resolution mechanism and targeted interventions are essential to address service delivery challenges, enhance client satisfaction, and support the UNAIDS third "95" target for ART adherence.

HIV and development synergies

TUPEE138

Utilizing digital literacy for economic empowerment of adolescent girls and young women in the DREAMS program in Zambia

B. Mushiki[1], M. Musheke[1], C. Siame[1], W. Khondowe[1], F. Mwape[1], B. Siamasuku[2], H. Zulu[3], D. Mwamba[4], C. Kanene[4], A. Phiri[4]
[1]Centre for Infectious Disease Research in Zambia, Implementation Science, Lusaka, Zambia, [2]Young Women Christian Association of Zambia, Lusaka, Zambia, [3]Emmaton Libra Developers, Lusaka, Zambia, [4]United States Agency for International Development, Lusaka, Zambia

Background: Adolescents and young people account for around half of all new HIV infections in Zambia. As part of comprehensive HIV prevention, the USAID Controlling HIV Epidemic for Key and Underserved Populations (CHEKUP) I project through the Determined, Resilient, Empowered, AIDS-free, Mentored, Safe (DREAMS) initiative provides digital literacy training to adolescent girls and young women aged 15-24 years for formal or self-employment.
Description: The digital literacy training was based on four tiers, Tier 1 – school dropouts, Tier 2- school leavers, Tier 3- in-school and Tier 4 – any other AGYW in the age range. The training was customized to empower AGYW with digital skills to enable them acquire skills for formal or self-employment to dissuade them from engaging in transactional sex that predisposes them to the risk of HIV acquisition. We report on the utility of digital literacy training for economic strengthening of AGYW as part of comprehensive HIV prevention.
Lessons learned: Between October 2022 and September 2024, 9,991 AGYW were enrolled in a digital literacy course, of which 9,946 completed the mandatory modules. Pre-test scores of less than 40% and post-test scores of >95% demonstrated significant improvements (48% - 59% performance growth) in digital skills, including computer literacy, internet navigation, online communication, content creation and economic empowerment through online job opportunities, freelancing, and entrepreneurship among the 9,946 beneficiaries. The gained skills resulted in 486 (9.7%) AGYW securing internships and job placements out of the 4,996 enrolled in Tier 1 and 2 (school drop outs and school leavers) whilst 7,156 (71.9%) AGYW enrolled in all 4 Tiers embarked on self-employment, utilizing digital skills to advertise their different products and services, including tailoring, hair dressing and cosmetics, and online selling of both imported and local cosmetic products.
Conclusions/Next steps: In the era of digital advancement, digital literacy has the ability to economically empower AGYW as part of comprehensive HIV prevention.
This empowerment has the potential to reduce their risk of HIV acquisition through non-engagement in transactional sex as a source of livelihood. Further analysis is required to assess how economic empowerment has reduced their vulnerability to HIV acquisition.

Integration of HIV services with other health and support services

TUPEE139

Interruption in treatment (IIT) patterns among clients on antiretroviral therapy (ART) in the wake of enhanced person-centered interventions: the case for the USAID DISCOVER-Health Project in Zambia

A.P. Ndhlovu[1], J. Musangulule[1], L. Cicciò[1], L. Kawanga[1], M. Nyumbu[1], S. Hartchard[1], J. Posner[2], M. Musonda[3], D. Mwamba[3]
[1]John Snow Inc, USAID District Coverage of Health Services, Lusaka, Zambia, [2]John Snow Inc, Boston, United States, [3]United States Embassy/Zambia Mission, Lusaka, Zambia

Background: Interruptions in treatment (IIT) among clients on antiretroviral treatment (ART) can undermine the benefits of HIV treatment programs. Treatment interruption reduces the immunological benefit of ART and increases AIDS-related mortality and HIV transmission. There are many causes for IIT, including fear of stigma and difficulties in getting to the facility for re-fills. JSI, through the USAID DISCOVER-Health Project, supports the Zambian Ministry of Health in providing ART in 195 facilities, and is working to reduce IIT through combination person-centered interventions, to improve health outcomes for clients.
Description: The project structured ART services around client needs and had employed person centered strategies to keep people in care and on treatment. Such strat-

egies included issuing appointment reminders, same-day tracking in case of missed appointments, the scale up of various differentiated service delivery models (6 multi-month dispensing, community drug delivery, after-hours and weekend clinics), all within the case-manager model framework; whereby specific and skilled community-based volunteers are assigned clients to support.

Lessons learned: Between October 2022 - September 2024, the volume of clients on ART increased from 65,217 to 80,339. Within the same period of time, the IIT rate has gradually reduced from 10 clients per 1,000 active clients to 3 per 1,000 active clients. At the national level, the same IIT rate went from 19 clients per 1,000 active clients to 22 IIT per 1,000 active clients.

During the same time period, the death rate for project clients on ART has reduced from 2.8% to 2.4%, compared to the national rates of 1.5% to 1.3% respectively.

Conclusions/Next steps: The combination of person-centered interventions are effective at reducing IIT. Applying multiple tailored strategies designed to address peoples' lived experiences, and align with the treatment context, does appear to make a considerable difference in treatment interruption patterns, especially over the course of years.

TUPEE140

Person-centric models for HIV and mental health care integration: evaluating horizontal service delivery for HIV positive people who inject drugs in Abuja, Nigeria

G. Ezenri[1,2], J. Onyehalu[1,2], A. Ngige[1,2], C. Idabor[1,2], D. Attama[3], C. Nwachuya[1,2], A. Isah[1,2]

[1]Person-Centred HIV Research Team (PeCHIVReT), Nsukka, Nigeria, [2]University of Nigeria, Clinical Pharmacy & Pharmacy management, Nsukka, Nigeria, [3]University of Nigeria, Nsukka, Nigeria

Background: HIV-positive people who inject drugs in Nigeria face a dual burden of drug use and mental health disorders, which exacerbates their vulnerability and complicates their healthcare needs. The injection of harmful drugs leads to poor adherence to antiretroviral therapy and worsened mental health outcomes.

This study assessed the impact of integrating HIV and mental health services for HIV positive people who inject drugs, with a focus on person-centered approaches, to inform better healthcare practices and policies

Methods: This study adopted a cross-sectional design to obtain responses from 92 randomly sampled HIV positive people who inject drugs in Abuja, Nigeria in January 2025 using a validated 36-item questionnaire from two secondary healthcare facilities. Their access to services, experiences with integrated care, barriers, challenges and future perspectives were assessed. Descriptive and inferential analyses were used to summarize the study's findings. Ethical approval was obtained from the Institutional review board.

Results: A total of 69 HIV-positive people who inject drugs responded to the questionnaire (76.7% response rate) with 28 (40.6%) having injected drugs for 1–5 years and 25 (89.3%) of them experiencing stigma due to their positive HIV status (*p=0.024*). Over half 36 (52.2%), are aware of integrated HIV and mental health services in their community and 59(85.5%) feel that combining HIV and mental health services would improve treatment outcomes.

The majority, 61 (88.4%), believe that integrated care improves their overall health and well-being and 26 (37.7%) experienced reduction in stigma or discrimination since accessing integrated care. Also, 63 (91.3%) believe integrated care can improve their ability to stick to treatment regimens. Most, 52 (75.4%) feel that healthcare workers are not adequately trained to provide integrated care.

Conclusions: The majority of HIV-positive people who inject drugs reported improved health outcomes, reduced stigma, and better treatment adherence with integrated care models. However, our findings highlight the need for enhanced training of healthcare workers to address the unique challenges of delivering person-centered, integrated care.

Stakeholders should ensure resources are focused on improving healthcare worker training to effectively address the unique challenges associated with providing person-centered, integrated care and advocate for policy shifts toward scalable and sustainable horizontal service delivery approaches for this vulnerable population.

Innovations in data collection, monitoring and evaluation

TUPEE141

A retrieval-augmented generation (RAG) AI Chartbot to improve HIV programme coordination and decision support

M. Moszcynski[1], L. Metz[2], M. Niwa[3], R. Haggard[2], B. Klyn[2], T. Smith[3], H. Cooper[2], P. Khomani[3], D. Green[2]

[1]Cooper/Smith, Warsaw, Poland, [2]Cooper/Smith, Austin, United States, [3]Cooper/Smith, Lilongwe, Malawi

Background: HIV programme coordinators and health officials face challenges in using data for decision making due to limited time, data access, and technical ability. AI has emerged as a useful tool for facilitating access to data, navigating large data sources, and identifying actionable insights.

Description: We leveraged an existing HIV data pipeline and web-based dashboard in Malawi which collates 20 programmatic data sources including tens of millions of data points spanning over 1,000 health facilities, dozens of disaggregates, and nearly a decade of data.

We developed a web-based chatbot service called "Chartbot" which leverages this data pipeline as a primary input. In order to respect privacy and ethical concerns, as well as regulatory requirements for data sharing and hosting, we do not directly link the data pipeline to commercially available large language models (LLMs). Instead, we utilize a retrieval-augmented generation (RAG) approach.

To further ensure security and avoid misuse or hallucinations, "Chartbot" responses are restricted to indicators and queries in the RAG data repository (i.e., a query related to malaria will return an error message). For a given query the contents are passed to an embeddings layer and then to the data pipeline to retrieve the relevant data.

With the summarized relevant data in hand, the LLM (ChatGPT, Claude, Gemini) then generates the relevant visualizations and insights without a need for the LLM to access, store, and potentially misuse the source data.

Lessons learned: We successfully developed a real world RAG-enabled LLM chatbot for interfacing with HIV data using nationally supported routine data systems. "Chartbot" reliably returns tables, graphs, and statistics from user queries. This can include a simple request of "show me the latest ART adherence rates for women in Blantyre" or more complicated requests such as "generate a line graph combining trends for the past five years for HIV test positivity and STI diagnoses in rural facilities".

"Chartbot" also handles sequential requests for adding data layers to visuals, modifying formatting, or even changing the language of labeling.

Conclusions/Next steps: RAG-enabled LLM chatbots can be utilized in real-world settings to enhance data access and use, while adhering to ethical, privacy, and regulatory requirements.

TUPEE142

Empowering community-based organizations through gamification for enhanced monitoring & evaluation capacity

T.M. Ndhlovu[1], N. Tshuma[1], M. Malahlela[1]
[1]Best Health Solutions, Public Health, Johannesburg, South Africa

Background: Community-based organizations (CBOs) often face challenges in implementing effective Monitoring & Evaluation (M&E) frameworks due to technical complexities. These challenges hinder their ability to collect, interpret, and act on data critical for improving program outcomes in health services.

This initiative aimed to develop and test an innovative, gamified approach to M&E capacity building to simplify technical concepts, empower CBOs to take ownership of data processes, and enhance community-level interventions. Through transforming complex M&E processes into interactive, game-based activities, the initiative sought to build sustainable skills and promote a culture of continuous improvement.

Description: Conducted over six months across multiple communities in Gauteng, the initiative targeted CBOs engaged in health services. A gamified training model was developed using design thinking principles, focusing on core M&E competencies such as indicator selection, data flow, management, and reporting. Interactive role-playing and strategy games simulated real-world M&E scenarios, allowing participants to create hypothetical M&E plans and practice data collection and management. Game modules addressed practical challenges related to data cleaning, analysis, and tool development. Pre and post-training assessments measured improvements in M&E knowledge, skills, and confidence, while focus group discussions captured qualitative feedback on engagement, relevance, and scalability.

Lessons learned: The gamified approach led to a 41% improvement in participants' understanding and application of M&E concepts. Qualitative feedback highlighted high levels of engagement, with participants finding the gamified model approachable and practical. They reported increased confidence in applying newly acquired skills to enhance data collection, reporting, and evaluation within their programs. Hands-on exercises fostered a deeper understanding of M&E best practices, facilitating adaptation to diverse community contexts. CBOs demonstrated improved capacity to manage data independently and align programs with evidence-based planning.

Conclusions/Next steps: The gamified training model proved effective in building M&E capacity within CBOs, making complex technical concepts more accessible and engaging. This approach offers a scalable best practice for M&E capacity building, particularly in resource-limited settings.

Future efforts should focus on expanding the model to cover advanced topics such as adaptive management and real-time data analysis, further strengthening CBOs' ability to develop resilient, data-driven programs.

TUPEE143

Leveraging social network analysis to support epidemiological research on HIV prevention and case management

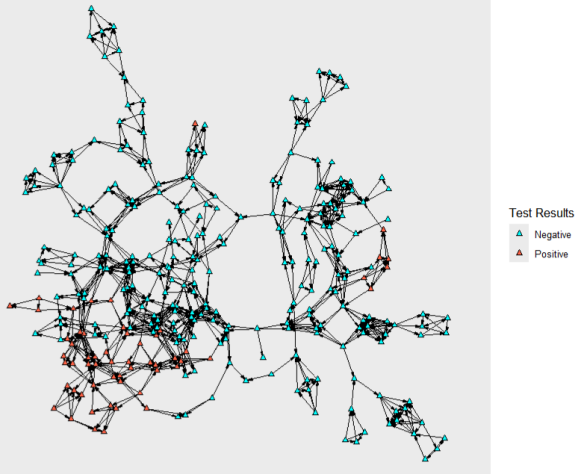
S. Karera[1], B. Kwizera[1], F.K. Rubuga[2], E. Remera[3], G. Rwibasira[4], C. Kamanzi[1], G. Gatete[4], C. Steiner[5], V. Mugisha[1], RFPs
[1]ICAP at Columbia University, Mailman School of Public Health, Kigali, Rwanda, [2]Center for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition (CIIC-HIN), Kigali, Rwanda, [3]Rwanda Biomedical Center, Division of Research, Innovation and Data Science, Kigali, Rwanda, [4]Rwanda Biomedical Center, Division of HIV, STIs, Viral Hepatitis and OVDC, Kigali, Rwanda, [5]ICAP at Columbia University, Mailman School of Public Health, Lusaka, Zambia

Background: The global fight against HIV benefits from innovative strategies like Social Network Analysis (SNA), which can enhance prevention and case management. Leveraging Rwanda's Active Case-Based Surveillance (CBS) program data, initiated in 2018, this study applied SNA to understand HIV transmission dynamics nationwide. By characterizing HIV contact networks, identifying factors linked to higher HIV positivity yields, and assessing their impact on transmission, this research aimed to optimize HIV prevention and case management in Rwanda, potentially accelerating efforts to end HIV.

Methods: SNA was used to classify participants into distinct networks/clusters, with similarity measures applied to describe community structures. A multivariate model-

ing approach was used to assess the impact of demographic factors, risk behaviors and index-contact relationships on positivity yields.

Results: A total of 100,777 confirmed cases were tracked, leading to the identification of 191,731 contacts (contact to index ratio: 1.9), of which 8,485 tested positive (positivity yield: 4.4%). Network density was low at 2%, indicating sparse networks with distinct clusters. Key factors associated with higher HIV positivity were age, gender, diagnosis status, and relationship type. Those aged 25 and below had the highest odds of testing positive compared to older age groups (OR:0.64, CI:0.6-0.69 for 25-44, OR: 0.55, CI:0.5-0.61 for 45+). Contacts from male clients (OR: 1.55, CI:1.57-1.64) and contacts from newly diagnosed clients (OR: 2.51, CI:2.38-2.64) showed increased positivity odds. Relationship types strongly influenced transmission, with the highest odds among social network contacts (OR:9.78, CI:8.44-11.3), casual partners (OR:3.51, CI:3.1-3.97), and cohabiting relationships (OR: 5.87, CI:5.15-6.7). Networks sharing these risk factors exhibited higher transmission rates compared to others.



Conclusions: The study findings underscore the importance of considering demographic factors, client characteristics, and relationship dynamics when designing targeted HIV control strategies. By leveraging SNA techniques to identify high-risk clusters, public health interventions can be optimized to focus on the most vulnerable subgroups.

TUPEE144

Quality improvement initiative to improve HIV viral load sample collection and result documentation at Ingwizi Clinic, Mangwe District, Zimbabwe

A. Chindore[1], T.W. Nhapi[1]
[1]*Organiztion for Public Health Interventions & Development (OPHID), Programs, Harare, Zimbabwe*

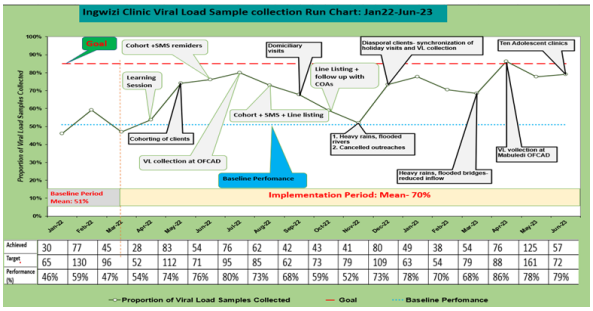
Background: Viral load (VL) monitoring is crucial for measuring antiretroviral therapy (ART) success and the goal is to surpass the 95% VL suppression by 2030. It's crucial to ensure timely VL sample collection, transportation, processing, issuing results and documentation. We observed that Ingwizi Rural Clinic in Mangwe District Zimbabwe had an annual VL sample collection coverage of 51% by April 2022, against an 80% national VL coverage target.

We designed a multi-pronged approach to VL sample collection quality improvement (QI) initiative aimed at improving VL sample collection to 85% by December 2023.

Description: Using the plan-do-study- act QI methodology, the district technical team and Ingwizi clinic staff created a multi-disciplinary team to identify the bottlenecks to VL sample collection and result documentation. All VL-related SOPs and guidelines were reviewed and adherence to. HIV positive clients on ART were reached through multiple strategies. These included line-listing eligible clients, creating calendar & village cohorts, sending SMS reminders, synchronizing VL sample collection with drug pick-up schedules, conducting domiciliary visits, leveraging off-clinic activity days for outreaches and addressing VL-related client concerns, myths & misconceptions.

Additionally, we tracked monthly VL sample collection coverage rates wall-pinned run charts and also iteratively identified areas for further refinement.

Lessons learned: Through systematic efforts, we improved VL sample collection rates significantly from 51% in April 2022 to 75% by June 2023. By 2024, Ingwizi VL coverage was 82% with suppression rates above 95%. Community VL collection strategies alone resulted in a 7% increase in VL sample collection rates, highlighting the value of tailored outreach efforts.



Conclusions/Next steps: This project underscores the effectiveness of targeted, client-centered approaches in improving healthcare outcomes in resource-limited settings. By addressing systemic barriers such as long travel distances, inconsistent client follow-up, and logistical constraints, we demonstrated that significant improvements in VL sample collection and ultimately VL coverage rates are achievable.

TUPEE145

Improving patient biometrics match outcomes in Cross River State: an implementation review on the deployment of Biometrics Confirmation Slip

C. Obi[1], C. Igbokwe[2], E. Isang[1], B. Okoh[1], K. Odey[1], J. Umana[1], A. Etim[3], O. Onwah[1], U. Akpan[1], O. Toyo[1], D. Ogundehin[4], R. Eneogu[4], U. Omo-Emmanuel[4], M. Katbi[4], D. Kimanga[4], C. Obiora-Okafo[4], A. Idemudia[4], O. Emmanuel[5], E. James[4], J. Pius[4], O. Oyelaran[4], O. Onyedinachi[1], A. Adegboye[1], A. Eyo[1]
[1]Excellence Community Education Welfare Scheme (ECEWS), Strategic Information, Uyo, Nigeria, [2]FHI360, Strategic Information, Abuja, Nigeria, [3]State Ministry of Health, Calabar, Nigeria, [4]United States Agency for International Development, Office of HIV and TB, Abuja, Nigeria, [5]Federal Ministry of Health, National AIDS, STI and Viral Hepatitis Control Program, Abuja, Nigeria

Background: The PEPFAR/USAID-funded ACE-5 project implemented the Patient Biometric Service (PBS) in line with national requirements to deduplicate and enhance medical records for people living with HIV (PLHIV). However, a review of PBS performance data in Cross River State, Nigeria identified low recapture rates and suboptimal fingerprint match outcomes.
This study describes the lessons learnt from implementing a quality improvement (QI) intervention to improve biometric recapture and match outcomes for PLHIV in Cross River State.
Description: The QI intervention was implemented using a Plan-Do-Study-Act cycle across all 64 project-supported ART facilities in Cross River. In the Plan phase, root cause analysis conducted for the cohort of PLHIV with fingerprint recapture as of March 2024 identified that ancillary staff conducting fingerprint recaptures could not accurately identify eligible clients, leading to repeat recaptures for clients with already matched prints. In the Do phase, a Biometrics Confirmation Slip (BCS) was developed and deployed in May 2024.
This was a checklist that required multi-level verification of client identity before fingerprint captured. This was integrated into routine service flow. Key healthcare staff were required to attest to the client's identity, sign on the checklist, as the client passed through each service delivery point.
Biometrics data (date of capture, date of recapture, and match outcome) for PLHIV aged ≥6 years were extracted from the National Data Repository and electronic medical records at the 64 facilities. Recapture rates (proportion of clients recaptured) and match rates (proportion of clients with matching capture and recapture prints) were compared before (January–April 2024) and after the intervention (May-August 2024).
Lessons learned: During the period, 14,441 PLHIV had their prints recaptured. Overall print recapture rate improved from 63.0%(21,906/34,747) to 99.0%(36,347/36,713) before and after the intervention respectively, and the match rate improved from 30.6% (6,710/21,906) to 95.0% (34,558/36,347) before and after the intervention respectively. Integrating the BCS with routine services facilitated its adoption by service providers, and the multi-level authentication process enabled accountability among healthcare staff.
Conclusions/Next steps: The introduction of multi-level systems to validate an implementation can effectively improve its outcomes. This approach is recommended for scale-up to other programs implementing PBS

TUPEE146

Deployment of SmartCare Pro (EHR) with biometric functionality in 2024 to address HIV duplicate healthcare records in Zambia

K.P. Poho[1], P. Shabangu[1], K. Sikwibele[1], S. Funda[2], B. Chiteba[3]
[1]Institute for Health Management - Southern Africa, Health Informatics, Lusaka, Zambia, [2]Centre for Disease Control and Prevention, Health Informatics, Lusaka, Zambia, [3]Centre for Disease Control and Prevention, Lusaka, Zambia

Background: Duplicate HIV individual healthcare records pose a significant challenge in health systems, causing fragmented patient information, reduced efficiency, and compromise Recipient of Care (RoC) safety. In Zambia, approximately 120,052 duplicate records of People Living with HIV (PLHIV) exist from the previous electronic health record systems namely, SmartCare Legacy and SmartCare Plus. Lack of a unique historical recipient of care record contributed towards silent transfers among PLHIV, and an increasing number of lost to follow up (LTFU) RoCs. To address this, we deployed SmartCare Pro to 779 health facilities in April 2024 countrywide. SmartCare Pro is an advanced Electronic Health Record (EHR) system with integrated biometric functionality for unique identification of individuals.
Description: The deployment involved integration of biometric (fingerprint) scanners within the SmartCare Pro EHR system. This ensured that each recipient of care is assigned a unique biometric identifier which is consistently used across all health facilities. The system was initially piloted in 4 high volume health facilities before expanding to broader deployment across 779 health facilities.
To analyse uniqueness of records, a descriptive and de-duplication fuzzy matching analysis was conducted on 15,742 biometric registrations from. individual registrations that occurred between April 2024 and September 2024. Descriptive counts of all registrations, and their uniqueness was conducted.
Lessons learned: As of September 2024, 15,742 individuals in Zambia had their biometrics registered in Zambia and none were duplicated as a unique rate of 100% was attained after a deduplication analysis procedure. Health facilities reported enhanced accuracy in recipient of care identification and a more streamlined process for accessing recipient of care histories as recipients of care were uniquely identified using their fingerprints unlike searching by other identifiers, thus reducing the patient waittimes.
Conclusions/Next steps: The deployment revealed that integrating biometrics with the SmartCare Pro EHR system effectively addressed the issue of duplicate health-

care records by providing an accurate method for patient identification. It was further revealed that SmartCare Pro with biometric functionality has the potential to transform health information management. The biometric system improved data integrity, operational efficiency, and the reliability of records.

HIV pathogenesis

WEPEA006

Early-life systemic inflammation correlates with depression, while HIV-1 cell-associated DNA reflects neuroinflammation in young people living with perinatally acquired HIV

S. Naidoo[1], A. Mudra Rakshasa-Loots[2], K. van Wyhe[1], M. Cotton[1], B. Laughton[1], R. Glashoff[3]
[1]Stellenbosch University, Peadiatrics and Child Health, Cape Town, South Africa, [2]University of Edinburgh, Hub for Metabolic Psychiatry, Edinburgh, United Kingdom, [3]Stellenbosch University, Medical Microbiology and Immunology, Cape Town, South Africa

Background: Adolescents with perinatally acquired HIV (PHIV) are at increased risk for depressive symptoms and neuroinflammation, despite early antiretroviral therapy (ART). Systemic inflammation during early life has been linked to depressive symptoms, while persistent HIV-1 reservoirs, measured by integrase cell-associated HIV-1 DNA (iCAD), may reflect neuroinflammation.
This study investigates longitudinal associations between early-life inflammatory biomarkers, iCAD levels, depressive symptoms, and neuroinflammation.
Methods: Thirty-nine adolescents with PHIV (56% female) from the Children with HIV Early Antiretroviral Therapy (CHER) trial in Cape Town, South Africa, were included. Median age was 16.0 years (IQR: 15.0–16.0), with 89.4% achieving virological suppression.
Depressive symptoms were assessed at age 16 using the nine-item Patient Health Questionnaire (PHQ-9). Plasma inflammatory biomarkers (41 total) were quantified via ELISA and Luminex™ at six time points: pre-ART (n=20), 1 year post-ART (n=14), 2 years post-ART (n=13), 3–4 years post-ART, 4–5 years post-ART, and at age 8 years (n=36).
Neuroinflammatory biomarkers were measured at age 16. iCAD levels were measured pre-ART, post-ART, and at age 8. Correlations between biomarkers, iCAD, and PHQ-9 scores were analysed using Pearson and Spearman rank coefficients.
Results: PHQ-9 scores at age 16 were significantly correlated with pre-ART concentrations of high-sensitivity C-reactive protein (hsCRP) (ρ = 0.56, p=0.008), MCP-1/CCL2 at 1 year post-ART (ρ = -0.56, p = 0.036), and soluble CD163 at 2 years post-ART (ρ = -0.59, p=0.033). A moderate, non-significant correlation was observed between PHQ-9 scores at age 16 and hsCRP levels at 1 year post-ART (ρ = -0.50, p=0.084). None of the other inflammatory biomarkers were significantly associated with PHQ-9 scores at age 16 (all p>0.05). At age 16, YKL-40 concentrations, a marker of neuroinflammation, were significantly associated with pre-ART iCAD levels (ρ = 0.91, p=0.03), suggesting a potential link between HIV-1 reservoirs and neuroinflammatory pathways.
Conclusions: This study highlights the roles of early-life inflammation and HIV-1 reservoirs in adolescent mental health and neuroinflammation. Pre-ART hsCRP and post-ART immune markers were linked to depressive symptoms, while iCAD correlated with YKL-40.
These findings underscore the need for longitudinal studies integrating viral persistence, neuroinflammation, and mental health to inform targeted interventions.

WEPEA007

Immunometabolism of innate lymphocytes in people living with HIV-1 versus HIV-2

M. Khan[1], C. Pardieu[1], A. Umaipalan[2], H. Rahman[3], H. Miras[3], S. Rowland Jones[4], J. Deayton[1,3], S. Henson[5], C. Orkin[1,3], N. McCarthy[1], SHARE Collaborative
[1]Queen Mary University of London, Immunobiology, London, United Kingdom, [2]Barking Hospital NHS Trust, HIV & Sexual Health, London, United Kingdom, [3]The Royal London Hospital, Grahame Hayton Unit, London, United Kingdom, [4]University of Oxford, Nuffield Dept of Medicine, Oxford, United Kingdom, [5]Queen Mary University of London, Centre for Translational Medicine and Therapeutics, London, United Kingdom

Background: HIV-2 displays an indolent clinical progression relative to HIV-1, including decreased T-cell activation and limited immune exhaustion. However, it remains unclear how different HIV types impact unconventional lymphocytes that mediate gut barrier defense and mucosal inflammation (including mucosal-associated invariant T-cells [MAIT], invariant natural killer T-cells [iNKT], and Vδ2+ T-cells).
We therefore investigated whether divergent clinical course of HIV-1 and HIV-2 is associated with altered gut-homing potential, mitochondrial profiles, and exhaustion of unconventional lymphocytes.
Methods: PBMCs from people with HIV-1 (n=7) and HIV-2 (n=7) were analysed by 28 colour flow-cytometry. MAIT, iNKT, and Vδ2+ subsets were assessed to determine cell frequency and expression of exhaustion markers (PD1, TIGIT), mitochondrial function (MTG, TMRM) and gut homing potential (α4β7,CD69).
Results: Both cohorts were virally suppressed (VL<50 c/mL) and ART adherent (clinical demographics are summarized in table 1.)
iNKT frequency did not differ between cohorts (p=0.7). HIV-1 was associated with increased MAIT cell frequency (p<0.02) and expression of TIGIT (p<0.02) relative to HIV-2, although the mitochondrial profile of MAIT cells was comparable between HIV cohorts (p=0.4).
Circulating Vδ2+ frequency was higher (p<0.03) in HIV-1 than in HIV-2, but gut-homing potential (p<0.02) and mitochondrial activity (p<0.03) were elevated in HIV-2 relative to HIV-1.

		HIV-1	HIV-2
Median Age (IQR)		42 (36-50)	39 (34-45)
Sex		4/7 female	6/7 female
Ethnicity		4/7 Black-African, 3/7 Caucasian	7/7 Black-African
Median CD4 (cells/µl) (IQR)		680 (580-909)	670 (434-760)
Median CD8 (cells/µl) (IQR)		964 (488-1196)	752 (584-1166)
Median % of overall lymphocyte population (95%CI)	iNKT	0.02 (0.01-0.02)	0.01 (0.007-0.01)
	MAIT	0.57 (0.32-1.9)	0.26 (0.24-0.36)
	Vδ2+	0.7 (0.62-1.2)	0.42 (0.21-1.18)

Conclusions: Preliminary analysis suggests that blood MAIT and Vδ2+ T-cell frequencies are higher in HIV-1 than in HIV-2, but gut-homing potential and mitochondrial function of Vδ2+ cells are elevated in HIV-2. These data suggest that the innate lymphocyte pool is differentially impacted by HIV types, which may influence gut reservoir size and clinical course of infection.
Future work will assess additional markers of mitochondrial function including mtDNA copy number, ROS generation, and cellular respiration.

Host immune responses

WEPEA008

HIV-associated chronic inflammation and intestinal injury do not mediate reduced transplacental transfer of anti-enterovirus antibodies in pregnant women with HIV

F. Esemu Livo[1,2,3], R. Ngamaleu[1,2,4], R. Djounda[1,2], H. Awanakam[1,2], K. Tchamda[1,2], M. Tsague[2], M. Schmiedeberg[5], E. Gutenkunst[5], R. Leke[1,2], C. Kouanfack[1], K. Nganou-Makamdop[5], M. Besong[2]
[1]Centre for Research on Emerging and Reemerging Diseases, Laboratory of Fundamental Virology, Yaounde, Cameroon, [2]University of Yaounde I, The Biotechnology Centre, Yaounde, Cameroon, [3]University of Buea, Department of Biomedical Sciences, Buea, Cameroon, [4]Catholic University of Central Africa, Immunology, Yaounde, Cameroon, [5]Universitätsklinikum Erlangen, Institute of Clinical and Molecular Virology, Erlangen, Germany

Background: The efficient transfer of protective antibodies from mother to child during pregnancy is crucial for infant immunity during early life. However, the efficiency of transplacental antibody transfer has been shown to be reduced in HIV-positive women for common childhood infections such as enteroviruses, respiratory syncytial virus (RSV), and cytomegalovirus (CMV), though the underlying mechanisms remain unclear.
We hypothesize that HIV-associated inflammation, induced by intestinal injury, may contribute to this reduced transfer. This study aims to investigate the role of HIV-associated inflammation, driven by gut injury, in the reduced transplacental transfer of antibodies to enteroviruses, RSV, and CMV among virally suppressed pregnant women living with HIV at delivery, addressing conflicting findings in the literature.
Methods: We sampled 107 HIV-positive and 103 HIV-negative mothers during their third trimester of pregnancy. Antibody transfer to RSV, CMV, and enteroviruses was assessed in maternal-cord dyads. Markers of inflammation (sCD14) and gut injury (iFABP) were quantified using enzyme-linked immunosorbent assay (ELISA). Statistical significance was set at P<0.05
Results: All pregnant women living with HIV (PWHIV) were on antiretroviral therapy. Compared to HIV-negative mothers, PWHIV were older (P<0.001P < 0.001P<0.001), had higher levels of intestinal injury (P=0.0037) and chronic inflammation (P<0.0001), and delivered earlier (P=0.039). Cord blood antibody levels to enteroviruses were significantly lower in HIV-exposed neonates (P=0.0078).
However, there was no significant correlation between markers of intestinal injury or inflammation and reduced antibody transfer among PWHIV.
Conclusions: Our findings indicate reduced transplacental transfer of anti-enterovirus antibodies in HIV-exposed neonates, while transfer for RSV and CMV antibodies remained normal.
The observed reduction in cord antibody levels did not correlate with intestinal injury or chronic inflammation in mothers living with HIV.

WEPEA009

Trained immunity underlies persistent inflammation in PLWH

M. Bukrinsky[1], D. Sviridov[2]
[1]The George Washington University School of Medicine and Health Sciences, Microbiology, Immunology and Tropical Medicine, Washington, United States, [2]Baker Heart and Diabetes Institute, Melbourne, Australia

Background: Persistent inflammation drives HIV-associated comorbidities, including cardiovascular and neurocognitive disorders. Despite antiretroviral therapy (ART) suppressing HIV replication, chronic inflammation persists in people living with HIV (PLWH), with its mechanisms remaining poorly understood. We proposed that persistent inflammation in PLWH may stem from innate immune cells retaining a memory of their initial encounter with HIV.
This hypothesis is supported by our findings that extracellular vesicles (EVs) carrying the HIV-1 protein Nef induce a memory-like phenotype in myeloid cells, leading to hyperresponsiveness to inflammatory stimuli—a phenomenon akin to *trained immunity*. Trained immunity involves epigenetic changes, such as chromatin opening in genes linked to inflammation, cholesterol metabolism, and oxidative glycolysis.
Methods: In this study, we investigated trained immunity in cells from PLWH and mice injected with Nef EVs. Monocytes from PLWH and uninfected controls were analyzed for cytokine production after TLR agonist stimulation. Microglial cells from brain samples and bone marrow cells from mice were examined using ATAC-seq and RNA-seq.
Results: Monocytes from PLWH produced significantly higher levels of pro-inflammatory cytokines (IL-6, TNFα, and IL-1β) than those from uninfected controls, indicat-

ing a pro-inflammatory state consistent with trained immunity. Monocyte-derived macrophages (MDMs) from PLWH, particularly in males, showed heightened cytokine responses to TLR ligands, suggesting sex-specific differences. ATAC-seq revealed chromatin opening in promoters of inflammation- and cholesterol metabolism-related genes, mirroring changes in Nef EV-treated MDMs.
Similarly, bone marrow myeloid precursor cells from mice injected with Nef EVs exhibited activation of these genes and pathways compared to controls.
Conclusions: These findings underscore trained immunity as a key driver of persistent inflammation in PLWH. Importantly, they suggest that even complete HIV provirus elimination—through advanced therapies like CRISPR—may not resolve chronic inflammation or its comorbidities, as inflammatory memory persists in bone marrow progenitor cells.
This highlights the need to address trained immunity in HIV cure strategies. These insights highlight the need to consider and address trained immunity in the development of HIV cure strategies.

WEPEA010

HIV-1 broadly neutralizing antibodies in treatment naïve and long-term virologic failure populations from Tanzania where multiple subtypes co-circulate

I. Ngare[1,2], A.M. Jalloh[1], T. Kuwata[1], S. Matsushita[3], G. Barabona[1], T. Ueno[1]
[1]Kumamoto University, Joint Research Center for Human Retrovirus Infection, Kumamoto, Japan, [2]KAVI-Institute of Clinical Research, University of Nairobi, Medical Microbiology, Nairobi, Kenya, [3]Kumamoto University, Joint Research Center for Human Retrovirus Research, Kumamoto, Japan

Background: Various Env immunogen designs have failed to sufficiently elicit HIV-1 broadly neutralizing antibodies (bNAbs), in part, due to an incomplete understanding of the Env characteristics and antigen stimulation dynamics necessary for bNAb development in natural disease progression. Hence, we investigated optimal viral stimulation conditions for bNAb development by screening treatment naïve and virologic failure participants, and analyzed their Env gene sequences.
Methods: We enrolled treatment naïve (n = 230) and virologic failure (n = 167) Tanzanians, with the latter being viremic for ≥ 2 years without treatment regimen changes. We pre-screened plasma cross-neutralization using 2 pseudoviruses expressing subtype B (JRFL) and AC (246F3) Envs. Virologic failure plasmas were pre-screened by drug resistant pseudoviruses. Cross-neutralizers from both groups had their polyclonal IgG purified and neutralization signatures determined on a panel of 12 globally representative Envs, whereby neutralizers of ≥ 5 Envs were classified as bNAb elicitors. Envs were sequenced from plasma virions and cytokines quantified by a multiplex assay.
Results: Virologic failure participants, relative to their treatment naïve counterparts, had fewer bNAb elicitors (1.2% vs 6%) and narrower IgG breadths (p = 0.03). Cumulatively, IgG potency correlated with plasma IL-21 (r = 0.53, p = 0.01). A follow-up of 4 treatment naïve bNAb elicitors after 3 years of suppressive treatment revealed stunted breadth development and a marginal decline in bNAb potency.
Analyzing Env sequences showed that the V1 region amino acid length was a strong predictor of IgG breadth, albeit restricted to subtype A1 participants. Further, we generated Env clones from a subtype A1 elite neutralizer (100% breadth) with multiple mutations at known bNAb epitopes within the V1, V2, V3, and CD4-binding site regions.
The mutations mediated escape from neutralization by monoclonal bNAbs including PG16, PGT 128, and VRC01, suggesting the presence of multiple bNAb lineages in this participant, as portrayed by extensive viral diversification in regions flanking the known bNAb epitopes, following an extended analysis of ancestral clones from proviral DNA.
Conclusions: Maintaining high antigenic stimulation has potential to elicit potent bNAbs with moderate durability after antigen suppression. Env immunogens targeting to elicit multiple bNAb lineages could result in highly potent bNAbs.

Understanding and targeting persistent HIV reservoirs

WEPEA011

Methylseleninic acid enhances HIV reactivation induced by other latency reversing agents

R.A. Shepherd[1], J. Stern[2], A. Tan[1], B.M. Fisher[1], C. Tumpach[1], J. McMahon[3], P. Cevaal[1], Y. Kim[1], S. Telwatte[1], S.R. Lewin[1,4,3], M. Roche[1,5]
[1]University of Melbourne/Doherty Institute, Department of Infectious Disease, Melbourne, Australia, [2]University of Melbourne/Doherty Institute, Department of Microbiology and Immunology, Melbourne, Australia, [3]Monash University/Alfred Hospital, Infectious Diseases, Melbourne, Australia, [4]Victorian Infectious Disease Service, Royal Melbourne Hospital at the Doherty Institute, Melbourne, Australia, [5]Royal Melbourne Institute of Technology (RMIT), School of Health and Biomedical Sciences, Melbourne, Australia

Background: Reversal of HIV latency is one strategy being investigated to reduce the HIV reservoir in people living with HIV (PLWH) on antiretroviral therapy (ART). We explored whether the organic selenium compound Methylseleninic acid (MSA), an activator of transcription of the transcription factor BMAL-1 that drives HIV long terminal repeat (LTR) mediated viral transcription, could synergise with other known latency reversing agents (LRA).
Methods: CD4+ T-cells isolated from peripheral blood mononuclear cells from PLWH on ART were cultured with MSA alone, or in combination with the SMAC mimetic, AZD5582; bromodomain inhibitor, JQ1; or protein kinase C (PKC) agonist, PEP005 for 48 hours. Cell associated HIV RNA

was quantified by digital PCR targeting transcript initiation (TAR), elongation (Long LTR, Pol), completion (PolyA) and splicing (Tat/Rev; n=7-8). Synergism between MSA and other LRAs was determined by Bliss model of independence, where scores (excess over bliss score; EOB) greater than zero indicate synergy.

Results: Compared to vehicle control, all compounds alone and in combination increased TAR, Long LTR, and Pol, PolyA and Tat/Rev transcripts (Fig1) in CD4+ T-cells from PLWH. MSA in combination with AZD5582 showed greater upregulation of PolyA (mean fold change [MFC]=20.6) and Tat/Rev (MFC=15.4) transcripts, with high synergism in the induction of Tat/Rev (EOB = 11.6).

The largest increases were seen in PolyA (MFC=115.8) and Tat/Rev (MFC=170.4) expression after combination treatment of MSA and PEP005, demonstrating high synergism in the expression of Tat/Rev mean (EOB = 36.0). We observed minimal toxicity across conditions.

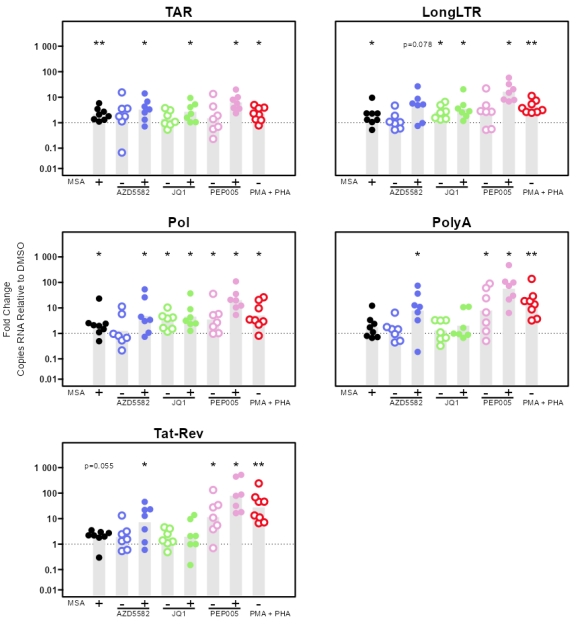


Fig1-MSA enhances LRA induced expression of cell associated HIV RNA transcripts. Mean fold change cf.Vehicle control, mean depicted by grey bar. Wilcoxon Signed rank test, *p<0.05, **p<0.01; n=7-8 donors.

Conclusions: MSA synergised with SMACm AZD5582 and PKC agonist PEP005, enhancing latency reversal in primary CD4+ T-cells from PLWH. MSA represents a novel approach to enhance latency reversal.

WEPEA012

Harnessing HOPE transplants to open a novel cure pipeline - collaboration between the bench and the HIV bedside

D. Nattere[1], N. Alavian[2], M. Tuyishime[1], T. Schappe[3], J. Granek[3], S. Carr[4], N. Archin[5], D. Margolis[5], J. Pollara[1], G.F. Ferrari1[1], C. Wolfe[2]

[1]Duke University Medical Center, Surgery, Durham, United States, [2]Duke University Medical Center, Medicine, Durham, United States, [3]Duke University Medical Center, Center for Human Systems Immunology, Durham, United States, [4]Duke University Medical Center, Pediatrics, Durham, United States, [5]The University of North Carolina, Chapel Hill, Medicine, Chapel Hill, United States

Background: Lymph nodes (LN) are a major tissue reservoirs where latent HIV persists in CD4 T cells. Access to these tissues in virologically suppressed individuals is traditionally limited, with open biopsy subject to complications and scarring, and fine needle aspirates producing insufficient cell recovery. People living with HIV (PLWH) suffer from increased rates of chronic organ failure, yet with ongoing expansion of the organ donor pool through the HOPE Act, more PLWH are undergoing transplantation. Organ transplantation typically requires the resection of native lymphoid tissue as part of surgical technique, tissue which would be otherwise be discarded. Surgically resected deep lymphoid tissue can be collected to analyze the reservoir size in PLWH and to define transcriptional changes and impact of latency reversing agents (LRAs) on the tissue resident cells. The results of these analyses can inform future efforts to target and eliminate cells harboring HIV.

Methods: PLWH undergoing solid organ transplant were identified in Infectious Diseases Clinic at Duke University. Over a 5 year period, LNs from 24 PLWH were collected during transplantation of heart (1), lungs (3), kidney (17), liver (2), or combined heart/lung (1). Lymph nodes were manually dissected and washed with media prior to Ficoll separation if cell count was over 50 million, then cryopreserved and stored.

Results: The 24 surgeries collected a median 40.9 million LN cells. Mean initial viability was 86.6% (ranged 40.7-99.6%) or 95.4% if samples not processed via Ficoll were excluded. Total viable cell counts were notably higher from LNs collected during lung or heart/lung transplants (avg yield= 567 million) compared to heart, liver or kidney transplants (avg yield= 48 million).

Upon thaw, LN retained viability over 82% (range 82-94.5%), acceptable for scRNA gene analysis. Quantitative viral outgrowth assay revealed a burden of latently infected cells ranging from less that 0.2 - 18.2 IUPM.

Conclusions: HOPE Act transplantation is an opportunity to partner with PLWH to foster the collection of lymph nodes obtained during solid organ transplant. It represents a high yield source for deep lymphatic tissue that is extremely viable at time of freeze and thaw, and can help evaluate strategies to target the lymphoid reservoir.

WEPEA013

Concurrent tuberculosis promotes the persistence of genetically-intact HIV in people living with HIV

S. Cronin[1,2], A. Pereyra Casanova[2], E. Lee[2,1], K. Fisher[2], J. Simpson[2], J. Marin-Rojas[2], A. Kelleher[3], N. Laufer[4], G. Turk[4], F. Quiroga[4], C. Vérollet[5], L. Balboa[4], S. Palmer[2,1], G. Duette[2,1]

[1]The University of Sydney, Faculty of Medicine and Health, Sydney, Australia, [2]The Westmead Institute for Medical Research, Centre for Virus Research, Sydney, Australia, [3]The Kirby Institute, Sydney, Australia, [4]Instituto de Investigaciones Biomédicas en Retrovirus y Sida, Buenos Aires, Argentina, [5]Université de Toulouse, Institut de Pharmacologie et Biologie Structurale, Toulouse, France

Background: The persistence of HIV-infected cells containing replication-competent virus remains the primary obstacle in achieving HIV cure. *Mycobacterium tuberculosis* (Mtb), which causes tuberculosis (TB), is the most common confection among people living with HIV (PLWH) but the impact of TB on the immune response to HIV and the persistent HIV reservoir, is poorly understood.

To address this, we studied the effect of Mtb/HIV coinfection on the persistence of cells infected with genetically-intact HIV.

Additionally, we used therapeutically aspirated pleural effusions (TB-PE) from persons living with TB/HIV to analyse the impact of the TB microenvironment on both HIV persistence and the functionality of HIV-specific CD8+ T-cells.

Methods: We used full-length individual proviral sequencing (FLIPS) to quantify the frequency of genetically-intact HIV in peripheral blood mononuclear cells (PBMCs) from 4 PLWH (75% assigned female at birth [AFAB]) and 4 individuals with TB/HIV (25% AFAB) living in Argentina. In one participant with TB/HIV, mononuclear cells from TB-PE (PEMCs) and PBMCs were also sequenced using FLIPS.

To evaluate the effect of the TB microenvironment on HIV-specific cytotoxicity, CD8+ T-cells from 4 PLWH were cocultured with autologous HIV-infected CD4+ T-cells in the presence or absence of TB-PE. Moreover, the impact of TB-PE on the transcriptome of CD8+ T-cells was characterized by bulk RNAseq in cells from 3 healthy donors.

Results: Our analyses revealed a 2.1-fold increase in the frequency of cells infected with genetically-intact HIV in individuals with TB/HIV coinfection compared to PLWH. Notably, within the individual with TB/HIV, PEMCs exhibited a 15.6 fold increase of intact HIV-infected cells compared to PBMCs.

Interestingly, CD8+ T-cells exposed to TB-PE demonstrated a significantly diminished capacity to eliminate HIV-infected cells (p=0.0021). Transcriptomic analysis revealed TB-PE downregulated pathways related to T-cell activation and inflammatory responses.

Conclusions: This study reveals the TB-associated microenvironment hampers CD8+ T-cell-mediated HIV control, which promotes genetically-intact HIV at the site of coinfection. This impaired cytotoxic response likely contributes to the persistence of the viral reservoir in blood of individuals with TB/HIV coinfection.

Our study highlights the significant challenge that concurrent TB poses to HIV curative strategies and underscores the critical need for targeted interventions for individuals living with TB/HIV.

Novel treatment and prevention strategies, vaccines and immunotherapies

WEPEA014

HLA-E restricted RL9 and KF11-specific CD8+ T cells detected in acutely HIV-acquired people with HIV using novel multimer synthesis protocol

K. Maroney[1], M. Rose[1], A. Duerr[2], A. Bansal[1], P. Goepfert[1]

[1]University of Alabama at Birmingham, Infectious Diseases, Birmingham, United States, [2]University of Washington, Seattle, United States

Background: HLA-E restricted CD8+ T cells have been underexplored in HIV research, with only two reported epitopes, both of which are also restricted by classical HLA-I alleles. We postulated that the apparent rarity of these cells might be due to many HLA-E binding peptides exhibiting low affinity.

Methods: To investigate this, we assessed the HLA-E stabilization potential of 180 predicted T cell epitope (PTE) 15-mers derived from HIV-1 Gag in HLA-E01:01 and HLA-E01:03 cell lines. Using the well-characterized high-affinity RL9 epitope, we developed tetramers employing a refined peptide exchange and multimer staining protocol. To enhance the detection of low-affinity interactions, we also created high-valency HLA-E KF11 dextramers.

Results: Tetramers based on the RL9 epitope identified responses in 4 of 19 participants (26.7%) during acute HIV acquisition, notably including the only probable elite controller. High-valency HLA-E KF11 dextramers successfully detected low-affinity interactions, identifying HLA-E restricted KF11-specific CD8+ T cells in chronically acquired PWH that tetramers did not detect *(Figure 2)*.

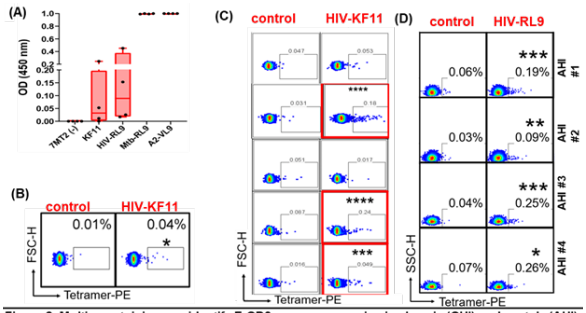

Figure 2: Multimer staining can identify E-CD8 responses ex-vivo in chronic (CHI) and acutely (AHI) HIV-acquired PWH. (A) Barplot of peptide exchange rate of indicated peptides for HLA-E*01:01 monomer preloaded with VMAPJTLVL peptide (7MT2) in an ELISA assay. Data for KF11 and RL9 is shown in relation to positive controls (Mtb-RL9 and A2-VL9 peptides). **(B)** KF11 loaded monomer was tetramerized and used to ex-vivo detect E-CD8s in an elite controller. **(C)** KF11 loaded monomer was dextramerized and the sensitivity and specificity tested in the same elite controller as in **(B)** in relation to a person living without HIV (PWO). Significance (* and **** are p < 0.05 and 0.0001 respectively) based on Fischer's exact T test between counts of parent and child response gate between indicated condition and control. **(D)** Tetramer staining of RL9 specific E-CD8 responses ex-vivo in people with acute HIV acquisition (AHI). Data is shown for all 4 tetramer+ HLA-A*02 individuals. Significance based on Fischer's exact T test between HIV-RL9 and the negative control is shown (*, **, *** are p-values of < 0.05, 0.01, 0.001 respectively).

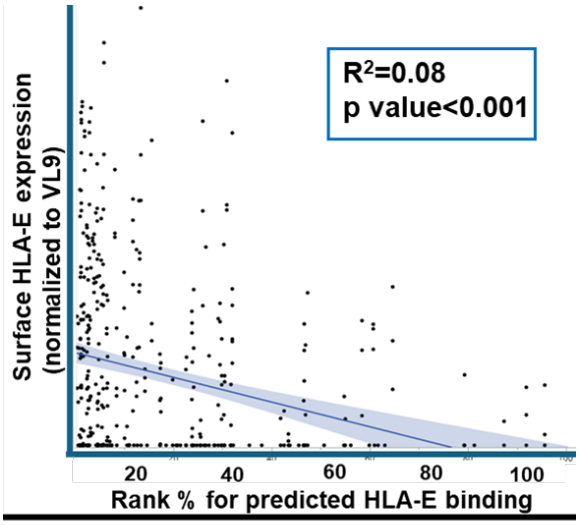

Figure 1. Use of high throughput HLA-E stabilization assay can identify potential candidate HIV peptides predicted to bind HLA-E. Correlation plot data is shown for Gag peptides for their binding to HLA-E*01:03. Scatter plot of 3 replicates each of HLA-E stabilization for 180 predicted T cell epitope (PTE) peptides (15 mers) normalized between no peptide (0% VL9) and A*02-VL9 (100% VL9). Normalized %VL9 α-E*01-APC (3D12 clone) stabilization over no peptide values post overnight 26°C pulse are shown on Y-axis against the rank percentile for the highest predicted binding epitope (9-14-mer) among all epitopes predicted to bind to E*03 through Net-MHC on X axis. Inverse correlation (lower percentile number indicates tighter binding) is represented as a line.

These findings demonstrate that HLA-E restricted CD8+ T cell responses are primed early during HIV-1 acquisition and are more prevalent than previously recognized.

Over 10 peptides were found to stabilize HLA-E, though typically at lower levels compared to the high-affinity RL9 epitope *(Figure 1)*.

Conclusions: Our work underscores the previously underappreciated prevalence and functional importance of HIV-specific HLA-E restricted CD8+ T cells.

WEPEA015

Detection of hepatitis B virus in cerebrospinal fluid of people living with HIV-associated cryptococcal meningitis in Botswana

B. Phakedi[1,2], B. Phinius[2,1], K. Molebatsi[2], N. Kelentse[2,3], L. Bhebhe[2], L. Mpofu Dobo[2], K. Baruti[2], C. Tsayang[2], G. Mulenga[2], T. Ratsoma[2], G. Mpebe[2], N.S. Ndlovu[2], W. Choga[2,1], D.S. Lawrence[2,4], S. Moyo[2,1,5], J.N. Jarvis[2,4], M. Anderson[2,6,7], S. Gaseitsiwe[2,5]

[1]University of Botswana, Health Science, Gaborone, Botswana, [2]Botswana Harvard Health Partnership, Research Laboratory, Gaborone, Botswana, [3]Yale University School of Medicine, New Haven, United States, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Harvard T.H Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [6]University of Pretoria, School of Health Systems and Public Health, Pretoria, South Africa, [7]The Francis Crick Institute, London, United Kingdom

Background: Concomitant hepatitis B virus/human immunodeficiency virus (HBV/HIV) accelerates HBV disease progression. HBV is mainly hepatotropic but may establish distinct populations in non-hepatic sites, including within central nervous system (CNS) cell lines or white cells. This may serve as a reservoir, particularly in people living with concomitant HBV/HIV, contributing to HBV persistence.

This study investigates HBV presence in cerebrospinal fluid (CSF) of people living with HIV (PLWH) with cryptococcal meningitis (CM) in Botswana.

Methods: Baseline samples (N=85) from the AMBITION-cm study which enrolled PWH with CM aged 18 years or older in Botswana between 2018-2021 were utilized. We screened for hepatitis B surface antigen (HBsAg) and quantified HBV viral load (VL).

We compared HBV VL using the Wilcoxon rank-sum test between CSF and plasma. We estimated proportions with HBsAg and HBV DNA using binomial exact method and compared the prevalence of occult hepatitis B (HBsAg- & HBV DNA+) using the Fisher's Exact Test. We determined the association between HBsAg in CSF by demographics (sex, age, mental status, mortality) using Fisher's exact test. P-values < 0.05 implied statistical significance.

Results: Most participants were male 70% (59/85) with a mean age of 39 ± 8 years. The median HIV CD4 count was 30 cells/μL (IQR: 9–63). HBsAg was screened on 81% (69/85) CSF samples and 77% (65/85) plasma samples. HBsAg prevalence in CSF was 18.8% (13/69) (95% CI 11-30) than in plasma was 29.2% (19/65) (95%CI:20-41) (p=0.2). HBV positivity in CSF was not associated with age or sex. Among the 13 HBsAg positive CSF samples, 23.1% (3/13) tested negative in plasma.

Occult Hepatitis B prevalence was 1.8% (1/56) (95%CI:0.3-9.5) in CSF compared to 23.9% (11/46) (95%CI:14-38) in plasma, (p=0.001). Only 5 CSF samples had quantifiable HBV

DNA. The median HBV VL was 3.5 log copies/mL (IQR: 1.3-4.2) compared to 5.3 log copies/mL (IQR: 3.2-8.2) in their plasma pairs (p=0.06).
Conclusions: HBsAg and HBV DNA is detectable in CSF of PLWH with CM, suggesting the CNS as a potential reservoir for HBV replication. Further investigation into the impact of HBV compartmentalization on neurological outcomes, treatment response and HBV evolution is warranted.

WEPEA016

Novel approach for the simultaneous prevention of HIV and *Mtb* infection

R. Smeltz[1], M. Kim[1], K.J. Ryan[2], E.P. Acosta[2], A. Wahl[1], J.V. Garcia[1]
[1]University of Alabama at Birmingham, Microbiology, Birmingham, United States, [2]University of Alabama at Birmingham, Birmingham, United States

Background: Tuberculosis (TB) is the cause of 1 in 4 HIV-related deaths. Therefore, there is an unmet need to establish treatments that can simultaneously prevent HIV and/or TB infections. Long-acting (LA) drug formulations are advantageous because they require infrequent administration, reduce pill burden and associated stigma, allow enhanced bioavailability, and improve patient adherence.
Here, we evaluated the pharmacokinetics (PK) of an LA cabotegravir (CAB) formulation co-administered with an LA rifabutin (RFB) formulation.
Methods: BALB/c mice received a subcutaneous injection of either:
1. LA RFB [mean RFB concentration: 1,205 mg/kg] (n=5),
2. LA CAB [mean CAB concentration: 461 mg/kg] (n=5), or;
3. Two injections – one injection of LA RFB [mean RFB concentration: 1129 mg/kg], and one injection of LA CAB [mean CAB concentration: 489 mg/kg] (n=5).
Serum was obtained from mice at 3, 7, 14, 21, 28, 42, and 59-days post drug administration for PK analysis. Drug levels in tissues (lung, liver, kidney, spleen, and brain) were analyzed 59 days post drug administration. Liquid chromatography tandem mass spectrometry was used to quantitate drug concentrations in serum and tissues.
Results: Individual formulations resulted in sustained levels of RFB and CAB in serum (mean AUC: 56,860 ng/mL· day and 2,288,761 ng/mL· day, respectively) over 59 days. There were no statistical differences in serum RFB and CAB concentrations when both formulations were injected into the same animals (mean AUC: 23,918 ng/mL· day and 3,461,534 ng/mL· day respectively, p = 0.0556). Whereas there was no statistical difference in the tissue levels of RFB in animals also receiving CAB, we noted higher CAB concentration in the lung (p < 0.016), kidney (p = 0.016), and brain (p = 0.032) of mice that received both LA RFB and LA CAB.
Conclusions: Co-administration of LA RFB and LA CAB does not alter the individual drug concentrations in serum. Additionally, administration of RFB did not result in lower levels of CAB in tissues. Rather in animals that also received LA RFB, we found higher concentrations of CAB in lung, kidney, and brain.
Our results demonstrate that the co-administration of LA RFB and LA CAB is a promising avenue for HIV and *Mtb* prevention.

Course of HIV disease

WEPEB017

Advanced HIV disease diagnosis and other predictors of treatment outcomes among newly-diagnosed people living with HIV in Oyo State, Nigeria

D. Adetoye[1], A. Olafare[1], A. Ojo[1], O. Olajide[1], M. Odido[2], T. Omole[2], P. Jwanle[2], I. Onwuatuelo[2], J. Osi Samuels[2], P. Okonkwo[2]
[1]APIN Public Health Initiatives, Ibadan, Nigeria, [2]APIN Public Health Initiatives, Abuja, Nigeria

Background: Despite the increasing number of people living with HIV (PLWH) being placed on effective antiretroviral therapy (ART), data has shown that HIV-related deaths are not declining as expected. Advanced HIV disease (AHD) has been linked to increased mortality and morbidity among PLWH. AHD is defined as CD4+ lymphocytes less than 200/mm3 or WHO Stage 3 or 4 for PLWH aged five years and above. This study aimed to assess AHD diagnosis and other predictors of treatment outcomes among newly diagnosed PLWHs in this age group in Oyo State.
Methods: We conducted a data review of newly-diagnosed PLWH aged ≥5 years on ART between October 2021 and September 2023 who were screened for AHD using the CD4 count or the WHO clinical staging or both in the comprehensive ART sites in Oyo State. Treatment outcomes were assessed in September 2024. Client-level data were extracted from the electronic medical record and analyzed using SPSS. We considered viral suppression and clients being alive after one year as favorable treatment outcomes. AHD diagnosis and other predictors of treatment outcomes were examined using a multivariate logistic regression.
Results: Fifteen thousand, one hundred and twenty-nine participants were enrolled in the study. The mean age of participants was 38 years (SD-11.4), and the majority were female (66%, n = 9,908). The AHD diagnosis rate among participants was 21.9% (3,309 of 15,129). AHD diagnosis did not predict viral suppression among participants (OR 1.11; 95%CI: 0.86- 1.44). However, age, marital status, and job status were found to be associated with viral suppression. Clients who were diagnosed with AHD (OR 0.47; 95%CI: 0.38-0.59) were less likely to be alive after one year of commencement of ART than those who were not AHD diagnosed.
Conclusions: There was a poor survival rate as a treatment outcome among AHD-diagnosed clients compared to non-AHD-diagnosed clients. This is despite receiving the WHO-recommended package of care provided for AHD-diagnosed clients. Prevention of new acquisitions

and early diagnosis and treatment are still the most effective ways of reducing morbidity and mortality associated with HIV. Governments, funders, and other stakeholders must actively and continuously support these.

Cure interventions and other strategies and therapies

WEPEB018

Vesatolimod pharmacodynamic responses in a trial of vesatolimod and broadly neutralizing antibodies in early-treated South African women with clade C HIV-1

Y. Cai[1], L. Zhang[1], R.W. Omange[1], K. Dong[2], L. Gama[3], J.J. Wallin[1], M. Mehrotra[1], E. Vendrame[1], D. SenGupta[1], T. Ndung'u[4]
[1]Gilead Sciences, Inc., Foster City, CA, United States, [2]Ragon Institute of Mass General, MIT and Harvard Medical School, Cambridge, United States, [3]Vaccine Research Center, NIAID, NIH, Bethesda, United States, [4]The Doris Duke Medical Research Institute, University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa

Background: Vesatolimod (VES), an oral Toll-like receptor-7 (TLR7) agonist, has been shown to upregulate interferon-alpha (IFNα) and interferon-stimulated genes (ISGs). However, VES pharmacodynamic responses in women have not been extensively assessed.
We investigated VES pharmacodynamic responses and associations with analytical treatment interruption (ATI) outcomes in an open-label study of VES combined with 2 broadly neutralizing antibodies (bNAbs), VRC07-523LS and CAP256V2LS, in virologically suppressed (VS) women with clade C HIV-1 (NCT05281510).
Methods: This study enrolled 20 acutely treated VS Black women (age ≥18 years, antiretroviral therapy [ART] for ≥12 months) from the Females Rising through Education, Support, and Health (FRESH) cohort in South Africa. Participants received up to 10 doses of VES (6 mg for 2 doses, up to 8 mg thereafter) every 2 weeks and intravenous infusions of VRC07-523LS (20 mg/kg) and CAP256V2LS (20 mg/kg) 1 week after the first VES dose.
Participants stopped ART by week 5 and remained off ART for 44 weeks or until meeting ART restart criteria (HIV-1 RNA ≥1000 copies/mL for 8 consecutive weeks; or confirmed HIV-1 RNA >100,000 copies/mL; or confirmed CD4 count <350 cells/μL). Blood samples were collected at baseline and 24 hours after VES doses 1, 5, and 10 for quantification of ISG mRNA expression and serum cytokine levels. Statistical analyses included Wilcoxon rank-sum test and Cox proportional hazards model.
Results: 13/20 participants received all 10 VES doses; 6 participants discontinued VES due to viral rebound, and 1 due to adverse events. Consistent upregulation of ISGs (ISG15, MX1, OAS1), cytokines (IFNα, IP10, IL1RA), TLR7, and chemokines (CCL19, CCL8, MCP-1) was observed after each VES dose, with no increase in magnitude after dose escalation. ISG upregulation was more sustained throughout dosing in participants with delayed ART restart (DR; 16-44 weeks) and long-term delayed ART restart (LTDR; >44 weeks), with minimal overall differences in absolute ISG levels across ATI outcomes including early ART restart (ER; <16 weeks), DR and LTDR groups.
Conclusions: VES induced consistent upregulation of ISGs in Black female participants in this small study, suggesting a similar pharmacodynamic effect in this population, compared with previously studied populations.

ART resistance

WEPEB019

Switching to Doravirine/Islatravir (100 mg/0.25 mg) once daily maintained viral suppression in the presence of archived M184I/V resistance-associated mutations in proviral DNA

T.L. Diamond[1], A. Grandhi[1], M. Fuszard[1], A. Xu[1], U. Nwoke[1], Y. Zhang[1], S. Klopfer[1], K. Eves[1], J. Benner[1], M. Li[1], W. Greaves[1], R. Lahoulou[2], J. Kim[1], M.C. Fox[1], E. Asante-Appiah[1]
[1]Merck & Co., Inc., Rahway, United States, [2]MSD France, Puteaux, France

Background: In three Phase 3 studies (P051: NCT05631093; P052: NCT05630755; P054: NCT05766501) virologic suppression was maintained in people living with HIV who switched to doravirine/islatravir (DOR/ISL 100 mg/0.25 mg); 2 studies (P051 and P052) were comparative and demonstrated noninferiority to baseline antiretroviral therapy (bART) or bictegravir/emtricitabine/tenofovir alafenamide (BIC/FTC/TAF).
This analysis examined the impact of preexisting resistance-associated mutations (RAMs) in proviral DNA on the virologic response to DOR/ISL in these studies, with a primary focus on M184I/V; non-nucleoside reverse transcriptase inhibitor (NNRTI) RAMs were also analyzed.
Methods: Participants with HIV-1 RNA <50 copies/mL and no known treatment failure or documented DOR resistance at baseline were randomized (2:1) to switch to DOR/ISL 100 mg/0.25 mg once-daily or to continue bART in P051 or BIC/FTC/TAF in P052. P054 is an open-label, single-arm study in adults who previously received DOR/ISL 100 mg/0.75 mg and switched to DOR/ISL 100 mg/0.25 mg. Baseline reverse transcriptase RAMs present in HIV-1 proviral DNA were identified using the GenoSure Archive assay (Monogram Biosciences).
Results: Baseline resistance data were available for 90.5% of study participants (1545/1708) across the 3 studies. Of the 1227 participants with baseline data who received DOR/ISL through 48 weeks (P051 or P052) or through a mean of approximately 57 weeks (P054), 70 (5.7%) had preexisting M184I/V and 323 (26.3%) had preexisting NNRTI RAMs with 2 (0.16%) having Y188L, an exclusionary DOR RAM.

Among participants with preexisting NNRTI RAMs, 2 DOR/ISL participants (both in P051 and the only 2 with Y188L) discontinued due to lack of efficacy. Both had multidrug resistance including M184 substitutions at baseline. No other DOR/ISL participants with M184 substitutions discontinued due to lack of efficacy.

Overall, 5/166 (3.0%) bART participants (P051) and 10/152 (6.6%) BIC/FTC/TAF participants (P052) had preexisting M184I/V and 33/166 (19.9%) bART participants (P051) had preexisting NNRTI RAMs, none of these participants discontinued due to lack of efficacy. BIC/FTC/TAF has no NNRTI, so impact of preexisting NNRTI RAMs was not evaluated.

Conclusions: Switching to DOR/ISL 100 mg/0.25 mg in Phase 3 clinical studies maintained viral suppression for at least 48 weeks in the presence of preexisting M184I/V in proviral DNA.

Pandemics, conflict and climate

WEPEB020

Examining COVID-19 knowledge, attitudes, and practices among people vulnerable to HIV in Uganda

J. Tonzel[1,2], J. Kasule[3], N. Burns[1,2], T. Hamby[1,2], R. Ying[1,2], B. Mwesigwa[3], G. Mirembe[3], H. Kibuuka[3], I. Nakabuye[3], M. Yacovone[4], T. Crowell[1,2], the Multinational Observational Cohort of HIV and other Infections (MOCHI) Study Group

[1]U.S Military HIV Research Program, Silver Spring, United States, [2]Henry M. Jackson Foundation, Bethesda, United States, [3]Makerere University Walter Reed Program, Kampala, Uganda, [4]National Institute of Allergy and Infectious Diseases, Rockville, United States

Background: COVID-19 knowledge, attitudes, and practices (KAPs) are influenced by behavioral and social factors that can differ by region and population subgroups. Implementation of COVID-19 preventive measures among people vulnerable to HIV may differ due to social marginalization and barriers to accessing healthcare. We examined COVID-19 KAPs and factors associated with COVID-19 preventive measures among individuals in Uganda with behavioral vulnerability to HIV.

Methods: From October 2022 to September 2024, participants aged 14-55 years with behavioral vulnerability to HIV (self-reported sexually transmitted infection, transactional sex, condomless sex, and/or injection drug use) were enrolled into an HIV incidence cohort in Uganda. At enrollment, participants completed questionnaires regarding COVID-19 KAPs COVID-19 knowledge was assessed through true/false questions, attitudes through agree/disagree questions, and practices through yes/no questions. Frequency distributions were used to assess the COVID-19 KAPs.

Results: Of 412 participants analyzed, 232 (56.3%) were female. The median age was 21.0 years (interquartile range: 19.0-24.0) and 156 (38.7%) had a secondary education or higher.

Participants were least knowledgeable about the prompts "I can still have a COVID-19 infection even if I do not have symptoms" (n=136, 33.4%) and "variants (mutated strains) of COVID-19 may increase the chance that people can be infected with COVID-19 multiple times" (n=120, 30.5%). Participants generally agreed that having COVID-19 poses a risk to others (n=390, 94.9%). The most endorsed preventive practices were washing hands (n=372, 91.0%), wearing face masks (n=313, 76.2%), and avoiding people with symptoms (n=303, 74.1%) [Figure].

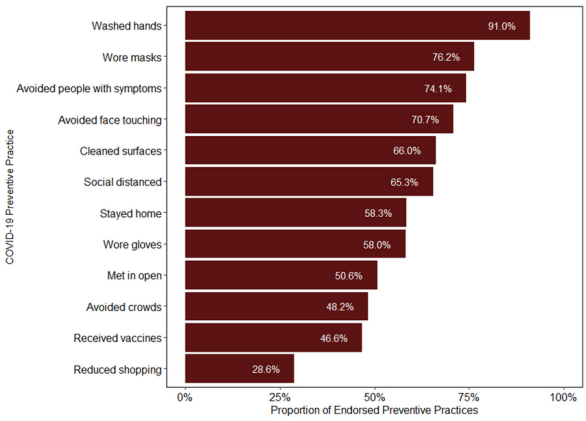

Figure. Proportion of Ugandan participants that endorsed COVID-19 preventive practices.

Conclusions: We observed gaps in understanding COVID-19 epidemiology among HIV vulnerable Ugandans. Future outreach to this population should prioritize education about disease transmission, potential virus mutations, and effective preventive measures.

HIV and ageing

WEPEB021

Cannabis use disorder diagnoses in the United States from 2000-2022 by HIV status, age, and comorbidity

D. Haley[1], K. So-Armah[2], A. Justice[3,4], F. Kidwai-Khan[3,4], Z. Xuan[1], R.S. Adams[5], M. Fox[6], E.J. Edelman[4], A. Wrona[3,4], M. Silverberg[7], D. Satre[7,8], A. Trickey[9], S. Ingle[9], K. McGinnis[4,3]

[1]Boston University School of Public Health, Department of Community Health Sciences, Boston, United States, [2]Boston University School of Medicine, Clinical Addiction Research and Education Unit, Boston, United States, [3]VA Connecticut Healthcare System, West Haven, United States, [4]Yale School of Medicine, Department of Internal Medicine, New Haven, United States, [5]Boston University School of Public Health, Department of Health, Law, Policy, and Management, Boston, United States, [6]Boston University School of Public Health, Departments of Global Health and Epidemiology, Boston, United States, [7]Kaiser Permanente Northern California, Division of Research, Pleasanton, United States, [8]University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States, [9]Bristol Medical School, University of Bristol, Population Health Sciences, Bristol, United Kingdom

Background: Cannabis use has increased with its widespread legalization in the United States and is more common among people with HIV (PWH) than people without HIV (PWoH). Cannabis use disorder (CUD) produces financial, social, and health harms. CUD risk among aging PWH and those with comorbid disease is not well understood. We examined CUD trends from 2000-2022, by HIV status, age, and comorbidity.

Methods: Using data from the Veterans Aging Cohort Study-HIV, a United States cohort of PWH matched 1:2 to PWoH, we assessed the percent with CUD diagnoses documented in the electronic medical record by dividing the number of individuals with at least 1 International Classification of Diseases, Clinical Modification (ICD-CM) CUD code by the total individuals with any ICD-CM code in each year.

We examined trends by age (<50, 50-64, 65+ years old), comorbidity (Charlson Comorbidity Index [CCI], excluding HIV in index scoring), and HIV status graphically and with multivariable models adjusted for race/ethnicity, gender, and year.

Results: Demographic characteristics were comparable for PWH (n=58,959) vs. PWoH (n=126,413): 45% Black non-Latinx; 35% White non-Latinx; 7% Latinx; 3% women, and mean age 48 years. CUD increased from 2000 to 2022 in all age and comorbidity groups and was consistently higher among PWH (Figure 1; HIV adjusted OR=1.14 [95% CI=1.10-1.18]).

In adjusted models, higher comorbidity (reference CCI=0) was associated with an increased odds of CUD among PWH and PWoH. ORs were higher for PWH (CCI=1 OR=1.40 [95% CI=1.33, 1.48]; CCI=2+ OR=1.60 [95% CI=1.51, 1.70]) than PWoH (CCI=1 OR=1.26 [95% CI=1.21, 1.31]; CCI=2+ OR=1.34 [95% CI=1.28, 1.39]).

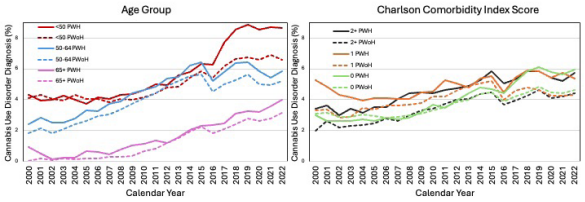

Figure 1. Percent with a cannabis use disorder over time, by age and comorbidity burden, among 58,959 people with HIV (PWH) and 126,413 people without HIV (PWoH), receiving clinical care at the United States Veterans Health Administration, 2000-2022.

Conclusions: CUD increased dramatically over time and is higher among PWH. The increase in CUD among older PWH and those with comorbid disease is especially alarming as cannabis interacts with many prescription medications and can compromise cognition. HIV providers should routinely screen for cannabis use and CUD.

Diagnostic and monitoring tools

WEPEB022

The role of high-sensitivity C-reaction protein in the prediction of long-term mortality in HIV-positive patients: results from the IDEA-TB cohort study in Kenya

F. Ciccacci[1], B. Welu[2], H. Ndoi[2], I. Karea[2], A.M. Doro Altan[3], D. Brambilla[4], K. Munene[2], B. Opanga[5], A. Ronoh[6], S. Mukwanjagi[7], G. Guidotti[8], S. Orlando[1]

[1]University of Rome Torvergata, Biomedicine and Prevention, Rome, Italy, [2]DREAM Program, Community of Sant'Egidio, Meru, Kenya, [3]Link Campus University, Rome, Italy, [4]DREAM Program, Community of Sant'Egidio, Rome, Italy, [5]National AIDS and STIs Control Programme, Nairobi, Kenya, [6]National Tuberculosis, Leprosy and Lung Disease Program, Nairobi, Kenya, [7]Consolata Hospital, Nkubu, Kenya, [8]ASL Roma 1, Rome, Italy

Background: HIV remains a major cause of morbidity and mortality, particularly in sub-Saharan Africa. Despite advances, long-term mortality remain high among people living with HIV (PLWH). High-sensitivity C-reactive protein (HS-CRP) is a potential biomarker for predicting mortality in PLWH.

This study assessed the predictive value of HS-CRP levels for long-term mortality among PLWH in Meru County, Kenya, comparing its utility to models based on CD4 count, viral load, and BMI.

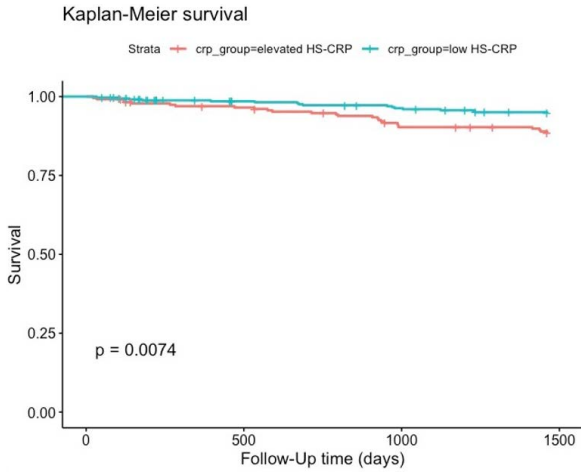
Methods: This cohort study involved PLWH from three DREAM centers in Meru County suspected of having TB on symptom screening, followed for four years. HS-CRP levels were measured at enrollment.

Statistical analyses included Kaplan-Meier survival curves, ROC curve analysis, and Cox proportional hazards regression models.

Results: Among the 574 HIV-positive patients screened for TB symptoms, 43(7.5%) died during the four-year follow-up period. The mean HS-CRP levels were 11.80 mg/L in the non-deceased group and 29.08 mg/L in the deceased group (p = 0.046).

ROC curve analysis showed an AUC of 0.5814, with an optimal HS-CRP cutoff of 3.68 mg/L, yielding a sensitivity of 60.5% and specificity of 61.2%. Kaplan-Meier survival curves indicated lower survival probabilities for patients with HS-CRP levels above 3.68 mg/L (p=0.0074).

Cox regression analysis revealed that elevated HS-CRP, age, and CD4<500 were independently associated with mortality. Including HS-CRP in predictive models improved the AUC from 67.2% to 76.2% when combined with CD4 and viral load.



Covariate	HR (exp(coef))	95% CI	p-value
HS-CRP Group (Low vs High)	0.4218	[0.2056-0.8652]	0.01853 *
Sex (M vs F)	0.7809	[0.3987-1.5295]	0.47087
Age at baseline	10.364	[1.0107-1.0627]	0.00527 **
CD4 Group at baseline (>500 vs <=500)	0.3089	[0.1263-0.7555]	0.01004 *
BMI at baseline	0.9281	[0.8495-1.0141]	0.09891
log VL at baseline	10.741	[0.9794-1.1780]	0.12922
TB at baseline (Yes vs No)	15.023	[0.6973-3.2364]	0.29868

***p<0.001, **p<0.01, *p<0.05

Conclusions: The findings suggest that HS-CRP could be a biomarker for improving the clinical management of PLWH. However, the implementation of this test must carefully consider the costs and resource availability.

WEPEB023

Validity of small volume blood testing for HIV viral load: phase 1 results in participants with undetectable and detectable HIV viral loads

B. Prusty[1], A. MacLaren[1], G. Gopalakrishnan[1], E. Cheserem[2], D. Marinopoulos[2], A. Uriel[3], C. Fox[3], J. Mason[1], E. Martyn[4], S. Watters[5], S. Noureen[5], O. Stirrup[1], D. Dunn[1], M. Gandy[5], I. Ghosh[6], S. Tariq[1], L. Waters[6,1], P. Matthews[4], R. Gilson[1], S. Flanagan[6,1]

[1]University College London, Institute of Global Health, London, United Kingdom, [2]North Middlesex Hospital, HIV Medicine, London, United Kingdom, [3]North Manchester General Hospital, HIV Medicine, Manchester, United Kingdom, [4]Francis Crick Institute, London, United Kingdom, [5]Sonic Healthcare, Research and Innovation, London, United Kingdom, [6]Central and North West London NHS Foundation Trust, Mortimer Market Centre, London, United Kingdom

Background: New technology for small volume testing (known as TINIES) allows self-collection of blood for routine tests. Phase 1 of this study prospectively validates TINIES sampling for HIV-1 viral load (HIV VL). We report Phase 1 interim results.

Methods: People attending UK HIV clinics in London and Manchester for routine blood tests were invited to participate. Each participant had paired blood samples drawn: routine venous blood (VB) collection (1xEDTA for HIV VL) and TINIES finger prick samples (2xEDTA microcontainers for HIV VL).

Using 95% target sensitivity and specificity, a sample size calculation required 73 with HIV VL detectable (>50 copies/mL), and 73 with undetectable HIV VL (<50 copies/mL) for 95% confidence interval of +/-5%.

Due to sample dilution, TINIES undetectable cut-off is <90 copies/mL.

Results: 145 participant samples were analysed (20 female, 123 male, 2 other; 65% White UK/European; 20% Black African, 6% Asian, 9% other). Analysis of HIV VL on VB was not performed in five cases and there was one case of laboratory error.

In 90/139 samples, HIV VL was undetectable on VB. There was insufficient sample for TINIES analysis in 7 cases, TINIES analyses was not performed in two cases and there was laboratory error in one. HIV VL was undetectable on TINIES analysis in all remaining 80 cases, corresponding to a specificity of 100% (95% CI 96.0-100).

For 49 VB samples with detectable HIV VL, one paired TINIES sample was insufficient. 42/48 were reported as HIV-detectable by TINIES (VL>90 copies/ml), yielding a sensitivity of 87.5% (95%CI 74.8% - 95.3%). Of six samples with detectable VB VL reported as undetectable on TINIES testing, five had VL values <1000 copies/mL, four of which were < 200 copies/mL.

Conclusions: Interim results from 145 samples show TINIES delivers 100% concordance where HIV VL is undetectable on VB sampling (n=80).

48 samples showed TINIES testing has 87.5% sensitivity for detectable HIV-1 viral load. Reasons for sample failure (n=2) and discrepancy (n=6) are under investigation. Recruitment to the detectable HIV VL cohort is ongoing.

Phase 2 explores participant acceptability of this sampling method when undertaken at home.

Project funded by a BHIVA Research Grant awarded 2021.

Co-infections (including opportunistic infections)

WEPEB024

Incidence, causes, and predictors of re-admission of people with cryptococcal meningitis enrolled in ASTRO-CM study

S. Jjunju[1,2], E. Nuwagira[3], C. Muzoora[2], D. Meya[4], D. Boulware[5]

[1]Soroti University, Internal Medicine, Soroti, Uganda, [2]Mbarara University of Science and Technology, Internal Medicine, Mbarara, Uganda, [3]Mbarara University of Science and Technology, internal Medicine, Mbarara, Uganda, [4]Makerere University, Internal Medicine, Kampala, Uganda, [5]University of Minnesota, Medicine, Minnesota, United States

Background: Cryptococcal meningitis is the most common form of meningitis among adults with advanced HIV disease in Sub-Saharan Africa. It remains one of the leading causes of death among people living with HIV in resource-limited settings. Despite quality care given to them in clinical trials, a larger number of participants are re-admitted back after their initial discharge with re-occurrence of symptoms or clinical deterioration. Re-admission increases the unit cost treatment results in poor prognosis.

Our goal was to identify the incidence, causes, and predictors of re-admission in the first 10 weeks among participants who were enrolled in the Adjunctive Sertraline for Treatment of Cryptococcal Meningitis (ASTRO-CM) trial.

Methods: This was a retrospective cohort study involving people living with HIV with cryptococcal meningitis who were enrolled in the ASTRO-CM clinical trial and were discharged after the initial admission. Data was extracted and analyzed using Stata version 16. Continuous variables were expressed as mean and standard deviation.

Categorical variables expressed as frequencies and percentages. Incidence of re-admission was presented as simple proportion with 95% confidence interval.

Causes of re-admission were expressed as frequencies and we used Cox proportional hazard model to determine the predictors of re-admission, p value < 0.05 was considered significant and 95% confidence interval was reported.

Results: Our study analyzed 304 out of 460 participants enrolled in the ASTRO-CM trial. We found cumulative incidence of 29.6% (95% CI:24.7-35.0%). We found baseline low CSF WBC count (HR: 15.2, 95% CI: 2.5-92.4) and High CSF protein (HR: 20.0, 95% CI: 3.6-111.4) to be independently associated with re-admission of people with cryptococcal meningitis. We also found anemia (25.2%), bacterial infection (19.4%), extra pulmonary tuberculosis (7.8%), Pulmonary tuberculosis (4.8%), cryptococcal meningitis relapse (4.8%) and raised creatinine (4.8%) to be the commonest causes of re-admission of people with cryptococcal meningitis.

Conclusions: Our study showed that people with cryptococcal meningitis had a re-admission incidence of 29.6% and the main causes of re-admission were due to anemia, bacterial infection, extra pulmonary tuberculosis, cryptococcal meninigitis relapse, increased creatinine and pulmonary tuberculosis. High baseline CSF protein and low CSF WBC predicted re-admission in our study.

WEPEB025

Rationally designed antimicrobial peptides with anti-mycobacterial and immunomodulating activity

H. Nkamba[1,2], S. Newton[3], J. Khara[4,5], P. Langford[4]

[1]National Heart Hospital, Laboratory Department, Lusaka, Zambia, [2]University Teaching Hospital, Department of Pathology & Microbiology, Lusaka, Zambia, [3]Imperial College London,, Department of Medicine, London, United Kingdom, [4]Imperial College London, Department of Medicine, London, United Kingdom, [5]National University of Singapore, Department of Pharmacology, Queenstown, Singapore

Background: Tuberculosis (TB) now ranks alongside HIV as a leading cause of death worldwide. Globally, there is a growing public health concern over the increasing level of Mycobacterium tuberculosis (MTB) resistance to anti-mycobacterial treatment resulting in the emergence of multidrug-resistant (MDR), and extensively drug-resistant (XDR) TB cases.

To overcome the challenge of drug resistance new drugs with novel mechanisms of action are urgently needed. Antimicrobial peptides (AMPs) have emerged as a promising new form of antibiotics.

Methods: In this study we determined whether synthetic, rationally designed AMPs have anti-mycobacterial and immunomodulating activity to enhance growth inhibition of mycobacteria.

Five peptides were evaluated in broth medium compared to standard anti-tuberculosis drugs for anti-mycobacterial activity against the luminescent reporter strain, M. bovis BCG lux, by standard minimum inhibitory concentration (MIC) screening. Safety of the AMPs was assessed through haemolytic and cytotoxicity assays.

Anti-mycobacterial intracellular activity for the most promising active candidate (W8TP5), was assessed in both THP-1 derived macrophages and whole blood, together with the cytokine response profile.

Results: The AMPs were found to have anti-mycobacterial activity in broth against M. bovis BCG lux with W8TP5 being the most potent (MIC 63 μM) and also the least toxic to red blood cells and THP-1 cells at 1000 μM. W8TP5 also elicited TNFα production alone in THP-1 derived macrophages (140pg/mL and 412pg/mL for 32 μM and 63 μM peptide concentration respectively) and down-regulated IFNγ production in the whole blood assay demonstrating immunomodulating activity.

Conclusions: Synthetic rationally designed AMPs were found to have anti-mycobacterial and immunomodulatory activity, making them potential candidates as novel antibiotics.
Further work is required to determine the mechanisms of action of these peptides and how they modulate immune responses in mycobacterial conditions.

WEPEB026

Tuberculosis preventive treatment initiation and factors associated with adherence among newly diagnosed people living with HIV initiated on anti-retroviral therapy (ART) in Cameroon, 2020-2022

E.N. Shu[1], L. Simo[1], B.T. Youngui[1], R. Kana[1], A.T. Ayuk[2], S. Djamilatou[1], J. Fokam[3,4], Y.M. Fadil[2], A. Rogers[5,4], M. Fabou[1], C. Keleko[2], B. Tchounga[1], A. Kuate[6], L. Denoeud-Ndam[7], E. Takem[2], S. Lekeumo[1], N. Bhatt[8], J. Ditekemena[9], Z. Bissemou[1], G. Ndayisaba[1], M. Casenghi[7], A. Tiam[8,10], M. Jalloh[2], P. Tchendjou[1]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Yaounde, Cameroon, [2]Centers for Disease Control and Prevention, Yaounde, Cameroon, [3]National AIDS Control Committee, Yaounde, Cameroon, [4]Faculty of Health Sciences, University of Buea, Buea, Cameroon, [5]Ministry of Public Health, Coordination Unit for HIV, TB and Malaria, Yaounde, Cameroon, [6]Ministry of Health, National Tuberculosis Control Program, Yaounde, Cameroon, [7]Elizabeth Glaser Pediatric AIDS Foundation, Geneva, Switzerland, [8]Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States, [9]Elizabeth Glaser Pediatric AIDS Foundation, Kinshasa, Congo, the Democratic Republic of the, [10]George Washington University, Milken Institute School of Public Health, Washington, United States

Background: Tuberculosis preventive treatment (TPT) is recommended to reduce the burden of tuberculosis (TB) among people living with HIV (PLHIV) globally. However, implementation remains challenging in sub-Saharan Africa. Six months of isoniazid preventive therapy (IPT) is the recommended TPT regimen in Cameroon.
We assessed TPT uptake and factors associated with poor adherence to TPT among PLHIV in two regions of Cameroon.
Methods: We performed a retrospective cohort analysis using programmatic data collected between October 2020 and September 2022 from 72 PEPFAR-supported HIV clinics. All newly diagnosed PLHIV starting antiretroviral therapy (ART) and for whom active TB disease was excluded were eligible for TPT.
We described the initiation rate and adherence to TPT and performed logistic regression analysis to identify factors associated with non-initiation and adherence to TPT.
Results: Overall, 25,098 PLHIV were eligible for TPT, with a median age of 36 years (IQR: 29-45), and 62.6% were female. Among the 22,419 (89.3%) who started TPT, 17,728 (79.1%) began ART the same day, and only 11,584 (51.7%) completed treatment. The median time on TPT was 183 days (IQR: 181-190). In multivariable-adjusted analysis, factors associated with a lower odds of TPT initiation included delayed ART initiation (>7 days post-HIV diagnosis), compared to same-day initiation (aOR: 2.77, 95% CI: 2.25-3.38), and receiving care in rural areas compared to urban settings (aOR: 1.64, 95% CI: 1.42-1.90). PLHIV aged ≥20 years had a higher odds to initiate TPT compared to children/adolescents 0-19 years (aOR: 0.63, 95% CI: 0.51-0.78). ART interruption was associated with poor adherence to TPT (aOR: 2.84, 95% CI: 2.59-3.12), while initiating (aOR: 0.77, 95% CI: 0.71-0.83) or switching to a dolutegravir-based regimen (aOR: 0.71, 95% CI: 0.62-0.82) or another regimen as part of treatment optimization or tolerance decision (aOR: 0.66, 95% CI: 0.57-0.76) were associated with better adherence to TPT.
Conclusions: While TPT initiation among new ART clients was high overall, it is important to focus efforts on children, adolescents, and PLHIV who delay initiation. TPT adherence remained suboptimal, with ART interruption being one of the main risk factors for poor adherence, hence the need to benefit from enhanced adherence TPT interventions.

WEPEB027

Outcomes of pneumocystis pneumonia (PCP) in people living with HIV (PLHIV) in a high HIV/TB prevalence South African population

A.T. Mnguni[1,2,3], J. Kolls[4], R. Lai[5], G. Meintjes[3,6,7], S. Wasserman[1,6,8]
[1]University of Cape Town, Centre for Infectious Disease Research in Africa, Cape Town, South Africa, [2]University of Cape Town, Africa Mycology Unit, Cape Town, South Africa, [3]University of Cape Town, Medicine, Cape Town, South Africa, [4]Tulane, Medicine, New Orleans, United States, [5]Imperial College London, Infectious Diseases, London, United Kingdom, [6]University of Cape Town, Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, [7]Blizard Institute, Medicine, London, United Kingdom, [8]St George's University, Institute for Infection and Immunity, London, United Kingdom

Background: Pneumocystis pneumonia (PCP) is a common cause of severe respiratory illness among people with advanced HIV in sub-Saharan Africa. Clinical characteristics and outcomes are not well-characterised in this population.
Methods: We are undertaking a prospective observational cohort study to describe outcomes and evaluate non-invasive diagnostic tests for HIV-associated PCP. Consecutive PLHIV adults with probable (clinical case definition) or definite (positive immunofluorescent staining on sputum or bronchoalveolar lavage fluid) PCP are enrolled from Khayelitsha District Hospital, Cape Town. Eligible participants undergo bronchoscopy and evaluation for co-infections as inpatients and followed for 90 days to ascertain functional outcomes and mortality. This is an interim analysis to describe clinical characteristics, prevalence of co-infections, and short-term outcomes.
Results: 96 participants were enrolled over the period June 2023 to December 2024 and 56/96 (58%) underwent bronchoscopy. The median age was 36 years (interquar-

tile range, IQR 31-43) and 49 (51%) were women. The median CD4 count was 20 cells/mm^3 (IQR 8-58); 11 (11%) participants were currently on antiretroviral therapy (ART), 33 (34%) were ART-naïve, and 52 (54%) had interrupted ART. Only 5/95(5%) participants had HIV RNA < 50 copies/ml.
46/96 (48%) had definite PCP and 43/96 (45%) had probable PCP. 20/89 (22%) had severe acute respiratory distress syndrome (ARDS) (median 158 mmHg, IQR 122-177), 25/89 (28%) had moderate ARDS (median 246 mmHg, IQR 225-260) and 44/89 (49%) had mild ARDS (median 439 mmHg, IQR 342-545).
24/96 (25%) were newly diagnosed with tuberculosis co-infection. 73/96 (76%) had detectable cytomegalovirus (CMV) DNA in serum (median 2032 IU/ml, IQR 330-14058) and 45/56 (80%) had detectable CMV DNA in bronchoalveolar lavage (BAL) fluid (median 5122 IU/ml, IQR 925-279822). 62 patients had detectable Beta-D-glucan in serum (median 116 pg/ml, IQR 69-203). Median Beta-D-glucan was (133 pg/ml, IQR 101-240) among those with definite PCP and 93pg/ml (IQR 38-160) among those with probable PCP. There were 24 (25%) deaths.
Conclusions: HIV-associated PCP is associated with high mortality. Disengagement from ART continues to drive incidence and poses significant challenges in PLHIV. There was a high prevalence of tuberculosis co-infection. CMV viraemia and detection on BAL fluid was common; the clinical significance of this requires further investigation.

WEPEB028

Clinical and virologic outcomes in children with TB/HIV coinfection are poor compared to children with HIV on WHO-recommended antiretroviral therapy

A. Kwara[1], H. Yang[2], C. Martyn-Dickens[3], A. Enimil[4], A. Dompreh[5], E. Sly-Moore[3], D. Bosomtwe[3], A.K. Amissah[3], O. Ojewale[1], P. Asiedu[6], A. Frimpong Appiah[3], T. Opoku[3], A.D. Sarfo[3], I. Kusi Amponsah[5], S. Adams Sallar[1], S. Antwi[4]
[1]University of Florida, Medicine, Gainesville, United States, [2]University of Rochester School of Medicine and Dentistry, Biostatistics and Computational Biology, Rochester, United States, [3]Komfo Anokye Teaching Hospital, Child Health, Kumasi, Ghana, [4]Kwame Nkrumah University of Science and Technology, Child Health, Kumasi, Ghana, [5]Komfo Anokye Teaching Hospital, Clinical Microbiology, Kumasi, Ghana, [6]Komfo Anokye Teaching Hospital, Pharmacy, Kumasi, Ghana

Background: The treatment of human immunodeficiency virus (HIV) infection in children with HIV and tuberculosis (TB) coinfection is complicated by delays in antiretroviral therapy (ART) initiation, high pill burden and drug-drug interactions. This study examined the clinical and virologic outcomes in children with TB/HIV coinfection on concomitant TB therapy compared to those with HIV.
Methods: A prospective study of ART outcomes in children with TB/HIV coinfection on rifampin-containing TB treatment and those with HIV alone was conducted at a teaching hospital in Ghana between 2019 and 2024. Children aged 3 months to 14 years old with HIV with or without TB coinfection on or eligible to initiate ART were enrolled and followed for 12 months. Children with TB coinfection on first-line antituberculosis therapy were prescribed a double dose of lopinavir/ritonavir (LPV/r) or dolutegravir (DTG) while on TB treatment according to WHO guidelines. Differences in baseline characteristics, clinical and virologic outcomes at 6- and 12-months follow-up were compared using Wilcoxon test, Chi-square or Fisher's exact test.
Results: Of 213 participants, 92 (43.22%) had TB coinfection, 117 (54.9%) were males and 146 (68.5%) were aged 3–10 years old. At study entry, participants with TB coinfection compared to those with HIV were more likely to be younger, have lower BMI-for-age, lower CD4 count, and a more recent diagnosis of HIV. Also, children with TB coinfection were less likely to be on DTG-based ART and more likely to have HIV RNA ≥ 1000 copies/mL. At 6 months of follow-up, the proportion of participants with HIV RNA <50 copies/mL (HIV suppression) was 34.3% and 74.3% in participants with TB coinfection compared to those with HIV (P<0.0001), and at 12 months, the proportions were 40.4% vs. 75.5%, respectively (P<0.0001). Participants with TB coinfection compared to those with HIV were significantly more likely to died (6.5% vs. 0.0%), discontinued the study (11.8% vs. 3.3%) or be lost-to-follow-up (14.0% vs. 5.8%), respectively, (P=0.0001).
Conclusions: Children with TB/HIV coinfection had more severe HIV disease, poor clinical outcomes and high rates of HIV non-suppression on WHO-recommended ART. Strategies to improve the outcomes of children with TB/HIV coinfection are needed.

Co-morbidities and clinical complications of HIV and antiretroviral therapy

WEPEB029

Comparison of clinical outcomes in people with HIV receiving liver or kidney transplants from HIV-positive and HIV-negative donors

A. Cervo[1], I. Baldisserotto[2], M. Albertini[2], F. Casari[2], E. Ghidoni[2], G. Mori[3], F. Damiano[3], B. Catellani[4], S. Di Sandro[4], G. Donati[3,2], F. Di Benedetto[4], C. Mussini[1,2], G. Guaraldi[1,2]
[1]Infectious Diseases Clinic, University Hospital of Modena, Modena, Italy, [2]Surgical, Medical and Dental Department of Morphological Sciences, University of Modena and Reggio Emilia, Modena, Italy, [3]Nephrology, Dialysis and Kidney Transplant Unit, University Hospital of Modena, Modena, Italy, [4]Hepato-Pancreato-Biliary Surgery and Liver Transplantation Unit, University Hospital of Modena, University of Modena and Reggio Emilia, Modena, Italy

Background: This study aims to compare outcomes in people with HIV(PWH) who received liver or kidney transplant from HIV-positive donors(D+/R+) versus those who underwent transplantation from HIV-negative donors(D-/R+).

Methods: Retrospective study including PWH who underwent liver and/or kidney transplant in Modena(Italy) from Jan 2003 to Jan 2024. Recipients were compared according to donor HIV-serostatus. Data collected included demographics, HIV-related characteristics, clinical and graft-related outcomes.

Results: Among 118 transplants in PWH, 8 belonged to the D+/R+ group (5 liver, 3 kidney; 1 living liver donor) and 110 to the D-/R+ group (77 liver, 27 kidney, 6 combined liver-kidney; 2 living donors). Clinical characteristics are shown in the figure and table.

Figure. Clinical characteristics of recipients with HIV of a transplant (Tx) from an HIV positive donor

	Organ/Year	Age/Gender	Liver/Kidney disease	MELD-Na/ Type and time on dialysis	Donor	CD4 at Tx	ART at Tx	Immunosuppressive drugs after Tx	Graft/patient status
Case 1	Liver/2017	55/male	HCV-related cirrhosis	15	Deceased (antiHBc +)	164	RAL+ ABC/3TC (switch post Tx: RAL+TAF/FTC)	Basiliximab + tacrolimus (then sirolimus), steroids	Failure/death (cause unkown)
Case 2	Liver/2020	61/male	HCC in HCV/HBV/HDV related cirrhosis	10	Deceased	117	RPV/TAF/FTC (switch post Tx: BIC/TAF/FTC)	Basiliximab + tacrolimus, steroids	Alive/Death (HCC recurrence)
Case 3	Kidney/2021	54/female	Chronic glomerulonephritis	Haemodialysis (0.83 yrs)	Deceased	600	DRV/cobi + RAL (switch post Tx: BIC/TAF/FTC)	Basiliximab + tacrolimus (then everolimus), mycophenolate, steroids	Alive/Alive
Case 4	Liver/2021	59/male	HCV-related cirrhosis	13	Deceased (antiHBc+)	145	BIC/TAF/FTC	Basiliximab + tacrolimus	Alive/Alive
Case 5	Liver/2022	60/male	HCV/HBV/HDV related cirrhosis	14	Living (antiHCV+)	744	BIC/TAF/FTC	Basiliximab + tacrolimus	Alive/Alive
Case 6	Liver/2023	62/male	HCC in HCV-related cirrhosis	9	Deceased (antiHCV and antiHBc+)	145	BIC/TAF/FTC	Basiliximab + tacrolimus	Alive/alive
Case 7	Kidney/2024	58/male	Iatrogenic	Haemodialysis (0.89 yrs)	Deceased (antiHBc+)	397	DRV/r+ABC/3TC (switch post Tx: DTG/3TC)	Basiliximab + tacrolimus, mycophenolate, steroids	Alive/Alive
Case 8	Kidney/2024	69/male	Probable HIVAN	Peritoneal dialysis (1.26 yrs)	Deceased (antiHBc+)	210	DTG/RPV+MVC (switch post Tx: BIC/TAF/FTC)	Basiliximab + tacrolimus, mycophenolate, steroids	Alive/alive

	D+/R+ (n=8)	D-/R+ (n=110)	P value
Age (years), median (IQR)	59.5 (54-69)	53 (38-65)	0.011
Positive HCV IgG, n (%)	5 (62.5)	78 (70.9)	0.440
Time from HIV diagnosis (years), median (IQR)	32.8 (16.7-37.0)	23.2 (5.6-38.2)	0.014
CD4 at Tx (cell/mmc), median (IQR)	164 (117-744)	341 (127-1154)	0.055
Time in dialysis (years), median (IQR)	0.8 (0.8-1.2)	3.2 (0.61-11.9)	0.016
MELD-Na, median (IQR)	13 (8-14)	27 (10-49)	0.028
Donor age (years), median (IQR)	51.5 (39-59)	56.5 (23-82)	0.321
Length of stay (days), median (IQR)	13 (5-25)	15 (7-47)	0.227
Graft rejection, n (%)	0 (0)	26 (23.6)	0.127
Alive recipients at last available follow-up, n (%)	6 (75.0)	74 (67.3)	0.493

Table. Comparison of characteristics between people with HIV receiving solid organ transplant according to donor HIV-serostatus (n=118).

Recipients in D+/R+ group had longer HIV duration (33 [IQR17-37] vs 23 [IQR6-38] years, p=0.014) and lower CD4 at transplant (164 [IQR117-744] vs 341 [IQR127-1154] cell/mmc, p=0.055). At transplant, all recipients had HIV-RNA<50 copies/ml. HIV and ARV management were similar in the two groups with only few viral blips occurring in the follow-up and one case only (D+/R+) showing persistent low-level viremia(no emergent resistance muntations).

Graft rejection occurred only in D-/R+ group (0% vs 23.6%); recipients' survival was 75% vs 67.3% with a mortality incidence rate of 14.8 (IQR3.7-59.3) per 100PYFU in D+/R+ vs. 5.7 (IQR4.1-8.1) per 100PYFU in D-/R+(p=0.278).

Conclusions: This study demonstrates that solid organ transplantation from HIV-positive donors is a viable option for PWH, with comparable recipient and graft clinical outcomes to transplants from HIV-negative donors. These findings support the expanding use of HIV-positive donors in carefully selected cases to address organ shortages.

WEPEB030

Prevalence, incidence, and risk factors for dermatological conditions in people with HIV in the modern antiretroviral (ART) era: observational cohort study, Washington, DC

Y.M. Akiska[1,2], M. Byrne[2], W.L.A. Koay[3], M. Nasseri[1], M.A. Horberg[4], A. Monroe[2], A. Friedman[1], N. Rakhmanina[5,6,7]

[1]The George Washington University School of Medicine and Health Sciences, Department of Dermatology, Washington, United States, [2]The George Washington University Milken Institute School of Public Health, Department of Epidemiology, Washington, United States, [3]Medical University of South Carolina, Division of Pediatric Infectious Diseases, Charleston, United States, [4]Mid-Atlantic Permanente Research Institute, Rockville, United States, [5]Children's National Hospital, Division of Infectious Diseases, Washington, United States, [6]The George Washington University School of Medicine and Health Sciences, Department of Pediatrics, Washington, United States, [7]Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States

Background: Dermatological conditions affect 90% of people living with HIV (PWH) over their lifetime. Despite advancements in antiretroviral therapy (ART), gaps in understanding dermatologic risk factors among PWH persist, warranting re-examination. We examined dermatologic conditions among PWH in Washington, DC.

Methods: DC Cohort participants between 2011-2023 with ≥2 HIV-care encounters and ≥1 CD4 lab were included. The outcome was the presence of a dermatologic condition (categorized as infectious, inflammatory, or cutaneous malignancy) identified with diagnostic codes. Covariates included demographic and clinical factors (e.g., age per 10 years, gender, race, CD4 counts, smoking, alcohol use). Descriptive statistics, stratified by condition category, were generated. Incidence of new conditions was assessed among PWH who enrolled in DC Cohort <1 year after HIV diagnosis over the study period.

Multivariable logistic regression estimated adjusted odds ratios (aOR) and 95% confidence intervals (95% CI) for factors associated with observed conditions.

Results: Among 11,231 participants (median age: 47 years [IQR:36–55]; 63% Black; 6% Hispanic; 72% cisgender men; 78% on ART at time of condition diagnosis; 33% with nadir CD4 <200 cells/μL), 53% (n=5,905) had a dermatologic condition. Among these, infectious conditions were most common (86%), followed by inflammatory (31%), and malignancies (13%). Incidence declined significantly for infectious (471 to 45), inflammatory (302 to 41), and malignancies (25 to 7), per 1,000 people (all p<0.0001).

Cisgender women had higher odds of malignancies (aOR:6.97; 95%CI: 5.49–8.84; p<0.001) compared to cisgender men, while Black PWH had lower odds of malignancies (aOR:0.39; 95%CI: 0.31–0.51; p<0.001) and inflammatory conditions (aOR:0.67; 95%CI: 0.56–0.81; p<0.001) compared to White PWH.

Older age increased odds of malignancies (aOR:1.2; 95%CI: 1.1–1.3; p<0.001), while higher nadir CD4 count (>500 cells/μL) reduced odds of malignancies (aOR:0.59; 95%CI: 0.45–0.77;

p<0.001) and inflammatory conditions (aOR:0.67; 95%CI: 0.56–0.80; p<0.001). Smoking (aOR:1.2; 95%CI: 1.1–1.3) and alcohol use (aOR:1.1; 95%CI: 1.0–1.3) were associated with increased odds of infectious conditions (p<0.01).

Conclusions: Declining dermatologic condition incidence observed in our cohort may reflect advancements in HIV management.

However, nadir CD4, smoking, alcohol use, and demographic disparities highlight the need for targeted interventions, enhanced screening, and immune restoration to improve dermatologic outcomes.

WEPEB031

The intersection of HIV care outcomes and CVD-related comorbidities among Black sexual minority men living with HIV in the U.S. Mid-Atlantic region

D. Hickson[1], R. Turpin[2], D. Dangerfield[3]
[1]Us Helping Us, People Into Living, Inc., Washington, United States, [2]George Mason University, Fairfax, United States, [3]George Washington University, Washington, United States

Background: Heart disease, diabetes and hypertension–leading causes of death among U.S. Black men–are further exacerbated among those living with HIV (LWH), and Black sexual minority men (SMM) LWH in particular, a population who experiences a higher rate of HIV-related mortality than white SMM. However, little is known about the relationships between cardiovascular disease (CVD)-related outcomes and care outcomes in Black SMM LWH.

This study tested the hypothesis that higher care outcomes are associated with a lower prevalence of co-morbid CVD-related outcomes.

Methods: Data came from a digital feasibility study among 1,016 Mid-Atlantic Black SMM LWH recruited between 2023 and 2024. Data included self-reported CVD (myocardial infarction, congestive heart failure, and stroke), hypertension, and diabetes; HIV care outcomes included HIV viral load, current ART use, ART taken as prescribed, HIV care visits in past year, and viral load tests in the past year.

To estimate the relationship between CVD-related outcomes and HIV care outcomes, we used modified Poisson regression models with robust standard errors to calculate prevalence ratio (PR; 95% confidence intervals [CI]) before and after adjustment for socio-demographic characteristics.

Results: The prevalence of CVD was 6.8% followed by 11.7% for diabetes and 21.2% for hypertension. In unadjusted models, the three CVD-related comorbidities were associated with having lower prevalence of three outcomes: 3 or care visits in the past year, having 3 or more viral load tests in the past year, and taking ART as prescribed.

After adjustment, CVD was associated with a 79% lower prevalence of 3 or more HIV care visits in the past year (aPR=0.21, 95% CI=0.08,0.55). Diabetes was associated with a 65% lower prevalence of taking ART as prescribed in fully adjusted models (aPR=0.35, 95% CI=0.12,0.99).

	Cardio-vascular Disease		Hyperten-sion		Diabetes	
	Unadjusted	Adjusted	Unadjusted	Adjusted	Unadjusted	Adjusted
Detectable HIV Load	**0.50 (0.26, 0.95)**	0.67 (0.20, 2.24)	**0.60 (0.40, 0.91)**	1.57 (0.74, 3.33)	0.62 (0.38, 1.02)	0.43 (0.15, 1.23)
Current ART Use	0.35 (0.12, 1.07)	0.37 (0.08, 1.62)	0.72 (0.28, 1.82)	0.69 (0.21, 2.25)	0.69 (0.23, 2.06)	0.70 (0.18, 2.80)
ART Always or Almost Always Taken as Prescribed	**0.38 (0.20, 0.73)**	0.44 (0.12, 1.63)	**0.62 (0.41, 0.94)**	1.04 (0.50, 2.17)	**0.59 (0.36, 0.98)**	**0.35 (0.12, 0.99)**
3 or more HIV Care Visits in Past Year	**0.43 (0.23, 0.82)**	**0.21 (0.08, 0.55)**	1.47 (0.93, 2.31)	1.32 (0.69, 2.54)	1.06 (0.63, 1.79)	1.67 (0.71, 3.95)
3 or more Viral Load Tests in Past Year	**0.46 (0.24, 0.89)**	0.80 (0.23, 2.79)	**0.60 (0.40, 0.91)**	1.15 (0.55, 2.40)	**0.53 (0.32, 0.87)**	**0.21 (0.07, 0.65)**

Conclusions: Study findings illustrate a significant association of engagement in HIV care and treatment adherence with reduced cardio-metabolic health outcomes among Black SMMLWH, suggesting a need for a deeper understanding of these relationships in this population.

Antiretroviral therapies and clinical issues in adults

WEPEB032

Risk of developing low-level viremia (LLV) among people with HIV (PWH) with current HIV-RNA≤50 copies/mL receiving 2DR vs 3DR: a case control study

A. Vergori[1], A. Cervo[2], A. Roen[3], R. Gagliardini[1], T. Clemente[4], V. Mazzotta[1], E. Quiros-Roldan[5], F. Maggiolo[6], C. Mussini[2], A. Antinori[1], A. Cozzi-Lepri[3], On Behalf Of The ICONA Fouondation Study
[1]Clinical Department, INMI L. Spallanzani, Rome, Italy, [2]Infectious Diseases Clinic, University Hospital of Modena, Modena, Italy, [3]Centre for Clinical Research, Epidemiology, Modelling and Evaluation (CREME), Institute for Global Health, University College London, London, United Kingdom, [4]Infectious Diseases, Vita-Salute San Raffaele University, Milan, Italy, [5]Division of Infectious and Tropical Medicine, ASST Spedali Civili, Brescia, Brescia, Italy, [6]Infectious diseases' specialist Freelance, None, Fabro, Italy

Background: Low-level viremia(LLV) occurs in 7-22% of people with HIV(PWH). It is unclear whether the risk of developing LLV may be higher under the pressure of dual-drug regimens (2DR) vs. triple regimens (3DR).

Methods: PWH enrolled in the Icona Foundation Study cohort with virological suppression (≥2 consecutive HIV-RNA≤50copies/ml over 6 months) after 01/11/2014 (baseline) were included. A 1:3 Matched case-control study was performed, matching on previous gaps in care (>12 months between visits) and number of regimens failed (proxy for adherence to ART).

Cases defined as individuals experiencing LLV (2consecutive HIV-RNA 51-199copies/ml or 1 HIV-RNA 51-199copies/ml followed by ART change within 30 days) after baseline.

Controls defined as PWH who, after the same time from baseline to the date of LLV of the matched case (index date), still had HIV-RNA≤50 copies/ml.

The main exposure of interest was the type of regimen at the index date [2DR(DTG/3TC, DTG/RPV, DTG/DOR, CAB/RPV) vs. 3DR(DTG/BIC or RPV/DOR or boosted DRV or ATV + TXF/XTC)].

Follow-up for cases and controls accrued from baseline and was censored at time of viral rebound(HIV-RNA>200 copies/ml) or last available HIV-RNA. The association between regimen received(2DR vs. 3DR) and risk of LLV evaluated using conditional logistic regression.

Results: Among 979PWH, 243 had LLV. Sixty-seven (28%) cases were receiving 2DR compared to 231 (31%) of controls.

Among those on 2DR, 83% were on DTG/3TC. Among those prescribed 3DR, 31% were on RPV+TXF/XTC followed by 20% BIC+TXF/XTC. MSM and participants with higher education were more likely to use 2DRvs.3DR; 2DR were more common in more recent years compared to 3DR (Figure A).

After adjusting for confounding, there was no evidence for a difference in risk of LLV for 2DRvs.3DR [OR=0.95, 95%CI(0.63, 1.42)] (Figure B).

Figure: A: Comparison of case/control status and of baseline characteristics stratified by 2DR vs 3DR and B: Odd Ratios for developing low level viremia (LLV) on 2DR vs 3DR after adjusting for confounding from fitting four separate conditional logistic regression models

A

		2DR N	2DR %	3DR N	3DR %	Overall N	Overall %	p-value
Control		231	77.5	505	74.2	736	75.2	0.263
Case		67	22.5	176	25.8	243	24.8

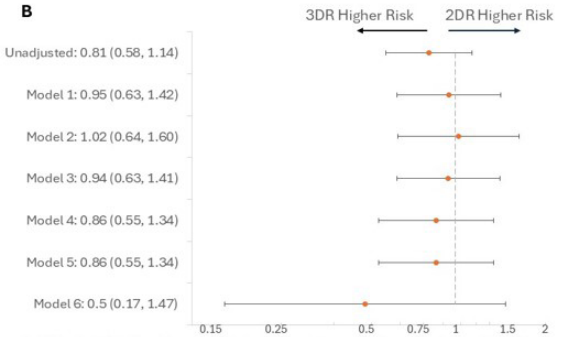
Year at baseline – median (IQR)		2018 (2016, 2019)		2016 (2015, 2019)		2017 (2015, 2019)		<0.001

B



Model 1: adjusting for the minimum sufficient adjustment set according to our directed acyclic graph (not shown): drug class, duration of HIV-RNA suppression, year at baseline, duration of ART, CD4 at baseline CD8 at baseline AIDS at baseline, mode of HIV transmission, and level of education at baseline.
Model 2: same as model 1, restricting to cases defined by 2 consecutive HIV-RNA values.
Model 3: same as model 1, including uncommon 3DR regimens (DTG ABC 3TC and RPV ABC 3TC)
Model 4: same as model 1, restricting 2DR to only DTG/3TC
Model 5: same as model 1, restricting 3DR to only BIC+TXF/XTC
Model 6: same as model 1, restricting 3DR to only BIC+TXF/XTC and 2DR to only DTG/3TC

Conclusions: On modern ART era, the use of DTG-based 2DR is not associated with a higher risk of developing LLV after achieving suppression compared to TXF-based 3DR.

WEPEB033

Rapid virologic suppression with DTG/3TC facilitates early switch to CAB+RPV LA for treatment-naive people living with HIV: suppression phase outcomes from the Phase 3b VOLITION study

E. Cordova[1], K. Hove[2], L. Hocqueloux[3], R. Moodley[2], B.-E.O. Jensen[4], J. Priest[5], A. Antinori[6], P. Patel[5], G.C. Tascón[7], C. Polk[5], M. Johnson[8], M. St Clair[5], F.X.Z. Vargas[9], S. Somvanshi[10], J. Szabo[11], J. Radford[2], L. Garside[12], R. Grove[12], H.P. Garges[5], J. van Wyk[2], B. Jones[2]

[1]IDEA Foundation, Buenos Aires, Argentina, [2]ViiV Healthcare, London, United Kingdom, [3]Centre Hospitalier Universitaire d'Orléans, Orléans, France, [4]Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University, Department of Gastroenterology, Hepatology, and Infectious Diseases, Düsseldorf, Germany, [5]ViiV Healthcare, Durham, United States, [6]National Institute of Infectious Diseases, L. Spallanzani, IRCCS, HIV/AIDS Department, Rome, Italy, [7]Hospital Universitario Infanta Leonor, Departamento de Medicina Interna, Madrid, Spain, [8]Atrium Health Carolinas Medical Center, Charlotte, United States, [9]Espacio EME, Región Metropolitana, Chile, [10]Development Statistics, GCC, GSK, Bengaluru, India, [11]L'Actuel Medical Clinic, Clinical Department, Montréal, Canada, [12]GSK, London, United Kingdom

Background: Both dolutegravir and lamivudine (DTG/3TC) and long-acting injectable cabotegravir plus rilpivirine (CAB+RPV LA) are two-drug regimens with established efficacy and safety profiles and limited drug–drug interactions. Offering treatment options with different delivery modalities and dosing frequencies allows for greater choice. VOLITION (NCT05917509) is the first study to evaluate optional switch from DTG/3TC to CAB+RPV LA immediately after attaining virologic suppression in antiretroviral therapy (ART)-naive adults with HIV-1. We present VOLITION Suppression Phase outcomes.

Methods: VOLITION is a Phase 3b, multicenter, non-randomized, parallel-group, open-label study evaluating initial viral suppression with DTG/3TC up to ~16 weeks followed by participant-determined optional switch to CAB+RPV LA dosed every two months or continuation of DTG/3TC through Month 11/12. The primary endpoint during the Suppression Phase was time to virologic suppression (HIV-1 RNA <50 copies/mL).

Results: A diverse population of 171 participants was enrolled and initiated DTG/3TC, including 26% women, 30% Black or African American, and 51% Hispanic/Latinx (*Table*). Median (95% confidence interval) time to suppression with DTG/3TC was 4.14 (4.14–4.29) weeks and 97.7 (n=167/171) achieved virologic suppression within the 16-week Suppression Phase.

One participant had protocol-defined confirmed virologic failure (two consecutive HIV-1 RNA values ≥200 copies/mL after prior suppression) with no resistance-associated mutations detected.

Overall, 12% (n=21/171) of participants had a drug-related adverse event (all Grade 1 or 2), with few (<1%) treatment-related discontinuations. Participants reported high levels of treatment satisfaction with DTG/3TC

(mean score, 57/66) during the Suppression Phase. Most participants eligible to switch chose CAB+RPV LA at Day of Choice and the majority reported a positive opinion about switching.

Parameter	DTG/3TC (n=171)
Median age, years (range)	31 (18–70)
≥50 years, n (%)	18 (11)
Women (self-identified gender), n (%)	45 (26)
Race, n (%)	
Black or African American	51 (30)
White	106 (62)
Other races or not reported or unknown*	14 (8)
Hispanic/Latinx ethnicity, n (%)	88 (51)
Plasma HIV-1 RNA (copies/mL) category, n (%)	
<100,000	106 (62)
100,000 to <500,000	50 (29)
500,000 to <1,000,000	11 (6)
≥1,000,000	4 (2)
CD4+ (cells/mm^3) category, n (%)	
<100	8 (5)
100 to <200	19 (11)

350 to <500	45 (26)
≥500	53 (31)

*Other race participants: American Indian or Alaska Native, Native Hawaiian or Other Pacific Islander, and Multiple, n=3; Asian, n=4, not reported or unknown, n=7.
3TC, lamivudine; DTG, dolutegravir.

Table. Baseline characteristics (Suppression Phase).

Conclusions: Once-daily DTG/3TC achieved rapid virologic suppression in a diverse population of treatment-naive adults with HIV-1, confirming its high potency and providing a pathway to person-centered treatment, allowing people to choose an early switch to LA therapy of their own VOLITION.

WEPEB034

Safety and efficacy of ANV/3TC/TDF vs E/C/F/TAF for maintaining virologic suppression in adults living with HIV-1: week 96 results from the phase 3, noninferiority SPRINT randomized trial

F. Zhang[1], H. Wu[2], W. Cai[3], P. Ma[4], Q. Zhao[5], H. Wei[6], H. Lu[7], H. Wang[8], S. He[9], Z. Chen[10], Y. Chen[11], M. Wang[12], H. Fu[13], H. Qin[13]

[1]Clinical and Research Center for Infectious Diseases, Beijing Ditan Hospital Capital Medical University, Beijing, China, [2]Clinical and Research Center for Infectious Diseases, Beijing Youan Hospital, Capital Medical University, Beijing, China, [3]Infectious Disease Center, Guangzhou Eighth People's Hospital, Guangzhou Medical University, Guangzhou, China, [4]Department of Infectious Diseases, Tianjin Second People's Hospital, Tianjin, China, [5]Department of Infectious Diseases, The Sixth People's Hospital of Zhengzhou, Zhengzhou, China, [6]Department of Infectious Diseases, The Second Hospital of Nanjing, Najing, China, [7]National Clinical Research Centre for Infectious Diseases, The Third People' s Hospital of Shenzhen, The Second Affiliated Hospital of Southern University of Science and Technology, Shenzhen, China, [8]Department of Infectious Diseases, Shenzhen Third People's Hospital, Shenzhen, China, [9]Department of Infectious Diseases, Public Health Clinical Medical Center of Chengdu, Chengdu, China, [10]Drug Clinical Trial Institution, Public Health Clinical Medical Center of Chengdu, Chengdu, China, [11]Division of Infectious Diseases, Chongqing Public Health Medical Center, Chongqing, China, [12]Institute of HIV/AIDS, The First Hospital of Changsha, Changsha, China, [13]Clinical Research & Development, Jiangsu Aidea Pharmaceutical Co., Ltd, Yangzhou, China

Background: The SPRINT study demonstrated that immediate switch to tenofovir DF- (TDF-) containing, ainuovirine- (ANV) based regimen (ANV/3TC/TDF) resulted in non-inferior virologic efficacy, and improved cardiometabolic conditions compared to that to tenofovir alafenamide-containing, cobicistat-boosted elvitegravir-based regimen (E/C/F/TAF) at 48 weeks.

Methods: In the extensional study between weeks 48, and 96, people with HIV-1 (PWH) on ANV/3TC/TDF continued the assigned regimen (immediate switch arm), while those on E/C/F/TAF re-switched to ANV/3TC/TDF FDC (delayed switch arm). The E/C/F/TAF arm (weeks 0 to 48) was used as comparator for the extensional study. The primary efficacy end point was proportion of PWH with HIV-1 RNA titer at 50 copies per millimeter or above at a non-inferiority margin of 0.05.

Results: The primary efficacy end points were both 3.4% (13/381, and 13/377) for the two intervention arms at week 96, noninferior to that of the comparator arm at week 48 (1.6%; estimated treatment difference [ETD], 0.018, 95% confidence interval [95% CI], -0.005 to 0.043, P <0.001; 0.019, -0.004 to 0.044, P<0.001). The treatment-emergent adverse events were generally similar between the two intervention arms during the extensional period. The delayed switch arm showed modest reduction in body weight (mean± standard error of mean [SEM], -0.66±0.80

kg), in contrast to the immediate switch arm with slight weight gain from week 48 (0.05±0.82 kg; -0.71 kg, -1.18 to -0.24, P=0.003 for difference). Fasting serum low-density lipoprotein cholesterol remained generally unchanged in the immediate switch arm (0.01±0.04 mmol/L) but improved greatly in the delayed switch arm at week 96 from week 48 (-0.37 ± 0.08 mmol/L; -0.38, -0.46 to -0.31; P<0.001; Figure 1).

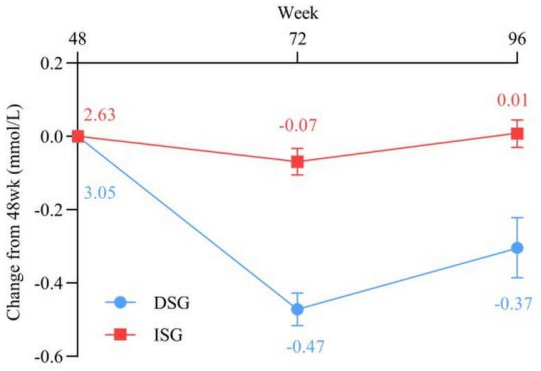

Figure 1. Change from week 48 in LDL-C

ISG, immediate switch arm, ISG; DSG, delayed switch arm.

Conclusions: Both immediate and delayed switches to ANV/3TC/TDF maintained high viral suppression through 96 weeks. Delayed switch could offset weight gain, and lipid dysmetabolism associated with previous exposure to E/C/F/TAF.

WEPEB035

Persistent and long-acting intracellular three HIV drug concentrations in participants after subcutaneous TLC-ART 101

S. Perazzolo[1], L. Duan[1], R. Delle Fratte[1], Z. Stephens[1], C. Jonsson[2], A. Angeldekao[2], G. Wood[2], E. Padullo[2], E.P. Acosta[3], R.A. Bender Ignacio[2,4], R.J.Y. Ho[1,5]

[1]University of Washington, Pharmaceutics, School of Pharmacy, Seattle, United States, [2]University of Washington, Division of Allergy and Infectious Diseases, School of Medicine, Seattle, United States, [3]University of Alabama, Division of Pediatric Infectious Diseases, School of Medicine, Birmingham, United States, [4]Fred Hutch Cancer Center, Vaccine and Infectious Disease Division, Seattle, United States, [5]University of Washington, Department of Bioengineering, Seattle, United States

Background: Current oral or long-acting ART drugs and injectables have low intracellular concentrations in lymphocytes. Injectable TLC-ART101, a Drug-combination NanoParticle (DcNP) platform with lopinavir, ritonavir, and tenofovir, targets lymphoid tissues during first-pass distribution. This enhances lymphocyte drug uptake and retention, achieving higher and long-acting intracellular concentrations in PBMCs compared to plasma-based delivery.

Methods: People without HIV received TLC-ART101 in 1.5 mL (n=4) or 4 mL (n=5) doses (NCT06850728). Blood samples were collected frequently for three days post-injection, then weekly for two months. Plasma drugs (≥0.1 ng/mL) and PBMCs (isolated via GLP, lysed at 2×10⁶ cells/tube) were quantified by validated LC-MS/MS assays (limits: 1.8–8.8 pg/mL). The area under the curve (AUC) was calculated using trapezoidal methods for plasma and PBMC concentration-time profiles.

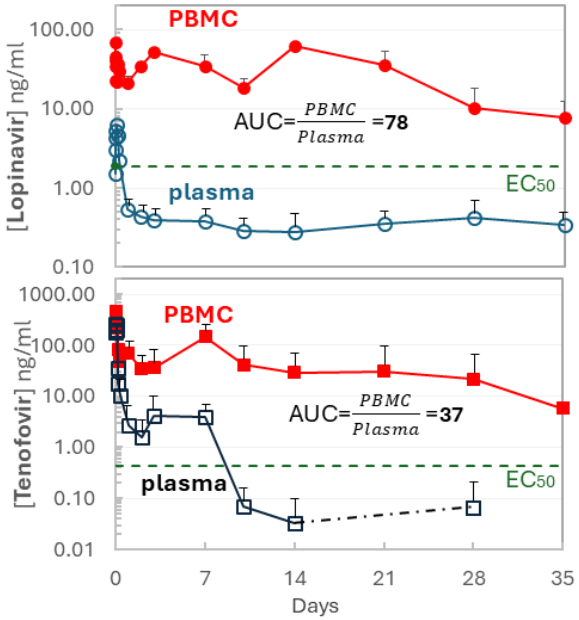
Results: All participants showed sustained intracellular lopinavir and tenofovir levels in PBMCs, with substantially higher concentrations than plasma for 35 days (Figure, ritonavir not shown).

Results indicate:

i. Prolonged cellular retention of lopinavir and tenofovir with TLC-ART101,

ii. PBMC-to-plasma AUC ratios of 78 (lopinavir) and 37 (tenofovir), demonstrating enhanced cellular uptake and retention.

PBMC concentrations exceeded combined EC50 values (1.9 and 0.4 ng/mL for lopinavir and tenofovir, Figure) in the 1.5 mL group. In the 4 mL group, PBMC concentrations at 57 days reached 14 ng/mL (lopinavir) and 8 ng/mL (tenofovir), with 22-fold and 7-fold higher AUC ratios in PBMCs, respectively.



Time-course of cellular (PBMC) and plasma concentration for Lopinavir (top panel) and Tenofovir (lower panel), after a single SC TLC-101 in 1.5mL (low dose). Plasma's LOD = 0.1 ng/ml, PBMC's LOD= 0.5 and 2.5 pg/10^6 cells (0.29 pL/cell conversion); EC_{50}=1.9, 0.4 ng/ml, for lopinavir and tenofovir. AUC of cell (PBMC)-to-plasma are expressed as a ratio. Data presented as mean and SEM.

Conclusions: Current oral or injectable ART exhibits PBMC-to-plasma ratios below 1. TLC-ART101, using a DcNP platform, achieved higher intracellular than plasma drug levels. This study provides evidence that a cell-targeted, long-acting product can enhance intracellular concentrations.

Extending this approach to combinations like dolutegravir, lamivudine, and tenofovir may improve potency against HIV replication in HIV-targeted lymphocytes.

WEPEB036

Clinical outcomes among women in the OPERA cohort initiating CAB+RPV LA with viral loads ≥ 50 copies/mL

J. Altamirano[1], B. Levis[2], C. Markarian[3], Q. Cochran[4], C. Sherman[5], M.-G. Toeque[3], L. Armas[6], G. Sridhar[7], V. Vannappagari[7], K. Brown[7], J.S. Fusco[2]
[1]CAN Community Health, Miami, United States, [2]Epividian, Inc., Raleigh, United States, [3]AIDS Healthcare Foundation, Los Angeles, United States, [4]AIDS Healthcare Foundation, Fort Lauderdale, United States, [5]CAN Community Health, Arlington, United States, [6]Human Centered Consulting & Care, McKinney, United States, [7]ViiV Healthcare, Durham, United States

Background: Cabotegravir + rilpivirine long-acting (CAB+RPV LA) injectable is indicated for treatment-experienced individuals with viral loads (VL) <50 copies/mL. However, 1 in 5 women receiving CAB+RPV LA in the OPERA cohort initiate the regimen with VL ≥50 copies/mL. This study assessed clinical outcomes among these women from 2021-2024.
Methods: Treatment-experienced women with HIV ≥18 years old who received ≥1 CAB+RPV LA injection between 21JAN2021-31AUG2023 and had VL ≥50 copies/mL at first injection were followed through 29FEB2024. Complete initiation was defined as first 2 injections within 67 days.
For monthly dosing schedules, maintenance injections were categorized as on-time (23-37 days after last injection), delayed (38-52 days), missed (53-67 days), or discontinued (≥68 days).
For every 2-month dosing, the respective windows were 53-67, 68-112, 113-127, and ≥128 days. Confirmed virologic failure (CVF) was defined as VL suppression to <50 copies/mL followed by 2 consecutive VLs ≥200 copies/mL or 1 VL ≥200 copies/mL and discontinuation.
Results: In total, 105 women were included. At baseline, median age was 43 (IQR: 35, 53), 79% were Black, 9% were Hispanic, 8% were transgender, 44% had a BMI ≥30 kg/m^2, median years since HIV diagnosis was 13 (IQR: 4, 22), and median VL was 1090 copies/mL (IQR: 89, 24700).
Among 95 (90%) women with complete initiation, 69 (73%) were on CAB+RPV LA with median follow-up of 19 months (IQR: 13, 25) at the time of analysis. Among 82 women (93%) with known dosing schedules and ≥1 maintenance injection, 39% of women received all maintenance injections on-time; 33% had ≥1 delayed maintenance injection and 17% had ≥1 missed maintenance injection. Among 92 women (97%) with ≥1 VL over follow-up, 92% achieved VL <50 copies/mL at any point during follow-up (87% at last follow-up). Of 66 women with ≥1 VL available after suppression to <50 copies/mL, ≤5* experienced CVF after a median of 13 months (IQR: 9, 17).
Conclusions: In this diverse cohort of 105 women in routine clinical care in the US who started CAB+RPV LA regimen with VL ≥50 copies/mL, most suppressed to VL <50 copies/mL and CVF was rare.
*Not reported due to HIPAA regulations.

WEPEB037

Polypharmacy in older adults with HIV: how to collect, assess, and manage

J. Milic[1], A. Pugliese[2], M. Belli[1], T. Albano[1], M. Visicaro[1], M. Ricciardetto[1], G. Mancini[3], M. Menozzi[3], G. Cuomo[3], P. De Cosmo[4], C. Grana[1], C. Mussini[1], G. Guaraldi[1]
[1]University of Modena and Reggio Emilia, Modena, Italy, [2]Distribuzione Diretta AUSL Modena, Dipartimento Farmaceutico Interaziendale, Modena, Italy, [3]Infectious Diseases Clinic, Policlinico of Modena, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy, [4]Infologic Srl, Padova, Italy

Background: This study aimed to develop a machine learning algorithm for people with HIV (PWH) to generate (i) a medication reconciliation list (MRL) and (ii) a report to assist physicians in identifying drug-drug interactions (DDIs) and potentially inappropriate prescriptions (PIMs).
Methods: A cross-sectional study was conducted in 2024 among older PWH attending the Modena HIV Metabolic Clinic (MHMC). Inclusion criteria included age >50 years, polypharmacy (PP, defined as chronic use of >5 drugs in addition to antiretroviral therapy), and the ability to use WhatsApp.
MRLs were created by uploading photos of medication boxes, which were converted into ATC codes and compared with electronic patient charts. Agreement between the prescribed and taken medication lists was evaluated, identifying medications prescribed but not taken and those taken but not prescribed.
Data from MRLs, patient demographics, HIV characteristics, and comorbidities were analyzed using Navpharma, generating reports on major and minor drug-drug interactions (DDIs) and PIMs, including nephrotoxicity risk, anticholinergic burden, and QT prolongation.
Results: 87 PWH with PP were included, 64 (73.6%) were men, median age was 63 (Q1, Q3: 59, 67), median current CD4 count was 631.5 cells/ml (Q1, Q3: 369, 791). Multimorbidity was present in 80 (92%). The mean number of medications per patient was 7 (Q1, Q3: 5,9). A total of 58 (40%) PWH did not participate due to technological barriers and/or unwillingness. Agreement between prescribed and taken medications was 76.8%, with 10.3% of medications prescribed but not taken and 21.8% taken but not prescribed.
Major drug-drug interactions (DDIs) were observed in 54%, while minor DDIs were observed in 47.1%. PIMs included potential nephrotoxicity (73.6%), significant anticholinergic burden (13.8%), and QT prolongation (59.8%).
After consultation with physicians and pharmacists, 20.8% medications were discontinued, and 18.1% new medications were initiated.
Conclusions: Polypharmacy is a significant issue among older PWH. AI tools like the one developed in this study show promise in improving medication reconciliation and prescribing appropriateness, ultimately enhancing patient safety and care.

Antiretroviral therapies and clinical issues in adolescents and young adults

WEPEB038

The relationship between economic well-being and antiretroviral therapy adherence in youth with HIV in the United States

M.C.D. Stoner[1], T.B. Neilands[2], K. Ming[2], L. Smith[2], C. McCuistian[3], C. Balaban[2], H. Patani[4], K. Asman[1], V.A. Gruber[3], E. Moore[2], Y. Granados[4], M.O. Johnson[2], P. Saberi[2]

[1]RTI International, Oakland, United States, [2]Center for AIDS Prevention Studies, University of California San Francisco, San Francisco, United States, [3]University of California San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States, [4]AIDS Healthcare Foundation, Los Angeles, United States

Background: Youth and young adults have high attrition across the HIV care continuum, including increased risk of antiretroviral therapy (ART) nonadherence and virologic failure. Long-acting injectable ART (LAI-ART) may improve adherence to ART, but structural barriers remain. Our study examined the relationship between economic well-being and ART adherence in youth with HIV (YWH) including YWH using LAI or oral ART.

Methods: We used baseline data from YWH (18–29 years old) in the US enrolled from 2023-2024 in a randomized trial addressing HIV care barriers, mental health, and substance use. Daily oral ART adherence was measured using a validated self-reported measure on a scale from 0–100. High adherence was defined as having a score of ≥80 for oral ART or not having missed/delayed visits for LAI-ART. We examined relationships between measures of economic well-being (subsistence needs and financial situation) with adherence using descriptive statistics and estimated adjusted risk ratios (RRs) using log-Poisson models with robust standard errors.

Results: Among 91 YWH enrolled at baseline, the median age was 27 years (interquartile range 24-28). Over half 69.2% (n=63) identified as cisgender male and the sample was racially diverse, with 28.6%, (n=26) identifying as Black or African American, 33% identifying as White (n=30), and over half identifying as Hispanic/Latino (56.0%, n=51). Most participants (87.9%, n=80) were taking oral ART and 11.0% (n=10) were on LAI-ART. Roughly 62% (n=47/76 with available data) were adherent to oral ART and 90% (n=9/10) were adherent to LAI-ART.

Those who said that they 'could not get by with the money they had' experienced significantly lower adherence (33.3%) compared to those who had enough money to live comfortably (75%; RR 0.50, 95% confidence interval (CI) 0.26-0.96) after adjusting for age, sex at birth, and race/ethnicity. This association remained when examining adherence only among those who used oral ART (RR 0.30, 95% CI 0.11-0.81).

Conclusions: Economic well-being was associated with adherence among YWH using both oral and LAI-ART. Approaches are needed that address financial barriers to improve ART adherence.

WEPEB039

HIV-1 drug resistance in children and implications for pediatric treatment strategies: a systematic review and meta-analysis

Background: Failure in the prevention of mother-to-child HIV transmission (PMTCT) and pediatric treatment challenges led to pretreatment drug resistance (PDR) and acquired drug resistance (ADR) in children living with HIV (CLHIV). This review investigates drug resistance patterns in CLHIV and their significance at the global level.

Methods: A systematic review with meta-analysis was conducted on interventional and observational studies published between 2010 and 2024 with data on PDR and ADR in CLHIV (aged 0-15 years) worldwide. We analyzed children with PDR and without prior PMTCT exposure separately, using random effects to pool proportions and meta-regression to assess PDR and ADR subgroup differences by drug class and geographical regions.

The study is registered in the International Prospective Register of Systematic Reviews (Prospero) under CRD42023470034.

Results: Overall, 72 studies from 38 countries worldwide were included, encompassing 9,973 children (52.5% males). The overall pooled prevalence [95%CI] of PDR was 32.48% [26.08-39.21], with a high rate among those who failed PMTCT-prophylaxis (43.23% [32.94-53.82]) compared to those without PMTCT-intervention (19.40 [14.45-28.84]), p<0.01. PDR was higher in sub-Saharan Africa (SSA) at 39.13% vs. 22.56% in other regions (p<0.01) and was driven by non-nucleoside reverse transcriptase inhibitors (NNRTI)-mutations (OR [95%CI]: 2.46 [2.12-7.86]; p=0.013). Nucleoside reverse transcriptase inhibitors (NRTI) and Integrase strand transfer inhibitors (INSTI) related-PDR were 12.06% [5.97-19.73] and 1.29% [0.0-7.37], respectively. The pooled

prevalence of ADR was 61.43% [49.82-72.45] among CLHIV experiencing virological failure, with SSA being the most affected region worldwide (67.58% vs. 18.75% in other regions, p<0.001), driven by NNRTI mutations (OR [95%CI]: 3.84 [3.36-4.38]; p<0.001) and associated with high pre-ART viral load and WHO clinical stage II. INSTI-ADR was low (5.53% [2.49-9.53]) and found with dolutegravir-associated mutations (E138K, G118R, and R263K).

Conclusions: There are high burdens of PDR and ADR among CLHIV, with alarming rates in SSA driven by NNRTI resistance, suggesting the need to phase-out pediatric NNRTIs used for either PMTCT or treatment in low- and middle-income countries (LMICs). Importantly, emerging INSTI resistance among CLHIV highlights the relevance of HIVDR surveillance strategies to preserve current and future regimens, especially in LMICs where personalized management remains challenging.

Antiretroviral therapies and clinical issues in neonates, infants and children

WEPEB040

Gestational exposure to an efavirenz-containing compared to a dolutegravir-containing antiretroviral regimen is associated with lower anthropometrics at 18 months of life among children HIV-exposed uninfected in Botswana

G. Masasa[1], S.W. Kgole[1], N. Mmasa[2], S.R. Schenkel[3], J. Legbedze[4], D. Bitran[3], B. Phale[1], G. Elija[1], P. Maano[1], K. Setlhabi[1], L. Baotsenye[1], C. Kgathi[1], S. Moyo[1,5], J. Makhema[1], J. Jao[4,6], K.M. Powis[1,7,8]

[1]Botswana Harvard Health Partnership, Gaborone, Botswana, [2]Country Durham and Darlington NHS Foundation Trust, Darlington, United Kingdom, [3]Massachusetts General Hospital, Division of Pediatric Global Health, Boston, United States, [4]Ann & Robert Lurie Children's Hospital of Chicago, Chicago, United States, [5]Harvard T.H Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [6]Northwestern University Feinberg School of Medicine, Chicago, United States, [7]Harvard T.H Chan School of Public Health, Department of Immunology and Infectious Diseases,, Boston, United States, [8]Massachusetts General Hospital, Departments of Internal Medicine and Pediatrics, Boston, United States

Background: Children with gestational exposure to HIV and antiretrovirals (ARVs) who remain HIV uninfected (CHEU) experience risk of suboptimal growth compared to children born to persons without HIV. We evaluated growth outcomes at 18-months of life among CHEU with gestational exposure to efavirenz (EFV)- versus dolutegravir (DTG)-containing ARV regimens.

Methods: Pregnant women with HIV were enrolled in the Botswana-based Tshilo Dikotla (Aug-2016 – May-2019) and FLOURISH (Jul-2021 – Feb-2023) studies, with mother-infant pairs prospectively followed. Infant birth anthropometrics were abstracted from medical charts and trained study staff obtained child weight and length at 18-months. Z scores for weight (WAZ), length (LAZ), and weight-for-length (WLZ) were calculated using World Health Organization standards.

Mixed effects models with study, Tshilo Dikotla or FLOURSH, as random effects were fit to assess differences in infant anthropometrics at 18 months of life.

Results: Of 333 CHEU enrolled in the two studies, 110 (33%) were exposed to EFV-containing regimens antenatally (CHEU-EFV) and 223 (67%) to DTG-containing regimens (CHEU-DTG). Median maternal age was higher among CHEU-EFV compared to CHEU-DTG [32.9 years (Interquartile Range (IQR) 27.7, 36.1) vs 29.4 (IQR 25.5, 35.2)]. Infant birth WAZ and LAZ did not vary by ARV exposure. At 18 months CHEU-EFV had lower mean WAZ [-0.39 (Standard Deviation (SD) ±1.17) versus -0.08 (SD ± 1.27); p-value = 0.03] and WLZ [-0.16 (Standard Deviation (SD) ±1.15) versus +0.15 (SD ± 1.31); p-value = 0.03] compared to CHEU-DTG; LAZ was similar between groups.

After adjusting for maternal age, marital status, gravidity, timing of antenatal antiretroviral exposure (from conception vs later in gestation), birth WAZ, preterm birth, infant sex, and exclusive breastfeeding duration, CHEU-EFV had lower mean WAZ [β = -0.17 (95% Confidence Interval (CI) -0.34, -0.01); p-value = 0.03] and WLZ [β = -0.19 (95% CI -0.37, -0.02); p-value = 0.03] at 18-months compared to CHEU-DTG. Mean LAZ at 18-months was similar between groups.

Conclusions: Gestational exposure to an EFV- vs. DTG-containing regimen was associated with lower WAZ and WLZ at 18 months. Future studies are warranted to understand mechanistic pathways and monitor the long-term implications of these early growth differences by gestational ARV regimen exposure.

Epidemiology of HIV

Trends in HIV, syphilis and hepatitis prevalence among men who have sex with men in Rwanda: cross-sectional bio-behavioral surveys from 2015 through 2024

C. Kayitesi[1], B. Kurujyishuli[1], G. Twagirimana[1], C. Ndinda[1], Z. Nzeyimana[1], B. Ikuzo[1], V. Umubyeyi Mupenzi[1], G. Nshogoza Rwibasira[1]

[1]Rwanda Biomedical Center, HIV/AIDS, Diseases Prevention and Control, Kigali, Rwanda

Background: In 2015, the Rwanda Biomedical Center initiated Bio-behavioral Surveys (BBSs) to systematically assess HIV prevalence and sexual behaviors among Men who have Sex with Men (MSM). MSM are at a higher risk for HIV, syphilis, and viral hepatitis B and hepatitis C infection than the general population.

This abstract analyzes HIV, syphilis, and viral hepatitis B and C prevalence trends across four BBSs in Rwanda from 2015 to 2024.

Methods: Data presented here were drawn from MSM BBSs conducted in 2015 (n=452), 2020 (n=1292), 2021 (n=2217), and 2024 (n=3757), using Respondent-Driven Sampling to recruit, from the same provinces used in 2015, MSM aged 18 years and older who had engaged in anal sex within the last 12 months prior to the survey. Participants underwent HIV, active syphilis, and hepatitis B and hepatitis C testing in line with the national algorithm.

We used the Cochran-Armitage test, a nonparametric method, to test for trends in STATA version 18. Ethical approvals were obtained from local Rwanda National Ethics Committee and CDC.

Results: HIV prevalence varied from 4.0%(95%CI:2.2-5.8) in 2015 to 4.3% (1.2-7.3) in 2020, 6.9% (5.5-8.6) in 2021, and 5.8% (4.6-7.5) in 2024 (p-value for trend=0.01). Syphilis prevalence decreased from 4.0%(95%CI:1.0-6.0) in 2015 to 3.1% (1.8-4.3) in 2020 to 2.4% (1.7-3.4) in 2021 (p-value for trend from 2015 to 2021, p=0.04) but increased sharply to 5.9% (4.7-7.4) in 2024.

Information on hepatitis B surface antigen and hepatitis C antibody were first collected in 2021, showing a drop in the prevalence of hepatitis B from 4.2% (3.0-5.7) in 2021 to 1.5% (1.0-2.2) in 2024 (p<0.001) while the prevalence of hepatitis C increased from 0.7% (0.4-1.2) in 2021 to 1.6% (0.9-2.8) in 2024 (p=0.06).

Conclusions: The study revealed an increase in HIV prevalence, syphilis resurgence, and hepatitis C prevalence, emphasizing the need for robust prevention and treatment strategies to reduce disease burden and ensure healthcare access.

WEPEC043

HIV-1 retrospective molecular epidemiology analysis in Uruguay reveals genetic diversity and a new circulating recombinant form: CRF179_12B

A. A. Podchibiakin[1], R. Flieller[2], D. Ruchansky[2], M. Brasesco[2], V. Bormida[3], M. Matias-Florentino[4], M.N. Cortinas[3], A. Lizasoain[5], H. Chiparelli[2], S. Ávila-Ríos[4], S. Cabrera[6], G. Bello[7], A.M. Soler[8], D. Mir[1]

[1]Universidad de la República - CENUR, Department of Biological Sciences, Genomics and Bioinformatics Unit, Salto, Uruguay, [2]Ministry of Public Health, Department of Public Health Laboratories, Virology Unit, Montevideo, Uruguay, [3]Ministry of Public Health, Department of Public Health Laboratories, Genomics Unit, Montevideo, Uruguay, [4]National Institute of Respiratory Diseases, Center for Research in Infectious Diseases, Mexico D.F., Mexico, [5]Universidad de la República - CENUR, Department of Biological Sciences, Molecular Virology Laboratory, Salto, Uruguay, [6]Universidad de la República, Faculty of Medicine, Montevideo, Uruguay, [7]Fiocruz, Oswaldo Cruz Institute, Arbovirus and Hemorrhagic Virus Laboratory, Rio de Janeiro, Brazil, [8]Universidad de la República - CENUR, Department of Biological Sciences, Human Molecular Genetics Laboratory, Salto, Uruguay

Background: In 2023, Latin America experienced a 9% increase in new HIV infections compared to 2010, with Uruguay reporting one of the highest regional incidence rates (0.51/1,000 adults). Around 16,000 individuals are living with HIV in Uruguay, with the epidemic concentrated in key populations. Although HIV-1 subtype B and B/F1 recombinants are recognized as prevalent, assessments of HIV diversity remain limited.

This study is the first nationwide longitudinal molecular analysis of HIV-1 in Uruguay, providing valuable insights into local and regional HIV trends.

Methods: Over 1,600 partial HIV-1 *pol* sequences and patient metadata from routine genotyping services (2007–2021) were analyzed. Subtyping was performed using online tools and phylogenetic methods. Statistical analyses assessed associations between demographic data and viral variants. A subset of samples was selected for full-length genome sequencing using the Illumina Miniseq platform.

Mosaic genomes were characterized through Bootscan analysis and further examined by phylogenetic inferences. Time-scale reconstruction was performed using BEAST.

Results: Our analysis identified HIV-1 variants B, C, A1, F1, and several recombinants (e.g., 12_BF1, 17_BF1, 28_BF1, 29_BF1, 31_BC, 38_BF1) in Uruguay, along with a clade of 107 B/F1-*like* strains, BF1.UY, unrelated to known variants. Subtype B was most prevalent (39.2%), followed by 12_BF1 (27.7%), 38_BF1 (12.8%), BF1.UY (8.3%), 28/29_BF1 (3.5%), and C (3.1%). Other variants comprised 5.4%. A decline in subtype B and an increase in B/F1 recombinants were observed over time.

Four full-length BF1.UY genomes revealed a consistent recombination pattern, identifying a novel circulating recombinant form, CRF179_12B, that probably emerged in Uruguay at the beginning of the 1990s.

Conclusions: This study provides important insights into the HIV epidemic in Uruguay, highlighting the cost-effective potential of resistance genotyping databases to track HIV dynamics. The prevalence of subtypes B, C, and 12_BF reflects shared transmission patterns with neighboring countries, given CRF12_BF's significance in Argentina and subtype C's in southern Brazil, both bordering Uruguay.
The decline of subtype B and the rise of B/F1 recombinants underscore changing local transmission dynamics. The identification of CRF179_12B suggests that recurrent recombination between prevalent B/F1 variants and circulating subtype B strains is likely playing a role in shaping the regional epidemic.

WEPEC044

Burden of non-communicable diseases among people living with HIV: a national cross-sectional analysis in Rwanda

A. Tuyishime[1], G. Gatete[1], F. Uwinkindi[1], G. Rwibasira[1]
[1]Rwanda Biomedical Centre, HIV/AIDS Disease Prevention and Control, Kigali, Rwanda

Background: With improved access to antiretroviral therapy (ART), life expectancy among people living with HIV (PLHIV) has increased, highlighting the growing burden of non-communicable diseases (NCDs) in this specific population. Understanding the prevalence, risk factors, and patterns of NCDs among PLHIV is critical to inform integrated and people-centered healthcare strategies.
Methods: A national cross-sectional study was conducted among PLHIV aged 15 years and above, targeting a sample size of 8,400 individuals. Data collection occurred from January to July 2024 across all provinces and the City of Kigali in Rwanda. Data were collected through standardized health assessments, including medical history, laboratory tests, and questionnaires on lifestyle and socioeconomic factors. NCDs assessed included hypertension, diabetes, asthma , and cervical cancer lesions. Data were analysed using STATA 17, with frequencies and proportions calculated for key variables. Logistic regression analysis was used to evaluate associations between demographic, behavioral, and clinical factors and NCD prevalence. Adjusted odds ratios, and corresponding 95% confidence intervals (CI) were reported.
Results: A total of 7,449 PLHIV participated in the study, 75.3% were female, and 56.6% were aged between 25 and 49 years. The overall prevalence of NCDs was 29%, with the most common condition being hypertension (24.2%), diabetes (1.1%), Asthma (1.1%) and cervical cancer lesions (17.2%).
Prevalence was significantly higher among individuals aged 50 years and above (38.8, p=<0.001), females (29.6, p =0.048), and those with a history of ART use for 20 years or more(30.8%, p < 0.001).
In the multivariable logistic regression analysis, having at least one NCD was independently associated with being aged 35-49 years (aOR:1.8, 95%CI:1.5-2.3), 50 years and above (aOR:3.7, 95%CI:3.0-4.6), and females (aOR:1.2, 95%CI:1.0-1.3). Additional factors included alcohol consumption (aOR:1.2, 95% CI: 1.1-1.4), overweight (aOR:1.4, 95%CI:1.2-1.7), obesity (aOR:1.7, 95%CI:1.3-2.2) and eating vegetables at least once a week was associated with a reduced likelihood of having an NCD (aOR: 0.8, 95%CI:0.7-0.9).
Conclusions: This study highlights a substantial burden of NCDs among PLHIV in Rwanda, particularly among elders, and those with prolonged ART use. Findings underscore the need for integrated HIV-NCD care models and targeted interventions to address modifiable risk factors and improve health outcomes.

Monitoring and population-level interventions for non-HIV outcomes

WEPEC045

Real-world liver outcomes in people with HIV and hepatitis B virus receiving antiretroviral therapy

C.-Y. Chuo[1], W. Zachry[1], M. de Boer[1], L. Telep[1], L. Tao[1]
[1]Gilead Sciences, Inc., Foster City, United States

Background: Simultaneous presence of HIV/hepatitis B virus (HBV) significantly elevates the risk of liver-related complications compared to HIV or HBV alone. While antiretroviral therapy (ART) is known to slow liver disease progression, the long-term effects of different ART regimens on advanced liver disease in people with HIV/HBV in real-world settings remain unclear.
Methods: People with HIV/HBV who initiated ART between January 2016 and December 2023 were included from HealthVerity, a de-identified US medical and pharmacy claims database.
Advanced liver disease events, including cirrhosis, liver decompensation, and hepatocellular carcinoma (HCC), were evaluated among people treated with tenofovir alafenamide (TAF)–based, tenofovir disoproxil fumarate (TDF)–based, or non–tenofovir-based ART regimens; people with advanced liver disease events prior to ART initiation were excluded. Kaplan-Meier methods were used to illustrate time to advanced liver disease events across treatment groups.
Cox proportional hazards models were used to calculate adjusted hazard ratios and corresponding 95% CIs for advanced liver disease events.
Results: Among 3095 people with HIV/HBV who were included (median age: 48 years, IQR: 38-57, 26% female), 76% received TAF-based, 13% received TDF-based, and 11% received non–tenofovir-based ART regimens. Those treated with TAF- or TDF-based ART regimens had significantly longer time to an advanced liver disease event compared to those on non–tenofovir-based ART regimens (log-rank *P*<0.01).
After adjustment, both tenofovir-based ART regimens retained significantly reduced risk of all advanced liver disease events versus non–tenofovir-based ART regimens *(Table)*. TAF-based ART was also associated with a risk reduction of developing cirrhosis and HCC versus non–tenofovir-based ART.

Table. HRs and corresponding 95% CIs for advanced liver disease events comparing people with HIV/HBV who received TAF-based, TDF-based, and non–tenofovir-based ART regimens.*

Advanced liver disease event	Regimen group	N (event/persons)	Crude HR (95% CI)	Adjusted HR (95% CI)†
All	Non–tenofovir-based	41/311	Reference	Reference
	TAF-based	155/2078	**0.61 (0.43-0.86)**	**0.55 (0.38-0.79)**
	TDF-based	30/368	**0.56 (0.35-0.90)**	**0.45 (0.27-0.75)**
Cirrhosis	Non–tenofovir-based	25/332	Reference	Reference
	TAF-based	77/2184	**0.50 (0.32-0.78)**	**0.42 (0.26-0.68)**
	TDF-based	24/379	0.74 (0.42-1.30)	0.66 (0.36-1.21)
Liver decompensation	Non–tenofovir-based	32/334	Reference	Reference
	TAF-based	129/2186	0.69 (0.47-1.01)	**0.63 (0.42-0.95)**
	TDF-based	23/386	**0.58 (0.34-0.98)**	**0.46 (0.26-0.82)**
HCC	Non–tenofovir-based	7/346	Reference	Reference
	TAF-based	17/2324	**0.40 (0.17-0.98)**	**0.28 (0.11-0.77)**
	TDF-based	7/402	0.75 (0.26-2.15)	0.41 (0.12-1.35)

ART, antiretroviral therapy; HBV, hepatitis B virus; HCC, hepatocellular carcinoma; HR, hazard ratio; TAF, tenofovir alafenamide; TDF, tenofovir disoproxil fumarate.
*Bolding denotes a statistically significant difference compared to the reference.
†HRs were adjusted for age, sex, baseline liver function, and comorbidities.

Conclusions: These results are consistent with an association between TAF-based ART regimens and a risk reduction of severe liver-related complications overall and, specifically, progression to cirrhosis and HCC, in people with HIV/HBV. Findings highlight the importance of optimizing ART regimens to include tenofovir to improve outcomes for people with HIV/HBV.

Methodology to support epidemiological studies

WEPEC046

Implementation of the Recent HIV Infection Program in Zambia, 2020 to 2024: lessons learnt

L. Phiri[1], M. Mubanga[1], C. Nkwemu[1], D. Siakavuba[1], M. Nsofu[1], R. Chiinda[1], M. Herce[1,2], M. Lumpa[1], S. Nyimbili[1], J.M. Pry[1,3], J. Mzyece[4], K. Kamalonga[5], D. Nsofwa[5], K. Nkwemu[5], M. Arons[6], K. Lee[6], S. Sivile[4], B. Tambatamba[4], L. Mulenga[4], T. Savory[1], S. Fwoloshi[4]
[1]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [2]Institute of Global Health and Infectious Diseases, University of North Carolina, Chapel Hill, United States, [3]School of Medicine, University of California, Davis, United States, [4]Ministry of Health, Lusaka, Zambia, [5]Division of Global HIV and TB, Global Health Center, U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, [6]Division of Global HIV and TB, Global Health Center, U.S. Centers for Disease Control and Prevention, Atlanta, United States

Background: In 2020, Zambia launched the recent HIV infection surveillance (recency) program that made use of a recent infection testing algorithm (RITA) and epidemiological data to identify areas of potential increased transmission for a targeted HIV prevention response. Here we describe the implementation of the recency program.
Description: The Ministry of Health (MOH) in collaborations with stakeholders, including the U.S. Centers for Disease Control and Prevention (CDC) and the Centre for Infectious Disease Research in Zambia (CIDRZ), developed the surveillance protocol and standard operating procedures. Program site selection was based on HIV prevalence and testing positivity reported from October—December 2019 in the national surveillance system. Site activation included stakeholder engagement and facility-based assessments. Staff training for laboratory testers and clinical teams was conducted, supplemented by technical support and mentorship. For RITA, testing was performed on persons ≥ 15 years and testing newly positive for HIV-1.
A recent result on the Asante HIV-1 rapid recency assay and baseline viral load ≥1000 copies/ml was classified as recent infection, while RTRI recent and BVL <1000 copies/ml or RTRI long term results were classified as long-term infection.
Lessons learned: By September 2024, 726 recency activated health facilities in 27 districts, supported by 98 laboratories with 856 certified laboratory testers and 1,000 healthcare workers were orientated across all levels.
Cumulatively, 160,808 rapid recency tests for 294,544 (55%) eligible HIV positive tests were done which yielded 4.3% (9473/160,808) RITA-recent results.
Using geospatial mapping and triangulated program data, we identified geographic locations of potential increased HIV transmission. Five precision public health responses were launched, and stakeholders were able to deploy focused interventions in these areas for purposes of halting potential transmission.
We learned the importance of early stakeholder engagement, having set criteria for site selection, leveraging existing surveillance tools, incorporating virtual platforms for meetings and trainings, conducting frequent supervision and regular data quality assessments, as crucial for program continuity.
Conclusions/Next steps: Program success was supported by MOH buy-in, effective communication between facilities, district and provincial health offices, and strong laboratory services. Further, defined roles and responsibilities for all implementing partners, and community partner participation were key components of the program.

Surveillance: Measuring the HIV pandemic

WEPEC047

Survival analysis of time to viral load suppression and its associated factors in a cohort of people living with HIV on antiretroviral treatment from 2019 to 2023 in Rwanda

G. Gatete[1], S. Karera[2], C. Kwizera[1], V. Mupenzi Umubyeyi[1], G. N.Rwibasira[1]
[1]Rwanda Biomedical Centre, National HIV program, Kigali, Rwanda, [2]ICAP at Columbia University, Mailman School of Public Health, Kigali, Rwanda

Background: A key goal of antiretroviral therapy (ART) is to achieve and sustain long-term viral suppression. Therefore, monitoring viral load is crucial for assessing the effectiveness of treatment following ART initiation. Understanding the time to viral load suppression and its

determinants is essential for optimizing care and improving outcomes. This study analysed the time to viral load suppression and associated factors among people living with HIV (PLHIV) on ART in Rwanda from 2019 to 2023.

Methods: A retrospective cohort study was conducted using routine data from the national HIV program extracted from a case-based surveillance system in Rwanda. PLHIV aged 18 years and above who initiated ART between January 2019 and December 2023 in all health facilities nationwide were included. Survival analysis techniques, including Kaplan-Meier survival curves and Cox proportional hazards regression, were used to estimate the time to viral load suppression and identify associated factors. The covariates analysed included demographic characteristics and baseline clinical parameters.

Results: A total of 17,103 participants were included in the study, with a median follow-up duration of 11 months. Of these, 65% were female, and the median age was 33 years (IQR: 27-41). The median time to viral load suppression was 7 months. Kaplan-Meier estimates revealed that being unemployed (HR: 0.94, CI: 0.91-0.98) or male (HR: 0.92, CI: 0.90-0.96) was associated with a longer time to viral load suppression. Conversely, older age: 50 years and above (HR: 1.10, CI: 1.02-1.19) was associated with shorter time to suppression. Multivariate Cox regression identified significant predictors of time to viral load suppression including unemployment, age, and sex.

Conclusions: Demographic and socioeconomic factors such as employment status, age, and sex, influence time to viral load suppression. Targeted interventions that address these disparities are critical for optimizing ART effectiveness and achieving sustained viral suppression among PLHIV in Rwanda.

WEPEC048

Success in Cameroon: a summary of changes in HIV program indicators following PEPFAR expansion, October 2019 – September 2024

K.A. Bosh[1], Y. Moussa Fadil[1], C. Keleko[1], A. Zeh-Meka[2], G. Djomand[3], S. Ghosh[3], F. Nembot Djouma[1], S. Lecher[3], S. Lloyd[3], K. Sleeman[3], C.B. Ndongmo[1,4], T.K. Nkwoh[1], C.J. Owens[3], D. Patel[3], J. Shang[1], E. Takem[1], R. Ajeh[5], M.F. Jalloh[1], J. Fokam[2,6]

[1]Division of Global HIV and TB, U.S. Centers for Disease Control and Prevention, Yaounde, Cameroon, [2]National AIDS Control Committee, Cameroon Ministry of Public Health, Yaounde, Cameroon, [3]Division of Global HIV and TB, U.S. Centers for Disease Control and Prevention, Atlanta, United States, [4]Division of Global HIV and TB, U.S. Centers for Disease Control and Prevention, Abidjan, Côte d'Ivoire, [5]Coordination Unit for HIV, TB, and Malaria, Cameroon Ministry of Public Health, Yaounde, Cameroon, [6]Faculty of Health Sciences, University of Buea, Buea, Cameroon

Background: Although the Government of the Republic of Cameroon (GRC) provided HIV services across Cameroon prior to 2019, U.S. President's Emergency Plan for AIDS Relief (PEPFAR) support in Cameroon rapidly expanded starting in 2019. PEPFAR support increased from four regions to all 10 regions to scale up a package of HIV prevention, care, and treatment services at high-volume clinical sites.

We evaluated changes in key HIV program indicators (HIV testing, antiretroviral therapy [ART] and viral load [VL]) in PEPFAR-supported sites following the nationwide expansion.

Methods: A descriptive analysis was conducted among people living with HIV (PLHIV) in PEPFAR-supported sites in the 10 regions of Cameroon between October 2019 (start of fiscal year [FY] 2020) through September 2024 (end of FY2024). Using PEPFAR Monitoring, Evaluation, and Reporting data for Cameroon, changes were assessed in the number of people who tested and received results for HIV, the number of HIV diagnoses, the number of PLHIV receiving ART, VL coverage, and viral suppression (<1000 copies/mL).

Results: Among PEPFAR-supported clients across all 10 regions of Cameroon, HIV testing and diagnoses peaked in FY2021 (1,559,792 tested; 62,345 diagnosed) and were lowest in FY2024 (894,528 tested; 28,024 diagnosed). HIV positivity decreased each year from 4.7% (56,011/1,197,563) in FY2020 to 3.1% (28,024/894,528) in FY2024. The number of people receiving ART increased each year from 311,524 in FY2020 to 415,062 in FY2024, representing about 90% of the entire ART-experienced clients at country level (454,578 by mid-2024). VL coverage increased but remained suboptimal, ranging between 59.1% and 67.7%. Viral suppression increased from FY2020 (87.6%) to FY2024 (94.9%).

Conclusions: In collaboration with GRC, there was great success in the national AIDS response in Cameroon following PEPFAR's expansion. The programmatic indicators were characterized by declining HIV positivity even with declining HIV testing (which aligns with reductions observed in national HIV incidence estimates), and increases in ART coverage and viral suppression, which underscore progress towards achieving epidemic control in Cameroon. Additional efforts to improve VL coverage could confirm ongoing treatment success and support efforts to eliminate HIV by 2030.

WEPEC049

Contribution of HIV recent infection cluster investigation strategy in Closing Gaps of HIV testing: lessons learned and public health interventions in Rwanda

B. Kwizera[1], E. Mpabuka[1], C. Kamanzi[1], S. Karera[1], V. Mugisha[1], G. Rwibasira[2], B. Ikuzo[2]

[1]ICAP at Columbia University, Mailman School of Public Health, Kigali, Rwanda, [2]Rwanda Biomedical Center, Kigali, Rwanda

Background: HIV recency testing is a methodology that differentiates between recent and long-term infections, offering valuable insights into transmission patterns and epidemic trends. Following the findings of the Rwanda Population-based HIV Impact Assessment (RPHIA), this approach was implemented in Rwanda in 2020 to address the 16% gap in HIV status awareness among adults. To better use recency testing data, ICAP supported Rwan-

da Biomedical Center (RBC) to introduce and implement both above and on-site HIV recent infection cluster investigation strategy. This abstract presents how the above-site cluster investigation strategy utilized recency testing data to trigger real-time public health response.

Description: The HIV recent infection cluster investigation strategy was implemented nationwide since 2020, leveraging on the case-based surveillance (CBS) data and Recency data to monitor sites with high numbers of recent HIV infections and low viral load suppression rates. According to Rwanda's cluster definition, a potential transmission hotspot is defined as a site with ≥2 RITA recent cases per facility per month. Identified hotspots triggered public health response activities, including rapid ART initiation, viral load suppression monitoring, index case testing, PrEP initiation, HIV self-testing, and social network testing to enhance program outcomes.

Lessons learned: Cluster investigation data from January 2020 to July 2024 identified 90 potential HIV transmission hotspots based on Rwanda's cluster definition. Among 215 index cases identified, 97%(205) initiated antiretroviral therapy (ART) on the same day. Partner notification services were offered and accepted by 93.7% (194/207) of eligible cases, yielding an index-to-contact elicitation ratio of 1:2.3. Of the 454 partners elicited, HIV testing coverage was 69.1% (282/408 eligible), resulting in a positive yield of 17.7% (50 HIV+), of which 24% (12) were RITA recent. However, only 5 of 28 eligible contacts initiated PrEP, highlighting the need to improve PrEP uptake.

Conclusions/Next steps: The implementation of The HIV recent infection cluster investigation strategy facilitated the identification of transmission hotspots and improved linkage to care through same-day ART initiation and robust partner notification.

The combination of HIV recency testing with other public health interventions like CBS has the potential to enhance partner engagement, improve access to PrEP and scale up targeted testing strategies.

WEPEC050

Eswatini prevention of mother-to-child transmission survey (E-PIMS)

N. Mthunzi[1], W. Mngometulu[2], C. Pierotti[3], N. Isidoro[4], N. Madlopha[2], C. Chouraya[5]

[1]Ministry of Health, Monitoring and Evaluation, Mbabane, Eswatini, [2]Ministry of Health, Sexual and Reproductive Health, Mbabane, Eswatini, [3]UNICEF, Chief Child Survival & Development, Mbabane, Eswatini, [4]UNICEF, Monitoring and Evaluation, Mbabane, Eswatini, [5]EGPAF, PMTCT, Mbabane, Eswatini

Background: Eswatini established ambitious targets for reducing Mother-to-Child Transmission rates of HIV to below 5% by 2030, aligning with the global commitment to the triple elimination of HIV, syphilis, and hepatitis B. Despite the program's nearly two-decade-long implementation, comprehensive data on its impact was limited.

The objective of the study was to determine the final mother-to-child transmission rates of HIV among children and associated factors in Eswatini.

Methods: The study was a prospective cohort design in which mother-baby pairs were enrolled at 6-8 weeks and followed up for a maximum of 24 months. The study was conducted in 51 health facilities, including private facilities, in Eswatini. Mother-baby pairs were followed up as part of the routine program as per the Eswatini PMTCT guidelines.

The mother-baby pairs were exited from follow-ups two months after cessation of breastfeeding. There were 4,611 mother-baby pairs, 1,761 HIV-positive and 2,474 HIV-negative.

The outcome of this study is the MTCT HIV transmission outcome at 24 months post-delivery.

Results: The MTCT rate was 1.34%. Half of the new child HIV transmissions emanated from either mothers who enquired HIV during breastfeeding or from mothers who did not receive ART during breastfeeding. Sources of transmission stacked bar

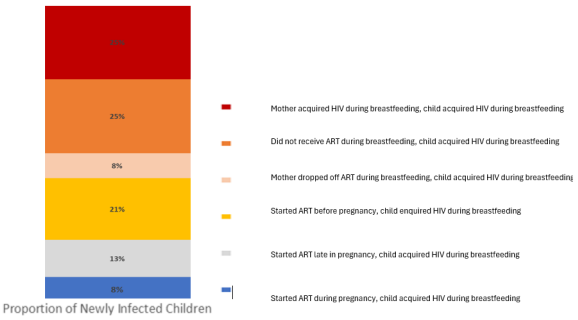

Figure.

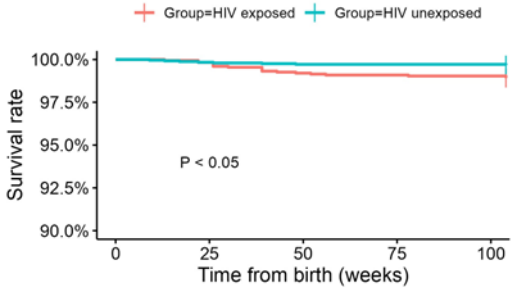

Figure. Survival rate.

Conclusions: This reduction underscores the effectiveness of the PMTCT program initiated in 2003. While substantial progress has been made, the program needs to strengthen strategies on PMTCT during breastfeeding and identify other potential socio-demographic, behavioral, and clinical risk factors that may influence MTCT risk and develop and implement targeted interventions specifically for high-risk populations.

Modelling the HIV pandemic

WEPEC051

Cost-effectiveness and impact of depression treatment implementation on HIV outcomes in western Kenya: a mathematical modeling study

D. Citron[1], H.-Y. Kim[1], R. Kasujja[2,3], S. Mwalili[4,5], D. Gathungu[4,5], C. Chambwe[6], I. Platais[1], F. Assefa[1], M. Jeetoo[1], R.S. Braithwaite[1], A. Bershteyn[1]
[1]NYU Grossman School of Medicine, Department of Population Health, New York City, United States, [2]Makerere University, School of Psychology, Kampala, Uganda, [3]Strongminds Uganda, Kampala, Uganda, [4]Strathmore University, Institute of Mathematical Sciences, Nairobi, Kenya, [5]Jomo Kenyatta University of Agriculture and Technology, School of Mathematical Sciences, Nairobi, Kenya, [6]Center for Infectious Disease Research in Zambia, Lusaka, Zambia

Background: In southern and eastern Africa, HIV is a leading cause of mortality, while depression is a leading contributor to morbidity. Depression increases HIV acquisition and impedes effective treatment, yet access to depression care remains limited.
We estimated the cost-effectiveness of psychotherapy for depression, and its impact on HIV outcomes, in western Kenya.
Methods: We adapted a previously validated HIV transmission model for Nyanza, western Kenya (EMOD-HIV), to include age- and sex-specific rates of depression incidence and prevalence. The model incorporated depression's effects on HIV: increased HIV incidence, reduced linkage to diagnostic tests, lower viral suppression outcomes, and higher ART dropout rates.
We assessed four depression screening and treatment strategies for adults (15+): community-wide screening; screening during HIV testing; people undergoing HIV screening; people living with HIV (PLHIV) receiving ART; and PLHIV receiving ART with unsuppressed viral load.
We assumed 100% specificity and sensitivity for screening and 65% treatment efficacy in reducing depression symptoms, and a US$14 cost of depression treatment.
We calculated incremental cost-effectiveness ratios (ICERs) as the cost of depression screening and treatment per disability-adjusted life-year (DALY) averted.
Results: Without depression treatment, we projected 136,000 new HIV acquisitions, 101,000 HIV-related deaths, and 8.84M episodes of depression between 2025–2035 in Nyanza. The community depression treatment strategy had the highest impact, averting 6.7% (95% CI 6.5–7.0%) of new HIV acquisitions, 3.9% (95% CI 3.7–4.1%) of HIV deaths, and 16.5% of depression episodes (95% CI 16.4–16.6%).
Depression screening and treatment for unsuppressed individuals on ART was the most cost-effective strategy at US$140 per DALY averted and (95% CI $134-$146) and US$517 per HIV-related DALY averted (95% CI $456–$592).
The next most cost-effective strategy was to expand to all PLHIV receiving ART (US$163 per DALY averted, 95% CI $159–$167), followed by community depression screening and treatment (US$185 per DALY averted, 95% CI $184–186). Screening during HIV testing was less cost-effective than the other strategies.
Conclusions: Integrating depression interventions into HIV care could substantially reduce HIV burden in southern and eastern Africa. Optimal expansion would initially focus on unsuppressed PLHIV and then expand screening/treatment to PLHIV on ART.

HIV prevention research

WEPEC052

Exploring adolescent girls and young women's perceptions of pre-exposure prophylaxis use: a qualitative synthesis of evidence from sub-Saharan Africa

M.T. Mwakilasa[1,2], D. Sabas[3], D. Kakoko[4], B. Gilmore[1], J. Gilmore[1]
[1]University College Dublin, School of Nursing, Midwifery and Health Systems, Dublin, Ireland, [2]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, the United Republic of, [3]Muhimbili University of Health and Allied Sciences, Directorate of Library Services, Dar es Salaam, Tanzania, the United Republic of, [4]Muhimbili University of Health and Allied Sciences, School of Public Health and Social Sciences, Dar es Salaam, Tanzania, the United Republic of

Background: Adolescent girls' and young women's perceptions of pre-exposure prophylaxis (PrEP), a biomedical HIV prevention method, significantly influence their decisions to initiate and continue its use, as well as their behavioural patterns while on PrEP. Their views shape how they intergrate PrEP into their daily lives and assess it value in managing their health and personal relatioship.
This systematic review study synthesises research on how AGYW perceive PrEP use in relation to their lives and sexual behaviour.
Methods: Electronic databases, including Embase, Medline, CINAHL, CABI, and PROQUEST, were searched for studies (May 2024-July 2024) that reported on actual, hypothetical perceptions of PrEP use among AGYW that are relevant to our review question. The PRISMA guidelines were used to direct the search, data collection, and report finding. Thematic synthesis was employed to synthesise data. The methodological quality of studies was evaluated using the Critical Appraisal Skills Program (CASP).This review used ENTREQ to guide the design and reporting of qualitative synthesis.
Results: Of the retrieved 3104 studies, 24 that met the inclusion criteria were carried out in 7 countries located in the SSA, which are South Africa, Uganda, Kenya, Malawi, Namibia, Zimbabwe, and Eswatini. Three paradoxical themes related to AGYW perceptions of PrEP use were found; these are protection and confidence, empowerment and agency, and risk compensation and behavioural concerns.

PrEP was perceived to empower AGYW by offering autonomy and confidence in sexual health, particularly when condom negotiation was unfeasible.
However, it often led to reduced condom use, increasing vulnerability to other risks like STIs and unintended pregnancies. Empowerment and agency about future health were undermined by stigma, secrecy, and relational challenges, with many fearing judgements for using PrEP.
Additionally, risk compensation behaviours, including condomless sex and multiple partnerships, further complicate the effective use of PrEP.
Conclusions: The findings from the systematic review highlight the complex and paradoxical perceptions of PrEP among AGYW, emphasising the need for comprehensive sexual health education and risk reduction counselling. These interventions are crucial to balancing and maximizing PrEP's benefits while mitigating potential risks.

WEPEC053

HIV incidence and use of pre-exposure prophylaxis among a large, national cohort of people with bipolar disorder

S. Bunting[1], M. Hyman[2], A. Hazra[3]
[1]University of Chicago, Dept. of Psychiatry & Behavioral Science, Chicago, United States, [2]University of Chicago, Center for Health and the Social Sciences, Chicago, United States, [3]University of Chicago, Section of Infectious Disease, Dept. of Medicine, Chicago, United States

Background: Bipolar disorder (BD) is a severe, chronic, and disabling mental illness characterized by periods of mania/hypomania and depression. People with BD have increased odds of acquiring HIV due to the impulsivity, grandiosity, and hypersexuality that characterize manic episodes. This is further exacerbated by systemic barriers to care including discrimination, care fragmentation, poverty, and housing instability. Utilization of highly-effective pre-exposure prophylaxis (PrEP) for HIV prevention among people with BD has not been systematically characterized.
Methods: We utilized the Merative MarketScan® Claims Database from 2010-2022 to identify people with bipolar disorder and without medical claims for HIV or pharmaceutical claims for antiretroviral medications. Restrictions were applied to account for presumed HIV post-exposure prophylaxis and HepB treatment.
Patients were followed in the database for the duration of available data following the index date, which was the date of initial diagnosis. We determined whether identified patients had outpatient encounters with primary care providers (PCPs) and/or psychiatrists.
Results: The cohort included 333,867 people with BD (61.9% female). There were 435 new HIV diagnoses. HIV diagnosis was more frequent among males (aOR=5.36 [4.27-6.72], p<.001) and those with BD and comorbid stimulant use disorder (aOR=2.56 [1.85-3.53], p<.001). HIV diagnosis was more common among people with BD receiving care only from psychiatrists compared to those following with PCPs only (aOR=1.58 [1.10-2.27], p=.01). There were 1,337 people with BD (0.40%) prescribed PrEP of any duration and 909 (0.28%) prescribed at least 3-months of PrEP. PrEP prescription was less common among people with BD following only with a psychiatrist (aOR=0.73 [0.56-0.97], p=.03) compared to only PCPs. Among people with ≥4 encounters for STIs, 3.53% (n=246) were prescribed PrEP of any duration and 2.73% (n=190) at least 3-months.
Conclusions: PrEP use among commercially-insured people with BD was critically low with <1% prescribed PrEP. Even among those with multiple encounters for STIs, <4% were prescribed PrEP, despite this being an indication for prescription. Engagement of people with BD in the PrEP care continuum is essential for ending the HIV pandemic, and integration of PrEP prescription with psychiatric care may represent an efficient method for increasing PrEP use.

WEPEC054

Safety and immunogenicity of vaccination with a synthetic DNA encoding native-like trimer alone and boosted with Env trimer 4571 for prevention of HIV-1: results from HVTN 304

R.M. Gravett[1], M.V. Villaran[2,3], W.O. Hahn[2,3], Y. Huang[2,4], L. Schmitzberger[2], L. Polakowski[5], J. Hanke[2], E. Domin[6], D. Montefiori[6], W.-H. Lee[7], L. van der Maas[7], K.N. Randall, Jr.[7], G. Ozorowski[7], A.B. Ward[7], J. Heptinstall[8], K. Seaton[8], G. Tomaras[8], D. Weiner[9], D. Kulp[9], M. Purwar[9], L. Humeau[10], Z. Sagawa[11], S.C. De Rosa[2], HVTN 304 Study Team
[1]University of Alabama at Birmingham, Division of Infectious Diseases, Department of Medicine, Heersink School of Medicine, Birmingham, United States, [2]Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division, Seattle, United States, [3]University of Washington, Division of Allergy and Infectious Disease, Department of Medicine, Seattle, United States, [4]University of Washington, Department of Global Health, Seattle, United States, [5]National Institute of Allergy and Infectious Diseases, Division of AIDS, Bethesda, United States, [6]Duke University Medical Center, Department of Surgery, Durham, United States, [7]The Scripps Research Institute, Department of Integrative Structural and Computational Biology, La Jolla, United States, [8]Duke University School of Medicine, Duke Center for Human Systems Immunology, Durham, United States, [9]The Wistar Institute, The Vaccine and Immunotherapy Center, Philadelphia, United States, [10]Inovio Pharmaceuticals, Inc, Preclinical R&D, San Diego, United States, [11]Access to Advanced Health Institute, Seattle, United States

Background: Vaccination is critical to eliminate HIV transmission, and the HIV envelope (Env) is a key vaccine target. HVTN 304 examined the safety and immunogenicity of a synthetic DNA plasmid encoding a native-like Env trimer (NLT) with IL-12 ("INO6160"), either alone or in a prime-boost regimen with a recombinant protein HIV Env Trimer ("Trimer 4571") adjuvanted with 3M-052-AF + alum.
Methods: HVTN 304 is a two-arm, randomized, open-label phase 1 trial examining DNA only (T1, n=10) and DNA prime-boost with Trimer 4571 (T2, n=10) among adult par-

ticipants without HIV in the U.S. 2mg doses of DNA were administered intradermally with electroporation (EP) in both groups at months 0, 1, 3, and 6; 300mcg of protein in T2 were co-administered intramuscularly at months 3 and 6. Safety, reactogenicity, and immunogenicity were assessed with intracellular cytokine staining (ICS), binding antibody multiplex assays (BAMA), and electron microscopy polyclonal epitope mapping (EMPEM).

Results: 15 participants received injections per protocol. Three participants discontinued due to solicited adverse events (grade 3 erythema), and 1 participant discontinued due to EP device-related adverse event (AE).

No unsolicited AEs were deemed related to study product. ICS showed 100% response rates for Env-specific CD4+ T-cells expressing IFNγ or IL-2 in both groups.

Env-specific CD8+ T-cell responses were 75% in T1 vs. 50% in T2. BAMA response rates were 10% after second vaccination in the DNA-encoded trimer and Trimer 4571 groups, increasing to 62.5% in T1 and 100% in T2 after the fourth vaccination.

The fourth vaccination markedly increased titers in all T2 participants. ID80 autologous neutralizing antibodies (nAbs) to BG505/T332N were detected in one T1 participant (also detected at baseline). EMPEM showed nearly all antibodies were directed to the gp41 base and epitope-specific antibodies detected in one participant in each group after the fourth vaccination.

Conclusions: INO-6160 with EP alone or in a prime-boost regimen was safe. Although DNA did not produce autologous neutralizing antibodies, it induced cellular responses and vaccine-specific binding antibodies.

DNA offers an alternate platform to mRNA and should be considered as a priming vaccine for subsequent Env NLT boost vaccine trials with improved Env plasmid inserts.

WEPEC055

Mobile men: a key population requiring targeted HIV prevention efforts – insights from the Mobile Men trial in Uganda and South Africa

E. Ruzagira[1,2], E. Webb[2], R. Beukes[3], L. Lebina[4], S. Kusemererwa[1], N. Ngcobo[4], S. Ngcobo[3], T. Manyaapelo[4], M. Mbonye[1], S. Nabukenya[1], L.-G. Bekker[3], J. Seeley[2], M. Shahmanesh[4,5], J. Fox[6]

[1]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [2]London School of Hygiene & Tropical Medicine, London united, United Kingdom, [3]Desmond Tutu Health Foundation, Cape Town, South Africa, [4]Africa Health Research Institute, Durban, South Africa, [5]University College London, London, United Kingdom, [6]Kings College London, London, United Kingdom

Background: Men who travel for work face high HIV risk and challenges in engaging in prevention and care. We are conducting a long-acting injectable cabotegravir (LA-CAB) and oral tenofovir/emtricitabine (TDF/FTC) pre-exposure prophylaxis (PrEP) implementation trial among mobile men.

Here, we describe service implementation, mobility, HIV and sexual risk, and PrEP uptake in this population.

Methods: MOBILE MEN is a phase 3b, open-label, hybrid type 2 implementation and effectiveness trial comparing LA-CAB and TDF/FTC (daily and event driven) in men who travel for work. Rapid ethnographic assessments identified optimal recruitment sites and methods.

From August and November 2024, men were enrolled through mobile clinics in East London and KwaZulu-Natal, South Africa, which also provided diabetes and hypertension screening, and via referrals from fishing communities to a research clinic in Masaka, Uganda. At enrolment, HIV risk and mobility was assessed, and PrEP initiated on the same day.

Results: Of the 428 men screened, 28 were excluded: 18 (4.2%) were HIV positive (all engaged in care), and 11 were ineligible for other reasons. A total of 400 men (median age 32 years, IQR 25-39) were recruited over 75, 58 and 21 days across the three settings, respectively. Of these, 399 received same-day PrEP, while one participant in the LA-CAB arm declined the injection.

Participants reported high mobility: 235 (59%) had moved residence in the past 3 months, predominantly for work, with a median (IQR) of 4 (2-14) days spent outside their primary residential community in the past two months.

High-risk sexual behaviour was common, with 86% reporting condomless sex in the past two months, 67% reporting ≥2 sexual partners in the past month, and 55% and 11% reporting sex after alcohol and drug use, respectively. Sexually transmitted infections (STIs) were common, with 12% testing positive for either chlamydia or gonorrhoea, and 5% for syphilis.

Conclusions: The high recruitment rate, mobility, HIV prevalence with engagement in care, STI prevalence, and PrEP uptake demonstrate that mobile men at risk of HIV acquisition can be effectively reached and engaged in HIV services. The MOBILE MEN trial will further investigate retention in care in this population.

WEPEC056

Safety and pharmacokinetic profile of a combination of two HIV broadly neutralizing antibodies, 3BNC117-LS-J and 10-1074-LS-J, in healthy American and African adults

J. Nyombayire Mutagisha[1], M. Caskey[2], E. Karita[1], W. Jaoko[3], N. Mugo[4], B. Okech[5], A. Mujugira[6], S. Delany Moretlwe[7], L. Baden[8], R. Ingabire[1], M. Nussenzweig[2], J. Mpendo[5], G. Mutua[9], V. Philiponis[10], D. Laufer[10], P.E. Fast[10], J. Maenza[11], A. DeCamp[11], B. Mayer[11], G. Tomaras[12], K. Seaton[12]

[1]Center for Family Health Research, Kigali, Rwanda, [2]The Rockefeller University, New York, United States, [3]Kenya AIDS Vaccine Initiative – Institute of Clinical Research, Nairobi, Kenya, [4]Partners in Health Research and Development, Thika, Kenya, [5]Uganda Virus Research Institute, Entebbe, Uganda, [6]Infectious Diseases Institute, Jinja, Uganda, [7]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [8]Brigham and Women's Hospital, Boston, United States, [9]International AIDS Vaccine Initiative, Nairobi, Kenya, [10]International AIDS Vaccine Initiative, New York, United States, [11]Fred Hutchinson Cancer Research Center, Seattle, United States, [12]Duke University, North Carolina, United States

Background: HIV prevention requires additional strategies to complement existing tools. We assessed the safety and pharmacokinetic profile of two HIV broadly neutralizing monoclonal antibodies (bNAbs).

Methods: A phase 1/2 double blinded placebo-controlled trial was conducted to assess safety and pharmacokinetics of 3BNC117-LS-J and 10-1074-LS-J, two HIV bNAbs targeting the CD4 binding site and the V3 loop region, respectively. HIV-uninfected adults aged between 18 and 45 years were randomized at 9 sites in the US and Africa to receive the two BnAbs either alone or in combination, intravenously or subcutaneously in the arm or abdominal area, in a single or multiple injections of different dose levels at baseline, week 12 and week 24.

Safety data included solicited and unsolicited AEs. Main PK profile assessed included longitudinal serum concentrations measured by Elisa and antibodies regimen administered subcutaneously that maintain a serum trough level of >10ug/ml in 80% of the population.

Results: From February 2020 through August 2023, three hundred forty-five individuals were screened and 184 participants (78 males, 106 females) were enrolled. Solicited adverse events were reported in 140 participants (76%) and were mostly mild to moderate in severity.

Two participants reported grade 3 administration site pain and 7 other participants reported grade 3 systemic events that resolved within 7 days of bNAbs administration. Two IP related unsolicited AEs of grade 3 were reported, including headache and dizziness both occurring in the subcutaneous injection group.

No related SAEs or potential immune mediated diseases were reported. Bioavailability of the 2 bNAbs was higher in the African study populations (10-1074-LS-J: 72% and 3BNC117-LS-J: 70%) compared to the US populations (10-1074-LS-J: 46% and 3BNC117-LS-J: 41%). 10-1074-LS-J showed a longer elimination half-life (Africa: 73.0 days; US: 85.5 days) than 3BNC117-LS-J (Africa: 61.5 days; US: 77.7 days) and was generally longer in US populations. Regimens maintaining a serum trough level of >10 ug/ml required a lower dose in African population.

Conclusions: Both 3BNC117-LS-J and 10-1074-LS-J have demonstrated an acceptable safety profile and there were no significant differences between administered dose levels, combinations and administration routes. Region of study participants (US vs Africa) was a major factor influencing the PK profile.

WEPEC057

Preferences for HIV PrEP choices and injectable PrEP delivery channels among pregnant and breastfeeding women in Malawi

R. Simika-Zimba[1,2], A. Bula[1,3], S. Schwartz[4], F. Kamanga[1], L. Msumba[1], R. Chilongosi[5], K. Murombedzi[6], D. Hoege[7], S. Allinder[7], B. Afirima[8], R. Nyirenda[9], Y. Kamgwira[8], J. Nkhonjera[9], W. Ozituosauka[9], T.R. Smith[10], R. West[11], L. Hill[12], S. Phiri[13], M.C. Hosseinipour[1,14], C.B. Holmes[7], F. Saidi[1,15]

[1]UNC Project-Malawi, Lilongwe, Malawi, [2]Kamuzu University of Health Sciences, Blantyre, Malawi, [3]University of North Carolina at Chapel Hill, School of Nursing, Chapel Hill, United States, [4]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [5]Family Health Services, Lilongwe, Malawi, [6]Population Services International, Lilongwe, Malawi, [7]Centre for Innovation in Global Health, Georgetown University, Washington, D.C., United States, [8]National AIDS Commission, Lilongwe, Malawi, [9]Ministry of Health, Department of HIV & AIDS, Lilongwe, Malawi, [10]Cooper/Smith, Valburn Cir, Austin, United States, [11]Ipsos, London, United Kingdom, [12]University of North Carolina at Chapel Hill, Gillings of Global Public Health, Chapel Hill, United States, [13]Partners in Health, Lilongwe, Malawi, [14]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States, [15]University of North Carolina at Chapel Hill, Department of Obstetrics and Gynecology, Chapel Hill, United States

Background: Pregnant and breastfeeding women (PBFW) in Sub-Saharan Africa are at increased risk of HIV acquisition and this is contributing to new pediatric cases. Pre-exposure prophylaxis (PrEP) has been established as an effective HIV prevention method, although delivery has been a challenge.

This study sought to inform future scale-up by examining preferences for PrEP choices and injectable PrEP delivery channels among pregnant and breastfeeding women (PBFW) in Lilongwe and Blantyre, Malawi.

Methods: This cross-sectional, sequential mixed-methods pre-implementation study included a qualitative phase with in-depth interviews of 11 PBFW followed by a quantitative survey. The survey, incorporating discrete choice experiments (DCE), assessed preferences for injectable PrEP among 100 PBFW (50 each from Lilongwe and Blantyre). Qualitative data were analyzed using content analysis with a deductively developed codebook based on Consolidated Framework for Implementation Research (CFIR) domains and constructs in NVivo 1.7. In the DCE, participants were presented with up to 16 factorially

designed choice scenarios, with responses entered as individual data rows. Preferences for PrEP attributes were determined using multinomial logit regression modeling.
Results: Results showed a strong preference for private clinics (47%) over government clinics (2%) as the location for receiving PrEP, with the remaining 51% reflecting diverse preferences across other levels of the location attributes or trade-offs involving attributes like waiting time. Waiting time was a significant factor, as participants strongly preferred waits under an hour. Injectable PrEP was strongly preferred, with administration in the buttock being significantly preferred compared to the stomach. Concerns about side effects and safety, especially during pregnancy, influenced preferences, with some women expressing apprehension about the impact of PrEP on the baby. Despite these concerns, many participants favored integrating PrEP with other health services like contraceptives, seeing it as a comprehensive approach to health. Misconceptions about and stigma related to PrEP use were also identified as barriers to its uptake.
Conclusions: This study highlights the need to tailor PrEP services to PBFW preferences, including offering injectable PrEP in preferred settings, integrating PrEP with maternal health services, and addressing stigma and misconceptions. These measures are critical for enhancing PrEP uptake and reducing HIV incidence among PBFW in Malawi.

WEPEC058

Drop in HIV transmissions among people seeking PEP after the implementation of PrEP at Switzerland's largest sexual health clinic

H. Komaromi[1,2], V. Braig[3], B. Hampel[1,2]
[1]Checkpoint Zurich, Zurich, Switzerland, [2]University of Zurich, Department Public & Global Health, Zurich, Switzerland, [3]City of Zurich, Stadtärztlicher Dienst, Zurich, Switzerland

Background: People who qualify for non-occupational HIV Post-Exposure Prophylaxis (nPEP) following potential sexual exposure show one of the highest risks of contracting HIV in future sexual risk situations. HIV Pre-Exposure Prophylaxis (PrEP) should therefore be offered to people who qualify for nPEP.
This study aimed to evaluate the proportion of people who started PrEP after a nPEP event, and the differences in HIV seroconversions among nPEP users pre and post PrEP implementation.
Methods: We conducted a single-center retrospective review of medical records for individuals consulting for nPEP at Checkpoint Zurich, Switzerland's largest sexual health clinic from January 2013 to June 2024. Data on consultation numbers and outcomes were analyzed before and after the nationwide introduction of the SwissPrEPared program in 2019, which greatly enhanced access to PrEP for individuals at higher risk of contracting HIV in Switzerland.
Results: A total of 1349 individuals consulted for nPEP after potential sexual exposures, accounting for 1669 events. Sixteen HIV seroconversions were recorded, 37% of individuals were transitioned to PrEP, and 302 people (22%) were lost to follow-up. Annual nPEP consultations rose from 75 in 2013 to a peak of 215 in 2019, plateauing thereafter, although the total number of consultations continuously increased from 2013 to 2024. Notably, 14 of 16 seroconversions were seen in people whose nPEP event occurred prior to 2019. Among individuals consulting for nPEP during 2013–2018, 79 of 479 (16%) were transitioned to PrEP, compared to 415 of 870 (48%) during 2019–2024.

Conclusions: The implementation of PrEP under the SwissPrEPared program starting in 2019 coincided with a decline in HIV seroconversions among nPEP users and an increase in the proportion of individuals transitioning to PrEP post-event. This data suggest that expanded PrEP access effectively complements nPEP, reducing HIV transmission risk and enhancing preventive strategies for at-risk populations.

WEPEC059

Assessment of Pre-exposure Prophylaxis (PrEP) retention among key populations in Northern Nigeria: a retrospective cohort analysis

E. Umechukwu[1], S.T. Adeyanju[1], B. Adebobola[2], M. Morka[3], T. Ileri[4], F. Agbo[4], O. Oyelaran[5], A. Kalaiwo[5], A. Idemudia[5], O. Fajemisin[6], J. Anyanti[7]
[1]Society for Family Health, Strategic Information Unit, Kano, Nigeria, [2]National AIDS and STDs Control Program (NASCP), Abuja, Nigeria, [3]National AIDS and STDs Control Program (NASCP), Strategic Information Unit, Abuja, Nigeria, [4]National Agency for the Control of AIDS, Abuja, Nigeria, [5]U.S. Agency for International Development (USAID), HIV and Tuberculosis Department, Abuja, Nigeria, [6]Society for Family Health, Strategic Information Unit, Abuja, Nigeria, [7]Society for Family Health, Technical-Growth Department, Abuja, Nigeria

Background: Pre-exposure prophylaxis (PrEP) is a critical intervention for HIV prevention, particularly among high-risk groups such as female sex workers (FSW), men who have sex with men (MSM), people who inject drugs (PWID), and incarcerated individuals. Despite efforts to scale up PrEP services, retention in PrEP programs remains challenging. This study examines PrEP enrollment and retention among KPs in two states in northern Nigeria.
Methods: This is retrospective cohort analysis of clients who initiated PrEP within the period 2022/2023, and outcome determined 2 years after in September 2024. Data were abstracted from the program database from the 2 study states. A client is classified as retained in PrEP if the client is still using PrEP consistently at the end of 2 years. Descriptive statistics with simple proportions were used to analyze categorical variables and binary logistic re-

gression models to analyze the association between various demographic, behavioral, and structural factors with retention.

Results: A total of 3,518 KPs records (FSW = 1,074, MSM = 812, PWID = 1,632) between 2022-2023 enrolled in PrEP were analyzed. By September 2024, only 414 participants (FSW = 71, MSM = 61, PWID = 282) remained yielding a retention rate of 11.8%. Retention was highest among PWID (17.3%, p = 0.019) compared to FSW (6.6%) and MSM (7.5%, p < 0.05). Older individuals (above 49 years) 18.5%; with employed individuals having highest retention, 15.2%: OR = 2.39, p = 0.002). PWID population (OR = 1.51, p = 0.019) and occupation have been identified as key predictors, while education level had no significant effect on retention. Barriers included stigma, access challenges, and socioeconomic instability, particularly among MSM. Conversely, community support and peer engagement were strong enablers of retention.

Conclusions: This study highlights the successful enrollment of large numbers of KPs in PrEP services. There is however very low retention among KPs in using PrEP. The findings point to the critical importance of devising innovative strategies to address individual and community-level barriers to sustain PrEP use, particularly among MSM. Similarly, the study has buttressed the impact of peer supports in ensuring retention on PrEP among KPs.

WEPEC060

Assisted partner notification as a strategy to enhance Pre-Exposure Prophylaxis (PrEP) screening and uptake – results from an urban STI clinic in Malawi

T. Munthali[1], S. Rutstein[2], M. Matoga[1], M. Hosseinipour[3], I. Hoffman[2], A. Masano[1], K. Chinthenga[1], M. Chagomerana[1], W. Kumwenda[1], E. Jere[1], E. Mathiya[1], N. Bonongwe[1], N. Nyirenda[1], B. Ndalama[1], C. Pedersen[2], J. Chen[2]

[1]University of North Carolina Project Malawi, Lilongwe, Malawi, [2]University of North Carolina, Chapel Hill, United States, [3]University of North Carolina, Lilongwe, Malawi

Background: Biomedical pre-exposure prophylaxis (PrEP) prevents HIV acquisition but requires strategies to improve uptake among high-risk groups. Assisted partner notification (aPN), proven for HIV case-finding, offers a novel way to expand PrEP services to sexual partners of STI individuals.

This study explored the feasibility and outcomes of integrating aPN into PrEP programs at a STI clinic in Malawi.

Methods: Between March 2022 and January 2023, this prospective cohort study enrolled men and women presenting for STI services who were initiating PrEP (index PrEP user) and their referred sexual partners at Bwaila STI clinic, in Lilongwe, Malawi. Using World Health Organization-recommended aPN methods, recent (within last 6 months) sexual partners named by index participants were traced via phone or in-person.

We assessed demographic characteristics of index participants and referred partners, tracing outcomes, and PrEP initiation among partners.

Results: 174 index PrEP user participants were enrolled, most were male (109/174; 63%) with median age of 27 years (IQR 22, 32). Of these, 69 named 101 sexual partners, mostly female partners (57%). These partners were primary partners (53%), casual partners (41%), or sex workers (6%). Tracing efforts targeted 52 partners, with phone tracing yielding better results (57% contact success) compared to physical tracing (10% contact success). 58 partners (including those not traced) presented at the clinic for screening. Most presenting partners were female (39/58; 67%) and the median age was 28 years (IQR 23, 31). Among the presenting partners, 34/58 were eligible for PrEP, and 31/34 (91%) initiated PrEP. 55/58 presenting partners agreed to HIV testing with 36% testing positive for HIV. Among those who tested positive, 20% were newly diagnosed during the PrEP screening process.

Conclusions: aPN effectively identifies and links at-risk partners of persons initiating PrEP to HIV prevention services, achieving high rates of PrEP uptake among eligible presenting partners. Notably, phone tracing was more effective than physical tracing. This study highlights the potential of aPN in expanding PrEP access and strengthening HIV prevention efforts among persons seeking STI services.

WEPEC061

Characterizing latent profiles of young long-acting injectable PrEP users in Cape Town, South Africa

E. Rousseau[1], R. Dawit[2], C. Pike[1], K. Lebelo[1], F. Bennin[1], P. Mapukata[1], P. Macdonald[1], O. Vanto[1], N. Chandiwana[1], L. Dean[2], L.-G. Bekker[1]

[1]University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States

Background: Effective HIV prevention requires products and services that meet specific needs of adolescent and young people (AYA) interested in pre-exposure prophylaxis (PrEP). This study explored how delivery methods and product preferences influence the choice between oral PrEP and long-acting injectable Cabotegravir (Cab-LA) among AYA.

Methods: The PrEPared to Choose (PtC) implementation study introduced, scaled-up and evaluated uptake of oral PrEP and Cab-LA from fixed-site and mobile clinics. Latent class analysis (LCA) classified participants based on PrEP demand generation methods, sexual behaviour, sex partner characteristics, prior PrEP use, and product preferences. Multinominal logistic regression analyzed factors associated with class memberships.

Multivariable logistic regression examined the association between latent classes and PrEP choice (injectable vs. oral).

Results: Between February and August 2024, 1152 participants (67% adolescent girls and young women) initiated PrEP, with 75% (n=863) choosing Cab-LA. Majority (70.2%) initiated PrEP at the mobile clinic. LCA identified three distinct participant groups.

Class 1, "curious risk-aware adopters" (19%) were PrEP naïve, uncertain about sex partner HIV status and support, reached through active outreach (social media or PrEP navigator) and prioritized product based on route of delivery.
Class 2 "exploratory lifestyle initiators" (62%) were PrEP-naïve, reached through passive outreach ("just saw the truck"), perceived sex partners as supportive of PrEP use, and prioritized lifestyle compatibility and convenience in PrEP choice.
Class 3 "cautious committed users" (18%) had prior PrEP experience, were uncertain about partner support, and prioritized product safety and efficacy.
Participants attending mobile compared to fixed-site clinics (aOR:2.62,95%CI:1.81–3.81) and "curious risk-aware adopters" compared to "cautious committed users" had higher odds of using Cab-LA (aOR:2.14,95%CI:1.27–3.62). AGYW had lower odds of choosing Cab-LA compared to male partners (aOR:0.59,95%CI:0.41–0.83).
The "exploratory lifestyle initiators" were equally likely to choose Cab-LA compared to the "cautious committed" users, however members of this class were less likely to be AGYW or have completed school.
Conclusions: PrEP delivery in community settings, such as mobile clinics, were highly effective in engaging AYA and facilitating Cab-LA initiation. However, AGYW were less likely to choose injectable PrEP, highlighting the need for targeted approaches to address barriers and ensure equitable access to PrEP.

WEPEC062

Evaluation of neutralization sensitivity of HIV-1 subtype C between lymph nodes, peripheral blood mononuclear cells and plasma derived viruses

K. Velan[1]
[1]*University of Kwa Zulu Natal, Durban, South Africa*

Background: There are genetic variations in the HIV-1 env single genome amplicons (SGA) derived from plasma, polymorphonuclear cells (PBMCs) and lymph node samples. However, the impact of these amino acid variations in the sensitivity of broadly neutralizing antibodies is not known.
Therefore, the aim of this study was to evaluate HIV-1 *env* sequence differences within bnAb epitopes and assess their neutralization sensitivity in HIV-1 subtype C between lymph nodes, PBMC and plasma-derived clones.
Methods: Full-length HIV-1 *env* was amplified from four HIV-1 subtype C infected ART naïve individuals selected from the FRESH cohort based in KwaZulu-Natal, South Africa. Single genome amplicons were produced from plasma, lymph nodes and PBMC samples, sequenced by Sanger sequencing and cloned into a TOPO 2.1 vector. Env-pseudotyped viruses were produced and the neutralization sensitivity was assessed against a panel of nine broadly neutralizing antibodies (bnAbs) targeting different epitopes. HIV-1 *env* sequences were analysed within bnAb epitopes and compared between lymph nodes, PBMC and plasma samples.
Results: A high frequency of discordant mutations was observed in the V2 and V3 loops, while few discordant amino acid mutations were observed in the conserved regions including the CD4 binding site, MPER and gp120-gp41 interface.
Discordant mutations were associated with the differences in neutralization sensitivity between viruses derived from plasma, lymph nodes and PBMCs. The highest number of resistant mutations were observed in the lymph node compartment.
Conclusions: Our findings suggest that amino acid variations in viral populations that are circulating in lymph nodes, PBMCs and plasma may lead to differences in neutralization sensitivity to broadly neutralizing antibodies. These findings may have implications in immunotherapy or vaccine development.

Integration of HIV services with other services, including sexual and reproductive health services

WEPEC063

Barriers to dual HIV and syphilis testing in low- and middle-income countries: lessons from ongoing program implementation in Zambia

N. Nyambe[1], P. Cheche[1], O. Chibebe[2], H. Lubemba[1], M. Qiu[3], C. Phiri[4], A. Konstantinova[5], M. Va de Reep[3], P. Lumano, Mulenga[4]
[1]*Evidence Action, Syphilis Free Start, Programs, Lusaka, Zambia,* [2]*Evidence Action, Syphilis Free Start, MLE, Lusaka, Zambia,* [3]*Evidence Action, Syphilis Free Start, Programs, Nairobi, Kenya,* [4]*Ministry of Health, HIV/PMTCT, Lusaka, Zambia,* [5]*Evidence Action, Syphilis Free Start, Programs, Washington, DC, United States*

Background: HIV and syphilis testing have been part of Zambia's antenatal care (ANC) services but were historically conducted separately, leading to disparities in testing and treatment rates, with syphilis lagging behind. To address these gaps, Zambia is transitioning to integrated dual testing for HIV and syphilis within ANC services. Evidence Action (EA), in collaboration with the Ministry of Health (MOH), is scaling up dual testing in over 3,000 facilities nationwide.
Since the program's launch in December 2021, it has reached 1,100 facilities, covering approximately 50% of ANC-attending women.
Description: The program employs a structured training cascade to ensure comprehensive capacity building. Master trainers, including clinical, laboratory, and Monitoring & Evaluation cadres, were trained centrally on dual testing processes, data entry, and supply chain management. The training then cascaded through provincial, district, and facility levels, equipping Health Care Workers (HCWs) and Community Health Workers (CHWs) with the skills to conduct tests, interpret results, and address service delivery gaps.

To sustain quality, Technical Supportive Supervision (TSS) is conducted monthly at underperforming facilities, providing mentorship to data clerks and ANC and laboratory staff.

Lessons learned:

- Data Discrepancies: Integrating syphilis data into well-established HIV systems revealed errors. Mentorship and validation during TSS have mitigated this.
- Testing Quality: Collaboration with the laboratory department and TSS improved quality.
- Staff Transfers: Frequent movements disrupted training continuity. Refresher sessions and targeted training addressed gaps.
- Transport Challenges: Difficult terrains during the rainy season limited access to facilities. Using local trainers and scheduling around seasonal challenges improved coverage.
- Disease Outbreaks: Cholera disrupted training schedules; adaptive planning ensured continuity.
- Supply Chain Gaps: Redistribution minimized stock-outs, and mentorship improved Electronic Logistics Management Information System (eLMIS) reporting accuracy.

Conclusions/Next steps: Zambia's experience demonstrates the complexities of integrating dual testing for HIV and Syphilis in ANC. Regular TSS visits, laboratory collaboration, and supply chain monitoring have improved service quality. Zambia's experience underscores the importance of robust support systems, reliable supply chains, and effective data management for LMICs scaling integrated health programs.

Population-specific interventions for HIV prevention

WEPEC064

Community-based delivery of pre-exposure prophylaxis to adolescent girls and young women in the DREAMS Program in Zambia: an observational cohort study

M. Musheke[1], J. Pry[2], W. Muyunda[1], K. Chiyenu[1], C. Mpundu Siame[1], W. Khondowe[1], B. Mushiki[1], M. Mwaba[1], P. Zulu[1], F. Mwape[1], I. Sikazwe[1], B. Siamasuku[3], D. Shula[3], M. Mweemba[4], D. Mwamba[5], C. Kanene[5], A. Phiri[5], M. E. Herce[6]

[1]Centre for Infectious Disease Research in Zambia, Implementation Science, Lusaka, Zambia, [2]University of California, Davis, USA, School of Medicine, California, United States, [3]Young Women Christian Association, Lusaka, Zambia, [4]Ministry of Health, Lusaka, Zambia, [5]United States Agency for International Development, Lusaka, Zambia, [6]University of North Carolina, Chapel Hill, School of Medicine, North Carolina, United States

Background: Despite being at high risk of HIV acquisition, uptake of pre-exposure prophylaxis (PrEP) among adolescent girls and young women (AGYW) remains low in Zambia. We describe PrEP uptake and continuation among AGYW receiving differentiated HIV prevention services in 37 community-based Determined, Resilient, Empowered, AIDS-free, Mentored, and Safe (DREAMS) Centres in 7 districts of Zambia, and examine behavioral, socio-demographic, and programmatic factors associated with PrEP continuity.

Description: We used individual-level, de-identified PrEP program data for AGYW aged 15-24 years enrolled in DREAMS from August 2022 to June 2024. Pearson's Chi-squared test was used to examine differences in beneficiary characteristics between clients with 1 PrEP visit and ≥2 PrEP visits, and mixed effects Poisson regression modelling to estimate the association between DREAMS enrolment criteria and PrEP continuation, and the association between components of the DREAMS package and PrEP continuation.

We also estimated the marginal probability of PrEP continuity. All analyses were performed using Stata (StataCorp LLC, College Station, TX, USA, release 18).

Lessons learned: From August 2022-June 2024, 15,502 AGYW enrolled in DREAMS were screened for PrEP. Of these, 15,072 (97.2%) were eligible, and 9,675 had sufficient follow-up time and complete data to be included in the analysis. The proportion of AGYW who had ≥1 PrEP visit within 180 days of initiation was 59.0% (n/N=5,706/9,675). In adjusted multivariate regression analysis, having a return PrEP visit was associated with being older (20-24 years) (prevalence ratio [PR] 1.23, 95% confidence interval [CI]:1.07,1.42), and convenience of access (living near the DREAMS center) (p≤0.001).

The probability of having a PrEP continuation visit within 6 months varied significantly by number of risk factors assessed at DREAMS enrolment. For instance, AGYW aged 15-19 years reporting ≥4 risk factors (91.7%, 95% CI: 41.2, 64.1) were significantly more likely to return for a refill than those reporting one risk factor (52.7%, 95% CI: 70.7, 112.7%).

Conclusions/Next steps: Community-based differentiated service delivery is crucial to expand and sustain the provision of PrEP to AGYW. Moreover, additional beneficiary-responsive wrap-around interventions are needed to motivate AGYW to remain on PrEP. Crucially, improving AGYW HIV risk awareness is vital to improve PrEP continuity.

WEPEC065

HIV/AIDS in West Africa: a thematic analysis of the Global Burden of Disease study 2021

M. Asika[1]
[1]Society For Disease Prevention Inc., Field Epidemiology, Manchester, United States

Background: The HIV/AIDS epidemic continues to burden sub-Saharan Africa, with West Africa exhibiting complex regional trends that influence both the scale and response to the epidemic. The Global Burden of Disease (GBD) Study 2021 published 2024 provides tactical information into the prevalence, mortality, and incidence of HIV across 204 countries, including the diverse nations of West Africa. While significant strides have been made globally in reducing HIV-related deaths, West Africa presents distinct challenges shaped by sociocultural, economic, and healthcare factors. This thematic analysis explores key patterns identified in the GBD study.
Methods: This study integrates data from the GBD 2021 study with region-specific reports, secondary data analysis, and qualitative insights to contextualize HIV trends in West Africa. Key themes derived from the GBD data - such as youth and gender disparities, prevention gaps, and urban-rural healthcare access - are explored through a socio-epidemiological lens. This comparative analysis spans the years 1990-2021, incorporating projections to 2050.
Results: Our findings show a striking persistence of HIV incidence and mortality, particularly among young people and marginalized populations. Despite global declines, West African nations like Nigeria, Côte d'Ivoire, and Ghana exhibit stagnation or slower progress in reducing HIV mortality, with disparities linked to healthcare access, gender inequality, and regional stigma. The urban-rural divide further compounds these challenges, with urban centers benefiting from greater healthcare access, while rural areas face significant barriers.
Additionally, gaps in prevention strategies, such as low uptake of PrEP and VMMC, highlight a critical need for tailored interventions. Forecasts through 2050 suggest that without significant policy shifts, HIV-related deaths and new infections will continue to disproportionately affect younger populations and key risk groups.
Conclusions: This thematic analysis highlights the need for a more balanced approach to HIV prevention, treatment, and care in West Africa. Tailored interventions, including improved access to PrEP, ART, and youth-focused education, are essential for mitigating the ongoing impact of HIV in the region.
The findings emphasize the importance of addressing systemic barriers, such as stigma, cultural attitudes, and inadequate infrastructure, to achieve sustainable HIV responses.

HIV testing

WEPEC066

Lack of community-based TB and HIV integrated services as a potential factor for gaps in HIV testing among presumptive TB cases in Mozambique: a 3-year retrospective cohort study

M. Lisboa[1], G. Amane[2], A.P. Simbine[1], P. Zindoga[1], A. Abdula[3], M. Swor[1], J. Mufume[4]
[1]US Agency for International Development, Integrated Health Office, Maputo, Mozambique, [2]Ministry of Health, National STI, HIV and AIDS Control Program, Maputo, Mozambique, [3]Development Aid from People to People (ADPP), Mozambique Local TB Response Project, Maputo, Mozambique, [4]Fundaçao para o Desenvolvimento da Comunidade-FDC, Maputo, Mozambique

Background: The World Health Organization's framework for TB and HIV collaborative activities recommends offering HIV testing services to people with presumptive TB (PP-TB). Despite well-integrated TB and HIV services at the facility level, significant gaps remain in HIV testing among PP-TB at both community and facility levels. This study aimed to estimate gaps in HIV testing among PP-TB within the community-based TB screening cascade.
Methods: We analyzed aggregated data from a retrospective cohort study of clients screened through community-based TB interventions and tested for TB in four high TB burden provinces from 2021 to 2023. Aggregated TB data were extracted from the Mozambique Local TB Response electronic reporting system. To estimate gaps in HIV testing among PP-TB, we performed a care cascade analysis and descriptive statistics were used to present the data.
Results: 4,607,257 clients were included, from whom 52% were female and 62% were aged 15 years and older, and 83% were reached through door-to-door visits. Of the 4,607,257 clients screened for TB, 9% were identified as PP-TB, of whom 85% were referred to facilities, and 97% successfully reached facilities, and 96% of those reached facilities underwent further examination. Of those examined, 22% were diagnosed with TB, and 85% were notified and initiated on anti-TB treatment. Three levels of gaps in HIV testing were identified: (i) community TB actors lack the skills and authorization for HIV counseling and testing; (ii) among PP-TB who were declared TB-free but had unknown HIV status, 76% were not tested for HIV; and (iii) clients diagnosed with TB, 17% of those with unknown HIV status were not tested for HIV. The overall gap in HIV testing across these levels was estimated at 84%.
Conclusions: While community-based TB interventions are strengthening the country's TB control efforts, the lack of guidelines and policies authorizing community TB actors to perform HIV testing has led to significant gaps in testing for HIV among PP-TB. Bidirectional integration of TB and HIV testing is a potential sustainable solution to ensure the timely diagnosis and treatment of individuals with TB and HIV co-morbidities

WEPEC067

Uptake of HIV testing among adolescents and young adults in Nigeria: a secondary observational analysis of a stepped-wedge, cluster-randomized trial

K.M. Tahlil[1], A.E. Pettifor[1], J.K. Edwards[1,2], W. Tang[3], D. Westreich[1], T. Gbajabiamila[4], H. Xian[5], U. Nwaozuru[6], S. Day[7], S.J. Shah[3], N.E. Rosenberg[8], D. Oladele[4], A.Z. Musa[4], L.A. Blessing[4], P. Ogunjemite[4], D.F. Conserve[9], T. Ojo[10], G. Ogedegbe[11], O. Ezechi[4], J. Iwelunmor[10], J.D. Tucker[3,12]

[1]University of North Carolina at Chapel Hill, Department of Epidemiology, Gillings School of Global Public Health, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Carolina Population Center, Chapel Hill, United States, [3]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [4]Nigerian Institute of Medical Research, Clinical Sciences Department, Lagos, Nigeria, [5]St. Louis University, Department of Epidemiology and Biostatistics, College for Public Health and Social Justice, St. Louis, United States, [6]Wake Forest School of Medicine, Department of Implementation Science, Winston-Salem, United States, [7]University of North Carolina at Chapel Hill, Department of Medicine, Division of Infectious Diseases, Chapel Hill, United States, [8]University of North Carolina at Chapel Hill, Department of Health Behavior, Gillings School of Global Public Health, Chapel Hill, United States, [9]George Washington University, Department of Prevention and Community Health, Milken Institute School of Public Health, Washington, DC, United States, [10]Washington University School of Medicine in St. Louis, Division of Infectious Diseases, John T. Milliken Department of Internal Medicine, St. Louis, United States, [11]New York University Grossman School of Medicine, Institute for Excellence in Health Equity, New York, United States, [12]London School of Hygiene and Tropical Medicine, Clinical Research Department, Faculty of Infectious and Tropical Diseases, London, United Kingdom

Background: Adolescents and young adults (AYA) in Nigeria who engage in multiple sexual partnerships, transactional sex, or needle-sharing are eligible for pre-exposure prophylaxis (PrEP) and are prioritized for HIV testing. HIV testing can link PrEP-eligible AYA to HIV services; however, little is known about HIV testing in these populations. We examined associations between these behaviors and two HIV testing modalities – facility-based and HIV self-testing (HIVST).

Methods: We analyzed data from Innovative Tools to Expand Youth-friendly HIV Self-Testing (I-TEST), a stepped-wedge trial examining the impact of a combination intervention package on HIVST among AYA aged 14 – 24 years in Nigeria. We fit generalized linear models, with an identity link and a binomial error distribution, using generalized estimating equations. We used a two-stage weighted approach to generalize I-TEST estimates to all AYA in Nigeria.

Results: Of 1,429 participants, the median age was 20 (IQR: 18 – 22), 50.3% were female, and 69.4% reported secondary school as their highest education level completed. Recent facility-based HIV testing uptake was higher among AYA with one (cRD: 11.7%, 95% CI: 8.1, 15.2), two (11% (5.3, 16.8)), and three or more sexual partners in the past three months (17.3% (10.5, 24)) compared to AYA with no recent sexual partners, while HIVST was higher for one (2.4% (-0.3, 5)), two (0.1% (-5.6, 5.9)), and three or more sexual partners (2% (-3.3, 7.2)). AYA who engaged in transactional sex had higher facility-based testing (14.7% (9.8, 19.5)) and HIVST (8.1% (4.8, 11.5)) uptake than AYA who never engaged in transactional sex. AYA who shared needles had lower facility-based testing (-3.3% (-6.7, 0.2)) and higher HIVST (2.1% (-0.4, 4.6)) than AYA with no needle-sharing history. The estimates were similar in adjusted models. Apart from AYA with two recent sexual partners who had lower HIVST uptake, the generalized and trial estimates were in the same direction.

Conclusions: While facility-based testing may reach AYA engaged in multiple sexual partnerships or transactional sex, AYA who share needles may require more tailored HIV testing approaches. Intensifying HIVST strategies for people engaging in these behaviors may ensure we identify AYA living with HIV and all AYA with greatest need for PrEP.

WEPEC068

Enhancing HIV case finding using Social Network Strategies (SNS) among key populations (KPs) and Priority Populations (PPs) in Shinyanga, Tanzania under the EpiC Project

S. Marwa[1], S. Nassoro[1], R.A. Khaji[2], V.M. Kabwebwe[3], J. Jovan[4], E. Machage[2], S. Msuka[5]

[1]SHDEPHA+, Program Management, Kahama, Tanzania, the United Republic of, [2]SHDEPHA+, Strategic Information, Kahama, Tanzania, the United Republic of, [3]SHDEPHA+, Governance and Administration, Kahama, Tanzania, the United Republic of, [4]FHI 360, Biomedical, Shinyanga Municipal Council, Tanzania, the United Republic of, [5]FHI 360, Governance and Administration, Shinyanga Municipal Council, Tanzania, the United Republic of

Background: Community-based HIV testing services are vital for reaching KP; Female Sex Workers (FSW) and Men who have Sex with Men (MSM), Priority populations (PPs); Adolescent Girls and Young Women (AGYW) and miners. SHDEPHA+ through EpiC Project used peer-led mobile testing and SNS to maximize HIV case identification. SNS leveraged social networks to identify HIV risk individuals from peers with similar risks. This tailored approach bridged gaps in traditional mobile HIV testing modalities focusing on risk networks for KPs and PPs. Despite these efforts, challenges in achieving optimal case identification persist, hindering progress toward the UN's 95-95-95 targets.

Description: Between October 2023-September 2024, the EpiC Project employed two SNS approaches; Enhanced Peer Outreach Approach (EPOA), that incentivize coupon distribution to risk individuals from KPs and PPs networks, and Risk Network Referral (RNR), where healthcare providers work with risk individuals to elicit risk networks. The program adhered to ethical guidelines, ensuring confidentiality and cultural sensitivity to build trust among individuals. HIV testing was offered following the coupon redeemed and reaching of elicited networks. HIV nega-

tive Individuals were offered condoms and PrEP service while HIV positive individuals were enrolled to Antiretroviral therapy (ART).

Lessons learned: 25,891 individuals were tested under mobile testing, yielding 337 (1%) of new HIV cases. SNS tested 1,549 (345 through EPOA and 1,204 through RNR) yielding 110 (7%) of new HIV cases were 19 (5.4%) and 91 (7.6%) HIV cases were through EPOA and RNR respectively. 36% and 64% of the SNS HIV testing positive were from KPs and PPs respectively and all were enrolled to ART. SNS approaches proved its effectiveness for identifying hidden populations, while peer-driven incentives enhanced participation in EPOA.

Conclusions/Next steps: This evidence demonstrates that SNS improves case identification among high-risk populations who lack health-seeking behaviors and are difficult to reach due to high mobility. It aids in early HIV diagnosis and ART initiation, ultimately reducing HIV prevalence and transmission. To scale the impact of SNS, increased funding and integration into national HIV testing strategies are essential. Policymakers should prioritize the adoption of SNS as a sustainable approach for achieving the UN's 95-95-95 targets in underserved regions.

Cascades of HIV prevention, treatment and care

WEPEC069

Progress towards the 95-95-95 targets among men who have sex with men: a respondent driven sampling survey in Rwanda 2024

C. Kayitesi[1], G. Twagirimana[1], V. Umubyeyi Mupenzi[2], Z. Nzeyimana[2], G. Nshogoza Rwibasira[2]
[1]Rwanda Biomedical Center, HIV/Diseases Prevention and Control Department, Kigali, Rwanda, [2]Rwanda Biomedical Center, HIV/AIDS, Diseases Prevention and Control, Kigali, Rwanda

Background: UNAIDS set 95-95-95 targets to aid the monitoring of progress towards ending the HIV/AIDS as a public health threat by 2030. We assessed the progress towards achieving the UNAIDS targets among MSM along with factors associated with achieving these targets.

Methods: The study analyzed bio-behavioral survey data conducted from May-July 2024 among MSM across 10 study sites in all 5 provinces using Respondent Driven Sampling (RDS). Participants aged 18+ years, who self-reported anal sex with a male partner in the past 12 months, resided in the survey area for at least 3 months, and who consented to participate in the interview and HIV, syphilis, and hepatitis B and C testing were recruited in the study. Ethical approval was obtained. RDS Analyst was used to compute weights, and STATA 17 to conduct bivariate and multivariate logistic regression. Socio-demographic, drug use, alcohol consumption, and Pre-Exposure Prophylaxis (PrEP) awareness and use variables were included in the models. Data were weighted using Gile's Sequential Sampling estimator, and weighted estimates were computed for each study site independently. Aggregated weighted estimates, at the national-level, and unweighted numerators are presented

Results: The study recruited 3,757 MSM with a median age of 27 years. More than half (n=1,944; 55.7%[95%CI:52.9–58.5]) had completed secondary school, and 1,895 (48.7% [45.9–51.5]) had ever heard of (PrEP). Of those, 93% [90.4–94.9] were those diagnosed HIV negative and 90.6% [85.9–93.9] of them had ever used PrEP.

Overall, HIV prevalence was 5.8% [4.6-7.8], and 70% [56.9-80.6] of MSM living with HIV knew their HIV status. Of these, 95.3% [88.5-98.1] were on antiretroviral therapy (ART), and all those on ART were virally suppressed (100%). Completing advanced secondary level of education was positively associated with awareness of HIV status [aOR=5.86, (1.17-29.24)].

Conclusions: HIV prevalence (5.8%) was disproportionately higher among MSM compared to the general adult male population in Rwanda (2.2%), with high PrEP usage. However, there was 25-percentage point gap in reaching the UNAIDS first 95 target among MSM, highlighting a need for appropriate approaches to identify MSM living with HIV but unaware of their status.

WEPEC070

Going beyond data: the back in care (BIC) initiative to return lost HIV infected clients to care in Rwanda

G. Mbaraga[1], L. Rangira[2], D. Sebuhoro[3], L. Buzaalirwa[4], D. Nduduzo[5], F. Ndayisaba[1], E.N. Mirimo[1], S. Tuyisenge[1], L. Naidoo[6], C. Baribwira[7]
[1]AIDS Healthcare Foundation, Medical, Kigali, Rwanda, [2]AIDS Healthcare Foundation, Programs Management, Kigali, Rwanda, [3]AIDS Healthcare Foundation, M&E, Kigali, Rwanda, [4]AIDS Healthcare Foundation, Quality Improvement and Medical Logistics, Kampala, Uganda, [5]AIDS Healthcare Foundation, Quality Improvement and Clinical Operations, Manzini, South Africa, [6]AIDS Healthcare Foundation, Programs Management, Manzani, South Africa, [7]Georgetown University, Independent Contractor, Kigali, Rwanda

Background: The BIC initiative launched in 38 AHF supported sites in Rwanda from september 2023 to august 2024 aimed to address the issue of people living with HIV (PLHIV) who were no longer in care (Lost to follow up (LTFU), transferred out and relocated). In 2023, AHF sites worldwide reported 238,660 new HIV cases and 130,000 individuals falling out of care.

Specifically, AHF Rwanda documented 1,168 PLHIV as NLIC from January to August 2024 which consisted of 512 LTFU, 522 transferred out and 12 relocated. Retaining PLHIV in care is essential to reduce morbidity, mortality and transmission.

Methods: The BIC initiative began by systematically reviewing medical charts of NLIC clients across 38 AHF-supported sites. Each month, sites used to report NLIC cases, but prior to the initiative, there was little engagement with these clients.

The BIC intervention consisted of several key steps:
1. The Monitoring and Evaluation team compiled a list of NLIC clients,
2. This list was provided to retention team for telephonic outreach,
3 If clients or their relatives were contacted, they were counseled and invited back into care,
4. Those not reachable by phone were referred for community tracking,
5. Clients who returned were given the contact details of a BIC champion at the facility,
6. The BIC champion communicated with these clients to set convenient appointments,
7. Reception staff was informed to provide a warm welcome during morning huddles,
8. Upon arrival, the BIC champion welcomed clients, registered them and explored reasons for their absence,
9. A RVs were re-initiated and appropriate treatments for opportunistic infections were provided,
10. BIC experiences were then shared in multidisciplinary team meetings .

Results: The charts of 1,872 NLIC clients were reviewed and1,541 (82.3%) were successfully contacted through phone calls (69%) and community efforts (31%). Ultimately, 616 clients (32.9%) returned to care. Close follow-ups contributed to 514 (83.4%) of them remaining in care after one year.

Conclusions: Most of NLIC clients remain contactable and are willing to return to care with an effective tracking programme such as BIC. BIC must be integrated among other strategies used in HIV services.

WEPEC071

Enhancing retention in HIV treatment through differentiated service delivery: an observational cohort of key populations on HIV treatment in 7 districts of Zambia

K. Chiyenu[1], M. Musheke[2], D. Mwamba[3], A. Phiri[3], C. Siame[2], A. Samona[2], B. Ngosa[2], F. Mwape[2], S. Shebo[1], M. Zimba[4], S. Malunga[5], M. Mulenga[6], C. Kanene[3], M. Herce[2,7]
[1]Centre for Infectious Disease Research in Zambia, Strategic Information, Lusaka, Zambia, [2]Centre for Infectious Disease Research in Zambia, Implementation Science, Lusaka, Zambia, [3]United States Agency for International Development, Lusaka, Zambia, [4]Key Population Alliance Zambia, Lusaka, Zambia, [5]The Lotus Identity, Lusaka, Zambia, [6]Sustainable Health Advocacy and Dynamic Empowerment Zambia, Lusaka, Zambia, [7]University of North Carolina, Chapel Hill, United Kingdom

Background: While Zambia has achieved the UNAIDS 95-95-95 targets, sustaining this success requires consistent retention in care. The USAID Controlling HIV Epidemic for Key and Underserved Populations (CHEKUP) I project implements a differentiated service delivery (DSD) model in which key populations (KP) - female sex workers (FSW), men who have sex with men (MSM), transgender people (TG) and people who inject drugs (PWID) - receive HIV treatment services at community-based KP Wellness Centres and through referrals to static Ministry of Health (MoH) facilities. This analysis examines retention outcomes for KP receiving care at Wellness Centres compared to MOH facilities in 7 districts of Zambia.

Description: This observation cohort analysis evaluated 12-month (October 2023 to September 2024) retention rates among KP initiated on HIV treatment between October 2022 and September 2023. Data were disaggregated by KP type to determine retention rates. For those not retained, treatment outcomes were categorised as died, lost to follow-up (LTFU), transfer out, or stopped treatment.

Lessons learned: Retention rates were significantly higher among KP accessing treatment at Wellness Centres compared to MOH facilities. Overall retention rates at KP Wellness Centres was 90% (565 initiated, 511 retained) - 90% for FSW (393 initiated, 358 retained), 89% for MSM (133 initiated, 118 retained), and 90% for TG (39 initiated, 35 retained). At MOH facilities, overall retention rate was 61% (1,388 initiated, 885 retained) -66% for FSW (878 initiated, 580 retained), 59% for MSM (394 initiated, 234 retained), and 61% for TG (116 initiated, 71 retained).
Among those not retained, Wellness Centres had 54 (10%)— 2 deaths, 14 LTFU, 19 transfer out, and 19 undocumented outcomes, while MOH facilities had 503 (36%)— 18 deaths, 181 LTFU, 175 transfer out, and 129 undocumented outcomes.

Conclusions/Next steps: The higher retention rates observed among KP receiving treatment at Wellness Centres highlights the effectiveness of community-based differentiated service delivery (DSD) models in providing convenient, client-centered, stigma-free treatment services. Our analysis underscores the need to strengthen collaboration with government health facilities, focusing on improved tracking and documentation of KP in care to sustain long-term treatment retention and enhance HIV care outcomes.

WEPEC072

Prevalence and determinants of late presentation to HIV care among people living with HIV newly enrolled in care in Rwanda: a retrospective cross-sectional study in AHF Rwanda-supported Health facilities

F. Ndayisaba[1], D. Sebuhoro[2], G. Mbaraga[1], S. Tuyisenge[1], E. Nkubito Mirimo[1], L. Rangira[3], L. Buzaalirwa[4], D. Nduduzo[5], C. Baribwira[6]
[1]AIDS Healthcare Foundation-Rwanda, Medical Department, Kigali, Rwanda, [2]AIDS Healthcare Foundation-Rwanda, Monitoring and Evaluation, Kigali, Rwanda, [3]AIDS Healthcare Foundation-Rwanda, Country Programs Manager, Kigali, Rwanda, [4]AIDS Healthcare Foundation, Quality Improvement and Medical Logistics, Kampala, Uganda, [5]AIDS Healthcare Foundation, Quality Management and Clinical Operations, Manzini, South Africa, [6]Georgetown University, Independent Contractor, Kigali, Rwanda

Background: Late presentation (LP) to HIV care not only predisposes to poor treatment outcomes and increased healthcare cost, but also eliminates the advantage of treatment as prevention. In sub-Saharan Africa about 30-50 % of people enrolling in care are late presenters. In Rwanda, despite universal access to free HIV diagnostic and care, many individuals are still presenting late. AIDS Healthcare Foundation (AHF)- Rwanda conducted a study to determine the prevalence of late presentation and its associated factors.
Methods: This was a retrospective cross-sectional study conducted in 38 AHF-supported health facilities in Rwanda. Data of PLHIV newly enrolled in care from July 2023 to June 2024, were extracted from electronic medical record (EMR), and analyzed to measure the prevalence of Late presentation and its associated socio-demographic factors. LP was defined as CD4 less than 350cells/mm. WHO clinical staging was not used. Descriptive statistics, Pearson's Chi-squared test and binary logistic regression were performed to determine the prevalence of LP and associated factors.
Results: Data from 2472 PLHIV were analyzed, with a median age of 34 years (IQR,28-41), and 63.7% were females. The overall prevalence of LP to HIV care was 33.3%, highest in Kigali City (38.2%) and Southern province (36.8%), and lowest in Western province (22.2%). LP was more prevalent in males (38.9%) than females (30.1%), and it increased with age, from 16.7% among those aged 0 to 14 years to 40.9% for those aged 45 years and older. Age (X^2=43.0132, p=0.000), and gender (x^2=19.9836, p=0.000) were significantly associated with LP.
Multivariate logistic regression revealed an increased risk of LP from individuals aged 25-34 years (AoR=2.1. p=0.047) to those aged 45+ years (AoR=3.4, P=0.001) compared to the under 15 years. Males were 1.3 times more likely to present late compared to females (AoR=1.3, p=0.001).
Conclusions: Late presentation to HIV care remains a challenge in Rwanda with a prevalence of 33.3%, the City of Kigali recording the highest prevalence. Male gender and older age groups are the key predisposing factors. Community engagement initiatives for early HIV diagnosis and enrollment in care focusing on older males in high-prevalence settings are crucial to address this challenge.

WEPEC089

Closing the gap in pediatric HIV care: impact of a case management approach in an OVC program on viral load suppression in Mashonaland West, Zimbabwe (2022–2024)

L. Mukwekwezeke[1], H. Chazuka[1], A. Masiyazi[2]
[1]Hospice and Palliative Care Association of Zimbabwe, Monitoring Evaluation and Learning, Harare, Zimbabwe, [2]Hospice and Palliative Care Association of Zimbabwe, Case Management, Harare, Zimbabwe

Background: Zimbabwe has made progress in adult HIV treatment but still faces challenges in pediatric care. While adult viral load suppression reached 90% by 2020, children lagged at 72% (National HIV Estimates, 2021). The 2023 HIV Spectrum Estimates showed overall virologic suppression at 96%, but 86% for children. This disparity increases morbidity and mortality risk, threatening Zimbabwe's goal to end AIDS by 2030. Barriers include insufficient adherence support, poor care linkages, and inadequate follow-up.
In response, the Hospice and Palliative Care Association of Zimbabwe initiated the OVC Program in 2022, funded by PEPFAR through USAID, employing a case management model to improve pediatric HIV care.
Description: The case management model utilizes a multidisciplinary team of case managers and community child care workers to develop individualized care plans and provide comprehensive services, including home visitations, adherence support, HIV treatment literacy, clinic appointment reminders, viral load monitoring referrals, support groups, and case conferencing. The model was implemented across 143 health facilities in the Chegutu, Hurungwe, Makonde, and Zvimba districts. Viral load data were collected annually from program participants from 2022 to 2024. A Cochran-Armitage trend test assessed changes in viral suppression over time with statistical significance set at $p < 0.05$.
Lessons learned: The program enrolled 5,669 HIV-positive children. Over three years, viral load suppression improved remarkably: 91% in 2022, 92% in 2023, and 96% in 2024. A Cochran-Armitage trend test revealed a statistically significant increasing trend ($p < 0.05$). The improvement was attributed to support for adherence, empowerment of caregivers, and strengthened community-facility linkages. These results highlight the effectiveness of case management model in addressing barriers to treatment adherence and retention in care.
Conclusions/Next steps: The implementation of case management in Mashonaland West, Zimbabwe, has demonstrated significant success in improving viral load suppression among HIV-positive children. This strategy addressed key challenges to treatment adherence and care through targeted interventions and strengthening community-facility linkages. The model has proved to be a scalable and effective strategy.

These findings underscore the potential of adopting case management approaches in pursuit of the global objective to end AIDS by 2030, particularly in addressing gaps in pediatric HIV care.

WEPEC090

Treatment interruption surpasses virological failure as barrier to HIV viral suppression in sub-Saharan Africa (2020-2023)

M. Farahani[1], S. Saito[1], S.M. Farley[1], T.F. Smart[1], R.K. Nyirenda[2], L. Maile[3], O. Mugurungi[4], W.L. Kirungi[5], E.S. Gudo[6], P.F. Njau[7], W. Hladik[8], H.K. Patel[8], A.C. Voetsch[8], S. Sendagala[9], T. Maphosa[10], M. Pasipamire[11], A. Kailembo[12], W.M. El-Sadr[1,13]

[1]Columbia University, ICAP, New York, United States, [2]Ministry of Health, HIV, Lilongwe, Malawi, [3]Ministry of Health, HIV, Maseru, Lesotho, [4]Ministry of Health and Child Care, HIV, Harare, Zimbabwe, [5]Ministry of Health, Kampala, Uganda, [6]National Institute of Health, Maputo, Mozambique, [7]Ministry of Health, Dar es Salaam, Tanzania, the United Republic of, [8]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Center for Global Health, Atlanta, United States, [9]Centers for Disease Control and Prevention (CDC), Kampala, Uganda, [10]Centers for Disease Control and Prevention (CDC), Harare, Zimbabwe, [11]Centers for Disease Control and Prevention (CDC), Mbabane, Eswatini, [12]Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, the United Republic of, [13]Columbia University, Department of Epidemiology, New York, United States

Background: Despite widespread antiretroviral therapy (ART) access in sub-Saharan Africa, achieving and maintaining population-level viral load suppression (VLS) remains challenging. The relative effect of in-treatment virological failure (VF) versus interruption in treatment (IIT) for unsuppressed viral load (UVL) is not well understood.

Methods: We analyzed data from 16,850 ART-experienced people living with HIV aged ≥15 years who self-reported ≥4 months on ART in population-based HIV impact assessments (PHIA) across 7 sub-Saharan African countries (2020-2023). We defined three outcomes: VLS: <1,000 copies/mL per WHO criteria; VF: ≥1,000 copies/mL with detectable antiretrovirals; and IIT: ≥1,000 copies/mL without detectable antiretrovirals. We used Poisson regression to identify factors associated with VF and IIT.

Results: Among ART-experienced participants, 74.8% achieved VLS, while 3118 (25.2%, 95% confidence interval (CI): 24.0-26.6%) had unsuppressed viral load (UVL), with rates ranging from 11.4% in Eswatini to 36.5% in Mozambique. Among those with UVL, IIT (21.6%, 95% CI: 20.4-22.9%) was nearly sixfold more prevalent than VF (3.6%, 95% CI: 3.2-4.1%).

Younger adults (aged 15-29 years) had a significantly higher likelihood of both VF (adjusted prevalence ratio [aPR]: 2.8, p=0.007) and IIT (aPR: 42.0, p<0.0001) compared with those aged ≥60 years; men had a higher risk for VF (aPR: 1.5, p=0.02) and IIT (aPR: 1.5, p=0.046) compared to women. Self-reported suboptimal adherence (missing ≥2 doses in the past 30 days) doubled the likelihood of both VF (aPR 2.2, p<0.0001) and IIT (aPR 1.9, p=0.008), while non-dolutegravir regimens, especially those containing nevirapine (aPR 6.2, p<0.0001) or lopinavir (aPR 5.9, p=0.001), were associated with increased VF.

Variable	Viral Failure (aPR†)	p-value	ART Interruption (aPR)	p-value
Male	1.5	0.017	1.5	0.046
Female	Reference	–	Reference	–
Efavirenz	4.1	<0.0001	NA	NA
Nevirapine	6.2	<0.0001	NA	NA
Atazanavir	3.3	0.01	NA	NA
Lopinavir	5.9	0.001	NA	NA
Dolutegravir	Reference	–	NA	NA
Suboptimal ARV adherence	2.2	<0.0001	1.9	0.008
Optimal ARV adherence	Reference		Reference	

Table 1. Factors Associated with VF and IIT Among PWH on ART for ≥4 Months

Conclusions: IIT, rather than VF, primarily drives UVL in these settings. Programs should prioritize preventing care disengagement and enabling rapid re-engagement, especially among young adults and men, while expanding access to dolutegravir-based regimens to reduce VF.

WEPED073

Exploring drivers of preference for implantable and injectable interventions as pre-exposure prophylaxis (PrEP) novel drug delivery forms among cisgender men-who-have-sex-with-women-only (MSW) and men-who-have-sex-with-men- (MSM) in South Africa

S.K. Zulu[1], E.N. Browne[2], C. Hart[2], M. Diaz[2], K. Reddy[3], N. Ndlovu[3], P. Sibiya[3], Z. Njengele-Tetyana[3], M. Atujuna[4], K. Gill[4], A. Minnis[2], T. Palanee-Phillips[3,5], E.T. Montgomery[2,6]

[1]Wits RHI, Wits RHI, University of the Witwatersrand, Faculty of Health Sciences, School of Public Health, Johannesburg, South Africa, [2]Research Triangle Institute (RTI) International, Women's Global Health Imperative, Research Triangle Park, United States, [3]Wits RHI, University of the Witwatersrand, Faculty of Health Sciences, School of Public Health, Johannesburg, South Africa, [4]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [5]University of Washington, Department of Epidemiology, School of Public Health, Washington, United States, [6]University of California, San Francisco, Department of Epidemiology and Biostatistics, School of Medicine, San Francisco, United States

Background: Men play a critical role in the cycle of HIV transmission. Their perspectives on and experiences with novel drug delivery platforms for PrEP are crucial to helping develop acceptable HIV prevention methods. Efforts to target and engage men have been inadequate, and to fill this niche, we explored factors influencing attitudes,

experiences and preferences for use of two placebo long-acting delivery platforms, implants and injections, among MSW and MSM as part of the SAMURAI study.

Methods: Between July 2022 and June 2023, SAMURAI enrolled 184 MSW and MSM in Johannesburg and Cape Town, South Africa. During this randomized crossover study, participants used each of two placebo delivery methods (bimonthly intralipid intramuscular injections and a subdermal implant rod) for six months each.

Men rated acceptability of each product after use and stated preferences after using both. This analysis used Chi-squared tests to examine sociodemographic factors and product feature acceptability associated with preferring the implant over the injection.

Results: There were 153 participants (83%) with final product preference assessment: 74 (48%) preferred the implant, 73 preferred injections (48%), 6 (4%) had no preference/were not sure. Preference for implant was associated with older age (34% 18-20 yr olds vs 53% of 21-35 yr olds, p=0.04); perceived ease of use (55% thought it 'very easy' to use vs. 28% did not, p=0.004); and acceptability of the implant's physical impact on the body (51% of those who found the implants impact on the body acceptable preferred the implant vs 20% who found the impact unacceptable, p=0.02).

Conclusions: The equal distribution of preferences, with 48% of participants favoring the implant and 48% favoring the injection, suggests that both products were well received. These data highlights willingness among men to explore use of new drug delivery methods.

While the results indicate several differences characterizing preference for future use of these two long-acting delivery forms, the findings also suggest potential benefits of exploring active drug delivery in long-acting delivery forms and expanding PrEP options for men.

Social and behavioural aspects and approaches to HIV prevention and living with HIV

WEPED074

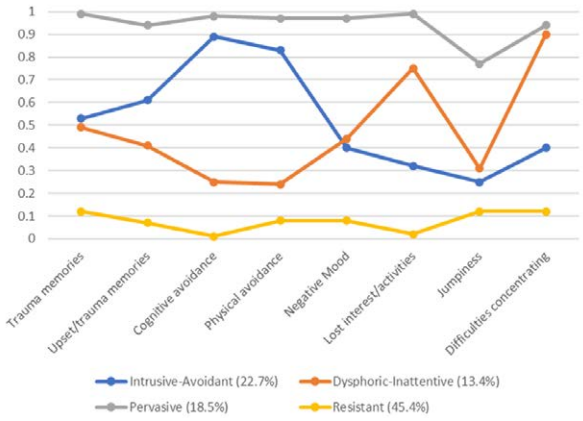
Associations between latent classes of PTSD symptoms, HIV care outcomes, and substance use among sexually minoritized men living with HIV in the United States

J.M. Wiginton[1], S. Baral[2], T. Sanchez[3]
[1]Johns Hopkins University Bloomberg School of Public Health, Mental Health, Baltimore, United States, [2]Johns Hopkins University Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Emory University, Epidemiology, Atlanta, United States

Background: Sexually minoritized men (SMM) with HIV in the United States (US) are disproportionately burdened by trauma, posttraumatic stress disorder (PTSD), and related sequelae. However, there has been limited study of PTSD symptom patterns and HIV care and substance use outcomes in this population.

Methods: Using online, cross-sectional, nationwide data from the American Men's Internet Survey (2020-2021), we performed latent class analysis on responses to a PTSD symptom scale to identify PTSD symptom classes among trauma-exposed SMM with HIV (N=597). We performed multinomial logistic regression and the manual Bolck-Croon-Hagenaars method to determine sociodemographic associations with latent class membership and assess class-specific HIV care (non-uptake of ART) and substance use outcomes (high-risk alcohol use, monthly marijuana use, monthly hard drug use), respectively.

Results: Participants' mean age was 44 years, with 46% (n=277) white, 33% (n=199) Black, and 14% (n=85) Hispanic. Latent classes are in the Figure.



Compared to white participants, Black participants were more likely to fall into the Intrusive-Avoidant relative to the Dysphoric-Inattentive class (aOR=4.13, 95% CI=1.04-16.41); unstably housed participants were more likely to fall into the Pervasive relative to the Resistant class (aOR=2.16, 95% CI=1.03-4.54).

Non-uptake of ART (9.6% vs 1.9%; p<0.05) and monthly hard drug use (19.6% vs 2.3%; p<0.01) were higher in the Pervasive relative to the Resistant class. Monthly marijua-

na (29.8% vs 17.4%; p<0.05) and high-risk alcohol use (23.5% vs 10.8%; p<0.05) were higher in the Intrusive-Avoidant relative to the Resistant class.

Conclusions: Among SMM with HIV in the US, PTSD symptoms diversely manifest and differentially shape ART uptake and substance use behaviors.

Integrating comprehensive interventions that target both PTSD symptoms and substance use into extant systems of HIV care is needed; intervention-tailoring to PTSD symptom classes may likewise be indicated.

Addressing trauma and related sequelae is crucial to optimizing HIV care and helping SMM live well with HIV.

WEPED075

Combining primary and secondary HIV prevention in the Dominican Republic: understanding need and acceptability of partner-based PrEP among sero-discordant partners

L. Sheira[1], G. Jimenez-Paulino[2], S. Khan[3], A. Then-Paulino[2], R. Acevedo[4], A. Gomez[5], G. Wagner[6], C. Talaveres[2], T. Neilands[7], P.C. Tien[7], K. Derose[8], K. Palar[3]

[1]University of California, San Francisco, School of Nursing, San Francisco, United States, [2]Universidad Autonoma de Santo Domingo, Santo Domingo, Dominican Republic, the, [3]University of California, San Francisco, Division of HIV, Infectious Diseases, and Global Medicine, San Francisco, United States, [4]Consejo Nacional de VIH y SIDA, Santo Domingo, Dominican Republic, the, [5]Servicio Nacional De Saludo, Santo Domingo, Dominican Republic, the, [6]Pardee RAND Graduate School, Santa Monica, United States, [7]University of California, San Francisco, San Francisco, United States, [8]University of Massachusetts, Amherst, United States

Background: The Dominican Republic (DR) has the highest HIV prevalence in Spanish-speaking Latin America, with individuals living with HIV (PLHIV) experiencing challenges in viral suppression, fueling onward transmission of HIV. Partner-based referrals is a cornerstone of HIV/STI care globally and is among the more feasible approaches for prevention and treatment; however, it is used less for pre-exposure prophylaxis (PrEP). PrEP is available in ~50% of public HIV clinics in the DR with availability increasing; uptake remains very low.

We sought to understand PrEP knowledge and preliminary acceptability of partner-based PrEP services among PLHIV experiencing adherence challenges enrolled in an ongoing food and adherence support trial.

Methods: We collected baseline data from 306 adult PLHIV enrolled in *ProMeSA* (Project to Improve Food Security) across twenty pair-matched clinics providing HIV care across the DR. *ProMeSA* includes urban gardening support and nutritional counseling for PLHIV. All enrolled PLHIV had evidence of adherence challenges (e.g. missed refills, virally non-suppressed), and had food insecurity.

The baseline survey included a module on PrEP knowledge, partner status, interest in partner-based PrEP, and knowledge of Undetectable=Untransmissible (U=U).

Results: Median age was 45 and median years living with HIV was 6.8; 74% self-identified as female, 90% were Dominican and 10% were Haitian; two-thirds were virally non-suppressed. Most (83%) had never heard of PrEP and 33% had a sero-negative or sero-unknown status partner (26% were sero-concordant).

Over two-thirds of those with sero-negative/unknown partners (69%) reported never being offered PrEP for their partners; just 2 reported partners currently taking PrEP. While 79% of those in sero-discordant partnerships would "greatly support" a partner taking PrEP, many felt somewhat (31%) or very (31%) uncomfortable discussing PrEP with HIV-negative or status unknown partners.

Among all participants, 21% percent completely and 11% somewhat disagreed with the premise of U=U.

Conclusions: Among PLHIV with adherence challenges, knowledge of PrEP – and known use among their partners – was low. Participants in sero-discordant partnerships reported hesitancy in initiating conversations about PrEP with their partners even when supportive of PrEP in theory. More research is needed to determine how to engage PLHIV with adherence challenges in partner-based PrEP to interrupt onward transmission of HIV.

WEPED076

Managing pill burden, fatigue, and pronounced NCDs to maximize ART outcomes in aging diverse persons living with HIV

G. Bonzo[1]

[1]Trans Smart Trust, Program Leadership, Harare, Zimbabwe

Background: Aging persons living with HIV (PLHIV) face compounded health challenges, including pronounced non-communicable diseases (NCDs) such as hepatitis, diabetes, cancers, menopause, and andropause. These conditions exacerbate pill burden and fatigue, compromising adherence to antiretroviral therapy (ART) and overall health outcomes.

To address this, Trans Smart Trust initiated a multi-faceted program targeting aging diverse PLHIV, aiming to optimize ART outcomes by mitigating the effects of these challenges.

Objectives included enhancing adherence support, integrating NCD management into HIV care, and improving the quality of life for participants.

Description: The program was implemented from 2021 to 2024 across Zimbabwe, focusing on urban and peri-urban areas with high HIV prevalence. The target population included individuals aged 50 and above on long-term ART.

Key activities included:

1. Integrated care clinics through offering combined HIV and NCD management, including screening, treatment, and counselling.
2. Pill burden reduction strategies by Promoting simplified ART regimens and synchronizing treatment schedules for HIV and NCDs.
3. Health literacy campaigns in educating participants on managing menopause, andropause, and NCD-related complications.

4. Peer support networks to creating safe spaces for aging PLHIV to share experiences and strategies for adherence and fatigue management.

Lessons learned: Findings revealed improved ART adherence and self-reported health outcomes among participants. Simplified regimens reduced pill fatigue, while integrated care minimized clinic visits, improving convenience. Peer networks effectively addressed stigma and emotional well-being, particularly for women experiencing menopause and individuals managing multiple NCDs. Challenges included inadequate specialized care for cancers and limited rural outreach.

Conclusions/Next steps: The program demonstrated that integrating NCD management with HIV care enhances adherence and quality of life for aging PLHIV. Scaling this model nationally, expanding cancer care, and bolstering rural outreach are critical next steps. Strengthened health literacy and advocacy are essential to sustain improvements and ensure equitable care for aging diverse PLHIV.

WEPED077

Factors impacting women's choice of PrEP product after the randomized blinded phase of PURPOSE 1

T. Palanee-Phillips[1], I. Hawley[2], J. Smit[3], N. Mosery[3], A. Kubeka[4], D. Potloane[5], M. Mdladla[5], H. Makkan[6], K. Gill[7], L. Jola[7], Z. Njengele-Tetyana[1], P. Sibiya[1], T. McClure[8], C.C. Carter[9], A. Kintu[9], M. Das[9], E.T. Montgomery[2]
[1]Wits RHI, University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [2]RTI International, Oakland, United States, [3]WMRU (Wits MatCH Research Unit), School of Obstetrics and Gynecology, Faculty of Health Sciences, University of the Witwatersrand, Durban, South Africa, [4]The Aurum Institute, Clinical Research Tembisa, Tembisa, South Africa, [5]Centre for the AIDS Programme of Research in South Africa, University of KwaZulu Natal, Durban, South Africa, [6]The Aurum Institute — Rustenburg Clinical Research Centre, Rustenburg, South Africa, [7]The Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [8]FHI 360, Durham, United States, [9]Gilead Sciences, Inc., Foster City, United States

Background: The PURPOSE 1 (NCT04994509) trial evaluated twice-yearly subcutaneous lenacapavir and daily oral emitricitabine/tenofovir alafenamide for HIV pre-exposure prophylaxis (PrEP) in adolescent girls and young women (AGYW). On demonstration of 100% HIV prevention efficacy of lenacapavir, participants were offered lenacapavir in an open label extension (OLE) phase, with >95% opting to join.

Methods: We conducted in-depth interviews (IDIs) at five South African sites in a qualitative sub-study of PURPOSE 1. IDIs followed study unblinding and OLE transition, offering an opportunity to explore participants' perspectives on the primary analysis results, unblinding, and OLE participation decisions. IDIs were in English and/or local languages among a subsample of young women (n=30), including randomly selected participants aged 18–25 years, purposively selected participants aged 16 and 17 years, and participants who discontinued study drug prematurely. Data were analyzed thematically using the Rigorous and Accelerated Data Reduction Technique.

Results: Most interviewed participants opted into the lenacapavir OLE, emphasizing preference for an efficacious, long-acting option compared with daily oral PrEP. Decisions were influenced by frequency of dosing and willingness to accept potential injection-site pain and nodules for extended duration of protection.

Participants described their decisions to continue injections as autonomous, although some noted input from key "influencers". Reactions to product arm unblinding included disappointment and regret about how well they had adhered to active or placebo oral PrEP. Some raised concerns about potential side effects upon transitioning to active lenacapavir.

Participants expressed optimism around continued use of lenacapavir, anticipating a reduced daily pill burden and increased confidence in HIV prevention. A minority opted for oral PrEP over lenacapavir, citing adherence familiarity or aversion to injection-site reactions. Participants framed their decisions as specific to their current context rather than definitive preferences for future prevention strategies.

Conclusions: Consistent with observations study-wide, most sub-study participants elected to use lenacapavir in the OLE, citing extended duration and optimal levels of protection as crucial to obviating the need for daily pill adherence.

These findings underscore the potential of twice-yearly subcutaneous lenacapavir to improve PrEP uptake and adherence in AGYW, and the importance of offering a choice of prevention options to meet varying needs and preferences.

WEPED078

Assessing HIV-related healthcare stigma and discrimination in Rwanda: findings from the Stigma Index Survey

R. Umutoni Mupende[1], F.K. Rubuga[1], A. Gashaija[1], J.D. Hagenimana[1], C. Karimba[1], C. Mundereri[1], E. Remera[2], G. R.Nshogoza[2], D. Mutambuka[3], J.B. Tugirimana[4], J. Condo[1]
[1]Centre for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition, Rwanda (CIIC-HIN), Kigali, Rwanda, [2]Rwanda Biomedical Centre (RBC), Kigali, Rwanda, [3]Rwanda Network of People Living with HIV/AIDS (RRP+), Kigali, Rwanda, [4]Rwanda Network of People living with HIV/AIDS (RRP+), Kigali, Rwanda

Background: HIV-related stigma and discrimination (SD) create significant barriers to accessing HIV prevention, care, and treatment services, impacting adherence among people living with HIV. To address these challenges, Rwanda conducted its second Stigma Index Survey in 2020, building on the first survey from 2009.

The aim was to assess the prevalence and nature of HIV-related SD, measure progress over the past decade, and inform advocacy efforts.

Methods: A cross-sectional study with mixed methods was conducted across 10 districts in Rwanda from October 2019 to June 2020. Quantitative data were collected from 938 people living with HIV enrolled in care at 38 health facilities using a structured questionnaire. Qualitative data were gathered through six focus group discussions and eight in-depth interviews.

The composite HIV Stigma Index was derived from five components: disclosure concerns, fear of transmission, judgment/blame, recent stigma experiences, and stigma's broader impacts. Descriptive statistics and thematic analysis were used.

Results: The HIV Stigma Index in Rwanda was categorized as very low (Index 15), indicating substantial progress since 2009. Of the 950 participants (99% participation rate), 72% were female, and the median age was 44 years.

Most respondents (87%) had completed primary education or less, and 51% reported challenges meeting basic needs. Stigma-related experiences showed an 80% reduction over the past decade, with declines in exclusion from social activities, family discrimination, and physical harassment. However, adolescents, women, and key populations (e.g., female sex workers, men who have sex with men) reported higher levels of stigma. Only 9.4% rated stigma related to human rights as very low.

Conclusions: Rwanda has made substantial progress in reducing HIV-related stigma and discrimination. Targeted interventions for vulnerable groups, along with efforts to raise awareness of the rights of people living with HIV, are needed to ensure equitable care and support.

WEPED079

The Intersection of HIV and Mental Health: a study of depression among adolescents and young adults in Rwanda

F. K. Rubuga[1], O. Wane[1], J.D. Hagenimana[1], C. Karimba[1], E. Remera[2], J. Ndayisenga[2], J.B. Tugirimana[3], G. N. Rwibasira[2], D. Mutambuka[3], J. Condo[1]

[1]Centre for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition (CIIC-HIN)., Kigali, Rwanda, [2]Rwanda Biomedical Center (RBC), Kigali, Rwanda, [3]Rwanda Network of People living with HIV/AIDS (RRP+), Kigali, Rwanda

Background: Depression represents a significant mental health challenge among adolescents and young people living with HIV (AYPLHIV). Global adolescent depression rates range from 1.4% (ages 10-14) to 3.5% (ages 15-19), with sub-Saharan Africa showing a markedly higher prevalence at 26.9%.

While research has established a clear connection between HIV status and mental health outcomes, there remains a critical gap in understanding the specific dynamics of depression among AYPLHIV in Rwanda. To address this knowledge gap, this study assesses the prevalence and factors of depression among AYPLHIV in Kigali and secondary cities of Rwanda.

This research aims to provide essential insights that can inform targeted interventions and support services for this vulnerable group.

Methods: A cross-sectional study was conducted between March and June 2024 from adolescents and young people living with HIV (10–24 years) in health facilities across Kigali, Musanze, Muhanga, Rubavu, Nyagatare). clinical and programmatic data were analyzed using descriptive, bivariate, and multivariate logistic regression.

Results: In a study of 457 adolescents and young adults living with HIV, depression was found to be prevalent, with 12% experiencing severe depression, 14% moderate depression, and 29% mild depression.

Multivariate analysis revealed that food insecurity (aOR: 6.68, 95% CI [3.42–13.05], p < 0.001) and recent caregiver changes (aOR: 1.97, 95% CI [1.07–3.62], p = 0.029) were independently associated with higher depression rates. The mode of HIV transmission was significantly associated with depression, with those who acquired HIV through mother-to-child transmission having lower odds of depression compared to those who acquired it through sexual violence (OR: 0.21, 95% CI [0.05-0.80], p = 0.023).

Additionally, individuals who had been admitted to the hospital in the last 12 months were more likely to suffer from depression (OR: 2.19, 95% CI [1.17-4.10], p = 0.014).

Conclusions: This study emphasizes the urgent need for integrated mental health services in HIV care programs, highlighting a high prevalence of depression influenced by multiple socio-economic and clinical factors among adolescents and young adults living with HIV in urban Rwanda. Enhanced care frameworks could significantly improve treatment outcomes and quality of life for this vulnerable population.

WEPED080

Treatment satisfaction was linked to improved adherence, and mental, physical, sexual and overall health among people living with HIV in the Positive Perspectives 3 study

R. Patel[1], B. Allan[2], G. Brough[3], M. Cascio[4], E. Castellanos[5], A. Cingolani[6], V. Dubula[7], W.D. Hardy[8], K. Iwahashi[9], S. Mbudwini[10], M. McBritton[11], M. Ndungu[12], B. Richman[13], M. Shibemba[14], A. Appiah[1], D. Fox[15], M. Mayer[16], S. Mellors[1], V. Vega[15], N. Nwokolo[1]

[1]ViiV Healthcare, London, United Kingdom, [2]National Association of People Living with HIV Australia, Newtown, Australia, [3]Transformation Partners in Health and Care, London, United Kingdom, [4]European AIDS Treatment Group (EATG), Bruxelles, Belgium, [5]Global Action for Trans Equality (GATE), Mijdrecht, Netherlands, the, [6]Fondazione Policlinico A. Gemelli, IRCCS, Catholic University of the Sacred Heart, Roma, Italy, [7]The Global Fund, Geneva, Switzerland, [8]USC Rand Schrader (HIV) Clinic, Keck School of Medicine of USC, Los Angeles, United States, [9]Akta, Tokyo, Japan, [10]Nelson Mandela University, Port Elizabeth, South Africa, [11]Barong, São Paulo, Brazil, [12]Women's Health in Women's Hands Community Centre, Toronto, Canada, [13]Prevention Access Campaign, New York City, United States, [14]Independent Consultant, Manchester, United Kingdom, [15]ViiV Healthcare, Durham, United States, [16]ViiV Healthcare, Paris, France

Background: Challenges to antiretroviral therapy (ART) adherence are well-documented. This study provides new insights into emotional, psychosocial, physical, and other treatment-related challenges.

Methods: This analysis utilized interim data from 834 participants in Positive Perspectives Study Wave 3 from adults on ART from Australia, Argentina, Chile, South Africa, Colombia, Italy, and USA. Treatment challenges assessed included emotional/ psychosocial (e.g. stigma, privacy concerns), physical issues (e.g. side-effects) and adherence barriers. Multivariable logistic regression examined the impact of treatment satisfaction on behaviours and self-rated health, adjusting for age, gender and income.

Results: Among 834 participants, 72.8% were <50 years, 49.3% female. 76.5% were on single-tablet regimens, 20.7% on multiple tablets, and 2.8% on injectables or other unspecified regimens.

While 67.2% were satisfied with their ART, half of all participants felt there was still room for improvement. Key treatment-related challenges included fear of missing doses (59.1%), side-effects (25.3%), and the emotional toll of a lifelong condition (18.3% struggling to adapt to lifelong treatment and 33.8% feeling worn out by its demands). Privacy concerns were also common: 71.4% were afraid that someone would discover their HIV status (e.g., friend, family member, co-worker). Additionally, stigma and isolation were common themes: 32.3% felt their medication was a reminder of their diagnosis, and 25.2% reported feeling lonely due to their HIV status.

Among 75% of participants who had ever switched ART regimen, reasons for switching included reducing side-effects (29.0%), addressing virological failure (18.0%), or reducing the number of pills (16.8%). Satisfaction with ART was closely linked to improved outcomes; satisfied individuals were less likely to skip doses (AOR=0.51, 95% CI:0.32–0.83), more likely to recommend their treatment (AOR=5.92, 95% CI:3.80–9.22), and to report optimal mental (AOR=2.74, 95% CI:1.76–4.25), physical (AOR=2.77, 95% CI:1.84–4.19) sexual (AOR=2.60, 95% CI:1.71–3.96) and overall (AOR=2.74, 95% CI:1.81–4.13) health.

Conclusions: A small majority of people expressed treatment dissatisfaction and emotional distress due to privacy and stigma related concerns.

These challenges must be acknowledged and addressed when offering people support services and new ART options.

WEPED081

Understanding depression among adolescents living with HIV in Tanzania: a mixed-methods study using the think-aloud approach

R. Maro[1], P. Msoka[1], N. Emmanuel[1], B. Mtesha[1], L. Masika[1], A. Mtenga[1], I. Swai[1], M. Sumari-de Boer[1,2]

[1]Kilimanjaro Clinical Research Institute, Data Management Unit, Moshi, Tanzania, the United Republic of, [2]Kilimanjaro Christian Medical University Collage, Public Health, Moshi, Tanzania, the United Republic of

Background: Adolescents living with HIV face a high risk of depression, which impacts their overall well-being, adherence to antiretroviral therapy, and ability to manage their health.

This study aimed to determine the prevalence of depression, explore adolescents' perceptions and experiences of depression in Tanzania, and understand their awareness of depressive symptoms and coping strategies.

Methods: This is a mixed-method study among participants of an ongoing two-arm randomized controlled trial (REMIND KID), which investigates the effect of customized digital tools in improving adherence among adolescents living with HIV aged from 15 to 19 years. Depression screening was conducted using the PHQ-9 tool, which categorizes depression as mild, moderate, moderately severe, or severe based on a score range of 5–20.

Additionally, 14 participants were randomly selected for think-aloud interviews to verbalize their thought processes while responding to the PHQ-9 tool. This was followed by in-depth interviews (IDIs) using a topic guide to explore emotional experiences in greater detail. Qualitative data were analyzed thematically.

Results: Among 182 adolescents, 95 (52.2%) were girls and 87 (47.8%) were boys, with a mean age of 17.1 years (SD 1.446). The prevalence of depression was 20.3% and 14 (0.07%) participants reported suicidal thoughts. Qualitative data from think-aloud interviews revealed how adolescents connected their experiences to depressive symptoms, providing context to the quantitative data.

Symptoms such as anxiety, stress, and sadness were linked to factors like stigma, and isolation. Participants mentioned different levels of understanding of emotional terms, often associating depression with "having many thoughts" or "feeling sorrowful". Perceived and actual stigma was identified as the main trigger for distress

and depression, especially after participants felt isolated or judged. Access to safe spaces and social adaptations helped reduce depressive symptoms.

Conclusions: Depression is prevalent among adolescents living with HIV, often influenced by contextual factors. Adolescents usually lack the exact words to describe depression but show their protective means through social support, positiveness, and faith. Understanding their narratives around depression helped with a deeper awareness of their mental health issues, which is essential for appropriate interventions. Promoting emotional expression among this population is crucial in improving mental health outcomes.

WEPED082

Perceptions regarding long-acting pre-exposure prevention (PrEP) among female sex workers and men having sex with men in San Pedro and Abidjan, Côte d'Ivoire

K.E.A. Kissi[1,2], J. Larmarange[3,4,5], R.-M. Dedocoton[1,2], M. Plazy[6,7,8], M. Nouaman[1,9], P.A. Coffie[1,9], S. Eholié[9], V. Becquet[10]

[1]Programme PAC-CI, Abidjan, Côte d'Ivoire, [2]Félix Houphouet Boigny, Ethno-sociologie, Abidjan, Côte d'Ivoire, [3]Ceped, Paris, France, [4]Université Paris Cité, Paris, France, [5]IRD, Paris, France, [6]University of Bordeaux, Bordeaux, France, [7]INSERM UMR 1219, Bordeaux, France, [8]IRD EMR 273, Bordeaux, France, [9]Félix Houphouet Boigny, Abidjan, Côte d'Ivoire, [10]Ined, Aubervilliers, France

Background: Demonstration studies showed that oral PrEP use and adherence can be complex among some populations, such as Female Sex Workers (FSWs) and men who have sex with men (MSM), especially due to their high mobility, unpredictable daily life or side effects. In this context, long-acting PrEP (currently at different stages of development), such as injectables, gel, implants, vaginal suppositories, vaginal/anal douching, or vaginal rings, may overcome some difficulties encountered with oral PrEP. This study aimed to explore the perceptions of these long-acting formulations among FSWs and MSM in Côte d'Ivoire.

Methods: Embedded within the ANRS 12381 PRINCESSE project, this qualitative sub-study was conducted in November-December 2023 within two community NGOs: Aprosam in San Pedro and Espace Confiance in Abidjan (FSWs and MSM). Overall, 32 FSWs (19 PrEP-naïve and 13 PrEP-experienced) and 12 MSM (3 PrEP-naïve and 9 PrEP-experienced) were interviewed (14 individual interviews, 5 focus groups).

A thematic analysis focused on practicality, discretion, autonomy/self-sufficiency, perceived efficacy, and anticipated side effects of the different formulations.

Results: Participants generally expressed favorable views toward long-acting PrEP, considered a less restrictive form than oral PrEP. Injections were particularly appreciated for discretion (no visible mark), with six-monthly injections preferred. Some concerns were expressed about injection pain. The gel, likened to a lubricant, was appealing for its dual protective and pleasurable function. However, some participants shared doubts about its effectiveness. Although the implant's long-acting time (1 year) was appreciated, they were not plebiscite due to a lack of discretion (scar) and anticipated potential side effects.

The autonomy and ease of use associated with vaginal suppositories were seen as advantageous, provided optimal hygiene conditions were met; the MSM drew a parallel with anal suppositories. Even though vaginal douching is widely practiced among FSWs, the intimate cleansing PrEP lotion received mixed reactions among them due to awareness of the risks of overuse. Lastly, the vaginal ring garnered little interest due to unfamiliarity with the product.

Conclusions: Overall, long-acting PrEP may offer alternative options for HIV prevention. Key elements include being easy to use, simplified follow-up (less often as possible), clear rules for start/stop, discretion, perceived effectiveness, and anticipated side effects.

Social, cultural, political, legal, environmental and structural determinants of health in different contexts

WEPED083

Effects of the Anti-Homosexuality Act on HIV service delivery in Uganda: evidence from community-led monitoring, 2022-2024

A. Nsubuga[1], F. Mugisha[1], B. Ajonye[2], K. Mwehonge[3], E. Lankiewicz[4], P. Drake[5], J. Kilande[3], A. Kayongo[6,7], A. Sharp[6,7,5]

[1]Sexual Minorities Uganda (SMUG), Kampala, Uganda, [2]International Community of Women Living with HIV - Eastern Africa (ICWEA), Kampala, Uganda, [3]Health Promotion and Social Development (HEPS), Kampala, Uganda, [4]amfAR, Andelson Office of Public Policy, Washington, United States, [5]Data, Et cetera, Washington, United States, [6]Georgetown University, O'Neill Institute for National and Global Health Law, Washington, United States, [7]Georgetown University, School of Public Health, Washington, United States

Background: In 2023, Ugandan enacted the Anti-Homosexuality Act (AHA), which included intensified criminal penalties for consensual same-sex relations, raising concerns for access to health services. While arrests, harassment, and violence have been reported, evidence of the AHA's impact on HIV healthcare delivery is limited.

Community-led monitoring (CLM) is an accountability mechanism that uses community-gathered evidence to advocate for improved healthcare access and quality, and is used to describe changes in access and quality of care.

Methods: Quantitative and qualitative data from the CLM programme in Uganda were used to identify changes in healthcare delivery and use related to the AHA. As

part of the CLM programme, routine survey data were collected from clients and managers in 448 public health facilities and drop-in centres (DICs). Survey data were analysed using a quasi-experimental statistical model to measure HIV services before and after AHA (2022-2024). Seven semi-structured individual interviews with DIC facility managers were conducted, coded, and analysed.

Results: In public health facilities and DICs, respondents identified as MSM declined significantly after AHA (4.4% to 2.8% and 22% to 11%, respectively). In facilities, all KPs reported high levels of discrimination.

After the AHA, MSM reported reductions in HIV-related services compared to other populations, including PrEP counselling (88% to 81%) and participation in support groups (64% to 47%). In DICs, all KPs experienced disruption to services.

Among MSM specifically, health facility referrals decreased from 65% to 44%, PrEP access from 80% to 48%, and those reporting easy DIC access declined from 96% to 68%. DIC managers described experiencing harassment and violence from community members, and staffing challenges due to AHA, which they responded to by leveraging partnerships with local and global allies, providing virtual services, and seeking accreditation as full-service clinics.

Conclusions: Data from the Uganda CLM programme provide an early view of the impact of the AHA on service delivery. While DICs and health facilities developed strategies to build resiliency and adapt, the AHA created significant barriers to care.

These findings provide empirical warnings of the barriers experienced by key populations when accessing healthcare services in a criminalised context.

WEPED085

"They go without informing us": applying mechanism mapping to identify heterogeneous pathways from clinic switching to HIV care discontinuity in rural Uganda

J.G. Rosen[1,2,3], N. Nakyanjo[4], W.G. Ddaaki[4], D. Isabirye[4], R. Nakubulwa[4], R. Kairania[4], F. Nalugoda[4], G. Kigozi[4], S.J. Reynolds[4,5,6], L.W. Chang[3,6], C.E. Kennedy[3], M.K. Grabowski[7], G. Nakigozi[4]

[1]Rhode Island Hospital, Division of General Internal Medicine, Providence, United States, [2]Brown University Warren Alpert Medical School, Department of Medicine, Providence, United States, [3]Johns Hopkins University Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [4]Rakai Health Sciences Program, Kalisizo, Uganda, [5]National Institute of Allergy and Infectious Diseases, Division of Intramural Research, Bethesda, United States, [6]Johns Hopkins University School of Medicine, Division of Infectious Diseases, Baltimore, United States, [7]Johns Hopkins University School of Medicine, Department of Pathology, Baltimore, United States

Background: Ubiquitous in African HIV treatment programs, clinic switching has been linked to poor viral load outcomes, especially among persons "silently" transferring or reinitiating care elsewhere without disclosing their antiretroviral therapy (ART) use histories. However, the mechanisms through which clinic switching precipitates HIV viremia are poorly understood.

Methods: In May-September 2022, we abstracted clinical records and conducted longitudinal in-depth interviews with 38 people exhibiting high-level HIV viremia (≥1000 RNA copies/ml), as well as interviews with 15 licensed clinicians and 6 focus group discussions with 47 lay peer health workers in public sector and non-governmental ART clinics across 3 south-central Ugandan districts (Kyotera, Masaka, Rakai).

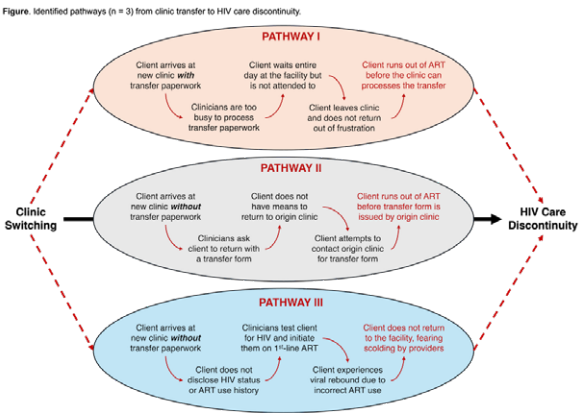
Following iterative thematic analysis, we constructed mechanistic maps to visualize the sequence/timing of processes, or "causal chains," through which clinic switching destabilizes HIV care continuity.

Results: Nearly half of interviewed persons living with HIV (median age: 34 years, 66% male) reported 1-3 ART clinic transfers since HIV diagnosis (median: 5 years), motivated by a constellation of forces, namely unpredictable occupational mobility, suboptimal care quality, provider mistreatment, privacy/confidentiality concerns, transportation-related challenges, and COVID-19 lockdowns.

Despite the presence of standardized clinic transfer protocols, clinician and peer narratives illuminated institutional constraints and disincentives to issuing or processing clinic transfers, including insufficient time and human resources; provider reticence to transfer clients with care attrition histories; and onerous documentation requirements for transfer paperwork.

Three distinct pathways from clinic switching to HIV care discontinuity emerged (*Figure*), each distinguished by the transfer mechanism (i.e., silent versus provider-led) and clients' (non-)disclosure or of their treatment status to destination/receiving facilities.

Figure. Identified pathways (n = 3) from clinic transfer to HIV care discontinuity.



Conclusions: We identified three discrete pathways from clinic switching to HIV treatment discontinuity, revealing heterogeneous drivers and mechanisms through which facility transfers (both provider-led and silent) resulted in delayed ART provision or care attrition altogether. Strategies to improve efficiencies in clinic transfer processes are urgently needed in Africa.

WEPED086

Examining the relationship between socioeconomic factors, opioid dispensing rates, and HIV prevalence in Appalachia

P. Oliva Pérez[1], A.T. Young[2], K. Keith[1], H. Arnold[3]
[1]Community Education Group, Operations/Grants, Lost River, United States, [2]Community Education Group, Executive, Lost River, United States, [3]Community Education Group, Lost River, United States

Background: Substance use disorders (SUDs) have profound implications across various aspects of daily life, with a strong association between SUDs and HIV, and other STDs (CDC, 2016). Appalachia is disproportionately affected by the nation's drug addiction crisis, with the 2020 overdose death rate for people ages 25-54 in the region being 72% higher than the rest of the country (ARC, 2023).
The present study aims to evaluate the influence of socioeconomic and healthcare access factors on two variables: the Opioid Dispensing Rate and HIV Prevalence Rate, in Appalachia.
Methods: The dataset comprises 2961 observations across 423 counties in the Appalachian region from 2016 to 2022, with 12 variables recorded at the county level. The analysis is performed using Python and R tools and AI techniques to refine the code. Missing values in particular variables are handled accordingly. A Random Forest model is used to analyze the relationship with the identified variables and HIV Prevalence Rate, while an Ordinary Linear Regression model explores the relationship between the Opioid Dispensing Rate and said variables.
Results: The Random Forest Model, with HIV Prevalence Rate as a dependent variable, presents an R-Squared of 0.514, explaining 51.4% of the variation of the HIV Prevalence Rate. Feature importance coefficients are calculated to determine the relevance of numerous factors in predicting the target variable. PCP rate (primary care physicians per 100 persons), the percentage of uninsured population and income inequality are found to be the most pertinent predictors.
The Ordinary Linear Regression Model shows that a 1-percentage point increase in the Poverty Rate is associated with an increase of 1.41 opioid prescriptions dispensed per 100 persons, and a 1-unit increase in income inequality is associated with an increase of 5.71 opioid prescriptions per 100 persons.
Interestingly, a 1-percentage point increase in high school graduation rates is associated with a 0.63 reduction in opioid prescriptions per 100 persons.
Conclusions: Together, these models allow the identification of factors beyond the health sector that are central for addressing the opioid crisis and HIV prevalence. Policy development to tackle these issues must also focus on increasing access to education and reducing economic inequalities.

WEPED087

Utilizing a Hope Framework to gauge perceptions of quality health care amongst women living with HIV and their healthcare providers in Rwanda

A. Bienvenue Ishimwe[1], W. Leonard[2], E. Chang[3], A. Gloria Uwitonze[1]
[1]TIP Global Health, Primary Care Research, Ruli, Rwanda, [2]TIP Global Health, Primary Care Research, Aptos, United States, [3]University of California, Los Angeles, Internal Medicine, Santa Monica, United States

Background: Inadequate antenatal care significantly increases maternal and child health risks, with the World Health Organization (WHO) estimating that 75% of maternal deaths are preventable through timely, quality healthcare interventions. Hope has emerged as a critical factor in healthcare, with healthcare recipients (HCRs) who feel hopeful demonstrating greater engagement and adherence to care plans, leading to improved outcomes. Similarly, hope reduces burnout among healthcare providers (HCPs), enhancing their capacity to deliver high-quality care.
This study explores the role of hope among women living with HIV and their HCPs, analyzing its three dimensions: interconnectedness (supportive relationships), readiness for change (willingness to adopt new behaviors), and future orientation (belief in positive outcomes).
Methods: This qualitative study was conducted in three district hospital catchment areas in Rwanda's Northern Province. Using a phenomenological approach, 28 focus group discussions (FGDs) and 23 key informant interviews (KIIs) were conducted with 141 HCRs (pregnant women and mothers of children under five), 84 HCPs, and 23 policymakers, researchers, and health facility managers. Data collection tools were guided by the Herth Hope Index-Kinyarwanda (HHI-K) and informed by the Capability, Opportunity, and Motivation-Behavior (COM-B) framework and the Health Belief Model. Audio recordings were transcribed, translated, and coded using Dedoose software to identify themes and sub-themes, with a sub-analysis for HIV-positive women.
Results: Three themes emerged: (1) supportive relationships foster trust and quality care; (2) continuous learning and communication drive readiness for change; and (3) HCP passion and work conditions influence future orientation. Trust in HCPs, mutual respect, and addressing prior trauma were key to fostering hope among women living with HIV. *Quote: "the way she welcomes you increases your strength and says; though I am sick and am not feeling well, I will get better, just because of how she welcomed me".*
Conclusions: Hope, defined by interconnectedness, readiness for change, and future orientation, is essential for behavior change and healthcare engagement, particularly for women living with HIV. Strengthening hope-driven interventions can enhance primary health systems, improve maternal and child health outcomes, and address the stigma and trauma experienced by high-risk populations. Governments must prioritize initiatives that empower HCPs to deliver trust-building, hope-inspiring care.

Community-engaged/participatory social science-based interventions

WEPED088

Using photovoice as a community-based participatory research tool to inform intervention development for young people's improved access to comprehensive sexual education and health services in Southern Zambia (2024)

G. Muchanga[1], K. Stoebenau[2], L.K. Mwango[3], C. Baumhart[4,5], C. Maambo[1], M. Mwale[1], B. Chimbala[3], M. Waitolo[3], J. Mwanza[3], C. Muleya[6], C.W. Claassen[1,4,5], L. Hachaambwa[3,5]
[1]Maryland Global Initiatives Corporation Zambia, Lusaka, Zambia, [2]University of Maryland College Park, College Park, United States, [3]Ciheb Zambia, Lusaka, Zambia, [4]Center for International Health, Education, and Biosecurity, University of Maryland School of Medicine, Baltimore, Baltimore, United States, [5]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, Baltimore, United States, [6]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Lusaka, Zambia

Background: In Zambia, adolescent girls and young women face heightened vulnerability to HIV due to socio-cultural, economic, and behavioral factors. Early sexual initiation, inadequate access to comprehensive sexual education (CSE), and entrenched discrimination based on sex, compound accessibility to comprehensive sexual education and health services.
We employed community-based participatory research to identify factors affecting adolescents and young people's (AYP) access to CSE and HIV prevention services.
Methods: In October 2024 our community participatory approach began by training 12 AYP (aged 18-24) from target communities in Southern Province as community-based researchers (CBRs). The CBRs were trained in qualitative research methods, including photovoice.
The research team partnered with CBRs to develop a photovoice project using the prompt: "*Take a picture that represents the reasons that might make young people feel uncomfortable or prevent them from accessing comprehensive sexual education and health services (CSEH) in your community*".
CBRs then worked with the team to recruit thirty AYP participants (aged 16-24) from the community and local schools, including some with hearing impairments, to each take and describe 1-2 photographs responding to this prompt. In total, 45 photographs were collected with accompanying descriptions.
Photos and captions were printed and analyzed by three teams of CBRs and research team members, first independently, and then jointly, to finalize main themes through group discussion and consensus.
Results: Five major themes emerged as factors preventing AYP from accessing CSE and HIV services:
i. Socio-Cultural and Religious Influences, encompassing stigma, myths and misconceptions, religious beliefs, and use of traditional medicine;
ii. Post Violence care-Related Barriers, highlighting post violence and sexual differences affecting young women;
iii. Knowledge and Awareness Deficits, encompassing limited understanding and awareness among AYP about CSEH services;
iv. Structural Barriers, including long distances to facilities, transport issues, delays in service delivery, and communication difficulties, particularly for hearing-impaired individuals;
v. Behavioral and Lifestyle Factors, including alcohol and substance use.
Conclusions: The photovoice participatory approach provided valuable insights into the challenges faced by AYP, fostered meaningful group participation, and effectively engaged participants with hearing impairments.
Our study revealed key barriers that can inform decision-making and improve targeted interventions for AYP, including those with hearing impairments on CSEH.

WEPED092

Leveraging digital health platforms to enhance HIV-related service access among youth in Zimbabwe: insights from the Youth Boost project

K. Choga[1], K. Webb[1], K. Takarinda[1], L. Gale[2], S. Moore[2]
[1]Organisation of Public Health Interventions and Development, Harare, Zimbabwe, [2]Avert, Brighton, United Kingdom

Background: Young people aged 10–24 face significant barriers to accessing HIV-related services, including stigma, lack of youth-friendly facilities, and limited health education. The Youth Boost project aimed to address these challenges by equipping community health workers with a digital job aid to deliver evidence-based HIV, sexual health, and mental health information, symptom screening and referrals to young people aged 10-24yrs in three provinces of Zimbabwe.
Our objective was to evaluate the effectiveness of the Boost platform in reaching and engaging young people, analyzing program reach, health screening outcomes and health-seeking behavior.
Methods: A mixed-methods approach was employed. Boost application screening data from April 2023 to December 2024, was analyzed to assess HIV, STI and mental health screening referrals. Endline surveys with 258 Community Health Workers captured knowledge, competencies, and health-seeking behavior changes. Focus group discussions (FGDs) explored feasibility and acceptability of application use and were analyzed thematically
Results: The Boost project reached 232,954 young people, the majority of whom were female (n=177,986; 76%) and 15-19 years (n=135,910; 58%). A total of 98,118 (42%) were referred for HIV testing, STI screening, or mental health services. Routine health facility data indicated a 30% increase in HIV testing uptake among young people during implementation of the program. FGDs with community health workers highlighted the importance of youth-friendly, confidential content in supporting youth engagement. In contrast, for 20-24-year-olds, gender sig-

nificantly influences HIV screening referrals (p = 0.014), and district remains a key factor in health-seeking behavior (p = 0.016).

Conclusions: The Boost digital job aid supported increased access to essential HIV testing, STI screening and mental health support among young people, particularly young women. These findings highlight the potential of integrated digital interventions in community-based programs to enhance health coverage. and have informed strategies for scaling Boost among community-based programming in Zimbabwe.

WEPED093

Using expressive ART therapy to empower indigenous and migrant communities affected by HIV: an analysis of PASAN's effect on women living with HIV

S. Shumba[1,2], A. Ngonyamo[3]

[1]Great Zimbabwe University, Sociology and Anthropology, Masvingo, Zimbabwe, [2]Prisoners with AIDS Support Action Network, Women Living With HIV, Toronto, Canada, [3]Young Advocates for Inclusion Network, Programs, Masvingo, Zimbabwe

Background: HIV-related stigma and discrimination disproportionately affect Indigenous and migrant women in Canadian reserves, creating barriers to healthcare, community integration, and self-expression. In response, PASAN (Prisoners' HIV/AIDS Support Action Network) introduced expressive art therapy sessions as a culturally responsive intervention to address these challenges. The program aims to empower women living with HIV by fostering emotional healing, enhancing self-esteem, and reducing stigma within their communities.

Through creative expression and community art projects, the initiative provides a safe space for participants to share their experiences, build resilience, and challenge stereotypes, promoting holistic well-being and social transformation in marginalized communities.

Description: The PASAN expressive art therapy program operates in Canadian reserves, targeting Indigenous and migrant women living with HIV who face significant stigma and discrimination. Over 12 months, the initiative integrates art-based workshops, community dialogues, and public art projects to promote emotional healing, reduce stigma, and foster social inclusion. Sessions are held in culturally responsive, safe spaces where participants engage in creating art, storytelling, and exhibitions to build resilience and challenge stereotypes.

A mixed-methods evaluation assesses the program's impact, including pre- and post-intervention surveys on stigma, self-esteem, and mental well-being, in-depth participant interviews capturing empowerment narratives, and community observations to identify shifts in attitudes toward HIV.

The program demonstrates a culturally grounded approach to transformative social change.

Lessons learned: The expressive art therapy program reduced stigma and enhanced self-esteem among Indigenous and migrant women living with HIV, fostering emotional well-being and community support. Through non-verbal expression and public art projects, participants gained confidence, built connections, and challenged stereotypes. Preliminary findings suggest increased self-confidence, reduced internalized stigma, and stronger social support networks, offering a culturally grounded, replicable framework to address systemic barriers and promote social transformation.

Conclusions/Next steps: The findings highlight the transformative potential of expressive art therapy in addressing stigma and fostering empowerment among marginalized women living with HIV. By improving emotional resilience, self-esteem, and community support, the program strengthens pathways to HIV prevention, treatment, and care.

Future initiatives should scale culturally responsive, art-based interventions to broader populations, emphasizing community engagement and integration into existing HIV support frameworks for sustainable impact.

WEPED094

Empowering health workers with AI: behavioral shifts and workflow impacts in HIV care

S. Morris[1], S. Frade[2], R. Mendonca[1], S. Cooper[1], S. Abdulrashid[3], M. Nedelman[4], E. Kathure[5], N. Mtshali[6], P. Potsane[6]

[1]Audere, Seattle, United States, [2]Audere Africa, Johannesburg, South Africa, [3]MyDawa, Nairobi, Kenya, [4]Maisha Meds, San Francisco, United States, [5]Maisha Meds, Nairobi, Kenya, [6]Shout-It-Now, Johannesburg, South Africa

Background: Integrating artificial intelligence (AI) into HIV programs could transform care delivery by improving diagnostic accuracy, supporting decision-making, and streamlining workflows.

We explore how AI tools shape differentiated service delivery models for HIV prevention and care, focusing on psychosocial and behavioral dynamics - specifically trust-building, workflow efficiency, and client-provider interactions.

Description: AI tools, such as large language models (LLMs) for conversational engagement, computer vision (CV) for diagnostic support, and predictive risk models were integrated into multiple AI-assisted programs to improve care delivery - a telehealth platform for HIV self-testing and PrEP/PEP delivery (MyDawa: Kenya), HIV testing and PrEP distribution (Maisha Meds: Kenya, Nigeria, Tanzania, Uganda), and a program for HIV education, virtual testing, and care linkage (Self-Care from Anywhere: South Africa).

In MyDawa and Maisha Meds, CV enhanced diagnostic accuracy by detecting subtle test indicators and providing real-time feedback, boosting health worker confidence. AI's accurate identification of true positive cases, including faint positives, strengthened trust in diagnostics and fostered collaboration between Health Care Workers (HCW) and AI systems. It also enabled clinical supervisors to efficiently audit clinician performance and target retraining, improving service delivery.

In incentive programs, AI streamlined claim processing through automation, allowing auditors to focus on claims requiring human oversight. LLM-powered tools deliver tailored guidance on HIV self-testing and care linkage, fostering user engagement and trust in healthcare systems. Predictive analytics empower health workers to make timely, data-driven decisions for appropriate care.

Lessons learned: AI enhances HCW confidence in decision-making and diagnostic accuracy. Preparing HWs to address client inquiries fosters trust and strengthens client-provider interactions. Efficiency optimizations allow QA auditors to prioritize nuanced investigations, supporting scalability without increasing personnel. Addressing psychosocial dynamics is crucial to position AI as a collaborative partner rather than a replacement.

Conclusions/Next steps: AI tools are poised to transform HIV care by augmenting human expertise and improving workflows. Future efforts should focus on optimizing AI platforms for speed and usability and seamless integration into workflows. Ongoing insights will inform strategies to scale AI-driven solutions while ensuring they enhance human-centered care.

WEPED095

Community advisory boards as pillars of community-engaged research: insights from the Africa Health Research Institute-South Africa

S. Mabuyakhulu[1], N. Majozi[1], B. Ngwenya[1], N. Ndlela[1], N. Myeni[1], W. Mbokazi[1], M. Ntombela[1], L. Zuma[1]
[1]Africa Health Research Institute, Public Engagement Unit, Mtubatuba, South Africa

Background: The Africa Health Research Institute (AHRI) prioritizes community-engaged research to address the health challenges faced by communities disproportionately affected by HIV. As a key mechanism to facilitate meaningful engagement, the Community Advisory Board (CAB) was established to ensure that research projects align with community needs and ethical standards.

This CAB initiative is guided by a constitution that outlines its structure, roles, and processes, emphasizing inclusivity, transparency, and representation. The CAB serves as a critical platform for fostering trust, disseminating knowledge, and empowering communities to actively participate in research.

Description: The AHRI CAB was constituted in accordance with a formalized process defined in its constitution, which emphasizes diverse representation from the community, including local leaders, health professionals, and civil society members. The constitution outlines the roles of CAB members, including providing input on research protocols, facilitating community engagement, and advocating for participant rights. CAB meetings are held monthly, supplemented by ad hoc consultations when urgent matters arise. Activities include capacity-building workshops, facilitated discussions on HIV prevention and care, and collaborative planning for community outreach events.

Lessons learned: The structured formation of the CAB, underpinned by a detailed constitution, has proven instrumental in fostering accountability and trust. Key lessons include the value of regular training for CAB members to navigate complex research topics and the importance of equitable representation in ensuring diverse community voices are heard. The CAB's involvement in planning outreach events has significantly improved community participation, with a high percentage of attendees reporting increased understanding of research and its impact.

Conclusions/Next steps: The AHRI CAB demonstrates the potential of structured community engagement to enhance the relevance and impact of HIV research. The constitutionally guided model provides a replicable framework for other institutions aiming to embed community voices in health research.

Future steps include expanding CAB membership to underserved areas, introducing digital platforms for broader participation, and conducting evaluations to measure the long-term impact of CAB-driven initiatives on research outcomes and community health.

WEPED096

Feasibility of integrating non-communicable disease management into HIV peer education at the community level in Rwanda

J. Ribakare Mutarutwa[1], D. Mutambuka[1], J.B. Tugirimana[1], M. Ribakare[2], I. Kamali[3]
[1]Rwanda Network of People Living with HIV/RRP+, Kigali, Rwanda, [2]WHO/Rwanda, Kigali, Rwanda, [3]Partners in Health/Rwanda, Kigali, Rwanda

Background: The extended life expectancy of people living with HIV (PLHIV), due to antiretroviral therapy(ART) has led to a rise of non-communicable diseases (NCDs) such as hypertension and diabetes. Addressing this dual health challenge necessitate integrated care approaches.

This study assessed the feasibility of incorporating NCDs management into the Rwanda's HIV peer educator (PE) model to enhance healthcare delivery of NCDs at community level.

Methods: A mixed-methods study, was conducted from October to November 2024, across purposively selected rural and urban health facilities in four provinces and Kigali city. The study included a questionnaire survey administered to 107 HIV peer educators (PEs) to assess their readiness to provide hypertension and diabetes management services.

Additionally, three focus group discussions (FGDs), each comprising 6–8 participants living with HIV and NCDs, and in-depth interviews with healthcare providers and program managers were conducted to explore barriers, facilitators, and opportunities for integrating NCD care into the HIV peer education model.

Results: The integration of NCDs care into Rwanda's HIV peer education model is feasible, with 89.7% of PEs expressing willingness to support PLHIV and 97.2% reporting high community acceptance. However, only 9.3% of PEs had received formal training on NCDs management, revealing significant knowledge gaps.

Gender and age differences were noted, with younger and female PEs reporting lower confidence levels. Lack of essential tools, such as blood pressure monitors and glu-

cometers were identified as critical needs. Despite these challenges, healthcare providers and program managers emphasized the potential benefits of integration with appropriate training, resource allocation and policy support.

Conclusions: Integrating NCDs care into the HIV peer education model in Rwanda is a feasible approach to improving health outcomes for PLHIV. The willingness of peer educators, coupled with high community acceptance, demonstrates the model's feasibility.

However, addressing gaps in training, resources, and service synchronization is essential for successful implementation. Targeted investments, policy-level support, and cross-sector collaboration are critical for scalability and sustainability.

WEPED097

The critical role of socio-economic support in addressing food insecurity among CLHIV households

D. Mwakyoma[1], G. Maro[1], M. Ndile[2], V. Mollel[2], J. Joshua[2], G. Kabendera[1], A. Mongi[2], P. Wilbroad[3]

[1]Evangelical Lutheran Church in Tanzania, 2 USAID Tanzania, Health Department, Arusha, Tanzania, the United Republic of, [2]Evangelical Lutheran Church in Tanzania, 2 USAID Tanzania, Arusha, Tanzania, the United Republic of, [3]USAID-Tanzania, Health Department, Dar es Salaam, Tanzania, the United Republic of

Background: USAID Kizazi Hodari (Brave Generation) is a child-focused and family-centred project implemented by the Evangelical Lutheran Church in Tanzania through USAID funding with the main goal of improving health, well-being and protection of Orphans and vulnerable children (OVC) and youth aged 0-17 years in HIV burden communities. During FY2024 (October 2023 to September 2024), the project in its central zone covering two regions (*Dodoma and Singida*) identified 133 CLHIV with persistent high viral load. Technical field review findings noted that, barriers and contributing factors to poor ART adherence were as follows: 72.9% household food insecurity, 20.2% poor parenting, 1.9% shortage of pediatric right drug regime, and 5% is other factors.

Description: Through the gaps identified causing persistent VL, the project developed comprehensive care plans for CLHIV and their families with need to address the underlying root causes. The project linked the CLHIV families with food insecurity to stakeholders providing food support, offered economic empowerment services, and developed household long-term plans for sustainability by linking them to Savings and Lending Groups for IGAs as well as other social support groups.

In addition, Faith community leaders were involved in mobilizing social and economic resources to support the families in need. OVC caregivers were capacitated with better parenting skills through trained project Community Case Workers (CCWs). Through collaboration with a clinical partner, proper quantification and ordering of the correct pediatric regimen were done to ensure adequate stock at catchment health facilities.

Lessons learned: 83 (62%) out of 133 CLHIV who are in age range of (0-17.5yrs) with persistent high viral load attained viral suppression by September 2024, ongoing collaborative efforts are in place to support the remaining CLHIV who are yet to attain Viral Load suppression. Key contributing factors to viral suppression was to address all social-economic barriers to proper ART adherence identified during household technical visits. The support was provided in a multi-disciplinary approach (*Community Case Workers, clinicians, ART Nurses, Social Workers, and OVC program coordinators*).

Conclusions/Next steps: The provision of ART services needs to be complemented with other supporting services to address social-economic barriers to attain Viral Load suppression

WEPED098

Engaging unreached men who have sex with men via Internet-based venues to participate in a mhealth-based HIV prevention trial in India: differences by online recruitment source and GIS analysis

N. Mutyala[1], J. Chaudary[1], V. Patel[2]

[1]The Humsafar Trust, Research, Mumbai, India, [2]Albert Einstein College of Medicine, Division of General Internal Medicine, Bronx, United States

Background: Despite the widespread use of internet-based socializing and dating platforms among gay, bisexual, and other men who have sex with men (GBM), strategies to effectively engage and retain GBM in HIV prevention programs and research remain unclear.

This study evaluates multiple diverse Internet-based recruitment strategies for reaching and engaging MSM reached through diverse online venues in an mHealth-based randomized controlled trial and examines differences in participant characteristics associated with these virtual venues.

Methods: Participants were recruited from April 2022-August 2023 in Mumbai/Thane, India. Participants were sexually active MSM aged ≥18 years, and not recently been tested for HIV. Community designed and implemented recruitment strategies (eg online paid promotions, community-based online influencers, and WhatsApp groups) were utilised to reach/engage participants.

Participants were grouped by source of enrollment as (1) social media (e.g., Instagram, Facebook), (2) messaging apps (e.g., WhatsApp) (3) dating apps (e.g., Grindr, Blued) and (4) Snowball.

Analyses compared these groups on demographics, sexual behavior, and HIV testing practices, with $P < 0.05$ considered significant. Latitude-longitude data were plotted on GIS maps using QGIS to check for distribution of the participants and conduct location-based analysis.

Results: A total of 1004 participants enrolled, with the most frequent online recruitment sources being dating apps (42%), messaging apps (33%), and social media (18%). Participant characteristics significantly differed by online recruitment source including by income, preferred language, consistent condom use, and internet use for

seeking sexual health information, (P<.05). Participants enrolled from social media (54%) reported lower HIV risk perception than dating apps (46%) and messaging app (41%) (P<.05) and higher U=U awareness (38% for social media vs. 24% for dating apps). Those from messaging apps had higher difficulty in accessing free HIV testing compared to Snowball (63% vs 5.3%, P<.05). GIS analysis revealed GBM participants came from throughout Mumbai/Thane with no 'hot spots.'

Conclusions: While dating apps had the most enrollment, multiple platforms and strategies are needed to ensure equitable reach of diverse MSM. Different online platforms engaged diverse eligible MSM; such information could be leveraged for tailoring outreach and engagement strategies for service delivery and research.

Key populations and other vulnerable populations: Behavioural, social, cultural, structural and multilevel issues, contexts and interventions

WEPED099

Developing and testing digital solutions to improve HIV prevention among GBMSM engaging in chemsex: a feasibility study grounded in users' lived experiences

C. Strong[1], P.A. Joson[1], P. Huang[2], C.-C. Chen[3], C.-W. Li[4], Y.-C. Tseng[5], T.-T. Chuang[1], H.-J. Wu[6], S.W.-W. Ku[7]
[1]College of Medicine, National Cheng Kung University, Public Health, Tainan, Taiwan, Province of China, [2]Institute of Health Behavior and Community Sciences, National Taiwan University, Taipei, Taiwan, Province of China, [3]The Know Marketing Ltd., Kaohsiung, Taiwan, Province of China, [4]Center for Infection Control and Department of Internal Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, Province of China, [5]AIMS Fellows, National Tsing Hua University, Hsinchu, Taiwan, Province of China, [6]The Kirby Institute, University of New South Wales, Sydney, Australia, [7]Division of Infectious Diseases, Department of Medicine, Taipei City Hospital Renai Branch, Taipei, Taiwan, Province of China

Background: Chemsex, involving substances like methamphetamine, GHB/GBL, and mephedrone among gay, bisexual, and other men who have sex with men (GBMSM), poses HIV and health concerns. Despite existing integrated care programs, service uptake remains low, highlighting a missed opportunity for self-help harm-reduction digital strategies.

This study employs a collaborative design approach, integrating insights from the community on the app prototype and assessed usability to guide future interventions.

Methods: The app prototype was built on two theoretical foundations: recovery as a continuum with evolving goals like harm reduction and temporarily not using, and harm reduction dimensions on drug-, sex-, and HIV-related harms. Features were integrated into UPrEPU, a user-centered app supporting HIV PrEP adherence through flexible dosing and personalized reminders. Users could set goals, such as reducing chemsex frequency, supported by tailored feedback. The app includes an emergency alert system, local resources for clean needles and HIV testing, and myth-busting for the chemsex community. GBMSM with recent chemsex experience tested the app between January-December 2024. A one-month evaluation followed using the mHealth App Usability Questionnaire (1–7 scale, lower score indicates higher usability) and a 30-minute interview to assess usability and impact. Interview transcripts were analyzed based on design themes to gather users' reflections and suggestions for enhancing harm reduction features.

Results: Twenty GBMSM aged 23–46 in Taiwan reported a positive perception of usability (mean=2.16, SD=1.14). However, users indicated that HIV PrEP functions were utilized more frequently than drug-related functions.

Dynamic goal setting should be more intuitive and tied to lived experiences, reflecting one's physical and mental state. Inadequate social support led individuals to adopt self-reliance strategies, such as tracking HIV PrEP uptake, setting hydration reminders, and prioritizing self-care. This extended to managing cravings, adhering to dosage limits, and achieving control over their health.

Users emphasized the need for tools to go beyond drug-related features, focusing instead on helping them plan their time and set broader life goals, supporting a more holistic approach to well-being.

Conclusions: A collaborative, user-centered approach to app design shows promise for digital solutions addressing chemsex-related harms, including HIV prevention, with functions closely tied to lived experiences and holistic well-being.

WEPED101

Sexualized drug use among transgender women with HIV from Argentina: the mediating role of psychological distress in the relation with multiple stigmas and sexual violence

P.D. Radusky[1,2], R. Caballero[1], E. Frontini[1], E. Panizoni[1], M.C. Trejo[1], C. Serrao[1], A. Zeltman[1], R. Acuña[1], N. Cardozo[1,3,4], M. Duarte[1,4], S. Fabian[1,5], B. Brunori[1], C. Perez[1], V. Zalazar[1], M.I. Figueroa[1], I. Aristegui[1]
[1]Fundacion Huesped, Research Department, Buenos Aires, Argentina, [2]Universidad de Buenos Aires, Faculty of Psychology, Buenos Aires, Argentina, [3]REDLACTRANS, Buenos Aires, Argentina, [4]Asociación de Travestis, Transexuales y Transgéneros de Argentina (ATTTA), Buenos Aires, Argentina, [5]Asociación Civil Gondolin, Buenos Aires, Argentina

Background: High prevalence of sexualized drug use (SDU, i.e., substance use before or during sex) among transgender women (TGW) may be fueled by the co-occurrence of multiple indicators, including diverse forms of stigma, violence and negative mental health outcomes. However, the mechanisms through which these factors interact remain less clear.

The present mediation analysis examined the role of psychological distress in the relation between transgender and HIV-related stigmas, sexual violence, and SDU in TGW with HIV from Buenos Aires, Argentina.

Methods: This study analyzed baseline data (collected between September/2019-December/2022) of 175 TGW with HIV, participating in TransCITAR, a prospective cohort study of 500 transgender and nonbinary individuals.

A generalized linear model (GLM) mediation was employed. SDU (dependent variable) was measured as use of one or more illicit substances (except cannabis) before or during sex in the last year. Independent variables were: transgender stigma (Transgender Stigma Brief scale's total score), HIV-related stigma (Berger's Scale total score) and sexual violence (at least one sexual violence episode in their lifetime from family members, sex work clients, police officers and/or partners). Psychological distress (Symptoms Check List 27 items' total score) was introduced as mediator.

Results: Participants' median age was 32 years old (IQR=27-38), 60.6% were sex workers, and 38.3%, migrants. Prevalence of SDU in the last year was 42.9%, being cocaine (66.7%) and ecstasy (8.1%) the most frequent substances. A substantial proportion (21.1%) reported at least one episode of lifetime sexual violence, primarily from sex work clients (29.5%) and police (29.5%).

The mediation model pathways were statistically significant: psychological distress mediated the relation between HIV-related stigma (β=0.144, CI=0.003/0.012, p<.001), transgender stigma (β=0.177, CI=0.009/0.032, p<.001), and sexual violence (β=0.358, CI=0.074/0.358, p=.003) with SDU. Higher levels of both stigmas and report of sexual violence were associated with higher psychological distress, which in turn was associated with increased SDU.

Conclusions: Results shed light on the syndemic relation of these indicators, especially highlighting the critical role of mental health. Stigma and violence continue to be the primary drivers of adverse mental and sexual health outcomes among TGW, and interventions from a trauma-informed, intersectional approach are required to mitigate their impact.

WEPED102

"I know they're going to weaponize this:" Black and Latino sexual minority men's mpox-related sexual behaviors, stigma concerns, and vaccination barriers and facilitators

O. Harris[1], D. Boyd[2], G. Rabiu Abu-Ba'are[3], J. Egbunike[1], M. Wharton[4]

[1]University of California, San Francisco, School of Nursing, Community Health System, San Francisco, United States, [2]The Ohio State University, College of Social Work, Ohio, United States, [3]University of Rochester, School of Nursing, Rochester, United States, [4]Us Helping Us People Into Living, Inc, Washington DC, United States

Background: The Mpox epidemic disproportionately impacted Black and Latino sexual minority men (BLSMM) in the United States, with them having the highest prevalence of disease and the lowest rates of vaccination. Despite this disparity, BLSMM perspectives on the disease, Mpox-related stigma, and inequitable rollout of and distrust in the Mpox vaccine are absent from the literature.

The present study aims to describe experiences with Mpox-related sexual behaviors, stigma, and vaccine barriers and facilitators among a sample of BLSMM living in both California and New York.

Methods: In this qualitative interpretive phenomenological study, we utilized semi-structured individual interviews as the primary source for data collection. Data was collected between August 2021 and December 2022 from 41 adult participants in California and New York. Interviews were recorded, transcribed verbatim, and analyzed using thematic content analysis.

Results: Participants ranged in age from 19-65 years, with the majority identifying as Black (73%) and male gender (93%). Overall, participants' narratives revealed that initial messaging around Mpox produced stigma parallel to the HIV/AIDS pandemic with many participants curtailing their sexual behaviors as a harm reduction strategy. Mpox-related stigma negatively impacted sexual minority communities both internally and externally.

Participants' narratives also revealed general vaccine skepticism due to existing medical distrust, negative vaccine experiences by other BLSMM, and lack of prioritization of outreach and distribution efforts in communities of color.

Conclusions: Alterations to vaccine administration protocols and outreach efforts for reasons identified in this study are critical to addressing disparities in vaccine uptake among BLSMM. Public health practitioners must consider equitable frameworks, existing stigmas, and medical distrust when engaging BLSMM.

WEPED104

Leaving no one behind: reaching disabled people living with HIV in Umzingwane District, Matabeleland South

J. Dube[1], T. Nhapi[2], S. Marambire[3], A. Chindore[1]

[1]Organization for Public Health Interventions and Development, Programs, Harare, Zimbabwe, [2]Organization for Public Health Interventions and Development, Harare, Zimbabwe, [3]Ministry of Health and Child care, Health, Esigodini, Zimbabwe

Background: Globally, approximately 15% of the population lives with disabilities, with Zimbabwe reporting a prevalence of 9.3%, or about 1.9 million people. Among them, people living with both HIV and disabilities face unique challenges due to stigma, discrimination, and systemic exclusion. Women and girls with disabilities are particularly vulnerable to acquiring infection and other forms of violence. The Sustainable Development Goals emphasize inclusivity and ensuring that no one is left behind, particularly regarding access to health services. In Umzingwane District, Matabeleland South Province, 11% of the population (8,330) are people living with HIV, including 165 individuals (2%) who also have disabilities. These clients have been categorized as bedridden (13), wheelchair bound (10), other physical disabilities (17), sen-

sory disabilities (55) and mental illness (70). Addressing the needs of this marginalized group requires innovative, tailored approaches.

Description: A collaborative effort involving the Ministry of Health and Child Care Rehabilitation Department and ZNNP+ identified people living with HIV and disabilities within healthcare facilities. A needs assessment was conducted for 165 clients, revealing gaps in service coverage. Tailored interventions included door-to-door visits for 40 clients unable to access clinical services, utilizing a "supermarket approach" to deliver comprehensive care. Services provided included viral load testing, ART refills, family planning, and pediatric HIV prevention.

Lessons learned: The initiative yielded significant outcomes, including viral load sampling for 27 of 30 eligible clients. Additionally, enhanced adherence counseling sessions were conducted for 2 of 3 clients. Four children who were due to PMTC FO follow up had EID samples collected for testing. Two pediatric contacts were tested for HIV, and both tested negative. A total of 27 clients received ART refills, and six women were initiated on family planning-control pills.

Conclusions/Next steps: This project highlights the importance of disability-inclusive HIV interventions. Tailored, person-centered approaches can successfully address the unique needs of people living with both HIV and disabilities. The inclusion of rehabilitation services within HIV care, particularly for women and girls, is critical to overcoming systemic barriers and ensuring equitable access to healthcare. Future initiatives must prioritize inclusive strategies to uphold the principle of leaving no one behind in the continuum of care.

WEPED105

"People who are still injecting drugs are the ones who need injectable PrEP the most:" Preferences for injectable PrEP among people who inject drugs in Kampala, Uganda

K. Beima-sofie[1], B. Kamusiime[2], W.W. Dlamini[3], A. Nalumansi[2], M. Figgatt[4,5], V. Kasiita[2], J. Kibuuka[2], P. Smith[5], R. Kansiime[6], T. Muwonge[2], P. Kyambadde[7,6], H. Kadama[7], P. Mudiope[7], S. Glick[3], B. Lambdin[8], A. Mujugira[2,1], R. Heffron[5]

[1]University of Washington, Department of Global Health, Seattle, United States, [2]Makerere University, Infectious Diseases Institute, Kampala, Uganda, [3]University of Washington, Department of Epidemiology, Seattle, United States, [4]Brown University Health, Providence, United States, [5]University of Alabama at Birmingham, Birmingham, United States, [6]Most-At-Risk Populations Initiative (MARPI), National STI Control Unit, Kampala, Uganda, [7]Ministry of Health, Kampala, Uganda, [8]Research Triangle International, San Francisco, United States

Background: Access to oral PrEP and adherence among people who inject drugs (PWID) have remained low. Injectable PrEP products may be more acceptable and feasible, and potentially improve uptake and persistence. Understanding PWID perspectives on injectable PrEP could inform strategies for larger scale implementation.

Methods: We conducted semi-structured interviews with 20 PWID in Kampala, Uganda enrolled in a clinical trial evaluating integrated delivery of PrEP and harm reduction services. All participants were experienced with oral PrEP and purposively sampled to capture variation in adherence. Local social scientists conducted interviews that were audio recorded, translated, and transcribed. We employed thematic analysis to characterize oral and injectable PrEP preferences and key influences on PrEP acceptability.

Results: Participants were highly enthusiastic about injectable PrEP; all but one preferred injectable to daily oral PrEP. Many participants expressed significant fears of HIV acquisition, believed PrEP was an important HIV prevention strategy, but described challenges remembering to consistently adhere to daily medication (Table).

Participants viewed injectable PrEP as different from injecting drugs, and were not concerned that injectable PrEP would influence drug injecting behaviors. Participants believed injectable PrEP overcomes barriers to pill-taking by minimizing stigma from traveling with pills or disclosing use to sexual partners.

Despite high acceptance and enthusiasm, many reported fears of needles, pain at injection site, and product scarcity and cost as concerns. Several wanted the option to switch between oral and injectable regimens depending on life circumstances.

Participants preferred injectable PrEP delivery in health facilities located close to their residence, and injections by healthcare providers because of existing trusting relationships. Participants were concerned about long intervals between injectable PrEP visits and suggested reminder calls to ensure adherence.

Influential Factors	Example Quotation
Memory negatively influences adherence to oral PrEP	"An injection is better because I will know that it is expiring after two months. But when you are taking the oral pills, you could forget to take it sometimes so it makes it ineffective in the body, so the [Cabotegravir] PrEP is far better."
PWID have significant fears of acquiring HIV	"You mentioned that the pain after getting injected is not that much so why would I choose to have a lifetime of pain (HIV) when I can endure this momentarily pain but be safe all through."
PrEP pills are confused as ART for HIV treatment and introduce stigma	"Those oral pills can give you away that you are taking pills; when I move with the pills and someone sees me taking the pills they might think (I have HIV) yet when I get the injection no one will know."
PrEP injections will not influence drug use by injection	"[T]his injectable PrEP is only administered once in 2 months so it will not remind [people who used to inject drugs] of anything. PrEP is even being injected on the buttocks and not any other part that they used to inject so there won't be any problem."
Counseling messages will play a key role in acceptability	"I think it will depend on the counseling message, before someone understands the goodness of injectable PrEP and also becomes aware of the after-effects which are not so serious."
Easy access to injectable PrEP delivery will improve uptake	"The easiest way is to get the services at the nearest center from where I reside."

Table: Key Influences on Acceptability.

Conclusions: Injectable PrEP products may be an effective strategy to improve HIV prevention access for PWID. Implementation programs scaling up injectable PrEP among PWID should focus on addressing needle and site reaction fears and ensuring delivery by trusted providers.

Key populations and other vulnerable populations: Behavioural, social, cultural, structural and multilevel issues, contexts and interventions

WEPED103

Enhancing supportive environments for key populations: advocacy strategies to mitigate stigma, discrimination, and violence among key affected groups through engagement with Sri Lanka law enforcement

J. Weragoda[1], J. Vidanapathirana[2]
[1]National STD/AIDS Control Programme, Multisectoral Unit, Colombo, Sri Lanka, [2]Ministry of Health, Colombo, Sri Lanka

Background: In Sri Lanka, the estimated adult HIV prevalence is less than 0.1%, with the highest rates among men who have sex with men (1.5%) and transgender women (1.4%). Key populations often face stigma, discrimination, and violence, increasing their HIV vulnerability and exposing them to wrongful arrests, harassment, and human rights violations. Misleading laws, such as the Vagrancy Ordinance and Penal Code Sections 365 and 365A, criminalize transgender sex workers and MSM.

The National HIV & STI Strategic Plan prioritizes creating supportive environments to reduce stigma, discrimination, and violence against key populations through advocacy with Sri Lanka Police.

Description: The NSACP conducted advocacy programs over the past decade targeting police officers across Sri Lanka to reduce stigma and promote inclusive policing practices. These programs focused on legal awareness and respect for human rights, particularly concerning men who have sex with men and transgender sex workers.

Consequently, two circulars were issued by Sri Lanka Police, providing guidelines on handling transgender individuals and prohibiting condom-related arrests, emphasizing that condoms cannot be used in court to prove sex work.

This framework institutionalized non-discriminatory practices and upheld the dignity of key populations. Additionally, a high-ranking police officer was designated to address key population matters, and Sri Lanka Police supports ongoing discussions to repeal these punitive laws.

Lessons learned:

1. **Advocacy drives positive changes:** Continuous education for law enforcement officers on gender identity, human rights, and public health significantly improved their understanding and attitudes toward KAPs.
2. **Policy endorsement reinforces Action:** The assurance of official circulars legitimized advocacy efforts.
3. **Collaboration yields Impact:** The partnership between the NSACP and Sri Lanka police facilitated trust-building and fostered a shared commitment to reducing stigma and discrimination.
4. **Challenges in Implementation:** Resistance to change and deep-rooted prejudices among some officers highlighted the need for sustained engagement and periodic evaluations to monitor progress.

Conclusions/Next steps: Advocacy programs demonstrated their potential to transform attitudes and practices within law enforcement, creating a supportive environment for KAPs. it is essential to:

- Institutionalize regular training for new recruits and existing officers.
- Strengthen monitoring mechanisms to ensure adherence to circulars and guidelines in collaboration with community stakeholders

Mental health and well-being interventions, programmes and models

WEPED106

Sexual satisfaction in HIV-serodiscordant men-who-have-sex-with-men couples: a dyadic approach

E.G.-Y. Chai[1], D. Huang[2], C.-W. Li[3], S.W.-W. Ku[2], P. Huang[4], C. Strong[1]
[1]College of Medicine, National Cheng Kung University, Public Health, Tainan, Taiwan, Province of China, [2]Division of Infectious Diseases, Department of Medicine, Taipei City Hospital Renai Branch, Taipei, Taiwan, Province of China, [3]Center for Infection Control and Department of Internal Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, Province of China, [4]Institute of Health Behavior and Community Sciences, National Taiwan University, Taipei, Taiwan, Province of China

Background: Although U=U is a widely accepted concept, the anxiety and stigma associated with HIV still impact the sexual satisfaction of HIV serodiscordant couples. There is limited research on how sexual satisfaction affects the quality of relationships in this group.

This study examined the individual and cross-partner associations of sexual satisfaction on relationship satisfaction among HIV serodiscordant couples using a dyadic approach. We explored whether sexual satisfaction differed between people living with HIV and their HIV-negative partners.

Methods: This cross-sectional study included 50 HIV-serodiscordant men-who-have-sex-with-men couples recruited between May 2019 and December 2020 at outpatient clinics. Participants completed the New Sexual Satisfaction Scales, a self-report tool assessing sexual satisfaction across three dimensions: ego-focused, sexual activity-centered, and partner-focused. The association between sexual satisfaction and relationship satisfaction was analyzed using two-step hierarchical regression.

In the first step, the participant's own sexual satisfaction score predicted relationship satisfaction. In the second step, both the participant's and their partner's sexual satisfaction scores were included.

Results: Participants were aged 20 to 56 years. All participants living with HIV had an undetectable viral load. Among HIV-negative participants, 46% were using PrEP.

No significant differences in sexual satisfaction were observed between people living with HIV and their partners. For both groups, partner-centered sexual satisfaction was the only factor significantly associated with relationship satisfaction (β = 2.012 in the first step and β = 1.932 in the second step for people living with HIV; β = 2.154 in the first step and β = 2.096 in the second step for HIV-negative partners).

	Relationship satisfaction			
	People living with HIV (n = 50)		HIV-negative (n = 50)	
	β	t	β	t
Step 1				
[Self] Ego-focused	-0.103	-0.111	-0.327	-0.368
[Self] Sexual activity-centered	-0.802	-1.154	-0.269	-0.281
[Self] Partner-centered	2.012	3.214**	2.154	2.496*
R^2		0.215		0.160
Step 2				
[Self] Ego-focused	-0.012	-0.012	0.567	0.534
[Self] Sexual activity-centered	-0.823	-1.024	-0.956	-0.932
[Self] Partner-centered	1.932	2.583*	2.096	2.381*
[Partner] Ego-focused	0.066	0.071	-1.029	-0.888
[Partner] Sexual activity-centered	0.171	0.192	1.706	1.847
[Partner] Partner-centered	-0.070	-0.092	-0.549	-0.639
R^2		0.216		0.222
ΔR^2		0.002		0.063
F value		0.032		1.156

*p < .05; **p < .01. [Self]: Participant's own score. [Partner]: Partner's score.

Table. Individual and cross-partner associations of sexual satisfaction on relationship satisfaction using two-step hierarchical linear regression.

Conclusions: Regardless of one's HIV status, partner-centered sexual satisfaction—how one perceives their partner's sexual satisfaction—is the most important factor determining relationship satisfaction. This finding highlights the importance of fostering open communication and mutual understanding about sexual needs and satisfaction to strengthen relationship quality, regardless of HIV status.

WEPED107

High burden of mental health disorders among adolescents and young people living with HIV (AYPLHIV) in Nigeria: a cross-sectional study

M.-M. Akanmu[1], N. Otubu[1], O. Adewole[1], O. Nwobi[1], V. Nwakolobi[1], N. Ahmad[1], A. James[1], A. Mustapha[1], J. Drakes[2], S. Dowling[2], A. Carmone[2], C. Amole[2], O. Fasawe[1], T. Ojo[3], E. Duru[3], R. Oyewole[3], G. Ogunleye[3], E. Etiobhio[4]
[1]Clinton Health Access Initiative, Nigeria, Abuja, Nigeria, [2]Clinton Health Access Initiative, Boston, United States, [3]National Mental Health Programme, Abuja, Nigeria, [4]National HIV and STIs Control Programme, Abuja, Nigeria

Background: Nigeria faces a significant mental health (MH) burden, with adolescents and young people living with HIV (AYPLHIV) experiencing disproportionately higher rates than their peers without HIV (34.9% vs. 23.1%). Poor MH complicates access and adherence to HIV care, worsening outcomes. With 50% of mental illness beginning by age 14 and 75% by 24, the 171.5k AYPLHIV in Nigeria, including key populations (KPs) in that age group, are particularly vulnerable. In 2024, Nigeria, with CHAI's support, became one of the first countries to adapt and implement the WHO Mental Health Gap Action Programme-3.0 (mhGAP) to address MH service gaps with non-specialists. However, limited data on MH burden hinders resource allocation and scale-up. This cross-sectional study estimates point-prevalence of common MH disorders among AYPLHIV in Nigeria.

Description: MH screenings for adolescents aged 12-24 were integrated into routine services at ART clinics and One-Stop-Shops (OSS) for KPs across 22 facilities in six high-burden HIV states, representing each of Nigeria's geopolitical zones. Screenings using the Patient Health Questionnaire (PHQ-9) and the Generalized Anxiety Disorder (GAD-7) for depression and anxiety, were conducted by 93 trained HIV cadres. Data was recorded in CommCare. Positive screening scores were used as proxies for point-prevalence and severity classification among AYLPHIV and sub-populations, allowing comparison.

Lessons learned: From June to December 2024, 1,423 AYPLHIV were screened after MH talks. This initial data shows 38% screened positive for depression, 19% for anxiety, and 16% for both. Cases were mostly mild: 30% mild 5% moderate, 2% moderately severe, and 1% severe for depression, and 14% mild, 4% moderate, and 1% severe for anxiety. Anxiety was significantly higher in females (23%) than males (17%) [z=2.847, p=0.0044]; depression showed no gender differences. Depression prevalence increased with age: 12-14 (24%), 15-19 (27%) and 20-24 (46%). KPs had higher depression [z=9.014, p=<0.0002] and anxiety [z=3.240, p=0.0012] rates compared to others.

Conclusions/Next steps: These findings confirm the high burden of depression and anxiety among AYPLHIV in Nigeria, with a higher prevalence of anxiety in females, and depression in older AYPLHIV, and KPs, providing insight into the need for MH and HIV services integration for AYPLHIV in Nigeria.

WEPED108

Integrating and optimizing Mental Health and Psychosocial Support Services (MHPSS) in key populations HIV program through cART outreaches: lessons from Ondo State under the αCARES Project

O. Onumara[1], O. Amoo[1], K. Wudiri[1], O. Ibiloye[1], M. Oluwasemire[1], K. Ezechiedo[1], P. Jwanle[1], I. Onwuatuelo[1], S. Jay Osi[1], P. Okonkwo[1]
[1]APIN Public Health Initiatives, Continuum of Care, Abuja, Nigeria

Background: Key Populations (KPs) are disproportionately affected by the dual burden of HIV and mental health (MH) challenges, worsened by stigma, discrimination, and systemic barriers to care. Integrating Mental Health and Psychosocial Support Services (MHPSS) into HIV programs is crucial for improving comprehensive care.
This study evaluates the effectiveness of cART outreaches in delivering MHPSS to KPs compared to alternative integration models, using data from Ondo State under the αCARES Project.

Description: The study utilized data from cART outreaches conducted between July and September 2024, involving Female Sex Workers (FSW), Men who have Sex with Men (MSM), Transgender persons (TG), and People Who Inject Drugs (PWID). Comparative analysis was performed against facility-based and peer-led approaches over the same period. Key metrics included the number of KPs screened, eligibility for MHPSS, diagnoses (depression, anxiety, substance use), referrals, and follow-up return rates.

Lessons learned: cART outreaches screened 1,007 KPs, with 875 eligible for MHPSS, compared to 433 screened and 355 eligible in facility-based and peer-led approaches. First-line psychosocial support was provided to 742 KPs through cART outreaches, significantly higher than the 577 supported through other methods. Referrals for further assessment were also higher in cART outreaches (216 vs. 186). Diagnoses of depression (89 vs. 82), anxiety (128 vs. 77), and substance use (86 vs. 142) varied, with cART outreaches showing higher rates for depression and anxiety but lower for substance use. Follow-up return rates were notably higher in cART outreaches (60% vs. 34%).

Conclusions/Next steps: The αCARES Project highlights the feasibility and effectiveness of integrating MHPSS into HIV programs for KPs. cART outreaches demonstrated superior effectiveness in screening, providing MHPSS, and ensuring follow-up among KPs compared to facility-based and peer-led approaches. The higher engagement and return rates suggest that it offer a more accessible and stigma-free environment for KPs.

These findings support scaling up cART outreaches as a viable model for integrating MHPSS into HIV programs, addressing critical MH needs, and improving overall health outcomes for KPs.

WEPED109

Enhancing mental health support systems through empowering peer providers with improved screening techniques

K. Matyanga[1], L. Kandengwa[1], C. Chigamba[1], C. Shava[1], L. Gandaumanje[1], K. Muchirawehondo[1], V. Chitiyo[1], A. Mutsinze[1], M. Mawodzeke[1], N. Willis[1]

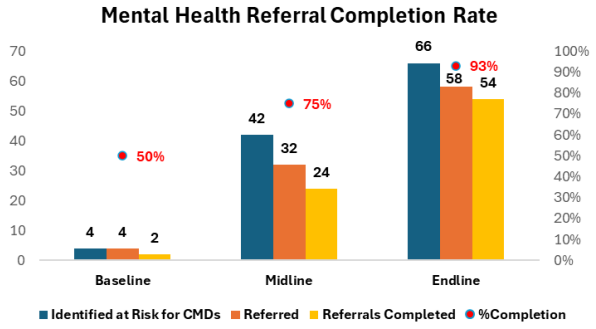
[1]Zvandiri, Programs, Harare, Zimbabwe

Background: Young Peer Providers, with lived experiences of HIV treatment and mental health issues, are uniquely equipped to provide empathetic and relatable support. Their roles include facilitating peer counselling sessions, mental health screening and literacy, and encouraging help-seeking behaviours. These efforts reduce stigma and create safe spaces for mental health discussions. Collaboration between Peer Providers and mental health nurses is often weak, resulting in incomplete referrals leading to worsened mental health outcomes.

Description: In September 2024 a a two-day training for 19 Peer Providers (Community Adolescent Treatment Supporters), 10 Health Care Providers from four Health Facilities in two districts, 2 specifically being mental health nurses, focused on effective mental health screening tool administration, interpretation, and reinforced referral pathways. Training clarified roles and referral processes. Weekly data updates and referral tracking meetings done after the training identified emerging challenges and reduced barriers in completing referrals in real time.

Lessons learned: Screening rate by Peer Providers improved from 10% 105 (63F:42M)/1,011 at baseline in August 2024 to 73% 801/1,093 (502F:299M) by December 2024, with intensive support. Identification of those at risk of common mental health conditions (CMC) increased from 4% to 8%.

Completion rate of referrals by mental health nurses rose from 50% to 93%, demonstrating success of enhanced collaboration. Effective collaboration between peer providers and healthcare workers is essential for smooth referral processes. Prioritizing mental health is integral part for compassionate healthcare systems and aids in improved outcomes.



Conclusions/Next steps: Peer providers work effectively when they are embedded in a supportive health system, training in mental health screening boosts identification of CMCs and referrals rate, improving HIV and mental health outcomes.

Continuous monitoring and capacity building enhance service quality. Collaboration between peer providers and mental health nurses fosters sustainable support systems tailored to young people's needs.

WEPED110

Prevalence and correlates of depression and anxiety among adolescents and young adults living with HIV in Western Kenya: social support, violence, drug use, and stigma as key determinants

S. Hicks[1], W. Jiang[2], J. Kibugi[3], J. Badia[3], B.A. Richardson[2,4], K. Agot[3], P. Kohler[2,5], G. John-Stewart[1,2,6]

[1]University of Washington, Epidemiology, Seattle, United States, [2]University of Washington, Global Health, Seattle, United States, [3]IMPACT Research & Development Organization, Kisumu, Kenya, [4]University of Washington, Biostatistics, Seattle, United States, [5]University of Washington, Child, Family, and Population Health Nursing, Seattle, United States, [6]University of Washington, Medicine - Allergy and Infectious Disease, Seattle, United States

Background: Adolescents and young adults living with HIV (AYLHIV) are at increased risk for common mental disorders (CMDs). There are few longitudinal studies comparing risk factors of CMDs among AYLHIV.

Methods: This analysis used data from the *Data-Informed Stepped Care* study (DiSC; NCT05007717), a cluster randomized trial in 24 facilities across three counties in Western Kenya. Depression (Patient Health Questionnaire [PHQ-9]) and anxiety (Generalized Anxiety Disorder-7 [GAD-7]) were measured every 6 months for 1 year. Correlates of CMDs were assessed using generalized linear mixed effects Poisson models, clustered by facility.

Results: Of 1,904 AYLHIV, baseline prevalence of mild depression (PHQ ≥5) was 8.3% (age subsets: 2.2% 10-14 yrs, 8.4% 15-19 yrs, 15.0% in 20-24 yrs) and mild anxiety (GAD-7 ≥5) was 3.7% (0.4% 10-14 yrs, 3.5% 15-19 yrs, 8.0% 20-24 yrs); prevalence of CMDs decreased significantly during 12-month follow-up (depression PR=0.48 95%CI: 0.36-0.64; anxiety PR=0.37, 95%CI: 0.24-0.59) and in age-subsets of 15-19 and 20-24 year olds (Figure 1).

In longitudinal models, among 15-19 year olds, low social support (PR=2.68, 95%CI: 1.41-5.11), violence (PR=4.66, 95%CI: 3.18-6.84), substance use (PR=3.17, 95%CI: 1.98-5.08), stigma (PR=2.61, 95%CI: 1.82-3.75), and having a sexual partner (PR=3.42, 95%CI: 2.41-4.86) were associated with increased risk of depression; being enrolled in school (PR=0.26, 95%CI: 0.18-0.37) and vertical HIV acquisition (PR=0.43, 95%CI: 0.28-0.64) were associated with lower risk.

Only social support influenced depression risk in 10-14 year olds, while stigma, violence, and substance use were associated with depression in 20-24 year olds. Correlates of anxiety were similar to depression with differences between age categories (Figure 1).

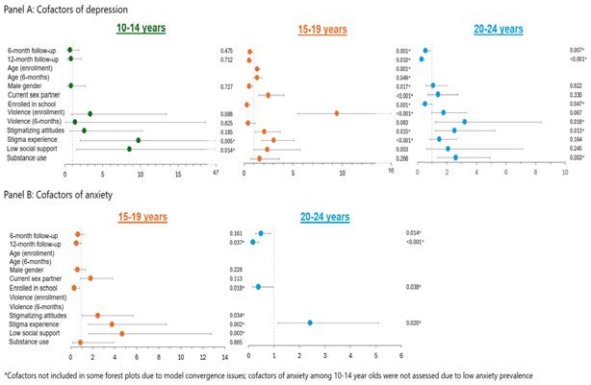


*Figure 1. Cofactors of depression and anxiety stratified by age**

Conclusions: In this cohort of AYLHIV, prevalence and correlates of CMDs differed in age-strata. Lack of social support, violence, stigma, and substance use were associated with depression and anxiety, particularly among older AYLHIV. Mental health strategies in AYLHIV programs may benefit from age-tailored approaches.

Gender, sexuality and sexual cultures: Meanings, identities, norms and interventions

WEPED111

Sexual behaviors and STI risk in transgender men and non-binary identities from the TransCITAR cohort in Argentina

E. Frontini[1], R. Caballero[1,2], E. Panizoni[1], M.C. Trejo[1], C. Serrao[1], A. Zeltman[1], R. Acuña[1], P.D. Radusky[1,2], N. Cardozo[1,3,4], M. Duarte[1,4], S. Fabian[1,5], B. Brunori[1], C. Pérez[1], V. Zalazar[1], M.I. Figueroa[1], I. Aristegui[1], TransCITAR Study Group

[1]Fundación Huésped, Research Deparment, Ciudad Autónoma de Buenos Aires, Argentina, [2]Universidad de Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina, [3]REDLACTRANS, Ciudad Autónoma de Buenos Aires, Argentina, [4]Asociación de Travestis, Transexuales y Transgénero de Argentina (ATTTA), Ciudad Autónoma de Buenos Aires, Argentina, [5]Asociación Civil Gondolín, Ciudad Autónoma de Buenos Aires, Argentina

Background: HIV and STI risk, and preventive behaviors among transgender masculinities and nonbinary people (TGMNB) have been understudied. This study explored these variables among TGMNB participating in TransCITAR, a prospective cohort study that follows the physical and psychosocial health of 500 transgender and nonbinary people in Buenos Aires, Argentina.

Methods: Between September 2019-September 2022, 61 TGMNB completed baseline psychosocial questionnaires, collecting information on socio-demographic variables, gender identity, sexual behaviors, substance use, and HIV and STIs testing. Descriptive statistics were used to summarize data.

Results: Median age was 26 years (IQR: 21-30), 50.8% had incomplete university or higher, 47.5% were unemployed, 27.9% had private or employer-provided health insurance. Participants identified as: trans men (39.3%), men (24.6%), nonbinary (19.6%), and transmasculine (14.8%).

Diverse sexual orientations were reported: heterosexual (39.3%), pansexual (18%), bisexual (16.4%), homosexual (9.8%), and asexual (3.3%). In the last month, 35.3% reported sex with cisgender women, 9.8% with cisgender men, 9.8% with transgender men, 9.8% with transgender women, and 5.9% with nonbinary people.

Almost half (42.6%) reported not using any HIV or STI preventive method in the last sexual relationship. Among those who did use, 31.1% used condoms, and 13.1%, dental dam. Only 25% would be willing to use PrEP.

Also, 7.8% reported ever engaging in transactional sex, and 21.3% reported use of alcohol or illicit substances before or during sex in the last month. While 67.2% TGMNB had an HIV test in the last year; 18% had never tested. The main reasons were: not considering themselves at risk (54.5%) and lack of opportunity/never been offered (18.2%).

Conclusions: TGMNB showed low engagement in safer sexual behavior, limited willingness to use PrEP and low perception of HIV/STI risk. These perceptions combined

with the high variability of sexual orientations and behaviors, and healthcare providers' failure to offer testing and preventive options, contribute to gaps in HIV prevention implementation. Further research is needed to design culturally sensitive HIV and STI prevention interventions for TGMNB.

WEPED112

Breaking the silence: exploring the lived experiences of intersex individuals in Tanzania's sociocultural context

M. Robert Mhando[1], A. Franky Mmbando[2], K. Mvungi Mbonea[3], A. Saidi Likule[3], L. Kilala[4], O. Kaffana[5], B. John[6]

[1]GABINET-Research Initiatives Organization (RIO), Public Health-Key Population, Dar Es Salaam, Tanzania, the United Republic of, [2]GABINET-Research Initiatives Organization (RIO), Public Health-Gender Diversity, Dar Es Salaam, Tanzania, the United Republic of, [3]Fine Art for Community Empowerment (FACE), Transgender and Intersex, Tanga, Tanzania, the United Republic of, [4]GABINET-Research Initiatives Organization (RIO), Gender Desk and HIV Prevention, Care and Treatment, Mwanza, Tanzania, the United Republic of, [5]Fine Art for Community Empowerment (FACE), Young KPs PLHIV, Tanga, Tanzania, the United Republic of, [6]Tanzania Voice of Humanity, Intersex Led Organization, Dar Es Salaam, Tanzania, the United Republic of

Background: This programme aimed to explore and address the challenges faced by intersex individuals in Tanzania, focusing on medical interventions, societal stigma, and access to safe spaces.

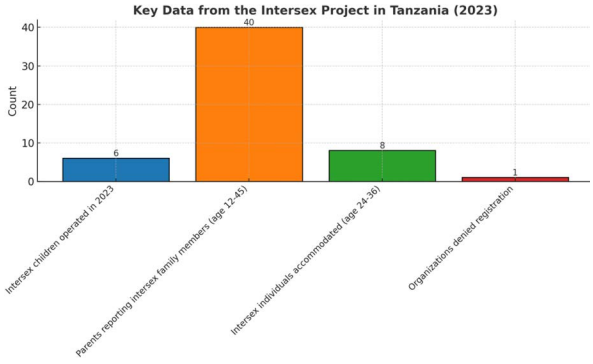
The objectives were to document the prevalence of non-consensual surgeries, understand the needs of intersex individuals, and provide support through safe accommodation and advocacy. The scope included improving awareness and promoting policy changes to protect intersex rights.

Description: In 2023, a project in Tanzania, supported by the Tanzania Safety and Security Taskforce for LGBTIQ (TSST), focused on addressing challenges faced by intersex individuals and their families. Key interventions included community outreach, safe housing, and legal advocacy.

During this period, more than six intersex children underwent non-consensual surgeries in health facilities, exposing the urgent need for healthcare reforms. Over 40 parents reported having intersex family members aged 12 to 45, highlighting the issue's wide-reaching impact. The TSST safe house provided temporary shelter and psychosocial support to eight intersex individuals aged 24 to 36. Additionally, an organization advocating for intersex rights faced registration denial and had to register under the disability category.

Lessons learned: The programme exposed gaps in healthcare, with non-consensual surgeries causing lasting harm. Lack of legal recognition perpetuated stigma and hindered advocacy. The safe house provided essential refuge but faced resource limitations, underscoring the need for sustainable solutions.

Community engagement revealed the importance of educating families to challenge harmful norms and support intersex individuals, highlighting the urgency for systemic reforms and increased resources.



Conclusions/Next steps: Healthcare reforms are urgently needed to end non-consensual surgeries and ensure ethical practices. Advocacy should prioritize policy changes to protect intersex individuals' rights.

Expanding safe housing and providing psychosocial and economic support are vital for reducing stigma and improving HIV care. Collaboration among healthcare providers, policymakers, and communities is essential.

Implementation research to scale up HIV testing

WEPEE113

Exploring barriers and facilitators of pediatric HIV services delivered via UNICEF's service delivery framework in Mozambique, Nigeria and Uganda

S. Nakubulwa[1], G. Nanyonjo[2], C. Osa-Afiana[3], H. Cossa[4], P. Kukundakwe[1], G. Basalirwa[2], R. Mulebeke[1], B. Mukasa[1], N.A. Sam-Agudu[3,5], B. Okech[2]

[1]Mildmay Research Centre Uganda, Kampala, Uganda, [2]Uganda Virus Research Institute - International AIDS Vaccine Initiative (UVRI-IAVI) HIV Vaccine Program, Entebbe, Uganda, [3]International Research Center of Excellence, Institute of Human Virology Nigeria, Abuja, Nigeria, [4]Manhiça Health Research Centre (Centro de Investigação em Saúde de Manhiça, (CISM), Manhiça, Mozambique, [5]Global Pediatrics Program and Division of Infectious Diseases, Department of Pediatrics, University of Minnesota Medical School, Minneapolis, United States

Background: Globally, of the estimated 1.4 million children living with HIV (CLHIV), 86% are resident in African countries. To tackle HIV service delivery gaps among CLHIV, the Pediatric Breakthrough Partnership (PBP) of local agencies and Non-Governmental Organizations implemented the Service Delivery Framework (SDF) in Mozambique, Nigeria and Uganda. The SDF was developed with the leadership of UNICEF to improve pediatric HIV Service delivery.

We present summative qualitative findings from the SDF evaluation to inform scalability of its strategies in similar contexts.

Methods: The SDF strategies focus on Locating, Linking, Treating and Retaining CLHIV. The evaluation was performed from January 2021-December 2023 in Uganda (Mubende and Isingiro Districts), Mozambique (Masinga and Morrumbene Districts) and Nigeria (Taraba and Rivers states).

Qualitative interview guides were designed with the Consolidated Framework for Implementation Research (CFIR), focusing on determinants of pediatric HIV service delivery in the Outer Setting (e.g. patient needs/resources, organizational operations) and Implementation Process domains. Nineteen focus group discussions, 56 in-depth interviews and 41 key informant interviews were conducted among PBP representatives, national, sub-national stakeholders, health-facility and community representatives, users of pediatric HIV services who consisted of adolescents, parents and caretakers. Transcripts were analyzed using NVivo v14.

Results: One hundred ninety-one participants, 102(53%) female, 89(47%) male, were interviewed. Barriers to pediatric HIV service utilization and adherence included: Few community-level health professionals; long distance to, and lengthy waiting time at health facilities, food insecurity, low income of caregivers affecting transport affordability, poor HIV awareness and knowledge among caretakers.

Facilitators included one-stop stations that reduced facility waiting time; community mobile brigades for easier access to HIV testing and treatment, promoting Community Savings and Loans Associations, PBP technical assistance to local government, PBP incorporating annual work plans at health facilities for timely service delivery, joint planning and collaborative approaches to avoid duplication of services and wastage of resources.

Conclusions: Our three-country SDF evaluation identified individual, community, and system-wide Outer Setting and Implementation Process barriers to pediatric HIV service delivery.

We identified that SDF could facilitate learning collaborative approaches, one-stop shops, community outreaches and income-boosting innovations essential for scaling up pediatric HIV services in similar settings.

WEPEE114

Effectiveness and cost of community-based dried blood spot sample collection for early infant diagnosis in Angola

W. Reidy[1], S. Saito[1], H. Liu[1], A. Dias[1], L. Chauca[1], R. Nunes[1], M.L. Furtado[2], B. Pocongo[2], M.d.R. Marques[2], F.L. Velho[1], F. Manuel[1], R.C. Branco[3], T. Soraya[2], G. Manuel[2], A. Macama[4], R. Fayorsey[1]

[1]ICAP at Columbia University, New York, United States, [2]INLS, Luanda, Angola, [3]AFENET, Luanda, Angola, [4]USAID, Luanda, Angola

Background: In Angola, 14% of infants perinatally exposed to HIV (IEH) received an Early Infant Diagnosis (EID) by 2 months of age in 2023. Community-based Dried Blood Spot (DBS) collection was piloted to improve time to first EID test in hard-to-reach communities in selected PEPFAR-supported health facilities (HF).

Methods: In collaboration with the National AIDS Institute, the Reaching Impact Saturation and Epidemic Control Program funded by United States Agency for International Development implemented the pilot at two HF with the lowest EID coverage at two months in Huambo province.

Pregnant and lactating women living with HIV receiving prevention of vertical transmission services were given the option to have the first EID sample collected at home by trained community counselors or bring the infant back to the HF. Two HF with similar EID coverage were used as control HF.

We used survival analysis to determine coverage and average times to first EID sample collection pre-intervention (January-March 2024) and post-intervention (April-July 2024). Unit cost/DBS collected were calculated, tallying training, supervision by program and laboratory staff, supplies and transportation costs.

Results: Pre-intervention, EID coverage at 2 months and average time for first EID sample collection were similar in the intervention [(21/30;70%) and 62 days] and control HF [(18/26; 69%) and 50 days] (p=0.9360; p=0.4927). Post-intervention, coverage at 2 months at the intervention HF increased to 94% (34/36) and remained unchanged at control HF at 72% (21/29) (p=0.0146); time to first EID sample decreased at intervention HF (35 days) and remained unchanged (50 days) at control HF (p=0.0004). Intervention start-up costs were estimated at $201/DBS collected while routine costs were $19/DBS collected.

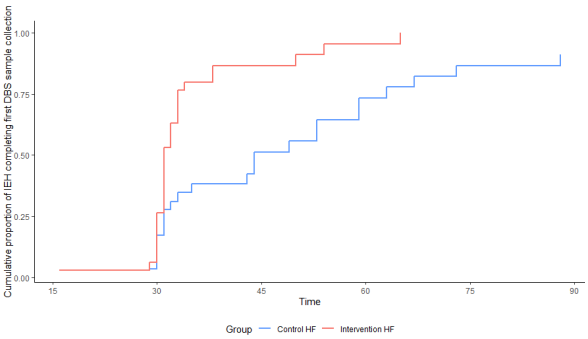


Figure. Time to first DBS sample collection for EID by intervention group, post-intervention period.

Conclusions: Community-based DBS collection is an effective and efficient strategy to decrease time to first EID to ensure timely care for IEH. This approach can be used to complement facility-based sample collection.

WEPEE121

Transformative harm reduction and empowerment strategies for PWUD: community-centric innovations in South Africa

L. Kgwedi[1], T.M. Ndhlovu[2], M. Malahlela[2], D. Mphuthi[3], N. Tshuma[2]

[1]Civil Society Forum, NGO - PWUD Sector, Johannesburg, South Africa, [2]Best Health Solutions, Public Health, Johannesburg, South Africa, [3]University of South Africa, Pretoria, South Africa

Background: People who use drugs (PWUD) in South Africa face numerous barriers to accessing harm reduction, treatment, and social support services. Stigmatization, limited healthcare access, and economic insecurity perpetuate health risks and hinder social reintegration.
To address these challenges, a series of targeted interventions were developed to reduce blood-borne infections, promote human rights, and support the socioeconomic empowerment of PWUD, with an emphasis on community-led initiatives and innovative outreach models.
Description: The program adopted a comprehensive, multi-tiered approach to harm reduction, treatment, and empowerment. Key initiatives included needle and syringe programs to curb infections, opioid substitution therapy to aid recovery, and the "Naloxone Project" to combat overdose fatalities.
The "Treat and Retain" program specifically addressed HIV and TB testing and retention to care among PWUD, while "Harm Reduction in Motion" provided mobile services to high-risk areas. To strengthen community engagement, peer navigators trained through the "Peer Navigator" program lead outreach and support efforts. Partnerships with local organizations further amplified the reach and impact of these interventions.
Lessons learned: Quantitative analysis revealed significant improvements in health outcomes and service uptake. Needle and syringe program distributed over 120,000 sterile syringes, resulting in a 45% decrease in reported needle-sharing practices. Opioid substitution therapy program achieved a 68% adherence rate, with participants demonstrating a 41% reduction in illicit drug use. The "Naloxone Project" trained 519 community members, leading to a documented 31% decrease in overdose fatalities. "Treat and Retain" program successfully linked 85% of participants to HIV and TB treatment, with a retention rate of 75% at the six-month follow-up. Peer navigators facilitated over 1,200 referrals to health and social services.
Conclusions/Next steps: Success of these programs underscores the value of a community-centered, peer-driven approach to harm reduction.
Challenges include the ongoing need to combat entrenched stigma and resistance to harm reduction practices in some areas.
Adaptability and close collaboration with local stakeholders have been critical in addressing these challenges and refining service delivery models.
Future efforts should focus on scaling up successful interventions, enhancing data collection mechanisms, and advocating for policy changes to support harm reduction strategies.

WEPEE122

Epidemiological trends and programmatic gaps in addressing people who use injecting drugs (PWID) and HIV control in Punjab: a NACO data-driven analysis (2017–2024)

M.K. Bawa[1], K. Ranbir[1], S. Sheik[1], H. Kaur[2]

[1]AIDENT Social Welfare Organization, M&E, Delhi, India, [2]AIDENT Social Welfare Organization, Target Intervention, New Delhi, India

Background: As per Sankalak report National AIDS control organization (NACO) and other govt data sources Punjab's PWID population poses a significant public health challenge, with rising prevalence and associated HIV risks. Between 2017 and 2024, the IDU population doubled, raising concerns about intervention efficiency and long-term outcomes.
This study evaluates trends in program coverage, needle-syringe distribution, HIV testing, and linkage to Antiretroviral Therapy (ART), incorporating advanced analysis to identify key patterns and gaps.
Methods: NACO data from 2017-2024 were analyzed using time-series analysis, cohort comparisons, and correlation studies. Annual growth rates, coverage efficiency, and resource utilization trends were calculated. Statistical tools assessed relationships between needle-syringe distribution and HIV sero-positivity rates. Discrepancies in ART linkage were examined through descriptive analysis to identify systemic bottlenecks.
Results: The IDU estimation population increased by 96%, from 22,961 to 45,098 through programmatic mapping population size estimation (p-MPSE), reflecting potential underreporting or actual growth. Coverage rates peaked at 90% in 2021-22 but declined to 70% by 2023-24. Needle distribution rose steadily, achieving 40.8 million in 2023-24, correlating with a decline in HIV sero-positivity rates (R^2 = 0.88). Resource anomalies in syringe distribution in 2021-22 (241.7 million units) suggested inefficiencies. HIV testing expanded by 150%, yet ART linkage remained inadequate, with only 255-298 individuals linked annually.
Conclusions: Harm-reduction strategies, particularly needle-syringe programs, contributed to HIV control among Punjab's IDUs. However, declining coverage and inconsistencies in ART linkage highlight gaps.
Integrating predictive analytics, resource optimization, and robust linkage-to-care frameworks is essential to sustain program impact and improve public health outcomes.

WEPEE123

High interest in DoxyPEP use among sexual and gender minority adolescents in Brazil

F. Soares[1], D. Zeballos[1], L. Magno[2], D. Greco[3], A. Grangeiro[4], L. Rodrigues[1], I. Dourado[1], PrEP15-19 Choices Study Group
[1]Federal University of Bahia, Institute of Collective Health, Salvador, Brazil, [2]State University of Bahia, Salvador, Brazil, [3]Federal University of Minas Gerais, Belo Horizonte, Brazil, [4]University of São Paulo, São Paulo, Brazil

Background: In Brazil, HIV acquisition is concentrated among sexual and gender minority adolescents, who also face high rates of other sexually transmitted infections (STIs). Bacterial STIs such as syphilis, gonorrhea, and chlamydia significantly increase the risk of acquiring HIV. Recent studies have demonstrated the efficacy of doxycycline as a novel biomedical prevention strategy for STIs when used as PEP (DoxyPEP) among MSM and TGW. However, there is limited real-world data on DoxyPEP in lower- and middle-income countries.
This study aimed to evaluate awareness, interest, and motivations for DoxyPEP use among adolescent MSM (AMSM), non-binary individuals assigned male at birth (ANB), TGW (ATGW) and men (ATGM) in Brazil.
Methods: PrEP15-19 Choices is a prospective, multicenter PrEP demonstration cohort study targeting AMSM, ATGW, ATGM and ANB aged 15–19 years. The study is being conducted in three major capital cities in Brazil. For this cross-sectional analysis, we included 258 adolescents enrolled between September 2023 and August 2024. We examined the sociodemographic and behavioral profile of participants as well as, their awareness, interest in using DoxyPEP, and motivations for its adoption.
Results: Most participants were AMSM (74.0%), followed by ATGW (17.1%), aged 18–19 (61.6%), mixed race or blacks (74.5%), and attending high school (64.9%). A large percentage reported having had sexual intercourse with casual partners in the past 3 months (75.9%), but only a third consistently used condoms during these encounters. Additionally, 15.5% of participants reported a history of at least one STI. Most participants were unaware of DoxyPEP (93.0%); however, a substantial majority expressed interest in its use (97.7%). Reasons for considering DoxyPEP included valuing additional prevention options (73.3%), finding comfort with this prevention strategy (16.3%), recognizing that PrEP does not protect against other STIs (5.6%), and dissatisfaction resulting from past STI experiences (2.8%).
Conclusions: Adolescents from sexual and gender minority groups demonstrate a strong willingness to use DoxyPEP, despite limited awareness of this prevention strategy. Expanding its availability, improving access, and integrating DoxyPEP into the national health system are critical steps toward effectively delivering this STI prevention intervention to adolescents at high risk for STIs in Brazil.

WEPEE124

Enabling robust viral monitoring through an integrated approach and building multidimensional capacities across Eastern Africa, Southern Africa and India: a data-driven perspective

T. Khera[1], J. Sutar[2], S. Balinda[3], D. Kitchin[4], R. Mullick[2], M. Mutava[5], P. Jayal[4], J. Serwanga[3], C. Ndekezi[3], J. Mukherjee[1], L.A. Dorner[6], A. Igiraneza[6], E. Landais[7], P. Kaleebu[3], W. Kilembe[8], E. Karita[9], J. Nyombayire[9], J. Bhattacharya[2], E. Hunter[10], R. Goyal[1], K. Chinyenze[5]
[1]IAVI, Gurgaon, India, [2]THSTI, Faridabad, India, [3]MRC/UVRI, Entebbe, Uganda, [4]NICD, Johannesburg, South Africa, [5]IAVI, Nairobi, Kenya, [6]University of oxford, Oxford, United Kingdom, [7]IAVI-NAC, San Diego, United States, [8]CFHRZ, Lusaka, Zambia, [9]CFHR, Kigali, Rwanda, [10]Emory University, Atlanta, United States

Background: Effective HIV prevention strategies, including vaccines and antibody-mediated prevention, must overcome viral diversity. Predicting changing broadly neutralizing antibody (bnAb) resistance dynamics at the population level is challenging, necessitating continuous virus surveillance to integrate HIV-1 genetic features into vaccine candidate selection. This research is crucial for prioritizing immunogens for vaccine development and bnAb prevention approaches targeted to specific populations.
Description: This multidisciplinary initiative aims to position diverse regions and consortia as pivotal players in building an affordable and accessible platform without compromising data quality. The initiative integrates real-time data and harmonizes analysis pipelines to enable data pooling for bioinformatics, neutralization assessments to identify bnAb-resistant strains, and evaluates bnAb combination cocktails. New partnerships with complementary and synergistic strengths, including machine learning and integration with national programs, have been established. This has facilitated the creation of a sustainable virus surveillance mechanism across Uganda, South Africa, Rwanda, Zambia, Europe, the US, and India through trainings, workshops, and the exchange of protocols and reagents.
Lessons learned:

- Data from Africa and India highlight differences in the suitability assessment of historical and contemporary viruses, underscoring the importance of viral evolution in altering bnAb sensitivity over time. The program emphasizes the rise of emerging recombinants in East Africa, the creation of consolidated new virus panels for evaluating new products, and region-specific antibody cocktails for HIV prevention.
- Partnering with national programs provides easier and sustainable access to samples compared to conventional, cost-intensive cohort building.
- Machine learning algorithms have proven crucial and cost-effective for predicting bnAb sensitivity and identifying recent acquisition of HIV from sequenced data.
- An integrated analysis pipeline, robust institutional sequencing capacities, and researchers trained in advanced bioinformatic tools have enabled stronger south-south collaboration.

- Ensuring ethical and best practices for data sharing, adhering to local laws, is of utmost importance.

Conclusions/Next steps: HIV viral surveillance is essential for providing near-real-time data to guide policy and programs. This has implications for developing tailored vaccines against newly emerging variants, ensuring their continued suitability.
Additionally, it will aid in planning future efficacy trials. This strategy sets a model for cost-effective surveillance, enhancing pandemic preparedness.

WEPEE125

Sexual behavior, drug use and PrEP among people who use drugs in Uganda

J. Kibuuka[1], P. Smith[2], J. Hao[2], T. Wood[2], M. Nakitende[1], F. Nambi[1], L. Nakabugo[1], R. Kansiime[3], G. Pande[4], P. Kyambadde[3,4], L. Komuhangi[5], H. Kadama[4], P. Mudiope[4], B. Lambdin[6], S. Glick[7], M. Figgatt[8], D. Donnell[7], A. Mujugira[1,7], R. Heffron[2], T. R. Muwonge[1]
[1]Infectious Diseases Institute, Kampala, Uganda, [2]University of Alabama at Birmingham, Birmingham, United States, [3]Most At Risk Persons Initiative, Kampala, Uganda, [4]STD/AIDS Control Program, Ministry of Health, Kampala, Uganda, [5]Makerere University College of Health Sciences, Kampala, Uganda, [6]RTI International, Research Triangle Park, United States, [7]University of Washington, Seattle, United States, [8]Brown University, Providence, Rhode Island, United States

Background: Medication for opioid use disorder (MOUD) programs and syringe services programs (SSP) can be leveraged to integrate the provision of pre-exposure prophylaxis (PrEP). Whether people accessing these services use PrEP when they have potential HIV exposure through sexual and/or drug use behavior is unknown.
Methods: In a novel cohort of people accessing MOUD and SSP in Kampala, Uganda, who also initiated PrEP, we assessed sexual behavior, drug use, PrEP refills, and tenofovir levels during one-year of follow up. We used multivariable GEE models to determine associations of sexual behavior (any potential HIV risk: >5 sex acts in past 3 months, any condomless sex in past month, or a new partner; high risk: all three) and drug use (any risk: daily injection frequency, reusing a syringe, or sharing of drug use equipment; high risk: all three) with PrEP refills and plasma tenofovir levels >10ng/ml.
Results: From January 2022 to March 2024, the study enrolled 277 people (42% recruited from MOUD and 58% from SSP), of which 87% were assigned male at birth and the median age was 30 years (IQR 25-27). In 63.4% of quarterly follow up visits, participants reported sexual behavior indicating potential risk for HIV, including 5.4% of visits with high risk. In 74.1% of visits, participants reported drug injection behavior that would confer any potential risk for HIV, including 0.3% of visits with high risk. PrEP was refilled during 47.5% of visits and among those dispensed PrEP, 37.4% had tenofovir >10ng/ml. Periods with any risk (versus no risk) through sexual behavior were associated with lower odds of receiving a PrEP refill (OR = 0.68, 95% CI 0.53-0.89) and periods where participants had any risk through drug use behavior were associated with greater tenofovir concentrations (OR = 1.62, 95% CI 1.14-2.29).
Conclusions: In this cohort of people who use drugs, periods with potential HIV exposure through drug use also had greater PrEP adherence. There is an opportunity to provide tailored HIV prevention counseling to people using drugs to encourage PrEP use when drug use and/or sexual behavior provides potential exposure to HIV.

WEPEE126

Evaluating seroconverters in the current PrEP program in Malawi to determine risk factors and linkage to care

R. Simika Zimba[1,2], M. Chagomerana[1], A. Jahn[3], W. Kumwenda[1], M. Hosseinipour[1,4]
[1]UNC Project-Malawi, Lilongwe, Malawi, [2]Kamuzu University of Health Sciences, Blantyre, Malawi, [3]Malawi Ministry Of Health Directorate of HIV, STI and Viral Hepatitis, Lilongwe, Malawi, [4]University of North Carolina at Chapel Hill, Department of Medicine., Chapel Hill, United States

Background: Pre-exposure prophylaxis (PrEP) has been essential in preventing HIV acquisition among high-risk populations. The Ministry of Health in Malawi implemented a national PrEP program to reduce HIV transmission in 2021, reaching 163 facilities and 157,552 individuals by April 2024. Despite its success, cases of HIV seroconversion during PrEP use have been reported.
This study aimed to evaluate seroconverters' demographic and behavioural characteristics and their linkage to ART care to inform future PrEP strategies.
Methods: A case-control study was conducted between July 2023 and September 2024 using routine data from 53 facilities in Malawi reporting at least one HIV seroconversion by April 2024. For each seroconverter, three controls matched by PrEP duration were selected, resulting in 140 cases and 420 controls. Data on demographics, HIV risk factors, PrEP adherence, and clinical outcomes were abstracted from client cards and registers. Descriptive statistics summarized the data, presenting continuous variables (e.g., age, duration on PrEP) as medians with interquartile ranges (IQR) and categorical variables as frequencies and percentages. Odds ratios from conditional logistic regression were used to assess differences between cases and controls, and linkage to ART care was described. Non-adherence to PrEP was assessed as a contributing factor to seroconversion.
Results: The median age of participants was 27 years (IQR: 22-33), with females comprising 82.2%. Seroconverters had a median PrEP duration of 4.6 months (IQR: 1.9-7.6) compared to 3.0 months (IQR: 0.9-7.0) for controls. Non-adherence to PrEP was significantly higher among seroconverters (99.3%) than controls (76.9%) (p<0.001).
Factors such as transactional sex, STI history, or older partners were reported but showed no significant differences between the two groups. Among seroconverters, 99.3% were linked to ART care, achieving viral load suppression in 96.8% at 6 months and 98.6% at 1 year.

Conclusions: This study underscores the critical role of PrEP non-adherence in HIV seroconversion. It also highlights the success of ART linkage and viral suppression among seroconverters. However, identifying a priority population based on risk factors such as transactional sex or STI history remains challenging and a focus on future research should be to refine PrEP populations to maximize public health impact.

WEPEE127

Optimizing pharmacy oral PrEP services for men who have sex with men (MSM) and transgender women (TGW) in Nigeria: an analysis of acceptability and challenges in PrEP uptake and continuation

C. Onyia[1], O. Ononye[2], W. Tun[3], J. Pulerwitz[3], D. Abegunde[1], C. Ndeloa[4], E. Daniel-Ebune[5]
[1]Population Council, Abuja, Nigeria, [2]Population Council, Lagos, Nigeria, [3]Population Council, DC, United States, [4]Elton John AIDS Foundation, London, United Kingdom, [5]Pharmacy Council of Nigeria, Abuja, Nigeria

Background: In Nigeria, key populations (KPs), including men who have sex with men (MSM) and transgender women (TGW), face barriers to quality HIV services due to stigma/discrimination, and criminalization. However, uptake remains low among these groups in Nigeria. Dispensing PrEP through community pharmacies (CPs) offers an alternative service delivery model. The Population Council (through the Elton John AIDS Foundation funding) established Nigeria's first pharmacy-based PrEP service delivery model. This abstract outlines the five-month outcome of PrEP uptake in CPs in Lagos and Abuja.
Description: A memorandum of collaboration was signed with the Pharmacy Council of Nigeria (PCN). Selected CPs in Lagos and Abuja were trained on key populations, PrEP and PrEP service delivery for KPs; they were also introduced to a Standard Operating Procedure co-developed with PCN. Under this model, trained peer educators (PEs) provide PrEP education, HIV counselling/testing services to MSM/TGW in the community. HIV-negative high-risk clients are then referred to participating CPs. Upon arrival at the CP, clients request to see the focal person, and present the referral form from the PE. After review per the SOP, the pharmacist issues a 30-day initial oral PrEP supply and requests the client to return after one month.
Lessons learned: A total of 749 MSM/TG who tested HIV-negative (August-December 2024) were referred for PrEP at CPs. Of those referred, 692 (92%) completed referrals and received a 30-day PrEP supply; 57 (8%) did not complete referrals.
The most common reasons for not completing the referral were distance from home (40%) and uncertainty about confidentiality (53%). The majority (74%) of the 692 clients returned and received the 90-day PrEP supply.
Reasons for missing the follow-up appointment include economic issues (49%), busy schedules (31%), and pill burden (20%). Twenty-five percent of pharmacy PrEP clients were surveyed about quality -- 48% rated it as excellent, 40% as good, 12% as fair/bad.
Conclusions/Next steps: The high acceptability of pharmacy-based PrEP among pharmacists and MSM/TGW populations indicates that CPs are a promising outlet for PrEP services.
Expanding such a model can be explored for other vulnerable populations. Implementing this model requires PCN and Ministry of Health partnership.

WEPEE128

Integrating mental health screening, treatment, and care into HIV services for key populations in Zambia

C. Mulubwa[1], M. Matomola[1], S. Shebo[1], F. Siluwale[1], C. Chambwe[1], V. Munthali[1], M. Chitala[1], J.M. Pry[1,2], M. Zimba[3], M. Sakala[4], M. Sakala[5], M. Musheke[1], T. Savory[1], C. Bolton-Moore[1,6], I. Sikazwe[1], M.E. Herce[1,7]
[1]Centre for Infectious Disease Research in Zambia (CIDRZ), Implemention Science, Lusaka, Zambia, [2]University of California, Davis, United States, [3]Zambia Sex Worker Alliance, Lusaka, Zambia, [4]Tithandizeni Umoyo Network, Lusaka, Zambia, [5]Intersex Society of Zambia, Lusaka, Zambia, [6]University of Alabama, Birmingham, Alabama, United States, [7]Institute for Global Health and Infectious Disease, University of North Carolina, Chapel Hill, North Carolina, United States

Background: Mental health issues among key populations (KPs)—including female sex workers (FSWs), men who have sex with men (MSM), people who inject drugs (PWIDs), and transgender individuals (TGs)—often go untreated, undermining HIV prevention and care. To address this, we introduced the Common Elements Treatment Approach (CETA)—an evidence-based cognitive behavioral therapy—tailored to KPs in Zambia. Here, we describe CETA implementation and preliminary outcomes integrated CETA services.
Methods: With KP civil society organizations (CSOs) and MoH, between March—November 2024, we trained and deployed CETA counselors to KP-led wellness centers to conduct mental health screening of all KPs visiting the wellness centers. To address counselor shortages, we also trained KP peer promoters in CETA. A Client Monitoring and Screening tool determined CETA eligibility according to validated scores for general distress (≥18), gender-based violence (≥1), and substance use (≥2). For those eligible, one-on-one CETA counselling was provided in 8-12 sessions over 3 months. Program data were used to assess uptake of CETA, ART, and PrEP continuation at 6-months post-initiation.
Results: Among 2,701 KPs screened (1,336 FSWs, 958 MSM, 335 PWIDs, 72 TGs), 63% (1,704) were eligible for CETA, with 49% (840) enrolled and 51% awaiting enrollment due to limited CETA personnel *(Figure)*.
Of 840 enrolled, 20% (172) completed CETA and 68% (572) remain in treatment. All the 103 (100%) KPs living with HIV who had discontinued ART restarted after CETA. Of 646 HIV-negative KPs on PrEP, 78% continued at 6 months, compared to the overall 6-month PrEP continuation rate of 67%.

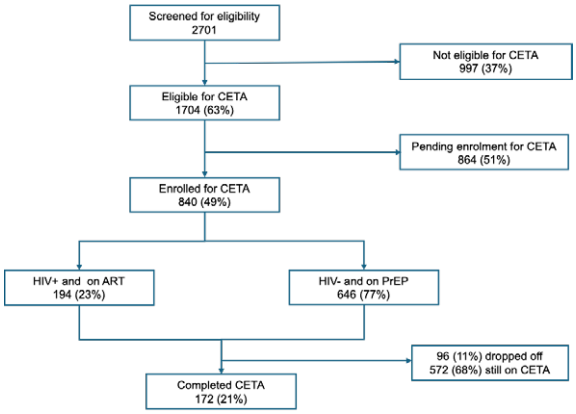

Figure. CETA uptake in the KP-led wellness centers.

Conclusions: Preliminary results show that CETA can help address mental health needs among KPs when integrated with HIV services. However, high demand for services and limited counselor availability underscores the need for expanded mental health resources and task-shifting to trained peer promoters.

WEPEE129

High levels of autonomous decision-making among women receiving multi-method pre-exposure prophylaxis (PrEP) counseling through the CATALYST study in sub-Saharan Africa

I. Segawa[1], H. Sisel[2], C. Kyampire[1], K. Louis-Charles[2], M. Otieno[3], K. Mamaphau[4], V. Fonner[2], C. McGuire[2], A. Kekana[5], I. Mahaka[6], H. Kadama[7], E. Irungu[8], CATALYST Study Team

[1]FHI 360, Kampala, Uganda, [2]FHI 360, Durham, United States, [3]LVCT Health, Nairobi, Kenya, [4]Jhpiego, Maseru, Lesotho, [5]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [6]Pangaea Zimbabwe, Harare, Zimbabwe, [7]Ministry of Health, Kampala, Uganda, [8]Jhpiego, Nairobi, Kenya

Background: As pre-exposure prophylaxis (PrEP) products expand, providers help clients make an informed autonomous decision about which PrEP method to use. We aimed to explore how client-provider interactions during multi-method PrEP counseling shaped clients' decisions and early continuation.

Methods: CATALYST, a study implemented by the PEPFAR/USAID-supported MOSAIC project, is delivering oral PrEP, PrEP ring, and injectable cabotegravir (CAB) PrEP to women at public facilities in Kenya, Lesotho, South Africa, Uganda, and Zimbabwe. We analyzed cohort data from June–October 2024 and adapted a six-question PrEP-ADM (Autonomous Decision Making, Figure 1) scale to explore whether clients received adequate counseling and support to make an autonomous decision.

We used factor analysis to validate the scale and logistic regression to determine factors associated with fully autonomous decision-making (defined as having a "high" PrEP-ADM score, 18/18) and refilling PrEP within three months. We thematically analyzed eight in-depth cohort interviews to explore experiences with PrEP counseling.

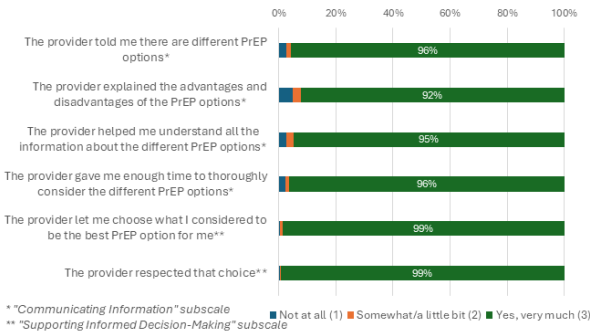

Figure 1.

Results: Overall, 91% (1,163/1,281) of participants had high PrEP-ADM scores, with no significant variation by socio-demographic characteristics. Factor analysis identified two subscales: "communicating information" and "supporting informed decision-making." Pregnant (aOR=0.36, 95% CI [0.17-0.76], p=0.008) or breastfeeding individuals (aOR=0.32, 95% CI [0.17-0.58], p<0.001) had lower odds of fully autonomous decision-making, even after controlling for country-level differences.

Additionally, those with high PrEP-ADM scores were somewhat more likely to return for a PrEP refill than those with lower scores (OR=1.77, 95% CI [0.92-3.43], p=0.089). Qualitative data confirmed that clients are receiving information about the different PrEP methods and are being supported by providers through attentive listening to make an autonomous decision.

Conclusions: Fully autonomous decision-making was high among CATALYST clients receiving multi-method PrEP counseling, indicating receipt of adequate information and support from providers. Ensuring PrEP counseling is provided equitably to pregnant and breastfeeding populations is essential. High levels of autonomous decision-making may improve PrEP continuation.

WEPEE130

Continuity on long-acting cabotegravir (CAB-LA) for HIV pre-exposure prophylaxis (PrEP): a comparison of naive and experienced clients in Zambia

A.P. Ndhlovu[1], J. Musangulule[1], L. Kawanga[1], L. Cicciò[1], J. Posner[2], M. Musonda[3], M. Nyumbu[1], S. Hartchard[1], D. Mwamba[3]

[1]John Snow Inc, USAID District Coverage of Health Services, Lusaka, Zambia, [2]John Snow Inc, Boston, United States, [3]United States Embassy/Zambia Mission, Lusaka, Zambia

Background: Long-acting injectable cabotegravir (CAB-LA) has the potential to reduce HIV transmissions, by expanding the array of preventive options provided. However, data on CAB-LA continuity are scarce.

The USAID DISCOVER-Health project, implemented by JSI, is providing CAB-LA to both naive clients - those starting PrEP for the first time - and experienced clients, transitioning from oral PrEP.

Description: In February 2024, the project started administering CAB-LA in Chibombo and Kitwe districts. Clients were monitored at injection appointments 1,3,5,7 and 9 months from initiation. Continuity was measured as the proportion of clients who attended their scheduled visits, at the specified time points, relative to the total number expected to attend based on the elapsed time since initiation.

Lessons learned: By November 2024, 1,116 naive clients started CAB-LA (females 62%; median age 28 years), while 354 experienced clients transitioned from oral PrEP (females 58%; median age 34 years). The median time spent by the experienced clients on oral PrEP before transitioning was 306 days. For naive clients' continuity: 78% were on CAB-LA at 1 month; 62% at 3 months; 45% at 5 months; 24% at 7 months; 7% at 9 months.

For experienced clients: 80% were on CAB-LA at 1 month; 66% at 3 months; 53% at 5 months; 39% at 7 months; 16% at 9 months. The observed widening difference in continuity over time was similarly recorded across the three main age groups (15-24, 25-34 and 35+).

Conclusions/Next steps: The preliminary data suggests that experienced PrEP clients have a better continuity of treatment than naive clients. This may be attributed to their prior familiarity with PrEP regimens and their demonstrated commitment to HIV prevention over an extended period. However, further data are required to corroborate these findings and tailor strategies to bolster uptake and retention for both populations.

Implementation research to scale up treatment

WEPEE131

Trends in ART medication adherence support and monitoring across IeDEA sites: results from three waves of consortium-wide site assessment surveys, 2017, 2020, and 2023

Background: Since 2013, global HIV treatment guidelines have included recommendations for medication adher-

ence support and monitoring. We examined trends in routine adherence support and monitoring for adults with HIV through recent consortium-wide site surveys conducted by the International epidemiology Databases to Evaluate AIDS (IeDEA).

Methods: Cross-sectional surveys were completed by clinics providing treatment for adults living with HIV across 43 countries in 2017 (n=206), 2020 (n=200), and 2023 (n=214). We examined routine adherence support and monitoring among sites completing all three surveys, stratified by country income-level (i.e., low/middle income versus high-income countries [LMICs/HICs]).

Adherence support was categorized as: none; minimal (counseling only); moderate (counseling with additional support); or enhanced (individualized counseling with peer support and other support/incentives).

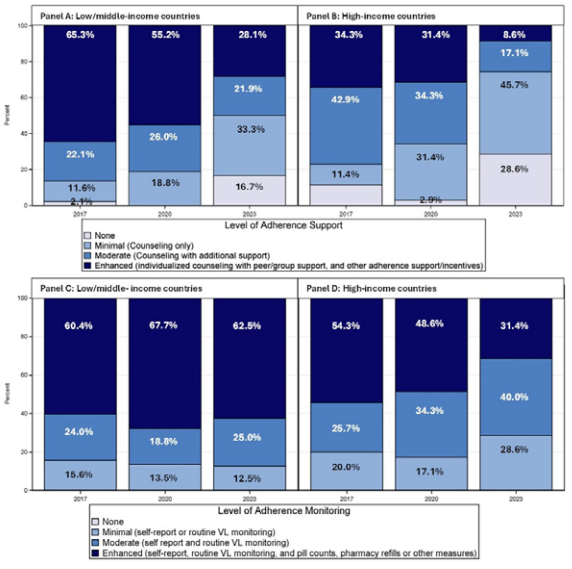
Adherence monitoring was categorized as: none; minimal (self-report *or* viral load [VL] testing); moderate (self-report *and* VL testing); or enhanced (self-report; VL testing; *and* pharmacy refill checks, pill counts; or electronic monitoring).

Results: Eligible sites included 131 clinics in health centers (57%) and hospitals (43%) in urban/mostly-urban settings (70%) and LMICs (73%). Among 96 LMIC clinics, an increasing proportion reported providing no or minimal adherence support from 2017 to 2023 (Figure, Panel A, 14% to 40%), with a corresponding decrease (65% to 28%) in reporting of enhanced adherence support.

Similar trends were observed among 35 HIC clinics, with increases in reporting of no or minimal adherence support and decreases in enhanced adherence support (Panel B).

At each timepoint, higher proportions of LMIC clinics (>60%) reported enhanced adherence monitoring (Panel C) compared with HIC clinics (31% to 54%), with more HIC clinics (17% to 28%) reporting minimal adherence monitoring (Panel D).

Figure. Trends in levels of adherence support and monitoring at 131 HIV clinics participating in IeDEA, by country income level



Conclusions: Participating IeDEA clinics reported decreased provision of adherence support over time. Further research is needed to examine whether these changes in adherence support are associated with worse HIV care outcomes.

WEPEE132

Use of men only clinics and community ART groups as differentiated service delivery models to enhance adherence in Ober Subcounty Hospital, Kenya

J. Kariuki[1], O. Akinyi[2], J. Onyango[3], J. Kwatampora[4], S. Kinyanjui[5], P. Ndiege[2]

[1]AHF Kenya, Care and Treatment, Homabay, Kenya, [2]Ngima Mogen, Care and Treatment, Homabay, Kenya, [3]Ober Level 4 Hospital, Care and Treatment, Homabay, Kenya, [4]AHF Kenya, Medical Director, Nairobi, Kenya, [5]AHF Kenya, Country Director, Nairobi, Kenya

Background: There is compelling evidence of men's disinclination to engage in health services. Differentiated service delivery models (DSDM) have demonstrated the potential to improve men's engagement in HIV care. Men living with HIV (MLHIV) attending the Ober clinic had a high number of missed appointments affecting treatment adherence, to address their challenges, the facility-based support group DSDM was introduced focusing on serving men separately from women and children.

The study objective was to assess the effect of men only clinics (MOC) and men only community antiretroviral therapy groups (CAGS) in enhancing treatment adherence.

Description: 355 men adult, were enrolled either in MOC or CAGS, between January and December 2023. Men with missed appointments were assigned to MOC and those with no missed appointments were assigned to CAGS. The MOC model offered the ART package as per the national guidelines including monthly psychosocial support, ART literacy, risk and harm reduction counseling, socioeconomic empowerment awareness, and the provision of a safe space within Ober hospital.

The CAGS groups held monthly sessions chaired by the peer educator with the support of the health care providers where the MOC package was offered outside the hospital. 195 were enrolled in MOC and 160 in CAGS.

The CAGS groups were further assigned into 4 sub-groups according to their social networks: 40 Brick makers, 40 motorcycle riders, 40 Widowers and 40 psychoeducation groups. To access adherence, we compared the viral loads at baseline with those one-year post study implementation.

Lessons learned: The overall viral suppression (VS) improved from 78.2% at baseline to 96.3%. By December 2023, 94% of the men in MOC and 99% in CAGS were virally suppressed , with 99% retention in the clinic.

Conclusions/Next steps: The MOC and CAGS models were successful strategies in improving treatment adherence while minimizing the burden on the healthcare system and can be adapted in similar settings.

WEPEE133

Expanding ART access through community pharmacies: lessons from South Africa's CCMDD programme during COVID-19

N. Ramdas[1], P. Roberts[1], M. Pillay[1], M. Munsamy[2]
[1]Project Last Mile, Pretoria, South Africa, [2]National Department of Health, Pretoria, South Africa

Background: South Africa has one of the world's largest HIV-positive populations, making uninterrupted access to antiretroviral therapy (ART) a critical public health priority. The COVID-19 pandemic strained the healthcare system, causing overcrowded facilities and limiting capacity for ART management. To address these disruptions, the Central Chronic Medicines Dispensing and Distribution (CCMDD) programme leveraged community pharmacies to decentralise ART delivery, ensuring treatment continuity during the crisis.

Description: The CCMDD programme, initiated in 2016, was designed to reduce congestion in public healthcare facilities by providing chronic medication, including ART, through community-based pick-up points. With the onset of COVID-19, the programme expanded its scope by incorporating community pharmacies into the pick-up point network and offering multi-month dispensing of ART. Enrolment criteria were broadened to include more clients, and real-time monitoring was facilitated using geographic information systems (GIS) to address the dynamic needs of ART clients. Between March 2020 and August 2022, the number of pick-up points increased by 39%, from 2,088 to 2,906, directly contributing to expanded ART access.

Lessons learned: Including community pharmacies as ART pick-up points was essential for ensuring uninterrupted access to ART during the pandemic. The programme's flexibility, particularly in adjusting enrollment criteria and expanding pick-up points, demonstrated its effectiveness in addressing the needs of a growing number of ART clients. Over 327,000 additional clients were reached during COVID-19, resulting in a 108% increase in clients receiving ART (from 973,487 to 2,026,101). These outcomes emphasize the vital role of strategic partnerships with community pharmacies in maintaining ART continuity, especially during crises.

Conclusions/Next steps: The success of the CCMDD programme in ensuring uninterrupted ART access during the COVID-19 pandemic highlights the significance of community pharmacy involvement in health system resilience. Moving forward, ongoing partnerships with local pharmacies and innovative service delivery models will be crucial to maintaining ART access for South Africa's HIV-positive population. Additional research is necessary to assess long-term health outcomes and the impact on client quality of life, while continuous monitoring is essential to adapt to changing client needs.

WEPEE134

Scaling differentiated service delivery models: a journey towards client - centered HIV care in Zimbabwe

C. Gwanzura[1], T. Apollo[1], C. Mupanguri[1], E. Govha[1], J. Mabuku[1], T. Matare[1], P. Mujuru[2], G. Gonese[2]
[1]Ministry of Health and Child Care, AIDS and TB Unit, Harare, Zimbabwe, [2]Zim - TTECH, Care and Treatment, Harare, Zimbabwe

Background: Zimbabwe started implementing differentiated service delivery (DSD) models for ART (DART) in 2017, and has been conducting DSD reviews annually since 2018. The DSD reviews assess implementation progress and provide peer-learning opportunities to share best practices, challenges and innovations. The 2024 DSD Review was conducted in July – August 2024.

Description: One hundred and forty eight facilities in 30 districts from four provinces in Zimbabwe participated. Data was collected using Survey CTO and analysed using PowerBI. A facility survey and individual client survey tool were used. Data was abstracted from 4,630 files for recipients of care (RoCs) in the 12, 24 and 36 months cohorts on ART.

Data was collected for services received from HIV testing to treatment outcomes, viral load monitoring and integration with TB, FP, Mental Health and NCDs. Analysis was done on the trends in DART enrolment and ART multi-month dispensing (MMD) at annual timepoints.

Lessons learned: In the 12 months cohort, DART coverage (DART-C) was 21% at 12months, in 24months DART-C was 15% at 12months and 22% at 24months, and in the 36 months cohort, DART-C was 12% at 12months, 19% at 24months and 25% at 36months. The commonest DART models were Fast Track and Community ART Refill Groups.

In contrast, significant upward trends were seen in the uptake of MMD for all three cohorts with coverage of 6MMD being 47%, 49% and 55% respectively at the last annual visit.

Conclusions/Next steps: It is evident that efforts towards making services more client centred are continually being made regardless of time on ART. Despite both DART models and MMD being available for RoCs there is clear preference for MMD versus enrolment in DART models.

The uptake of the two services by RoCs is not mutually exclusive thus a RoC in a DART model can still receive 6MMD. RoCs are free to choose services that align with their needs, therefore the national HIV programme will continue to differentiate services for PLHIV whilst strengthening quality service provision.

WEPEE135

Development of a priority research agenda for advanced HIV disease in Latin America and the Caribbean for the period 2025-2035

F. Perez[1], E. Chapman[1], J.O.M. Barreto[2], A. Camiro-Zuniga[1], J.E. Vidal[3], C.P. Cortes[4], B. Crabtree Ramírez[5], O. Sued[1]

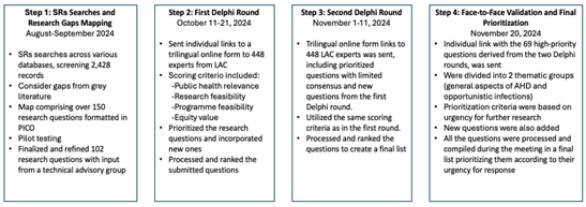
[1]Pan American Health Organization, Communicable Diseases Prevention, Control and Elimination Department, Washington DC, United States, [2]Oswaldo Cruz Foundation, Brasilia, Brazil, [3]Instituto de Infectologia Emílio Ribas, São Paulo, Brazil, [4]Facultad de Medicina, Universidad de Chile, Santiago, Chile, [5]Department of Infectious Diseases, Instituto Nacional de Ciencias Médicas y Nutrición „Salvador Zubirán', Mexico City, Mexico

Background: Advanced HIV disease (AHD) remains a critical public health challenge in Latin America and the Caribbean (LAC), contributing to high mortality rates and healthcare disparities.

Coordinated by the Pan-American Health Organization, this study aimed to identify and prioritize research questions to guide efforts to improve outcomes for people living with HIV (PLHIV).

Methods: A modified Delphi methodology was used, involving two online surveys targeting 449 experts from 17 LAC countries, followed by an in-person meeting with 24 specialists between August and November 2024. Over 100 research questions were identified from nearly 2,500 systematic reviews (January 2014-August 2024).

Questions were prioritized based on four criteria: public health relevance, research feasibility, program feasibility and equity value. Research needs were classified by urgency for short-, medium-, and long-term responses



Results: From 2,428 systematic reviews, 102 research questions were identified. The first Delphi round (16.5%, response rate) prioritized 59/102 questions; the second round, 15.4% response rate), added 10 more. In-person validation finalized 77 priority questions, of which 42 (54.5%) required short-term responses. Frequent topics included opportunistic Infections (45%), systems/services (35%), and epidemiology (18%). Only 19.7% addressed pediatric populations. Topics were evenly distributed across the perceived urgency timeframes.

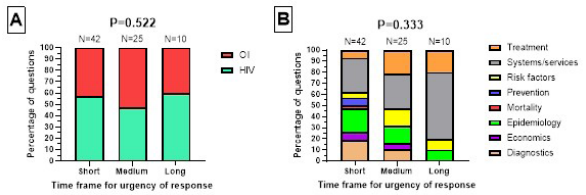


Figure 2: Here we show the categorized topics addressed in the prioritized research questions divided by the urgency time frame they were assigned during the Delphi process. These timeframes are divided in short-term (<2 years) medium-term (2-4 years) and long-term (>5 years). Panel A: here we show the questions dealing with general HIV-related problems and those related to opportunistic infections (OI). Panel B: here we show the questions categorized by type of problem addressed in the HIV continuum of care.

Conclusions: This research agenda represents a preliminary but crucial step in addressing AHD in LAC. The prioritized research questions provide a roadmap to bridge knowledge gaps and improve care outcomes for PLHIV in LAC.

Global and national financing, economic evaluation and sustainability

WEPEE136

Addressing gaps in HIV case finding: missed opportunities in first 95 coverage in non-PEPFAR sites in Mozambique

M. Lisboa[1], M. Donaldson[1], M. Swor[1], A.P. Simbine[1], G. Amane[2]

[1]US Agency for International Development, Integrated Health Office, Maputo, Mozambique, [2]Ministry of Health, National STI, HIV and AIDS Control Program, Maputo, Mozambique

Background: To maximize the impact of limited PEPFAR resources and address low treatment retention rates, PEPFAR investments in Mozambique are concentrated in health facilities with at least 500 individuals currently on antiretroviral therapy (TX_CURR ≥ 500). However, non-PEPFAR supported sites with increasing ART clients load (TX_CURR) are facing significant coverage gaps in the first 95. Our assessment explored the gaps and potential losses in HIV case finding opportunities in sites without PEPFAR support.

Methods: Data from a retrospective cohort study of TX_CURR in all sites with antiretroviral therapy services nationwide were analyzed. Data was extracted from PEPFAR's DATIM and Ministry of Health's DHIS2 platforms. Descriptive statistics were computed to assess the first 95 coverage gaps. The difference between total consultations and non-MCH HIV tests, multiplied by the average facility and MCH testing yield, were used to estimate the potential loss of HIV testing opportunities. Comparison between sites were made.

Results: A total of 1,649 sites with antiretroviral treatment services were included in the analysis, with a total TX_CURR of 2,001,783 people living with HIV (PLHIV) as of March 2024. Of the 1,649 sites included, only 41% receive PEPFAR support. Niassa (9%), Tete (23%), Sofala (30%), and Nampula (33%) are the provinces with less PEPFAR supported sites, while Zambézia (61%), Gaza (66%), and Maputo (92%) have more PEPFAR-supported sites. Within provinces with more PEPFAR-supported sites, we see a higher first 95 coverage: Gaza (93%), Maputo (91%), and Zambézia (90%), while in provinces with fewer PEPFAR-supported sites, we see lower first 95 coverage overall: Nampula (84%), Niassa (86%), Sofala and Tete (89%). Non-PEPFAR sites also accounted for 252,022 PLHIV, with an estimated 90,000 missed HIV case findings due to testing gaps. High numbers of potential loss of HIV testing are in the provinces with fewer PEPFAR supported sites.

Conclusions: Non-PEPFAR sites exhibit significantly lower first 95 coverage, risking 90,000 missed HIV diagnoses. The analysis highlights that achieving provincial-level first 95 coverage may not be possible without concurrent improvements in HIV testing coverage within non-PEPFAR supported sites through targeted donor support, optimized testing strategies, and improved linkage to care.

WEPEE137

NASA study on HIV sustainability in Nigeria: funding dependence, challenges, and pathways for long-term solutions

U. Sylvester[1], A. Andrew[1]
[1]National Agency for Control of AIDS, Research Monitoring and Evaluation, Abuja, Nigeria

Background: HIV sustainability in Nigeria represents the nation's ongoing efforts to maintain and expand effective HIV prevention, treatment, and care services despite significant challenges. As Africa's most populous country, Nigeria grapples with high infection rates, especially among key population, while heavily depending on international support from organizations like PEPFAR, the Global Fund, and UNAIDS. However, millions now receive antiretroviral therapy (ART), the country's reliance on external funding raises concerns about long-term program viability.
Methods: A comprehensive study examined HIV funding patterns across Nigeria's 36 states and federal capital territory, analyzing data from government institutions, donors, implementing partners, service providers, and civil society networks. Using the NASA classification system and UNAIDS Resource Tracking Tool, researchers evaluated funding sources and expenditure patterns from 2019 to 2021.
Results: The findings revealed overwhelming dependence on international donors. PEPFAR emerged as the primary funder, contributing 80%, 73%, and 76% of HIV spending across the three years studied. The Global Fund provided 11%, 21%, and 19% respectively, while UN agencies collectively contributed approximately 1% each year. Notably, domestic public expenditure from both central and state governments remained low at just 4% in 2020 and 2021.
Conclusions: This heavy reliance on external funding makes Nigeria's HIV programs vulnerable to changes in donor priorities and funding levels. The situation highlights the urgent need for increased domestic investment and stronger health system infrastructure to ensure program sustainability.
Moving forward, Nigeria must prioritize several key strategies to achieve HIV response sustainability. These include increasing domestic funding allocations, strengthening health systems, and implementing more efficient resource management practices. Success will require enhanced local ownership, integration of HIV services into broader health initiatives, and development of robust public-private partnerships.
The path to sustainability demands strong political commitment and systematic improvements in healthcare delivery systems. By focusing on these priorities, Nigeria can work toward independently managing its HIV response while maintaining and expanding access to essential services for affected populations.

Health systems, health systems strengthening and partnerships

WEPEE138

Utilizing the RE-AIM Framework to evaluate a transition clinic for adolescents living with HIV in a tertiary health facility in Nigeria

E. Nwanja[1], U. Prosper-Njoku[2], O. Dixon-Umo[3], U. David[3], B. Okon Edet[3], P. Peter Mba[3], T. Igwenagu[2], A. Morgan Ekanem[3], O. Onwah[1], U. Akpan[1], O. Toyo[1], O. Igboelina[4], D. Ogundehin[4], R. Eneogu[4], U. Omo-Emmanuel[4], M. Katbi[4], D. Kimanga[4], C. Obiora-Okafo[4], A. Idemudia[4], B. Adebobola[5], E. James[4], J. Pius[4], O. Oyelaran[4], O. Onyedinachi[1], A. Eyo[1]
[1]Excellence Community Education Welfare Scheme, Uyo, Nigeria, [2]Achieving Health Nigeria Initiative, Uyo, Nigeria, [3]University Teaching Hospital Uyo, Uyo, Nigeria, [4]United States Agency for International Development (USAID), Office of HIV and TB, Abuja, Nigeria, [5]National AIDS, STI and Viral Hepatitis Control Program, Abuja, Nigeria

Background: Adolescents in Nigeria transitioning from paediatric to adult HIV care often experience poorer treatment outcomes, particularly those in tertiary health facilities. In 2020, PEPFAR, through USAID-supported projects, initiated a transition clinic at a tertiary hospital – the University of Uyo Teaching Hospital (UUTH) to support the transition of adolescents living with HIV (AYLHIV) to adult care. This clinic was run by a multidisciplinary team that provided counselling and adherence support, treatment literacy and education on self-care, and held after school hours to enhance adolescent participation.
This study evaluates the intervention using the RE-AIM framework.
Methods: This mixed-methods cohort study used data from electronic medical records of AYLHIV aged 15-24 years and receiving ART at UUTH, who attended the transition clinics between November 2020 and September 2023. Feedback from AYLHIV and service providers were routinely collected as part of continuous quality improvement.
Outcomes assessed include Reach (number of AYLHIV who attended the clinic), Effectiveness (client retention in care (still receiving ART) and viral suppression (≤1000copies/ml) 12 months post-transition, by September 2024), Adoption (uptake and engagement of AYLHIV and feedback from paediatric staff on the intervention's acceptability and feasibility), Implementation (Adherence to planned clinic processes) and Maintenance (Clinic operations after 36 months).
Results: A total of 32 AYLHIV attended the clinic; 65.6% (21) were female, median age was 15.6 years (IQR:14.3 -16.9), median duration on ART was 9.7 years (IQR: 4.7-12.7), and

median duration in the transition clinic was 2.7 years (IQR: 2.7-2.9). AYLHIV accessing the service increased from 10 in November 2020 to 30 in January 2021 and 32 in March 2021. At 12 months after the intervention, 100% (32) of the YLHIV were retained on treatment and 87.5% (28) were virally suppressed. The clinic consistently held on Tuesdays as planned, staff were receptive to the initiative, but human resource shortages and uncomfortable clinic space created challenges. Despite initial success, the clinic was discontinued after 36 months.

Conclusions: The transition clinic reached AYLHIV transitioning to adult care and effectively retained them on HIV treatment. However, the post-transition viral load level was sub-optimal and intervention sustainability was challenged by limited human resources.

HIV and development synergies

WEPEE139

Physical and sexual violence among female sex workers in Rwanda: findings from the IBBSS 2023

J.B. Tugirimana[1], D. Mutambuka[1], C. Kayitesi[2], A. Gasozi Ntwali[3], M. Ribakare[4], F. K. Rubuga[5]

[1]Rwanda Network of People Living with HIV /AIDS (RRP+), Community Engagement in HIV responses, Kigali, Rwanda, [2]Rwanda Biomedical Center (RBC), HIV / AIDS and STIs Diseases, Kigali, Rwanda, [3]UNAIDS, HIV responses, Kigali, Rwanda, [4]World Health Organization (WHO), HIV responses, Kigali, Rwanda, [5]Centre for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition (CIIC-HIN), Research, Kigali, Rwanda

Background: Female sex workers (FSWs) in Rwanda face disproportionately high risks of physical and sexual violence, with an HIV prevalence of 35.5%, significantly higher than the 3% prevalence in the general population. This violence exacerbates vulnerability to acquisition of HIV and positive health outcomes.

This study, part of the Integrated Bio-Behavioral Surveillance Survey (IBBSS) 2023, assessed the prevalence and dynamics of physical and sexual violence among FSWs in Rwanda and its implications for HIV prevention, care, and support.

Methods: The IBBSS 2023 was a cross-sectional study involving 2,541 FSWs aged 15 years and older across Rwanda. Participants were recruited using privatized network sampling. Data on lifetime and past 12-month experiences of physical and sexual violence were collected through structured interviews. Prevalence estimates with 95% confidence intervals (CIs) were calculated, disaggregated by violence type and timeframe, and analyzed using descriptive statistics.

Results: Among FSWs, 20.9% (95% CI: 18.1–23.9) reported experiencing physical violence, and 16.8% (95% CI: 14.1–20.0) reported experiencing sexual violence in their lifetime.

In the 12 months preceding the survey, 55.5% of those reporting physical violence and 55.3% of those reporting sexual violence experienced these forms of violence. Additionally, 33% (95% CI: 24.8–42.3) of FSWs experienced both physical and sexual violence in the past year.

Conclusions: The prevalence of physical and sexual violence among FSWs in Rwanda is alarmingly high, with over half of the victims reporting recent occurrences. These findings highlight critical gaps in violence prevention and support mechanisms for FSWs.

Addressing these risks is essential to achieving HIV prevention and treatment goals, particularly the 95-95-95 targets, as violence disrupts care continuity and increases vulnerability. Interventions should integrate violence prevention, and trauma-informed care to enhance the safety and well-being of FSWs.

Future studies should explore the intersection of violence with HIV treatment adherence and health outcomes to guide comprehensive policy and programmatic responses.

Integration of HIV services with other health and support services

WEPEE140

Key population-led test and treat for hepatitis C virus infection in Thailand enables rapid initiation of treatment and achieved high virological success rates

A. Wongsa[1], R. Janamnuaysook[1], K. Sinchai[1], A. Phunkron[2], T. Pasansai[3], S. Sangtong[3], J. Boonruang[1], S. Thitipatarakorn[1], S. Tangcharoensathien[1], S. Janyam[2], P. Patpeerapong[3], S. Mills[4], N. Phanuphak[1], R.A. Ramautarsing[1]

[1]Institute of HIV Research and Innovation, Bangkok, Thailand, [2]Service Worker in Group Foundation, Bangkok, Thailand, [3]MPLUS Foundation, Chiang Mai, Thailand, [4]FHI360 and USAID EpiC Project, Bangkok, Thailand

Background: Two key populations (KP)-led clinics in Thailand have integrated hepatitis C virus (HCV) test-and-treat intervention into routine HIV-related services to address rising HCV prevalence and care barriers among key populations. We report outcomes of the first year of implementation.

Methods: Thai citizens aged ≥18 years who tested anti-HCV positive during routine services at two KP-led clinics were enrolled. They received counselling, laboratory testing (including HCV-RNA point-of-care testing), and basic examinations by trained KP-lay providers and virtual doctor consultations. Those who met simplified treatment criteria (absence of advanced fibrosis score, hepatitis B (HBV) co-infection, or other medical concerns) received 12-week oral direct-acting antivirals (DAAs – sofosbuvir 400mg and velpatasvir 100mg once daily). Sustained virological response (SVR) was measured 12-week post-treatment completion. Hospital referrals were arranged for those ineligible for simplified treatment. Descriptive analysis was conducted using STATA.

Results: From January-December 2024, 152 clients were enrolled. Median age (interquartile range, IQR) was 29 (25-36) years; 136/152 (89.5%) and 8/152 (5.3%) were men who have sex with men and transgender women, respectively. 52/152 (34.2%) were living with HIV and 14/152 (9.2%) engaged in chemsex.

Of these, 111/152 (73.0%) had active HCV-infection (HCV-RNA detected), 109/111 (98.2%) underwent pre-treatment investigation, and 85/109 (78.0%) met simplified treatment criteria, all of whom (100%) started DAAs within a median (IQR) 5.0 (2.0–7.0) days.

Fifty-three people had SVR assessment scheduled during the observation period, all (100%) completed treatment, 36/53 (67.9%) returned for testing, and 36/36 (100%) achieved SVR.

Furthermore, 24/109 (22.0%) were ineligible for simplified treatment (due to laboratory indications of fibrosis, or HBV infection). These were referred out for treatment, 11/24 (45.8%) initiated treatment within a median (IQR) 64.0 (23.0-87.0) days.

Conclusions: KP-led HCV test-and-treat intervention enabled quick confirmation of active HCV-infection, quick DAAs initiation, and high rates of treatment completion and SVR. Clients referred out for treatment often did not initiate DAAs or did so after significant delays.

To increase rates of SVR assessment, barriers for SVR testing should be explored to design and implement targeted interventions. Nevertheless, KP-led HCV test-and-treat intervention delivered in and by communities is a promising strategy to reach HCV elimination among key populations in Thailand.

WEPEE141

Community based cervical cancer screening bridging the access gap for women from hard-to-reach areas: the case of Masvingo province, Zimbabwe

V. Guvava[1], K. Masunda[2], G. Katsamba[2], A. Shamhu[3]
[1]JF Kapnek Zimbabwe, SIE, Harare, Zimbabwe, [2]JF Kapnek Zimbabwe, Programs, Harare, Zimbabwe, [3]Ministry of Health and Child Care, Masvingo, Zimbabwe

Background: Cervical is the most common cancer in women in Zimbabwe with approximately 3,000 women being diagnosed annually and close to 2,000 succumbing to the malignancy. HIV remains one of the top drivers of cervical cancer in Zimbabwe. It is estimated that in 2019 only 20% of women had access to cervical cancer screening.

Description: In collaboration with the Ministry of Health and Child Care, JF Kapnek Zimbabwe, a local NGO, is implementing the Target, Accelerate, Sustain Quality Care for HIV epidemic control, (TASQC program) in 6 districts in Masvingo province. Visual Inspection with Acetic Acid is offered to women living with HIV targeting the 25 to 49 years age group. Services are provided daily at 20 health care facilities while 150 facilities and health posts are visited quarterly for outreach services.

Between April 2022 and August 2024, a total of 86,499 VIAC screenings were done, reaching 119% of the target, which was 2500 per month. Over 40% of all screenings were done at community level with districts like Zaka (62%) and Chivi (57%) doing most of their screening at community level. A total of 115,105 WLHIV were mobilized for VIAC by community volunteers. VIAC positivity at facility level was 6% while at community level it was 5%. The difference was not statistically significant. A treatment coverage of 85% was achieved with most women treated via LEEP followed by thermocoagulation. Treatment was mostly at facility level.

Lessons learned: Some key lessons include:

- Community lay cadres are key in mobilizing their peers for VIAC screening. They can serve as a good reminder system within the community of when cervical cancer screening outreaches are due to be done and also remind WLHIV that they need to get screened for cervical cancer.
- Reaching more women continues to be limited by trained staff attrition, limited resources, competing community programs, and geographical access. Time caps for vehicle parking (donor-funded) can also act as a hindrance to implementation.

Conclusions/Next steps: Community based cervical cancer screening can be a way to scale up access to women from disadvantaged areas. Resources need to be availed to ensure more access to vulnerable women.

Innovations in data collection, monitoring and evaluation

WEPEE142

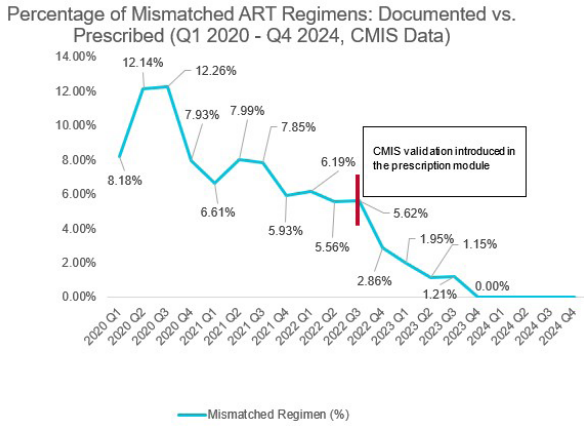
Closing the gap: enhancing ART regimen accuracy through automated validation in Eswatini's CMIS

S. Chiripashi[1], N. Mavuka[1], S. Shongwe[1], I. Hakasenke[1], M. Vilakati[1], D. Pereko[1], Z. Simelane[2]
[1]Palladium Data.FI Project, Health Management Information Systems, Mbabane, Eswatini, [2]Ministry of Health Eswatini, Health Management Information Systems, Mbabane, Eswatini

Background: In Eswatini, the Client Management Information System (CMIS) has been critical for patient management, including clients on antiretroviral therapy (ART). However, discrepancies in ART regimen documentation were prevalent as health care workers documented a regimen in the ART module but selected different medications in the prescription module to formulate a regimen, leading to mismatches. These discrepancies compromised data quality, hindered optimal health outcomes, and required labour-intensive manual data cleaning.

Description: To address this challenge, in September 2022, automated data validation rules were introduced in the CMIS, ensuring ART prescriptions conform to valid WHO and Eswatini HIV guidelines as well as align with the documented regimen in the ART module. To determine the efficacy of this initiative, we assessed CMIS data quality and consistency in ART regimen documentation from Quarter 1 (Q1) 2020 to Quarter 4 (Q4) 2024.

Lessons learned: Prior to implementation, ART regimen discrepancy rates averaged 8.03%, with peaks of 12.14% in Q2 2020 and 12.26% in Q3 2020. Manual data cleaning efforts contributed to a gradual decline, but significant discrepancies remained, with a rate of 5.56% recorded in Q2 2022, just before the enhancement.



Post-implementation, discrepancy rates dropped sharply to 2.86% by Q4 2022 and continued to decline, reaching 1.15% in Q2 2023 and 0.00% by Q4 2023. These levels were sustained throughout 2024, indicating the system's effectiveness in eliminating discrepancies and ensuring alignment between documented and prescribed regimens.

Conclusions/Next steps: The validation rules in CMIS substantially improved the accuracy and consistency of ART regimen documentation, ultimately ensuring optimal documentation of PLHIV, and positive health outcomes. These findings demonstrate the critical role of technology in addressing data quality challenges and better patient management.

Manual data cleaning efforts were insufficient to address discrepancies, and this intervention highlights the potential for similar digital health solutions to improve data reliability and healthcare outcomes in low-resource settings.

WEPEE143

Community-led monitoring: a pathway to improved mental health services

O. Obeten[1], F. Medayese[2], A. Ibrahim[2], J. Atusue[2], E.M. Okoh[2], A.B. Arop[3], A.U. Chinonyerem[4], A.M. Ekene[2], N. Ugbenyen[2], A. Opeyemi[5], U. Ugwoke[5], T. Adetiba[5], O. Olupitan[5], E. Vincent[5], M. Zamzu[6], N. Workneh[6]

[1]Network of People Living with HIV in Nigeria, Research and Learning, Abuja, Nigeria, [2]Network of People living with HIV in Nigeria, Research and Learning, Abuja, Nigeria, [3]General Hospital Asokoro, Abuja, Nigeria, [4]AIDS Healthcare Foundation, Abuja Capital Territory, Nigeria, [5]Global Fund N-THRIP, Institute of Human Virology, Research and Learning, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria,, Global Health Campus,, Geneva, Switzerland

Background: Mental health is a critical but often overlooked component of healthcare systems, particularly in resource-constrained settings. Community-Led Monitoring (CLM) offers a promising approach to bridging gaps in mental health service by engaging communities to assess, monitor, and advocate for better service delivery. This study explores the impact of CLM on identifying and addressing mental health challenges in underserved populations.

Methods: A cross-sectional approach was employed to collect data on mental health service delivery challenges through a combination of quantitative and qualitative methods in 13 states in Nigeria, where NEPWHAN implements CLM, within a period of January to June 2024. Study population included people living with HIV (PLHIV), Key Population (KP) and Adolescent and young People (AYP). Community iMonitor, a digital application, was used to collect feedback from community members, while focus group discussions provided deeper insights into lived experiences. Quantitative data from the app were analysed using IBM SPSS Statistics 23 while qualitative data using thematic analysis techniques.

Results: Preliminary findings reveal significant barriers to accessing mental health care, including limited availability of services, stigma, and lack of integration into broader health-systems. Out of the 17,657-self reporting, 47.9% of all the study population reported poor access to mental health services, including 48% among PLHIV, 47% among AYP, 43% among MSM, 44% among TG, 40% among PWID and 48% among FSW. The qualitative data findings shows that access to mental health and legal services were identified as major barriers to HIV treatment services by 3 out of 4 of the FGD participants.

Additionally, more than one-quarter of the respondents reported experiencing stigma and discrimination from healthcare workers. Community-led efforts highlighted critical needs, such as increased availability of mental health professionals, legal support for mental health advocacy, and access to psychosocial support services.

Conclusions: The integration of mental health into CLM frameworks has proven effective in identifying service delivery gaps and empowering communities. Addressing mental health challenges through community-driven efforts is essential for achieving equitable health outcomes

and ensuring health-system sustainability. Targeted interventions and continued engagement with policymakers are crucial to improving mental health services and reducing stigma among PLHIV, KP and the Vulnerable populations.

WEPEE144

Strengthening digital monitoring to scale up tuberculosis preventive treatment among new PLHIV in Akwa Ibom and Cross River States

E. Ezieke[1], O. Ogheneuzuazo[1], E. Nwanja[1], U. Akpan[1], O. Toyo[1], D. Ogundehin[2], R. Eneogu[2], U. Omo-Emmanuel[2], M. Katbi[2], D. Kimanga[2], C. Obiora-Okafor[2], A. Idemudia[2], B. Adebola[3], R. Agulu[4], E. James[2], J. Pius[2], O. Oyelaran[2], O. Onyedinachi[1], A. Adegboye[1], A. Eyo[1]
[1]Excellent Community Education Welfare Scheme, Uyo, Nigeria, [2]Office of HIV and TB, United States Agency for International Development, Abuja, Nigeria, [3]National AIDS and STDs Control programme, Abuja, Nigeria, [4]National Agency for the Control of AIDS, Abuja, Nigeria

Background: Tuberculosis preventive therapy (TPT) reduces the risk of active tuberculosis among people living with HIV (PLHIV). The PEPFAR/USAID-funded ECEWS ACE-5 project identified suboptimal TPT uptake among PLHIV initiating antiretroviral therapy (ART). To address this, the monitoring system for TPT uptake was revised using the WHO health systems framework.
This study describes the revised monitoring system and reports outcomes from the intervention to improve TPT uptake among PLHIV newly initiating ART.
Description: A Power-BI dashboard, used for weekly project review meetings, was updated to disaggregate TPT data by PLHIV ART status, as either 'newly diagnosed' and 'already on ART'. Designated focal persons identified underperforming facilities during the meetings and followed up via phone calls or in-person visits to line-list eligible clients and initiate TPT. The intervention was implemented across 218 health facilities in Cross River and Akwa Ibom states from May 2024 to October 2024. In this setting, TPT was provided to all individuals at ART initiation. TPT uptake (proportion of newly diagnosed PLHIV who received TPT) was compared over six months prior to the intervention (November 2023-April 2024) and for the six months of the intervention using a chi-square test, with significance set at $p < 0.05$.
Lessons learned: A total of 9,237 PLHIV initiated ART within the period, with 56.2% initiating ART before the intervention. 69.8% were females, median age was 34 years (IQR:26-43). Overall, TPT uptake was 76.4% (7,057). TPT uptake was significantly higher during the intervention compared to the period prior (92.3% (3733/4044) vs 64.0% (3,324/5193; $p<0.001$).
Compared by age and sex, TPT uptake was also higher in the intervention period. In-person visits were more effective in addressing TPT initiation gaps than phone calls but were limited by the availability of designated focal persons. When facilities started reviewing TPT data before transmission, there were fewer gaps identified during the project-level meetings.
Conclusions/Next steps: Improving the health information monitoring system and optimizing human resources for TB/HIV services significantly improved TPT uptake among PLHIV newly initiating ART. Sustaining these gains and expanding the intervention to other locations experiencing similar gaps could further reduce the burden of TB among PLHIV.

WEPEE145

Active monitoring to improve viral load testing coverage and suppression among people living with HIV receiving care at AHF-supported health facilities in Rwanda

D. Sebuhoro[1], F. Kayitesi[1], G. Mbaraga[2], L. Rangira[3], L. Buzaalirwa[4], N. Dube[5], C. Baribwira[6]
[1]Aids Health Care Foundation, Monitoring and Evaluation, Kigali, Rwanda, [2]Aids Health Care Foundation, Medical, Kigali, Rwanda, [3]Aids Health Care Foundation, Programs Management, Kigali, Rwanda, [4]Aids Health Care Foundation, Quality Improvement and Medical Logistics, Kampala, Uganda, [5]Aids Health Care Foundation, Quality Management and Clinical Operations, Manzini, South Africa, [6]Georgetown University, Independent Contractor, Kigali, Rwanda

Background: The goal of antiretroviral therapy (ART) for people living with HIV (PLHIV) is to achieve and maintain viral suppression. In Rwanda, viral load (VL) testing coverage is 91%, with a suppression rate of 94%. However, VL testing coverage in sub-Saharan Africa varies widely from 24.3% to 99.7%. To improve timely case management and avoid missed tests, active VL monitoring is crucial.
Due to gaps in paper-based tracking systems, AHF-Rwanda has introduced an annual chart review to validate active clients, assess VL testing coverage, and monitor suppression rates at supported health facilities.
Description: In 38 AHF-supported health facilities in Rwanda, an annual chart review activity is conducted to monitor active PLHIV in care, assess VL testing coverage, and track viral suppression rates. Healthcare providers, clinical mentors, and data teams jointly review patient files to verify facility attendance and ensure VL tests have been done within the past 12 months.
Lessons learned: The Monitoring and Evaluation (M&E) team extracts client files from OpenMRS quarterly to identify clients due or overdue for VL testing, sharing the list with healthcare providers and clinical mentors for follow-up.
This intervention has led to a significant increase in VL testing coverage, from 81.5% [range: 67.2%-96.9%] in 2019 to 95.3% [range: 85.2%-100%] in 2024 at AHF-supported health facilities.
The viral load suppression rate (<1000 copies/ml) also improved from 91.9% [80.1%-100%] in 2019 to 98.8% [range: 93.4%-100%] in 2024. Clients found inactive and those overdue for VL testing are followed up and re-engaged in care to ensure timely testing and retention.
Conclusions/Next steps: Annual chart review has proven to be effective in improving viral load testing coverage and suppression rates. This active monitoring process en-

hances the quality of care, ensures better outcomes for PLHIV, and fosters a collaborative environment between data team and healthcare providers.

WEPEE146

Introducing data sheets: improving HIV data visibility and use for data-driven decision making at sub-national and facility level

M. Ng'ong'ola Sesani[1], G. Nyirenda[1], D. Telela[1], S. Mbiriyawanda[2], T. Chimphandule[2], T. Masina[2], M. Muyaso[2], P. Nettleton[3], M. Ginivan[4], G. Chipendo[5], L. Mwandira[1], J. Nkhunga[6], C. Kachala[7], F. Bandawe Zintambila[8], T. Mwenifumbo[1], A. Gunda[1]

[1]Clinton Health Access Initiative (CHAI), Infectious Diseases, Lilongwe, Malawi, [2]Ministry of Health Malawi, HIV and AIDS, Lilongwe, Malawi, [3]Clinton Health Access Initiative (CHAI), Global HIV Testing Services, Johannesburg, South Africa, [4]Clinton Health Access Initiative (CHAI), Global HIV Testing Services, Harare, Zimbabwe, [5]Clinton Health Access Initiative (CHAI), Global HIV Testing Services, Vindhoek, Namibia, [6]Lilongwe District Health Office, HIV Testing Services, Lilongwe, Malawi, [7]Salima District Health Office, HIV Testing Services, Salima, Malawi, [8]Blantyre District Health Office, HIV Testing Services, Blantyre, Malawi

Background: HIV Testing Services (HTS) data is routinely collected at facility level and reported up to national level. However, gaps remain in data visibility and use at sub-national and facility levels to guide evidence-based decisions.

To address this, with support from CHAI, seven districts introduced the data sheet approach – a sustainable, low-cost solution to provide usable insights for decision making at district and facility level.

Description: Data sheets are tailored summaries of facility level HIV program indicators developed using current data systems (Scanform, DHAMIS and DHIS2) for use by district coordinators to inform decision making during facility-based mentorship and sub-national TWGs. The approach built the capacity of HIV district teams to extract data and develop tailored analyses to more effectively identify and address key bottlenecks.

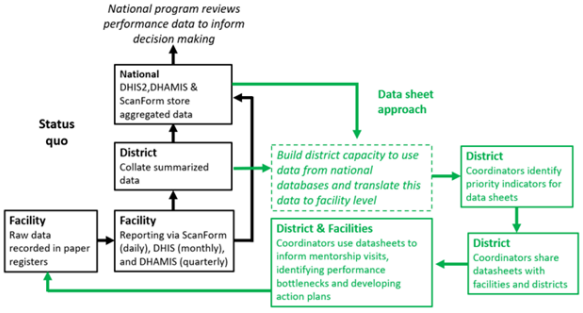


Fig. 1. Data sheet approach integrated into existing facility level mentorship.

Lessons learned: Data driven mentorships improved service delivery (Fig. 2) with some findings from the mentorship taken to sub-national TWGs for solutions. For example, data sheets and mentorship in Blantyre district revealed a gap in testing coverage at Maternity. Coordinators presented this to the sub-national TWG, where interventions resulted in a 21% increase in testing coverage at the affected Maternity sites.

Key lessons included accounting for biennial district coordinator turnover when building sustainable district level capacity. Training the entire district team to ensure institutional knowledge, supported by a forthcoming handbook on the data sheet development process, and closer coordination with PEPFAR partners, helped to address sustainable integration.

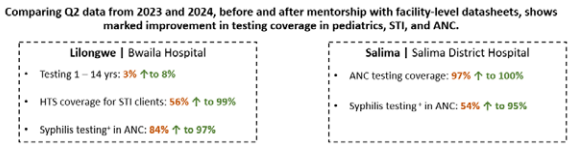

Fig. 2. Impact of data driven mentorship in facilities in Lilongwe and Salima.

Conclusions/Next steps: The data for decision making approach is an effective intervention and recommended for scale-up and integration into the national M&E system.

Host immune responses

THPEA007

Natural killer cell metabolism in PLWH and the effect of ART timing

K.K. Naidoo[1,2], R. Sewbachan[2], Z. Mncube[2], N. Ismail[2], K.L. Dong[3,4,5], M.J. Bunders[1,6], M. Altfeld[1,7], T. Ndung'u[2,3,8]

[1]Leibniz Institute of Virology, Virus Immunology, Hamburg, Germany, [2]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, [3]Ragon Institute of Mass General, MIT and Harvard, Cambridge, United States, [4]Massachusetts General Hospital, Boston, United States, [5]Harvard Medical School, Boston, United States, [6]University Medical Center Hamburg-Eppendorf, III Department of Medicine, Hamburg, Germany, [7]German Center for Infection Disease (DZIF), Partner Site Hamburg-Lübeck-Borstel-Riems, Germany, [8]Africa Health Research Institute, Durban, South Africa

Background: Natural killer (NK) cells are critical mediators of antiviral immunity. Immunological impairment by HIV-1 leads to expansion of a functionally aberrant CD56^{neg} NK cell subset. Antiretroviral therapy (ART) differentially rectifies immune damage caused by HIV-1, depending on the timing of ART initiation; however, the biological mechanisms underlying this immune restoration are not well understood. Metabolism is key to the modulation of cellular activities and deciphering mechanisms associated with antiviral immune function may prove beneficial in correcting NK cell dysfunction. We investigated the impact of HIV-1 infection and ART timing on NK cell metabolism.

Methods: Thirty-four females living with HIV-1 from South Africa who initiated ART during either very early acute HIV-1 infection (AHI) (N=18) or chronic HIV-1 infection (CHI) (N=16) were enrolled. PBMC samples collected pre- and post-ART initiation were available to assess uptake of fluorescently tagged metabolic surrogates and mitochondrial staining in NK cells by flow cytometry.
Results: All 34 participants had comparable CD4+ T cell counts after 12 months on ART, irrespective of the timing of ART initiation. AHI was accompanied by a transient increase in NK cell frequencies with ART initiation during AHI preserving NK cell frequencies and NK cell subset distributions for up to 12 months post-ART initiation.
In comparison, NK cell subset proportions in CHI were skewed toward expansion of $CD56^{neg}$ NK cells and a decline of $CD56^{dim}$ NK cells for up to 12 months post-ART initiation. $CD56^{neg}$ NK cells in CHI displayed significantly lower glucose uptake compared to the $CD56^{dim}$ NK cell subset prior to and up to 12 months after ART initiation, whereas the uptake of fatty acids and amino acids by $CD56^{neg}$ NK cells were comparable to $CD56^{dim}$ NK cells.
Furthermore, $CD56^{neg}$ NK cells exhibited higher mitochondrial mass and lower mitochondrial membrane potential compared to $CD56^{dim}$ NK cells pre- and post-ART initiation.
Conclusions: HIV-1 induced expansion of a $CD56^{neg}$ NK cell subset with reduced glucose uptake and mitochondrial perturbations that persist for at least 12 months when ART was initiated in CHI.
Notably, accumulation of metabolically impaired $CD56^{neg}$ NK cells was largely prevented when ART was initiated during AHI.

THPEA008

Total HIV DNA and inflammatory profile in older People with HIV: no evident association with the aging process within one year of follow-up

L.A. Osorio-Ocampo[1], A. Czernikier[1], P. Benencio[1], L. Cruces[1], A. Osegueda[1], L. Baquero[1], G. Mernies[2], M. Ceschel[2], A. Gun[2], P. Cahn[2], C. Cesar[2], M. Figueroa[2], Y. Ghiglione[1], G. Turk[1]
[1]Universidad de Buenos Aires, Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Ciudad Autónoma de Buenos Aires, Argentina, [2]Fundación Huésped, Ciudad Autónoma de Buenos Aires, Argentina

Background: People with HIV (PWH) have longer life expectancy thanks to improved ARV regimens. Still, HIV-driven persistent immune activation and higher reservoir size and activity, might synergize with the aging process contributing to earlier and more frequent age-related comorbidities.
This sub-study aimed to assess the inflammatory profile and the viral reservoir dynamics of people over 50 years old with HIV to the AGING/CCASAnet cohort, at baseline and one-year later as a follow-up.
Methods: Forty participants from Argentina belonging to the CCASAnet/Aging Research Network were enrolled: age ≥50 years old, on antiretroviral therapy (ART) ≥6 months and undetectable (UD) viral load (VL). Blood samples were obtained at enrollment (baseline, BSL) and after twelve months (12m). VL, CD4 count, Montreal Cognitive Assessment (MoCA) score and comorbidities were registered. Plasma cytokines (IL-1β, IL-6, IL-8, IL-10, IL-17a, TNF-α, MIF, IP-10) were measured by ELISA and LEGENDplex. Viral reservoir (total HIV DNA) was quantified by qPCR. Data were analyzed by nonparametric statistics.
Results: Out of the forty participants, 72% were male; median age: 62 years (IQR: 57-67); median time with UD VL: 9 years (IQR: 5-14.5); BSL median CD4 count: 745 cells/mm^3 (IQR: 521-975). IL-6, TNF-α, and MIF levels significantly increased from BSL to 12m ($p<0.0001$, $p=0.0298$, $p=0.0002$, respectively). Total HIV DNA showed no differences between BSL and 12m. Noteworthy, 40% of females and 69% of males showed higher HIV DNA levels at 12m compared to BSL. No significant correlations were observed between HIV DNA and VL, CD4 count, plasma cytokines or MoCA score. Even more, HIV DNA was inversely correlated with the number of comorbidities (BSL: $r=-0.4585$, $p=0.0108$; 12m: $r=-0.4221$, $p=0.0317$).
Conclusions: In this cohort of PWH aged ≥50, with a wide variability regarding time on suppressive ART, a progressive elevation of proinflammatory cytokines was observed, while the HIV reservoir remained stable within the short time-frame evaluated here.
Contrary to our initial hypothesis, the size of the HIV reservoir was not associated with cognitive function, as measured by MoCA, and was lower in PWH with a higher number of comorbidities.
Further studies with a more in-depth characterization of the reservoir over an extended period are warranted.

THPEA009

Cannabinoid receptor 2 agonists alter immune responses and decrease neuroinflammation in HIV infected humanized mice

Y. Persidsky[1], U. Sriram[1], V. Zuluaga Ramirez[1], S. Rom[1], S. Gajgahate[1], A. Seliga[1], M. Winfield[1], R. Potula[1]
[1]Temple University School of Medicine, Philadelphia, United States

Background: Despite effective control of HIV replication by antiretroviral therapies, a significant number of patients develop HIV-associated neurologic disorders (HAND). HAND is attributed to chronic immune activation, ongoing neuroinflammation and blood brain barrier (BBB) compromise.
We have recently shown that factors implicated in HAND pathogenesis could be mitigated by cannabinoid receptor 2 (CB_2) stimulation.
Methods: We have, for the first time, tested the effectiveness of three novel non-toxic and orally bioavailable CB_2 agonists provided by Roche Pharmaceuticals in chronic HIV infection using the huNSG mouse model. Using non-forceful feeding as the method of daily administration, we studied effects on HIV infection up to 12 weeks.
Results: All tested CB_2 agonists attenuated immune activation markers in the blood; however, none had an effect on HIV viral loads *per se*. The CB_2 agonists diminished im-

mune activation in the spleen and normalized cytokine profile in the blood. CB_2 agonists dampened microglial activation and improved expression of tight junction protein that stabilize the BBB. we evaluated microglial reaction (IBA1) and expression of the tight junction (TJ) protein, claudin-5 (indicator of BBB integrity), assessed by semi-quantitative analyses.
Moderate microglia reaction was detected in HIV-infected animals by IBA1 immunostaining and it was significantly higher as compared to untreated uninfected animals. Treatment with all agonists decreased microglial activation to almost control levels.
HIV infection was associated with significantly diminished claudin-5 expression as compared to controls, and administration of CB_2 agonists significantly improved TJ staining. Human HLA-positive mononuclear cells were found within meningeal and less often within cortical microvessels.
Some cells appeared in perivascular spaces. HIV-infected mice showed a trend in increased HLA+ cells. However, CB_2 agonist diminished the presence of such activated cells.
Conclusions: Our results indicate that orally administered CB_2 agonists diminished excessive immune activation, improved TJ expression and attenuated neuroinflammation. However, they failed to suppress HIV replication *in vivo*. Novel orally bioavailable CB_2 agonists warrant further investigation as candidates to be included in a HIV treatment regimen.

Understanding and targeting persistent HIV reservoirs

THPEA010

Networked cytotoxic T lymphocyte epitopes exhibit markedly reduced mutability in the latent HIV reservoir

F. Senjobe[1,2], I. Muzhingi[2], J. Urbach[2], R. Tano-Menka[2], A. Nathan[3], C. Kaseke[2], G. Gaurav[4,2]
[1]Harvard Virology, Virology, Cambridge, United States, [2]Ragon Institute of Mass General, MIT and Harvard, Cambridge, United States, [3]Harvard Medical School, Boston Program in Health Sciences and Technology, Cambridge, United States, [4]Massachusetts, General Hospital, Division of Gastroenterology, Boston, United States

Background: The persistent HIV latent reservoir presents a formidable challenge to achieving a functional cure for people living with HIV (PLWH) following anti-retroviral therapy (ART) cessation. A major challenge in Cytotoxic T lymphocyte (CTL) based strategies to control viral rebound has been the emergence of escape mutations, which allow HIV to evade immune detection. However, we identified a unique subset of CTL epitopes, termed networked epitopes, that are structurally constrained from mutation and are preferentially targeted by individuals who naturally control HIV.
In this study, we investigate whether networked epitopes serve as viable targets within the latent HIV reservoir, offering a promising avenue for a more effective and durable CTL mediated suppression of the virus.
Methods: To assess mutational frequencies of networked and non-networked epitopes within the reservoir, we performed integrated proviral and near full-length individual proviral (FLIP) sequencing on genomic DNA isolated from CD4+T cells of 22 PLWH who were fully suppressed on ART. Using a validated computational pipeline, we conducted detailed mutational sequence analysis of viral epitopes, assessing both the quantity and quality of mutations. We investigated the ability of CTLs to cross-recognize both wild-type (WT) and mutant (mt) epitopes, networked and non-networked, via cross-reactivity assays.
We examined the differential capacity of CTLs targeting networked and non-networked epitopes to eliminate target cells.
Results: Networked epitopes exhibited a significantly lower mutation frequency than non-networked epitopes in integrated ($P<0.0001$), and near full-length proviruses. The trend remained consistent in epitopes restricted by individual HLA class I haplotypes ($P<0.0002$).
Non-networked epitopes exhibited a marked enrichment for cumulative, conservative, and non-conservative mutations. CTL responses to highly networked epitopes maintained robust recognition of mutated variants, whereas mutated non-networked epitopes exhibited a significant reduction in recognition.
We hypothesize that CTLs targeting networked epitopes will exhibit superior target cell elimination compared to those targeting non-networked epitopes.
Conclusions: NNetworked epitopes exhibit markedly fewer mutations within the latent reservoir of ART-suppressed PLWH. CTLs recognize mutants of high networked epitopes better than mutants of non-networked epitopes. These results suggest that networked epitopes represent a set of mutationally constrained targets for therapeutic T cell vaccines that may enable durable viral suppression following ART cessation.

THPEA011

People living with HIV and TB has a reduced reactivation potential and an increase T cell exhaustion

C. Abana[1], J. Klutse[1], E. Kanda[1], M.A. Hanson[1], Y. Tay[1], P.A. Nartey[1], D. Attoh[1], J. Atanniba[1], J.O. Aboagye[1,2], H. Lamptey[3], E.Y. Bonney[1], G.B. Kyei[1,2]
[1]Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Virology, Accra, Ghana, [2]Medical and Scientific Research Center, University of Ghana Medical Center, Accra, Ghana, [3]Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Immunology, Accra, Ghana

Background: This study investigates the impact of latent tuberculosis infection (LTBI) on HIV persistence, focusing on T cell activation, response to latency-reversing agents (LRAs), and reservoir size in the HIV-LTBI persons. Provirus persistence in resting memory CD4+ T cells is the primary

barrier to curing HIV, and acquiring *Mycobacterium tuberculosis* exacerbates immune activation, potentially enlarging the HIV reservoir. In Ghana, routine screening and treatment for LTBI in people living with HIV are rare.
Methods: We screened 390 individuals living with HIV for latent tuberculosis infection (LTBI) and identified 37 cases (viral load <50 copies/ml) using the QuantiFERON®-TB Gold Plus assay. Of the 37 people with LTBI, T cell activation and exhaustion markers were assessed in 15 using flow cytometry, and respon3ses to LRAs in 10 (Vorinostat and MC1568) were measured ex vivo using RT-qPCR.
Results: Our results indicate that activation markers, such as CD69, CD25, HLA-DR, and CD38 are highly expressed in T cells isolated from people living HIV but not the HIV-TB persons. Conversely, we are found, high expression of PD1, LAG-3, and CD244 exhaustion markers on CD4+ and CD8+ T cells among the people living with HIV and TB. HIV reactivation potential was 20-fold in people living with HIV-only compared to 14-fold in the HIV-TB people, suggesting stronger immune activation and T cell exhaustion in these persons.
Conclusions: This suggests that there is stronger immune activation in the HIV-TB people resulting in T cell exhaustion which may impact response to latency reversing agents and reservoir size. It implies that alternative cure methods, or at least more aggressive latency reversal agents, will be necessary for these group of people (HIV-TB individuals). Additional research on reservoir size is ongoing, with results to be presented at IAS 2025.

Novel treatment and prevention strategies, vaccines and immunotherapies

THPEA012

Immunological features associated with the development of broadly neutralizing antibodies and Fc-effector functions in people living with HIV-1 subtype C

H.Z. Mlimi[1], A. Khairallah[2], S. Resehlo[2], T. Ndung'u[1,2], D. Muema[2], B. Ndlovu[1]
[1]University of KwaZulu-Natal - Nelson R. Mandela School of Medicine, School of Laboratory Medicine & Medical Sciences, Durban, South Africa, [2]University of KwaZulu-Natal., Africa Health Research Institute, Durban, South Africa

Background: The induction of broadly neutralizing antibodies (bnAbs) is highly desired for an effective vaccine against HIV-1. Few host genes and immune profiles were associated with the development of bnAbs. However, the functional impact of host genes in immune cell subsets and their association with the development of bnAbs are not fully understood. This study aims to assess the role of host gene transcripts and immune profiles associated with development of bNAbs and fc mediated function during acute HIV-1 clade C acquisition.
Methods: Bulk RNA-sequencing (RNA-seq) was performed in 25 chronically HIV-1-subtype C cohort in Durban, looking at individuals who developed bnAbs and without bnAbs. Furthermore, in-vitro co-culture of CD4+ T cells, B cells and NK cells was performed on healthy donors and flow cytometry was performed to quantify the frequency of class-switched memory B cells, plasmablasts and IgM positive B cells. Total IgG antibody production was measured using ELISA
Results: We identified five genes (CD244, KLRK1, BTK, CCR6 and MAPKAP1) that were upregulated in the group that developed bnAbs. These genes play a key role in the development and maturation of B cells and they stimulate antibody-mediated effector functions.
Furthermore, natural killer cells reduced the frequency of plasmablasts, IgM and IgG antibody production, while the frequency of class-switched memory B cells increased.
Conclusions: These findings suggest that genes that enhance B cell proliferation and maturation are upregulated in participants that develop bnAbs. However, activated NK cells reduce the maturation of B cells and antibody production.
This study may generate crucial information on host immune factors that should be considered in the design of future neutralizing antibody-based therapeutic and preventive vaccines.

HIV-associated viruses, co-infections and co-morbidities

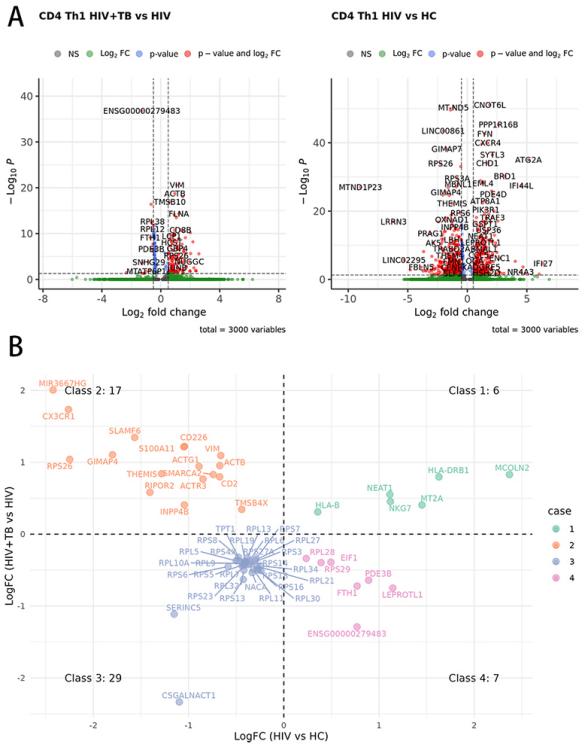
THPEA013

Dissecting early Th1 immune signatures in HIV/TB coinfection using a novel quadrant-based differential gene expression method

Z. Zhao[1,2], S. Huang[2], W. Huang[2], W. Song[2], L. Liu[2], J. Chen[2], R. Zhang[2], Y. Shen[2]
[1]Shanghai Institute of Infectious Disease and Biosecurity, Fudan University, Shanghai, China, [2]Shanghai Public Health Clinical Center, Fudan University, Shanghai, China

Background: *Mycobacterium tuberculosis* (MTB) remains a leading cause of mortality in HIV/AIDS patients. The 2024 Global Tuberculosis Report states that 1.25 million TB-related deaths occurred in 2023, with around 160,000 in HIV co-infected patients. Therefore, early diagnosis and immunological characterization of TB in HIV/AIDS populations are critical.
Methods: We collected peripheral blood mononuclear cells (PBMCs) from three newly diagnosed HIV/AIDS patients and three HIV/AIDS patients co-infected with MTB. Single-cell RNA sequencing focused on T cells, with Th1, Th2, and Th17 subpopulations annotated. Pairwise comparisons of Th1 cells (HIV_TB vs. HIV, HIV vs. HC) were conducted, and a novel method, common_de_marker_selection, was developed to visualize differentially expressed genes(DEGs) in both comparisons.

Results: Volcano plots are shown in Figure 1A, and shared DEGs in Figure 1B. Class 1 was enriched in processes such as "leukocyte mediated cytotoxicity" and "detection of bacterium" reflecting heightened Th1 immune activation under dual pathogen pressure. Class 2 highlighted T cell differentiation, IFN-γ production, and chromatin remodeling complexes (BAF/npBAF/GBAF), suggesting a compensatory or reactivated Th1 response upon TB coinfection. Class 3 encompassed ribosome biogenesis and protein translation pathways, implying a global translational repression potentially linked to chronic viral infection and nutritional/energetic stress. The significant downregulation of SERINC5 in both groups suggests that TB coinfection may enhance HIV particle entry into host cells. Class 4 included regulation of ferroptosis regulation and negative regulation of integrin-mediated adhesion, suggesting partial readjustment of HIV-induced pathways by TB.



Conclusions: Our new methods reveal that HIV/TB coinfection elicits complex Th1 immune responses. While some pathways are amplified (Class 1 and 2), others are profoundly suppressed or rebalanced (Class 3 and 4), and potential molecular markers, such as SERINC5, can also be identified.

These findings highlight that in HIV/TB coinfection, pathways are not "simultaneously suppressed or activated," but exhibit a finely tuned, spatiotemporal interplay.

THPEA014

Programmed Cell Death Protein-1 expression on monocytes and T-cells is associated with mortality from HIV-associated cryptococcal meningitis

[1]London School of Hygiene and Tropical Medicine, Clinical Research Department, Faculty of Infectious and Tropical Diseases, London, United Kingdom, [2]University of Minnesota, Division of Infectious Diseases & International Medicine, Department of Medicine, Minnesota, United States, [3]Kamuzu Central Hospital, University of North Carolina Project, Lilongwe, Malawi, [4]University of North Carolina at Chapel Hill School of Medicine, Department of Medicine, Chapel Hill, United States, [5]Malawi-Liverpool-Wellcome Programme, Blantyre, Malawi, [6]Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom, [7]University of Cape Town, Wellcome Centre for Infectious Diseases Research in Africa (CIDRI-Africa), Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, [8]Queen Mary University of London, Blizard Institute, London, United Kingdom, [9]University of Cape Town, Department of Medicine, Cape Town, South Africa, [10]Makerere University, Infectious Diseases Institute, College of Health Sciences, Kampala, Uganda, [11]Botswana Harvard Health Partnership, Gaborone, Botswana, [12]University of Botswana, Department of Internal Medicine, Faculty of Medicine, Gaborone, Botswana, [13]Mbarara University of Science and Technology, Department of Medicine, Mbarara, Uganda, [14]Kamuzu University of Health Sciences, Department of Medcine, Blantyre, Malawi, [15]University of Zimbabwe, Department of Internal Medicine, Faculty of Medicine and Health Sciences, Harare, Zimbabwe, [16]St George's University of London, Centre for Global Health, Institute of Infection and Immunity, London, United Kingdom, [17]University of Birmingham, Institute of Microbiology and Infection, College of Medicine and Health, Birmingham, United Kingdom

Background: HIV-associated cryptococcal meningitis (HIV-CM) accounts for up to 19% of all HIV-related deaths. Impaired host immune responses at presentation are associated with poor outcome but have not been clearly defined. Mice models of cryptococcal disease have demonstrated that persistent pulmonary disease is associated with increased and sustained Programmed Cell Death-1 (PD-1) expression on lung lymphocytes and that PD-1 blockade significantly improves pulmonary fungal clearance. Knowledge of the role of the PD-1 signalling pathway in human cryptococcal disease is limited.

We investigated PD-1and Programmed Cell Death Ligand-1 (PD-L1) signalling in peripheral blood mononucleocytes (PBMC) of individuals with HIV-CM.

Methods: We enrolled a consecutive sub-sample of participants with laboratory confirmed HIV-CM recruited into the AMBITION Phase 3 trial in Botswana, Malawi and Uganda. PBMC collected before treatment were immuno-

phenotyped and analysed by 8-color flow cytometry according to established protocols. Clinical outcomes and laboratory data were documented during 10-weeks of follow-up. Associations between immunophenotypes and mortality were investigated.

Results: 79 participants were enrolled into the sub-study between 2018-2019. 44% were male, median age was 36 (IQR 31-41 years), and median CD4 count 33 (IQR 12-73 cells/uL). Overall mortality was 9% (7/79) by 2-weeks, and 19% (15/79) by 10-weeks. PD-1 and PD-L1 surface expression on monocytes ($p<0.001$) and PD-1 expression on T-cells ($p<0.01$) was significantly higher in non-survivors than survivors at both 2- and 10-weeks (Figure 1).

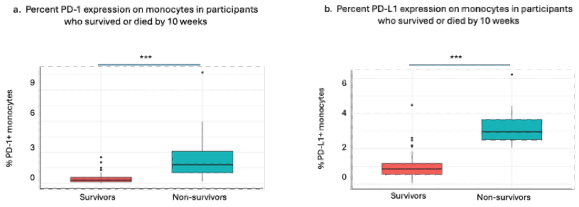

Figure 1.

Conclusions: PD1 expression on monocytes is associated with poor outcomes in HIV-CM in humans, replicating findings from animal studies. Further research is needed to determine the value of PD1 to stratify management of individuals with HIV- CM and determine whether PD1 blockade could improve clinical outcomes.

THPEA015

Genome-wide association study identifies novel variants associated with mortality in individuals with HIV-associated cryptococcal meningitis

D. Lawrence[1,2,3], R. Doyle[1], A. Pittman[4], K. Boyd[1], K. Ssebambulidde[5], K. Lechiile[2], J. Milburn[1,2], C. Kanyama[6], G. Meintjes[7,8], D. Meya[5], M. Mosepele[2,9], C. Muzoora[5,10], H. Mwandumba[11,12], C. Ndhlovu[13], T. Harrison[4], J. Jarvis[1,2]

[1]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [2]Botswana Harvard Health Partnership, Gaborone, Botswana, [3]University of the Witwatersrand, School of Pathology, Faculty of Health Sciences, Johannesburg, South Africa, [4]City St George's, University of London, London, United Kingdom, [5]Infectious Diseases Institute, Kampala, Uganda, [6]UNC Project - Malawi, Lilongwe, Malawi, [7]University of Cape Town, Cape Town, South Africa, [8]Queen Mary University of London, London, United Kingdom, [9]University of Botswana, Gaborone, Botswana, [10]Mbarara University of Science and Technology, Mbarara, Uganda, [11]Malawi-Liverpool-Wellcome Clinical Research Programme, Blantyre, Malawi, [12]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [13]University of Zimbabwe, Harare, Zimbabwe

Background: Cryptococcal meningitis primarily affects individuals with advanced HIV disease and two-week mortality in high-prevalence settings remains high (15-20%) despite effective antifungal therapy. There is a poor understanding of how compromised immune responses contribute to these outcomes. We conducted a Genome-Wide Association Study (GWAS) of individuals with HIV-associated cryptococcal meningitis to identify genetic determinants associated with mortality.

Methods: We genotyped participants recruited into the AMBITION trial from Botswana, Malawi, South Africa, Uganda and Zimbabwe using the Illumina Global Screening Array beadchip (Illumina, San Diego, USA). Each SNP was assessed by linear regression with PLINK comparing participants who died within two weeks with those that survived.

A subset of participants also had baseline cerebrospinal fluid analysed using multiplex Luminex immunoassays for cytokine quantification as well as bulk transcriptomics for differential gene expression.

Results: We included 828 participants; 103 died and 725 survived at two weeks. 53 SNPs were significantly ($P < 10^{-4}$) associated with 2-week mortality but did not reach genome-wide significance ($P < 10^{-8}$).

Functional annotation of these SNPs identified 2 associated with regulation of complement cascade (rs73079108 in an intronic region *CSMD2* and rs923879 upstream of *C4BPA* and downstream of *C4BPB*).

Another intronic SNP (chr12-6486831) was present in the gene *LTBR,* a receptor for TNF-α, and one SNP (rs7981864) was downstream of *LCP1,* which encodes an actin-binding protein that activates T-cells through co-stimulation with CD3. Gene set enrichment analysis of the transcriptomics data found genes associated with the classical complement pathway (*C1S*, *C1QB*) were overexpressed in participants that died (Log2 fold-change > 2, $P < 0.05$). Quantification of TNF-α showed a significant association between higher TNF-α concentrations and survival ($P= 0.0435$).

Conclusions: In the largest GWAS of individuals with HIV-associated cryptococcal meningitis to date we identified novel genetic biomarkers associated with mortality. We confirmed the GWAS association between mortality and overexpression of complement and the suppression of TNF-α signalling pathways with transcriptomics and multiplex immunoassays. These represent new potential treatment targets for severe disease.

Emerging, re-emerging and neglected virus: epidemiology, pathogenesis, host immune responses, vaccines, immunotherapies and overlap with HIV acquisition

THPEA016

Antibody neutralization capacity among SARS-CoV-2-infected individuals in Cameroon increases overtime

S.H. Tene[1], M. Castro[2], S. Schmidt[2], N.S. Lima[2], M. Basappa[2], R. Djounda[1], L. Serebryannyy[2], A. Spaulding[2], L. Esemu[1,3], D. Douek[2]

[1]Centre for Research on Emerging and Reemerging Diseases, Immunology, Yaounde, Cameroon, [2]Vaccine Research Center, NIH, Bethesda, United States, [3]University of Buea, Buea, Cameroon

Background: Understanding how our immune system responds to SARS-CoV-2, especially as the virus evolves, is crucial to predicting vaccines response across time. This study investigates antibody responses against SARS-CoV-2 variants in individuals across different time points with emphasis on variants of concern.

Methods: Plasma from 45 individuals following SARS-Cov-2 infection were collected at three dates corresponding to the day of diagnosis, 14- and 4Cross 4-days post-diagnosis. The cohort consisted of 49% symptomatic and 51% asymptomatic individuals, all with no prior vaccination history, and recruited during the pre-Omicron era. We evaluated binding responses using MSD variant pates with 9 antigens including CoV2-S, B.1.1.7, B.1.617.2, B.1.351, B.2.12.1, BA.1, BA.5, BA.2.75, and BA.2 as well as CoV-2-N.

The breadth of neutralization was determined with neutralization ID50 obtained after Luciferase based neutralization assay. The pseudoviruses used for Neutralization were respectively D614G.1, B.1.1.7. B.1.351. B.1.617.2, BA.2.86, BA.1, and BA.4/BA.5.

Results: Binding showed a time-dependent increase in reactivity across all variants with Omicron subvariant BA.2.86 showing highest reactivity (~80%). Antibodies titers however were significantly higher in early emerged variants (P<0.01). Symptomatic and Asymptomatic group exhibited similar trend with higher neutralizing titers in Symptomatic group (P=0.03). At baseline, antibodies titers were approximately 2x lower in variants compared to D614G.1. Overall, neutralization titers increased post diagnosis.

Considering that these titers correspond to primary infection, we generally observed a relative loss in breadth against most variants (gain<0).

Conclusions: These results suggest that immune responses to SARS-CoV-2 variants in Cameroon evolve over time, particularly against early variants. Immune response to early SARS-CoV-2 infection is broadly neutralizing against most variants of concern and this could have contributed to reducing morbidity and mortality in Africa.

Course of HIV disease

Geographic disparities in advanced HIV disease prevalence: identifying drivers in high-burden states to guide targeted public health strategies

P.N. Gado[1], A. Idemudia[1], M. Ijaiya[2], I. Iyamu[3], U. Omo-Emmanuel[1], C. Obiora-Okafo[1], O. Toyo[4], U. Akpan[4], B. Oyawola[1], C. Nwadike[1], B. Onimode[1], B. Pius[1], D. Kimanga[1], D. Ogundehin[1], B. Kagniniwa[5], A. Raji[5], F. Agbo[6], T. Ilori[6], B. Adebobola[7], E. James[1], J. Pius[1], O. Oyelaran[1]

[1]United States Agency for International Development (USAID), Abuja, Nigeria, [2]The Demographic and Health Surveys (DHS) Program, Rockville, Maryland, United States, [3]School of Population and Public Health, University of British Columbia, Vancouver, Canada, [4]Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, [5]United States Agency for International Development (USAID), Washington D.C, United States, [6]National Agency for the Control of AIDS (NACA), Abuja, Nigeria, [7]National AIDS, Sexually Transmitted Infections Control and Hepatitis Programme (NASCP), Federal Ministry of Health, Nigeria, Abuja, Nigeria

Background: Advanced HIV disease (AHD) remains a significant driver of morbidity and mortality, with notable geographic disparities in prevalence across Nigeria. This study investigates factors contributing to AHD in high-burden states to inform targeted public health interventions.

Methods: A cross-sectional study analyzed data from 12,000 people living with HIV (PLHIV) enrolled in care from 2018 to 2023 in six high-burden states. AHD prevalence was assessed using WHO criteria, and logistic regression was employed to identify predictors, including late presentation, ART coverage, and co-infections. Advanced statistical techniques, such as multivariate decomposition analysis, quantified the contribution of regional factors to observed disparities.

Results: AHD prevalence was significantly higher in northern states (48%) compared to southern states (27%, p < 0.01). Logistic regression identified late HIV diagnosis (aOR: 4.3, 95% CI: 3.6–5.2), poor ART adherence (aOR: 3.8, 95% CI: 3.1–4.7), and higher rates of tuberculosis co-infection (aOR: 2.9, 95% CI: 2.4–3.5) as significant predictors in the north. Decomposition analysis revealed that 62% of regional disparities were attributable to healthcare access and infrastructure gaps, while socioeconomic factors accounted for 28%.

Conclusions: Geographic disparities in AHD prevalence are driven by systemic inequities, co-infections, and delayed care initiation. Strengthening early diagnosis, ART coverage, and healthcare infrastructure in high-burden states is essential to addressing these disparities and improving outcomes for PLHIV in Nigeria.

ART resistance

THPEB018

Gender disparities in HIV transmitted drug resistance: evidence of rising resistance among women of childbearing potential in Argentina

D.M. Cecchini[1], G. Lopardo[2], F. Scarnato[1], A. Fiori[2], J. Nuevo[1], C. Villaverde[2], A. Sucari[3], I. Cassetti[1,2]
[1]Helios Salud, Medical Department, Buenos Aires, Argentina, [2]FUNCEI, Buenos Aires, Argentina, [3]Laboratorio Dr. Stamboulian, Buenos Aires, Argentina

Background: In women of childbearing potential (WOCP), understanding the prevalence of transmitted drug resistance (TDR) is crucial for selecting first-line antiretroviral therapy (ART) that ensures both virologic suppression and safety during pregnancy, while minimizing the risk of vertical transmission.
Furthermore, effective neonatal prophylaxis relies on the absence of resistant strains in mothers, as this impacts the effectiveness of ART administered to newborns. However, WOCP are often underrepresented in TDR surveillance studies. Therefore, this study aims to assess trends in TDR in WOCP in Argentina.
Methods: A post hoc analysis was conducted using data from a TDR resistance database derived from reference HIV clinics in Argentina (2016-2022). WOCP were defined as individuals aged 15-49 years. Mutations associated with resistance to reverse transcriptase inhibitors and protease inhibitors (PIs) were identified using the WHO mutation list (hivdb.org/s/who). Trends in TDR among WOCP were compared with those observed in cisgender men.
Results: Samples from 258 WOCP were included. The median (IQR) age, CD4 T-cell count, and viral load were 36 years (30-41), 358/µL (221-559), and 31,350 copies/mL (7,350-105,000) respectively; ninety-six percent acquired HIV sexually, and 86% were asymptomatic. Overall the prevalence of TDR was 14%, with 11% for non-nucleoside reverse transcriptase inhibitors (NNRTIs), 2.7% for PIs and 1.9% for nucleoside reverse transcriptase inhibitors (NRTIs). Predominant mutations included K103N (5.4%), Y181V (2.3%) and K103S, G190A and M41L (1.6% each).
Overall TDR increased through the years (p = 0.034): 2016/17, 9.6%; 2018, 9%; 2019, 11%; 2020, 21%; 2021/22, 36%, mostly at expense of PI resistance (2016/17: 2.7% vs 2021/22: 18%, p = 0.002). This increasing trend was not observed in cis-gender men (n = 1354), with overall TDR rates as follows: 2016/17, 9.4%; 2018, 14%; 2019, 11%; 2020, 13%; 2021/22, 12% (p =0.4).
Conclusions: This exploratory study shows an upward trend in TDR among WOCP in Argentina, suggesting a gender-specific pattern that warrants attention and was not previously described in the region.
These findings highlight the critical need for greater representation of WOCP in TDR surveillance studies to better understand the underlying factors driving resistance patterns and to support general and perinatal ART guidelines.

THPEB019

Evaluation of people living with HIV presenting with dolutegravir resistance in Kenya

J. Wagude[1], C. Mburu[2], F. Makokha[3], R. Moturi[4]
[1]Siaya County Government, Department of Health, Siaya, Kenya, [2]Elizabeth Glaser Pediatric AIDS Foundation, Nairobi, Kenya, [3]Bungoma County Government, Department of Health, Bungoma, Kenya, [4]National AIDS and STI Control Program, HIV Care and Treatment, Nairobi, Kenya

Background: Dolutegravir (DTG) was introduced in Kenya in 2017 for use in people living with HIV (PLHIV). HIV drug resistance (HIVDR) data is limited in PLHIV failing on DTG-based regimens in real world settings. We describe characteristics of PLHIV with DTG HIV drug resistance (HIVDR) mutations from seven high HIV prevalence counties in Western Kenya.
Methods: Results from PLHIV failing DTG-based regimens with documented viral loads (VL) >1,000 copies/mL) submitted for HIVDR testing were reviewed in November 2024. Client plasma samples were amplified before genotyping at research laboratories from July 2020 to October 2024 with DR sequencing for samples >200 copies/mL and Drug Resistance Mutations (DRMs) identified using Stanford HIVdb. Clinical, demographic and treatment data for those with DTG resistance was abstracted from client summaries shared with the NyaWest HIV Regional Clinical Technical Working Group.
Results: Out of 209 samples received, 98 (47%) had HIV-1 VL >200 cp/mL and were successfully genotyped with only 22 (11%) having major INSTI DRMs. 16 (73%) with INSTI resistance were treatment experienced PLHIV with multiple DRMs while 3 (14%) were on 1st line TDF/3TC/DTG and only had 1 DRM each after 17 – 49 months on therapy. The age range was 9 – 61 years while 12 (55%) were male. Mean CD4 count was 283.2 cells/uL; 7 (32%) were on treatment for tuberculosis co-morbidity while 14 (64%) had never suppressed on DTG before HIVDR testing. After switch decisions, 9 of 22 (41%) have achieved viral suppression below 50 cp/mL and 11 (50%) have VLs >1,000 while 2 (11%) died before any switch decision.
Conclusions: Most (89%) PLHIV with high VLs on DTG-based ART did not have DRMs and can re-suppress with adherence support. ART-experienced clients were more likely to report high level resistance to DTG compared to ART naïve clients on DTG-based ART.
The findings imply that adherence support in PLHIV failing DTG-based regimens should target those with prior treatment failure, viral non-suppression or TB-HIV co-morbidity. Our data shows that DTG resistance is likely to increase and may negatively impact future effectiveness of long-acting cabotegravir, thus making a case for continued monitoring of HIV drug resistance of INSTI-based regimens.

Pandemics, conflict and climate

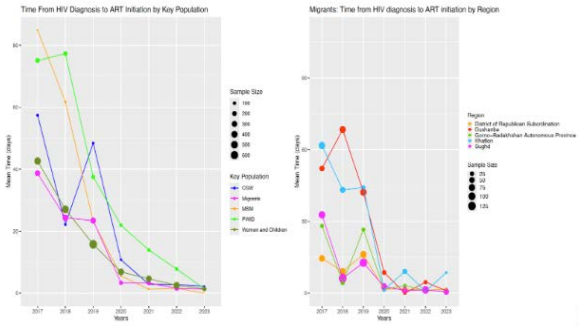
Minimizing COVID-19 disruption on the timely initiation of antiretroviral therapy (ART) following HIV diagnosis: lesson learn from Tajikistan

A. Zein[1], A. Hosseini[1], J. Nguyen[1], R. Chun[1], J. Abdullozoda[2], S. Yusufi[3], K. Alaei[1], A. Alaei[1], B. Kwan[1]

[1]California State University, Long Beach, Long Beach, United States, [2]Tajikistan Ministry of Health and Social Protection of Population, Dushanbe, Tajikistan, [3]National Academy of Science of Tajikistan, Dushanbe, Tajikistan

Background: The timely initiation of antiretroviral therapy (ART) post-HIV diagnosis is crucial for health outcomes. The COVID-19 pandemic has disrupted health services. This study aims to assess the extent to which COVID-19 has impacted HIV services in Tajikistan, particularly among key populations.

Methods: We analyzed national-level data from the Tajikistan Ministry of Health, focusing on 4,928 individuals living with HIV from 2017 to 2023. Time to ART initiation was assessed before, during, and after the COVID-19 pandemic, considering key populations (PWID, MSM, CSW, women, children), demographics (age, gender), region, area of residence, and labor migrant status. Trajectory plots were used to identify trends in linkage to care.



Results: 57.43% of the sample were 19-39 years old, 53.31% were female, and 57.31% resided in rural areas. In 2017, pre-COVID-19, mean times from HIV diagnosis to ART initiation exceeded 30 days for all key populations, with CSW experiencing fluctuations from 2017-2020. PWID and MSM consistently had longer mean times (>60 days) compared to other key populations in 2017-2018, with MSM showing a steeper decline pre-COVID-19. From 2019 onward, mean times decreased across all groups, with a dramatic reduction by 2023. Labor migrants had shorter mean times than PWID and MSM but significant regional disparities persisted, such as migrant HIV cases in Dushanbe taking approximately 70 days longer to initiate ART pre-COVID-19 compared to other regions like the Districts of Republican Subordination, Gorno-Badakhshan Autonomous Province, and Sughd. Post-COVID-19 Khalton was more impacted compared to other regions.

Conclusions: While the COVID-19 pandemic disrupted global health services, Tajikistan successfully minimized its impact on linkage to HIV care. Discrepancies in access among key populations were noted, but overall, waiting times for ART initiation decreased during and after the pandemic, reflecting improved healthcare delivery. Regional disparities in access remain a concern.

HIV and ageing

THPEB021

Association between cognitive performance and subclinical atherosclerosis among older adults with HIV: a cross-sectional evaluation from ELEA-Brasil Study

R.C. Moreira[1], S. Wagner Cardoso[1], P. Ranadive[2], B. Shepherd[2], T. Silva Torres[1], P. Corção[1], V. Veloso[1], C. Brites[3], E. Luz[3], G. Doria[3], R. Schiavon Nogueira[4], J. Valdez Ramalho[4], A.C. Coutinho Iglessias[4], V.I. Avelino-Silva[5], M. Bordignon Antonio[5], M.J. Romero Aliberti[5], J.L. Castilho[6], B. Grinsztjen[1], on behalf of ELEA-Brasil Study Group

[1]Fiocruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [2]Vanderbilt University Medical Center, Department of Biostatistics Vanderbilt University Medical Center, Nashville, United States, [3]Hospital Universitário Professor Edgard Santos (HUPES), Bahia, Brazil, [4]Centro de Referência e Treinamento DST/Aids (CRT), São Paulo, Brazil, [5]Faculdade de Medicina da Universidade de São Paulo (USP), São Paulo, Brazil, [6]Vanderbilt University Medical Center, Division of Infectious Diseases, Nashville, United States

Background: In the general population, increased carotid intima-media thickness (cIMT) has been associated with poor cognitive performance (CP). People with HIV (PHIV) are at higher risk for both atherosclerosis and cognitive decline, yet data on the relationship between cIMT and CP in this population are limited. We investigated this association in older PHIV in Brazil using baseline data from ELEA Study.

Methods: PHIV aged ≥50 years on antiretroviral therapy were recruited from four Brazilian healthcare sites (2022–2023). Cognitive performance was evaluated using the Montreal Cognitive Assessment (MoCA). cIMT was measured via B-mode ultrasonography, with high cIMT defined as mean cIMT >0.9mm. Participants with clinical atherosclerosis (stroke, myocardial infarction, N=94) and missing cIMT data (N=16) were excluded. Sensitivity analysis categorized participants as high cIMT with either mean cIMT >0.9mm and/or carotid plaques detected. Demographic, clinical, and social variables were compared between high and low cIMT groups. We assessed the association of cIMT and MoCA using Spearman correlation and multivariable ordinal regression models.

Results: A total of 593 individuals were included. The median cIMT was 0.70 mm (IQR: 0.62–0.81), 83 (14%) were classified as having high cIMT. Carotid plaques were observed in 69 (83%) of participants with high cIMT and 278 (55%) of participants with low cIMT. Compared to those

with low cIMT, individuals with high cIMT were older (median age 66 vs. 61 years, p<0.001), more often males (75 vs. 61%, p=0.035), had lower CD4/CD8 ratio (0.77 vs. 0.96, p=0.003), and higher prevalence of hypertension (70 vs. 58%, p=0.048) and frailty (12.0% vs. 4.1%, p=0.019). Median MoCA scores were similar (23 vs. 23, p=0.3), as were education and income (p>0.05). A non-significant negative correlation was observed between MoCA and cIMT (r = -0.02, 95% CI: -0.10, 0.06).
In multivariable regression models, cIMT was not significantly associated with MoCA scores as a continuous (aOR 1.06, 95%CI: 0.98–1.15) or dichotomized variables including presence of plaques (high cIMT or plaque aOR 1.15, 95%CI: 0.87–1.54).
Conclusions: In older PHIV, cIMT was not significantly associated with cognitive function, suggesting that other comorbidities and factors may play a more prominent role in cognitive decline.

THPEB022

Shorter telomere lengths and faster telomere attrition rates are associated with unsuppressed viraemia and lower CD4 count in antiretroviral-treated adolescents with perinatally-acquired HIV from Zambia and Zimbabwe

J. Shellard[1], H. Mujuru[2], H. Mabuda[3], M. Chisenga[3], T. Bandason[4], N. Dzavakwa[4,5], L. Kasonka[3], V. Simms[4,5], R. Ferrand[4,6], S. Rowland-Jones[1], A. Hsieh[1,7]
[1]University of Oxford, Oxford Centre for Immuno-Oncology, Nuffield Department of Medicine, Oxford, United Kingdom, [2]University of Zimbabwe, Department of Paediatrics, Harare, Zimbabwe, [3]University of Zambia, University Teaching Hospital, Lusaka, Zambia, [4]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [5]London School of Hygiene & Tropical Medicine, MRC International Statistics and Epidemiology Group, London, United Kingdom, [6]London School of Hygiene and Tropical Medicine, Clinical Research Department, Faculty of Infectious and Tropical Diseases, London, United Kingdom, [7]University of Oxford, Chinese Academy of Medical Sciences Oxford Institute, Nuffield Department of Medicine, Oxford, United Kingdom

Background: Shorter telomere length (TL), a biomarker of immune aging, is observed among adults with HIV and predicts morbidity/mortality later in life. However, there are few studies in children growing up with HIV and existing data are largely cross-sectional. We investigated relationships between markers of HIV control/progression and longitudinal TL attrition rate among Zambian and Zimbabwean adolescents, hypothesising that higher viral load (VL) and a lower CD4 count are associated with faster telomere attrition.
Methods: Buffy coat was obtained from 842 adolescents with perinatally-acquired HIV (11-19 years) taking combination antiretroviral therapy (cART) for >6 months with 783 samples available at week 48 follow up, from the VITALITY clinical trial [PACTR202009897660297] of high dose vitamin D and calcium supplementation. DNA was extracted using Qiagen Blood Mini kits and TL was measured using monochrome multiplex qPCR, standardising units for analysis. Zimbabwean samples were assayed using an ELISA kit for cytomegalovirus IgG. Cross-sectional analysis was undertaken using multivariable linear regression adjusting for age, sex and site, whereas longitudinal analysis additionally adjusted for baseline TL.
Results: At baseline, 678(80.5%) participants had undetectable (<60 RNA copies/ml) viraemia, 66(7.8%) had 60-1000 copies/ml and 98(11.6%) had >1000 copies/ml. Participants had mean(95%CI) 584(122,1122) CD4 cells/µl.
Compared to undetectable VL, participants with >1000 copies/ml had shorter TL (standardised β[95%CI] -0.239[-0.451,-0.026], p=0.028) whereas those with 60-1000 copies/ml did not (p=0.836).
Higher CD4 cell count was associated with longer TL (0.038[0.009,0.066] per 100 CD4 cells/µl, p=0.009). Zambian participants had on average longer TL than Zimbabwean participants (0.182[0.042-0.321], p=0.011). Cytomegalovirus IgG was modestly associated with TL (β=0.0138, p=0.057).
Telomere attrition rate was accelerated in participants with >1000 copies/ml at both timepoints when compared with participants with <1000 copies/ml at both timepoints (-0.276[-0.546,-0.005], p=0.046). Higher baseline CD4 cell count was associated with a reduction in telomere attrition rate (0.033[0.008,0.057] per 100 CD4 cells/µl, p=0.001). No difference in week 48 TL was observed between study trial arms (p=0.689).
Conclusions: Uncontrolled HIV viraemia leads to a continual degradation in immune age among adolescents with HIV on cART in sub-Saharan Africa, which may correlate with an increased risk of co-infection and co-morbidities later in life.

Co-infections (including opportunistic infections)

THPEB023

Recent syphilis incidence for gay, bisexual and men who have sex with men (gbMSM) versus non-gbMSM at a community health centre in Victoria, British Columbia, Canada

C. Fraser[1,2], M. Selfridge[3,2], T. Barnett[4,2], K. Besko[2], A. Drost[2], K. Guarasci[2], K. Lundgren[2]
[1]University of British Columbia, Faculty of Medicine - Department of Family Practice, Victoria, Canada, [2]Cool Aid Community Health Centre, Victoria, Canada, [3]University of Victoria, Victoria, Canada, [4]York University, Toronto, Canada

Background: Rates of syphilis, a sexually transmitted blood-born infection (STBBI), have surged over the last decade. This increase is driven by cases among gbMSM, individuals living with HIV (lwHIV) and females. The fifteen-fold increase of cases from 2017 to 2022 in females is over 90% with females of childbearing age, raising concerns about vertical transmission.

Cool Aid Community Health Centre in Victoria, BC serves 7,000 clients experiencing homelessness and mental health and substance use challenges. The weekly nurse-led STBBI clinic, Prism Wellness, partners with AVI Health and Community Services and is staffed by STI certified practice nurses and offers STBBI education, screening, treatment, pre-exposure prophylaxis (PrEP) and doxycycline post-exposure prophylaxis (doxyPEP). STBBI testing is also offered during regular client encounters.

Methods: A retrospective chart review was conducted to identify and include all clients tested for syphilis between January 1, 2021, to December 31, 2024. Client demographic variables included age, sex, gbMSM, lwHIV, and PrEP.

Results: 7828 syphilis tests were completed with 2994 unique individuals in the last 3 years (2725 non-reactive, 269 reactive). Of the 269 clients with reactive tests (mean age=46), 111 (41%) were determined to have an active case (149 previous, 9 false positive).

For those with current active cases, 106 (95%) were fully treated. Females, particularly those under 40, are disproportionately affected by recent syphilis diagnoses. While females account for 25% of all reactive syphilis tests, they represent 41% of current active cases.

	Previously Treated	False Positive	Current Infection	Current who completed treatment	Total
All Syphilis Reactive	149 (55%)	9 (3%)	111 (41%)	106 (95%)	269
Female	20 (30%)	1 (1.5%)	**46 (69%)**	**43 (93%)**	67
Men	127 (64%)	8 (4%)	63 (32%)	61 (97%)	198
Trans/non-binary	2 (50%)	0	2 (50%)	2 (100%)	4
Yes gbMSM men	**105 (78%)**	0	30 (22%)	**30 (100%)**	135
Non gbMSM men	14 (29%)	8 (17%)	**26 (54%)**	**24 (92%)**	48
HIV+ men	52 (76%)	2 (29%)	14 (21%)	14 (100%)	68
HIV+ women	2 (67%)	0	1 (33%)	1 (100%)	3

Conclusions: Evolving syphilis trends require new focused interventions as rates shift from gbMSM and plHIV to females.

THPEB024

The burden of tuberculosis and associated medico-obstetrical outcomes among pregnant women living with HIV in Africa: a systematic review and meta-analysis

B. Ukoaka[1], M. Ahmed[2], T. Wali[3], P. Wagwula[1], N. Udam[1], O. Adigun[4], F. Daniel[5], O. Okesanya[6], U. Ajaero[7], N. Aderinto[8]

[1]First On-Call Initiative, Community and Clinical Research Division, Port Harcourt, Nigeria, [2]SIMAD University, Faculty of Medicine and Health Sciences, Mogadishu, Somalia, [3]Bayero University, Department of Medicine and Surgery, Kano, Nigeria, [4]Nigerian Defence Academy, Department of Medical Laboratory Science, Kaduna, Nigeria, [5]London School of Hygiene and Tropical Medicine, Department of Public Health, London, United Kingdom, [6]University of Thessaly, Faculty of Medicine, Department of Public Health and Maritime Transport, Volos, Greece, [7]AIDS Healthcare Foundation, Department of Treatment Services, Abuja, Nigeria, [8]Ladoke Akintola University of Technology, Department of Medicine and Surgery, Ogbomoso, Nigeria

Background: Pregnant women living with HIV (PWLHIV) face severe immunocompetence, with tuberculosis (TB) contributing about 50% of mortality from HIV co-infections. Children born to these women face heightened risks of vertical TB transmission with potential adverse health outcomes.

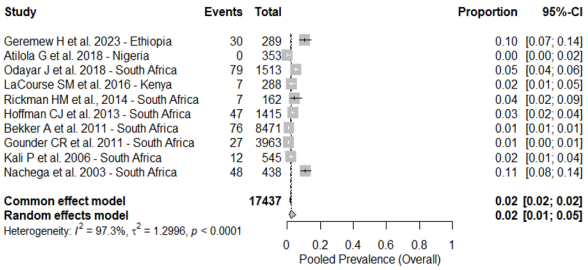
This review evaluates the prevalence, disease characteristics, and medico-obstetrical outcomes of TB among PWLHIV in the prevention of mother-to-child (PMTCT) programs in Africa.

Methods: A literature search across electronic databases such as PubMed, Scopus and Google Scholar included studies published between 2003 and 2023. The study protocol was registered with PROSPERO (CRD42025633892). Eligible studies examined tuberculosis's prevalence, characteristics, and outcomes among PWLHIV.

The review followed the PRISMA guideline, while quality assessment of included studies used the JBI Critical Appraisal Checklist for Prevalence Studies. The meta-analysis employed a random-effects model to determine prevalence and medico-obstetrical outcomes.

Results: From 12 reviewed studies, the pooled prevalence of TB among PWLHIV was 2% (95% CI: 0.02–0.05) from 17,611 participants (Fig. 1), with a mean age of 27±2.5SD. Pulmonary TB (76%, 95% CI: 0.71–0.81) was predominant, while extrapulmonary TB constituted 22% (95% CI: 0.18–0.27). Across studies, CD4 count <200 cells/mm3, poor ART adherence, and prior TB history were risk factors. Obstetric outcomes showed 93% live births and 5% stillbirths, with cohorts reporting 59% low birthweight and 65% preterm births.

Other medical outcomes included preeclampsia (6.5%), pregnancy-induced hypertension (5.3%), antepartum hemorrhage (1.3%), and prolonged rupture of membranes (7.5%). 78.7% was the highest recorded treatment success rate, with 8.5% relapse and 12.8% treatment failure. Funnel plot and Egger's test (p = 0.953) indicated no publication bias.



Conclusions: Tuberculosis-coinfection greatly influences birth outcomes and increases transmission risk to infants. With 1-in-20 deliveries being stillbirths, strengthening PMTCT programs in Africa is necessary to curb adverse obstetric outcomes. Multidisciplinary collaborations with TB partners can advance efforts toward ending TB for this population.

THPEB025

Effect of doxycycline post-exposure prophylaxis on sexually transmitted infections among men who have sex with men

Y.-T. Chen[1], H.-Y. Sun[2], Y.-S. Huang[2], A. Cheng[2], W.-D. Liu[3], P.-H. Kuo[4], T.-Y. Wu[5], P.-Y. Wu[1], Y.-Z. Luo[1], L.-Y. Chen[1], H.-Y. Chang[1], K.-Y. Lin[2], C.-C. Hung[2,5]

[1]National Taiwan University Hospital, Center for Infection Control, Taipei, Taiwan, Province of China, [2]National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Province of China, [3]National Taiwan University Cancer Center, Department of Internal Medicine, Taipei, Taiwan, Province of China, [4]National Taiwan University Hospital Hsin-Chu Branch, Department of Internal Medicine, Hsin-chu, Taiwan, Province of China, [5]National Taiwan University Hospital Yunlin Branch, Department of Internal Medicine, Yunlin, Taiwan, Province of China

Background: Doxycycline post-exposure prophylaxis (doxy-PEP) has demonstrated effectiveness in preventing sexually transmitted infections (STIs) among men who have sex with men (MSM) in clinical trials. This study aimed to assess the feasibility and effectiveness of doxy-PEP in real-world settings.

Methods: A multicenter retrospective study was conducted from October 2023 to November 2024. Adult MSM who initiated doxy-PEP immediately after receiving information about it were included and followed up every 3 months. A questionnaire survey was conducted to assess adherence to and satisfaction with doxy-PEP. STI testing, including serologic testing for syphilis and multiplex real-time PCR testing for *Chlamydia trachomatis, Neisseria gonorrhoeae, and Mycoplasma genitalium*, was performed every 3 to 6 months.

Results: A total of 472 participants were prescribed doxy-PEP immediately after receiving counseling. Of them, 356 (75.4%) were people with HIV (PWH), and 116 (24.6%) were HIV pre-exposure prophylaxis (PrEP) users. The median age was 36 years, and 48.7% had a history of STIs within the past year. At 3, 6, 9, and 12 months, the proportions of participants who continued doxy-PEP were 40.1%, 38.6%, 38.4%, and 42.2%, respectively, while adherence rates of 76-100% were 59.0%, 59.5%, 66.3%, and 69.7%. The proportion of participants who inconsistently used condoms remained between 80% and 90% throughout the study period. The rates of syphilis infections at 3, 6, 9, and 12 months were 0.6%, 3.2%, 4.1%, and 0%, respectively, which were significant lower than the baseline syphilis incidence over the past year (31.6%).

Similarly, chlamydia infection rates at 3, 6, 9, and 12 months were 1.9%, 4.3%, 4.2%, and 0%, respectively, showing a notable reduction from the baseline incidence within a year (17.8%).

However, gonorrhea infection rates increased over time, reaching 9.6%, 15.7%, 25.9%, and 50.0% at 3, 6, 9, and 12 months, respectively, compared to the baseline gonorrhea incidence of 13.6%.

Conclusions: In real-world settings, doxy-PEP was prescribed with consistent continuation and adherence. After its implementation, syphilis and chlamydia infections decreased without affecting frequency of condom use. However, the rise in gonorrhea infections over time may indicate the limited effectiveness of doxy-PEP against gonorrhea.

THPEB026

HPV detection and genotypes in vaginal swabs and urine in a cohort of female sex workers from Nairobi, Kenya

V. Schulz[1], C. Klenke[1,2], S. Gibbons[1], F. Roy[1], E. Irungu[3], M. Okumu[3], M. Kungu[3], R. Kabuti[3], J. Kimani[1,3,4], L. McKinnon[1,4,2], A. Sivro[1,2,5]

[1]Public Health Agency of Canada, National Microbiology Laboratory, Winnipeg, Canada, [2]University of Manitoba, Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [3]Partners for Health and Development in Africa, Nairobi, Kenya, [4]University of Nairobi, Medical Microbiology, Nairobi, Kenya, [5]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa

Background: Cervical cancer is one of the most common cancers in women, contributing to 90% of HPV related cancers. Self-sampling, including self-collected urine, has emerged as an important strategy to achieve the WHO's 90-70-90 HPV targets. Urine collection is thought to be an acceptable specimen for HPV-based cervical cancer screening and a promising approach to increase screening uptake, due to its non-invasive nature.

Methods: Ninety paired urine and cervical-vaginal swab (CVS) specimens were obtained from the Sex Worker Outreach Program (SWOP) in Nairobi, Kenya, where 13% of participants were people living with HIV. DNA was extracted from neat urine (n=70), CVS (n=90), and urine applied to in-house developed dried urine strips (DUS) (n=20). DUS were allowed to dry for 24 hours at room temperature before DNA extraction.

HPV genotyping of 46 mucosal types was done using a nested-PCR and microsphere-based in-house assay. Additionally, for 20 paired samples, quantification of HPV-16 was done using droplet-digital PCR (ddPCR).

Results: HPV was detected in 92.9% of CVS and 81.4% of all urine samples. Multiple HPV types were detected in 65.1% of CVS and 45.5% of all urine samples. Same HPV types in CVS were detected in 60.0% of all paired samples, with DUS in higher agreement (65.0%) than neat urine (58.0%). High-risk HPV types detected in CVS were detected in 68.4% of DUS and 63.2% of neat urine specimens.
Lastly, 37.1% of all urine samples detected more HPV types than their paired CVS sample, and 56.5% of those were high-risk HPVs. Quantification of HPV-16 using ddPCR showed no significant differences between CVS and neat urine (ρ=0.20).
Conclusions: Moderate concordance between CVS and urine specimens was observed, suggesting differences in HPV types detected through different sampling techniques. Of interest, the DUS, developed in-house for STI testing, performed well for HPV detection and genotyping and could be a useful strategy to improve HPV screening.

THPEB028

Cervical cancer screening and treatment outcomes in Women living with HIV: a cross-sectional study in Nasarawa State, Nigeria

F. Audu[1], O. Oni[1], O. Abodunde[1], C. Umeozulu[2], F. Isona[3]
[1]Equitable Health Access Initiative, Prevention, Care, and Quality Improvement Services, Abuja, Nigeria, [2]Equitable Health Access Initiative, Clinical Laboratories, Abuja, Nigeria, [3]Equitable Health Access Initiative, Strategic, Knowlegde, and Management Training, Abuja, Nigeria

Background: Cervical cancer is the fourth most prevalent cancer among women globally, with significant morbidity and mortality in low- and middle-income countries. Women living with HIV (WLHIV) are six times more likely to develop cervical cancer compared to the general population, with HIV contributing to 5% of all cases.
This study aimed to determine the prevalence of precancerous lesions and severe dysplasia (precancerous lesion greater than 75%) among WLHIV in Nasarawa State, Nigeria, identify the most affected age group, and assess treatment outcomes.
Methods: This cross-sectional study focused on women living with HIV (WLHIV) and was conducted across four secondary healthcare facilities in three Local Government Areas (LGAs) of Nasarawa State, Nigeria, from October 2023 to September 2024. The research aimed to determine the prevalence of precancerous lesions and severe dysplasia, identify the most affected age group, and assess treatment outcomes. Data was extracted from cervical cancer screening registers for WLHIV. Descriptive statistics were used to calculate prevalence rates and evaluate treatment outcomes.
Results: Among the 2,750 WLHIV screened, 111 (4.03%) had precancerous lesions, and 9 (0.32%) presented with severe dysplasia. The majority (73%) of precancerous lesions were observed in younger women aged 25–39 years.
All women with precancerous lesions treated with thermal ablation and those with severe dysplasia managed with LEEP at tertiary facilities achieved lesion clearance upon re-screening.
Statistical analysis confirmed a significant association between age and the prevalence of precancerous lesions ($p < 0.05$). These findings underscore the effectiveness of targeted screening and treatment interventions in this population.
Conclusions: This study highlights the high prevalence of precancerous lesions (4.03%) and severe dysplasia (0.32%) among WLHIV in Nasarawa State, with younger women (25-39 years) most affected. Effective interventions like thermal ablation and LEEP achieved 100% lesion clearance.
These findings underscore the need for targeted screening and treatment programs. Future research should explore the long-term outcomes and scalability of these interventions in diverse settings.

THPEB029

Scaling up advanced HIV disease screening, diagnosis and management in 2023: implementation of the Hub-and-Spoke model in Lusaka province, Zambia

S. Mwamba[1], M.S. Munamwimbu[1], N. Vlahakis[1], M. Wa Mwanza[1], W. Mumba[2], F. Mwape[2], O. Kanyanta[2], K. Moomba[1], C. Zulu[1], J. Simpungwe[3], M.E. Herce[1], T. Savory[1]
[1]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [2]Lusaka Provincial Health Office, Lusaka, Zambia, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Global Health Center, Lusaka, Zambia

Background: Advanced HIV Disease (AHD) services were not available at all healthcare levels in Zambia, presenting a significant challenge. In 2023, we implemented a WHO-recommended service package for managing AHD in Lusaka Province.
Description: A WHO-recommended hub-and-spoke model for AHD care was implemented across 193 health facilities, with 11 referral "hubs" (hospitals) managing complex cases, and 182 "spokes" providing screening and routine care for stable AHD patients. A provincial AHD team -clinical, pharmacy, lab, and Monitoring and Evaluation (M&E) staff- supported capacity-building at these sites. The model included staff training, mentorship, supervision, commodity management, and M&E tool development, with systematic screening for AHD and further TB and Cryptococcal infection among those with AHD.
Weekly data reviews informed quality improvement. Patients had AHD if CD4 <200 cells/ul or WHO stage was 3/4 among those newly diagnosed, returning to care, with unsuppressed viral load and inpatients. Data came from DHIS2, an electronic medical record tool for collection, analysis and presentation of patient data.
Lessons learned: From October 2023—September 2024, 13,506/ 27,568 patients (49%) were screened, with AHD identified in 5,287 (39%) based on CD4<200 cells/ul (4,523) or WHO stage 3/4 (764). Monthly trends showed 27% improvement in AHD screening from 42% of eligible patients in October 2023 to 69% in September 2024. Of those with AHD, 1,293 (24.5%) were investigated for TB with 301 (23.3%)

TB diagnoses, and of the 896 (17%) patients with AHD screened for cryptococcal infection, 58 (6.5%) had positive serum cryptococcal antigen and 15 (1.7%) had confirmed cryptococcal meningitis.

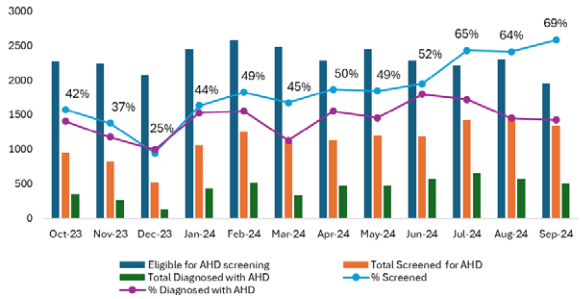


Figure 1: AHD screening and diagnosis monthly trends from October 2023 to September 2024, Lusaka Province, Zambia.

Conclusions/Next steps: Hub and spoke model implementation in 2023 increased the AHD screening rate over time, however, diagnoses remained largely unchanged. Scaling up TB and cryptococcal infection screening is crucial in averting morbidity and mortality from these conditions.

Co-morbidities and clinical complications of HIV and antiretroviral therapy

Profiles of body weight, glucose, and uric acid in PWH on ainuovirine-based antiretroviral regimen: week 96 results from SPRINT, a randomized phase 3 trial

W. Cai[1], H. Wu[2], F. Zhang[3], P. Ma[4], Q. Zhao[5], H. Wei[6], H. Lu[7], H. Wang[7], S. He[8], Z. Chen[8], Y. Chen[9], M. Wang[10], X. Yun[11], H. Fu[11], H. Qin[11]

[1]Guangzhou Eighth People's Hospital, Guangzhou Medical University, Guangzhou, China, [2]Beijing Youan Hospital, Capital Medical University, Beijing, China, [3]Beijing Ditan Hospital Capital Medical University, Beijing, China, [4]Tianjin Second People's Hospital, Tianjin, China, [5]The Sixth People's Hospital of Zhengzhou, Zhengzhou, China, [6]The Second Hospital of Nanjing, Nanjing, China, [7]Shenzhen Third People's Hospital, Shenzhen, China, [8]Public Health Clinical Medical Center of Chengdu, Chengdu, China, [9]Chongqing Public Health Medical Center, Chongqing, China, [10]The First Hospital of Changsha, Changsha, China, [11]Jiangsu Aidea Pharmaceutical Co., Ltd, Yangzhou, China

Background: In the SPRINT study, switch to ainuovirine, a novel non-nucleoside reverse transcriptase inhibitor, combined with lamivudine and tenofovir DF (ANV/3TC/TDF), resulted in favorable changes in body weight (BW) and serum uric acid (SUA), but constant fasting serum glucose (FSG), compared to that to cobicistat-boosted elvitegravir with emtricitabine and tenofovir alafenamide (E/C/F/TAF), in virologically suppressed (VS) people with HIV-1 (PWH). In the extensional study, PWH continued or switched to ANV/3TC/TDF until 96 weeks.

This secondary analysis aimed to evaluate the changes in BW, FSG, and SUA of PWH switching to ANV/3TC/TDF through 48 to 96 weeks.

Methods: Out of 762 randomized participants, 376 participants originally assigned to ANV/3TC/TDF (376/381, 98.7%) and 371 participants originally to E/C/F/TAF (371/381, 97.4%) completed the extensional study, respectively. The safety outcomes of special interest were absolute changes from 48 in BW, FSG, and SUA at 72 and 96 wk.

Results: Modest decline in BW was seen in both treatment arms at 72 wk (mean, ANV/3TC/TDF vs. E/C/F/TAF→ANV/3TC/TDF, -0.47 vs. -1.14 kg), to a lesser extent at 96 wk (-0.03 vs. -0.59 kg) at 96 wk (Figure 1, upper panel). FSG remained constant in both arms from 48 wk through 96 wk (72 wk, 0.7 vs. -0.10 mmol/L; 96 wk, 0.04 vs. 0.00 mmol/L).

Compared to that in ANV/3TC/TDF arm, SUA showed a marked and constant reduction in E/C/F/TAF→ANV/3TC/TDF arm at both 72 wk (24.4 vs. -17.8 μmol/L), and 96 wk (-2.9 vs. -37.6 μmol/L) (Figure 1, lower panel).

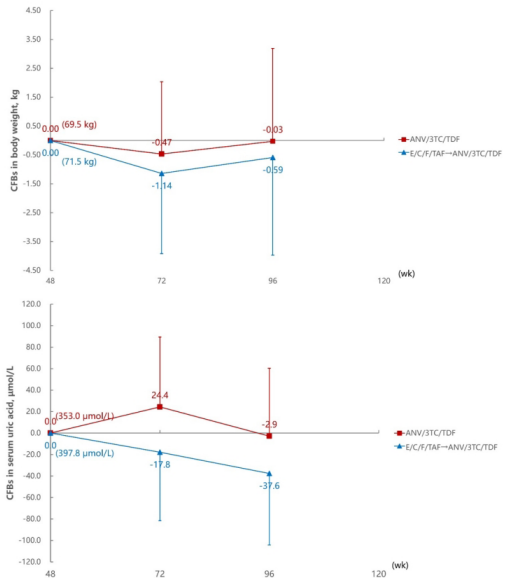

Figure 1. Changes in body weight and serum uric acid Levels at week 72 and 96
ANV/3TC/TDF, ainuovirine/lamivudine/ tenofovir disoproxil fumarate; E/C/F/TAF, elvitegravir/cobicistat/emtricitabine/tenofovir alafenamide; CFB, change from baseline; BW, body weight; SUA, serum uric acid.

Conclusions: Continuation of ANV/3TC/TDF treatment resulted in constant profiles of BW, FSG and SUA for VS PWH. However, switch from E/C/F/TAF favored profiles of BW and SUA in the SPRINT extensional period in contrast to that to E/C/F/TAF in the randomized study.

THPEB031

Oral microbiota signatures in relation to neurocognitive function in adolescents with perinatally acquired HIV

O. Peter[1], Q. Sheng[2], A. Kumar[3], I. Abulude[4], E. Osagie[1], N.L. Idemudia[5], O. Obuekwe[6], F.E. Eki-Udoko[7], S. Shiau[2], M.O. Coker[1,2,3], uBLOoM Study Team

[1]Institute of Human Virology Nigeria, International Research Centre for Excellence, Federal Capital Territory, Nigeria, [2]Rutgers University, Department of Biostatistics and Epidemiology, School of Public Health, New Brunswick, United States, [3]University of Pennsylvania, Department of Basic and Translational Sciences, School of Dental Medicine, Philadelphia, United States, [4]Instituto Politécnico Nacional, Centre of Biotechnology and Genomics, Mexico City, Mexico, [5]University of Benin Teaching Hospital, Medical Laboratory Services, Department of Medical Microbiology, Benin, Nigeria, [6]University of Benin, Department of Oral and Maxillofacial Surgery, Benin, Nigeria, [7]University of Benin Teaching Hospital, Department of Child Health, Benin, Nigeria

Background: Adolescents with perinatally acquired HIV (ALHIV) on antiretroviral therapy face an elevated risk for age-related disorders, including neurocognitive deficits and oral disease. While the gut microbiota has been implicated in cognitive dysfunction, the relationship between the oral microbiome and neurocognitive health in ALHIV is poorly understood.

This study investigates associations between oral microbiota composition and cognitive function in ALHIV.

Methods: Baseline data from an observational cohort, uBLOoM (Uncovering the Biologic Link between Oral Microbiota and Mental health in Adolescents Living with HIV) study, conducted at the University of Benin Teaching Hospital, Nigeria, were analyzed. Fifty-three ALHIV and 47 age-, sex-, and socioeconomically matched seronegative youth (HUU), aged 10 - 13 were enrolled. Cognitive function was assessed using the NIH Toolbox Cognition Battery, and composite scores were categorized as *Low* if below average (<85) or *Normal* if average or above average (85–115). Microbiota of oral rinse samples were profiled using shotgun metagenomics, characterization focusing on alpha (Shannon indices) and beta diversity (Bray-Curtis; PERMANOVA), and the identification of differentially abundant taxa (MaAsLin2).

Results: Distinct microbial patterns were observed when stratified by cognitive performance categories within ALHIV and HUU groups. Among ALHIV, Shannon diversity scores were lower in the *Low* cognitive category ($p = 0.07$). No differences were observed with Bray-Curtis distances. Specific taxa, including *Thauera*, *Candidatus Mycosynbacter*, and *Propionivibrio*, were significantly depleted in ALHIV with low cognitive scores ($p < 0.001$; $q < 0.25$). These taxa play neuroprotective roles related to nitrate metabolism and the production of short-chain fatty acids, which contribute to gut-brain axis regulation and blood-brain barrier integrity.

In contrast, adolescents in the HUU group exhibited no significant associations between alpha and beta diversity, or specific taxa and cognitive categories ($p > 0.05$).

Conclusions: This study provides novel evidence of a potential link between oral microbiota and neurocognitive health in ALHIV, with neuroprotective taxa being depleted in those with lower cognitive scores. These findings suggest a unique interplay in ALHIV distinct from HUU.

Future research should explore mechanistic pathways and validate these findings in larger cohorts and across various cognitive assessment tools, to inform targeted interventions to improve cognitive outcomes in ALHIV.

THPEB032

Identifying the most effective screening algorithm for anal high-grade squamous intraepithelial lesion among men who have sex with men in Bangkok, Thailand

S. Thitipatarakorn[1], S. Suriwong[1], W. Tasomboon[1], P. Hongchookiat[1], N. Teeratakulpisarn[1], N. Phanuphak[1]

[1]Institute of HIV Research and Innovation, Bangkok, Thailand

Background: Men who have with men (MSM), especially those living with HIV, are at heightened risk of anal high-grade squamous intraepithelial lesions (HSIL), a precursor to anal cancer. High-resolution anoscopy (HRA) with biopsy is the standard for diagnosing anal HSIL. This study evaluated screening algorithms alternative to HRA.

Methods: Thai MSM were enrolled at the Thai Red Cross AIDS Research Centre in Bangkok, Thailand, and followed for 12 months. At each visit, self-reported demographic data and HIV status from medical records were collected. Anal cytology, high-risk human papillomavirus (HRHPV) testing, and HRA with biopsies of abnormal findings were performed.

Using baseline data, we simulated screening algorithms: cytology alone, HRHPV alone, combined HRHPV and cytology, and universal HRA. Positive results in non-HRA algorithms led to HRA. We compared HSIL detection rates between algorithms using odds ratios (ORs) with 95% confidence intervals (CIs).

Results: A total of 246 MSM (123 living with HIV, 13.0% on antiretroviral therapy; 123 without HIV) with a median age of 28 years were enrolled between December 2009 and 2010. Anal HSIL prevalence was 11.5% among participants with HIV and 5.7% among those without HIV (P = 0.110). Strategies incorporating HRHPV testing detected HSIL at rates comparable to universal HRA (HRHPV alone: OR 0.60, 95% CI 0.27-1.29; Cytology+HRHPV: OR 0.82, 95% CI 0.39-1.67). In contrast, cytology alone detected fewer HSIL than universal HRA (OR 0.28, 95% CI 0.09-0.73). Adding HRHPV to cytology screening improved HSIL detection (OR 2.96, 95% CI 1.09-9.33).

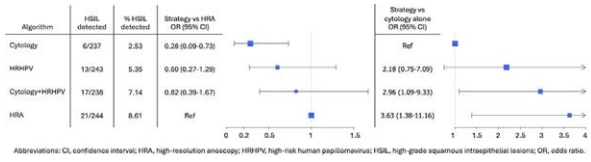

Figure. Anal HSIL detection rates of different screening strategies compared to cytology-alone and universal HRA strategies.

Conclusions: Screening for anal HSIL using HRHPV alone or combined with cytology, followed by HRA for positive results, produced detection rates comparable to universal HRA. Cytology alone identified 70% fewer HSIL cases. HRHPV testing shows potential as an effective screening tool for anal HSIL in this population, potentially reducing the need for universal HRA, which requires specialized equipment and experienced practitioners.

THPEB033

The impact of immune reconstitution inflammatory syndrome (IRIS) in HIV-positive people with CD4 <200 Cells/mm³ Initiating dolutegravir/lamivudine dual therapy: DOLCE study findings

C. Brites[1], M. Figueroa[2], D. Cecchini[3], A. Santos Ramalho Teixeira[4], J. Francos[5], M. Lacerda[6], J. Valdez Madruga[7], E. Sprintz[8], T. Newman Lobato Souza[9], P. Parenti[10], D. Converso[2], G. Miernes[2], M. Rolon[11], C. Perez[2], O. Sued[12], P. Cahn[2]

[1]Fundação Bahiana de Infectologia, Canela, Salvador - Bahia, Brazil, [2]Fundacion Huesped, Research Department, Ciudad de Buenos Aires, Argentina, [3]Hospital General de Agudos Dr. Cosme Argerich, Ciudad de Buenos Aires, Argentina, [4]Nova Iguacu Prefeitura, Nova Iguaçu, Rio de Janeiro, Brazil, [5]Hospital de Infecciosas Francisco Javier Muñiz, Ciudad de Buenos Aires, Argentina, [6]Fundação de Medicina Tropical do Amazonas, Manaus, Brazil, [7]Centro de Referência e Treinamento DSTAIDS, Sao Paulo, Brazil, [8]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [9]Instituto de Infectologia Emílio Ribas, San Pablo, Brazil, [10]Instituto Caici, Rosario,Santa Fe, Argentina, [11]Hospital Juan A Fernandez, Ciudad de Buenos Aires, Argentina, [12]Pan American Health Organization, Washington D. C., United States

Background: Immune Reconstitution Inflammatory Syndrome (IRIS) is a potential complication of antiretroviral therapy(ART), affecting up to one-third of people living with HIV(PLWH). Key risk factors include male gender, younger age, low CD4 count (<100 cells/mL), rapid CD4 recovery, swift suppression of HIV RNA, and pre-existing latent infections. However, there is limited data on IRIS in dual therapy.This study aims to report the incidence of IRIS.

Methods: The DOLCE study,a randomized trial in Argentina and Brazil, reported similar virologic suppression rates between dual therapy (DT) with Dolutegravir/Lamivudine and triple therapy (TT) with Dolutegravir, tenofovir disoproxil fumarate, and lamivudine or emtricitabine in PLWH with CD4 counts below 200 cells/mL.Participants were monitored for IRIS development over 48 weeks,diagnosed using clinical criteria (French Criteria, 2004) excluding other causes of symptoms. Baseline data, including CD4 counts, HIV RNA viral load, and prior opportunistic diseases, were collected to identify risk factors

Results: Among the 229 dosed participants,15 IRIS events were reported (overall incidence 7% over 48 weeks. In DT, the incidence was 5.9% (9/152), and in TT,7.8% (6/77) (p=0.6). Median time to IRIS presentation was 80 days in DT arm (IQR26-321);70 days in TT arm (IQR16-122),with no significant difference (p=0.5).Median baseline CD4 count was 116 cells/mL(IQR: 53.3-188), rising to 249 cells/mL (IQR: 159-308) at IRIS presentation similar in both arms:DT CD4 count:207 cells/mL(IQR: 141-304), and the TT;264 cells/mL (IQR: 199-305) (p=0.7). Most IRIS events were lymphoma and cerebral toxoplasmosis (Table 1).

Ten events (66.6%) were serious adverse events (SAEs), and five were treated with corticosteroids (33%). Two IRIS events were fatal.

IRIS Diagnosis	ART	Baseline CD4 cells count	Baseline HIV VL (copies/ml)	Time to IRIS onset from BSL (Days)	VL at the onset IRIS (copies/ml)	CD4 cells count at onset IRIS
Tuberculosis meningoencephalitis	DT	141	586.460	23	586460	141
Burkitt's lymphoma (non-Hodgkin's lymphoma)	DT	222	201.210	321	65	680
Bilateral herpetic retinitis	TT:	138	147.673	284	39	279
Possible lymphoma	DT:	328	47.306	324	39	176
Bilateral Pneumonia	TT	16	1.363.421	5	109	505
Disseminated TB with meningeal involvement	DT	145	66.454	26	39	123
Cytomegalovirus chorioretinitis and vitritis	DT:	31	222.923	80	32	250
Probable pulmonary tuberculosis	TT	234	1.075.000	126	39	313
Neurotoxoplasmosis	TT	102	40.594	108	37	78
Cryptosporidiosis	DT	102	826	9	349	207
Reactive arthritis	TT	8	278.494	11	39	249
Neurotoxoplasmosis	TT	17	136.963	32	39	182
Herpes zoster	DT	108	113.548	223	23	312
Hepatitis C flare (Hepatotoxicity)	DT	177	81.139	3675	96	304

IRIS: Immune Reconstitution Inflammatory Syndrome ;DT: DTG+3TC; TT: DTG+TDF/XTC; ART: antiretroviral therapy;BSL:baseline;TB:tuberculosis

Table. IRIS list.

Conclusions: The IRIS incidence in this study is within the expected range, reflecting the typical early presentation in PLHIV with low CD4 counts starting ART. No significant differences were observed between the DT and TT regimens.

These results highlight the importance of early IRIS monitoring, particularly in individuals with low baseline CD4 counts and pre-existing opportunistic diseases

Antiretroviral therapies and clinical issues in adults

THPEB034

Assessing the effect of co-administration of Rifapentine with Dolutegravir on viral load suppression among recipients of care on tuberculosis preventive therapy in Delta, Ekiti and Osun States

A. Oyetola[1], P. Agada[1], R. Kowam[1], B. Asuquo[1], D. Oqua[1], O. Omeh[1], K. Agu[1], E. Idoko[2], S. Ukwuaba[2], S. Oluwayinka[2], A. Egwuogu[2], B. Emah[2], U.-A. Augustine[2], P. Abojeh[2], P. Okoh[2], C. Law-Maduka[2], O. Ekele[2], A. Inedu[2], O. Onyedinachi[2], A. Eyo[2], M. Olu-Lawal[3], T. Kolawole[4]

[1]Howard University Global Initiative Nigeria, Abuja, Nigeria, [2]Excellence Community Education Welfare Scheme, Abuja, Nigeria, [3]State Specialist Hospital, Osogbo, Nigeria, [4]Federal Teaching Hospital, Ido-Ekiti, Nigeria

Background: Short-course once-weekly isoniazid-rifapentine (3HP) for three months is an effective regimen for latent Tuberculosis treatment among HIV Recipients of Care (ROC). Some studies have demonstrated that rifapentine reduces the plasma concentrations of Dolute-

gravir (DTG) through hepatic enzyme inductions possibly leading to treatment failure in the absence of dosage adjustment. The objective of the study was to assess viral load suppression rates among clients who were co-prescribed DTG and 3HP in selected facilities in Delta, Ekiti and Osun states.

Methods: The introduction of Isoniazid/Rifapentine (3HP) as an alternative Tuberculosis Preventive Therapy (TPT) regimen commenced May 2023 across 21 selected facilities in Delta, Ekiti and Osun states. Dolutegravir (DTG) forms part of the adult first line regimens in combination with Tenofovir/Lamivudine as TLD or Abacavir/Lamivudine as ALD. New clients were screened for eligibility.

There was no dosage adjustment when co-administered. The clients were followed up and provided adherence counselling. Treatment outcomes were documented in Facility TPT Cohort registers.

New clients had viral load collected after 6 months on treatment. Demographic data and viral load results were abstracted from the register and the National Medical Record System. Data were analyzed and summarized using frequencies in SPSS version 26.

Results: Medical records of 1258 ROC who started 3HP within the period (Male = 47%, Female = 53%) with median age of 36 (IQR=29-45) were reviewed out of which 63 were excluded for incomplete documentation. A total of 1195 clients had valid viral load results with 97.3% suppression rate (Male = 98.2%; Female = 96%)

Conclusions: Co-administration of 3-HP with Dolutegravir-based regimens did not have negative impact on viral load suppression rates in the absence of Dolutegravir dosage adjustment.

THPEB035

Integrating client-focused pharmacovigilance to prevent and manage commonly occurring Adverse Drug Reactions (ADRs) in HIV treatment in Zambia: a quality improvement initiative within the DSD-plus program

H. Fomundam[1], C. Maxwell[2], A. Tesfay[1], A. Maranga[1], D. Kaoma[3], M. Mando[3]

[1]Howard University, Howard University Global Initiative, South Africa (HUGISA), Pretoria, South Africa, [2]Howard University, College of Medicine, Washington, United States, [3]Howard University International Zambia, Lusaka, Zambia

Background: Adverse drug reactions (ADRs) to antiretroviral therapy (ART) impact client adherence and treatment outcomes, potentially leading to treatment discontinuation and failure. Zambia's pharmacovigilance system encourages ADRs reporting to the Zambia Medicines Regulatory Authority (ZAMRA) but lacks a platform for clinician's review and management. To address these issues, Howard University, through the Differentiated Service Delivery-plus (DSD-plus) program, partnered with Ministry of Health (MoH) in select healthcare facilities to integrate client-centered pharmacovigilance into routine HIV care and improve the identification, management, and reporting of ADRs, thereby enhancing client care and adherence to ART.

Methods: The program was implemented in 30 high volume facilities across three provinces, providing ART to approximately 131,200 clients. Over 450 healthcare providers were trained in ADRs identification, reporting to ZAMRA, and clinical management. A multidisciplinary pharmacovigilance committee incorporating clinicians, pharmacists, nurses, laboratory personnel, and community health workers were established in each facility. These committees reviewed the reported ADRs, determined causality and management strategies, and referred complicated cases to specialists. All ADRs cases were reported to ZAMRA through established channels.

Results: Between 2019 and 2024, 21,090 Adverse Drug Reaction (ADR) cases were identified and reported in DSD-plus supported facilities, accounting for >90% of all cases reported to ZAMRA.

The ADR management outcomes were as follows:

- 60% (12,652) of ADRs were mild
- 39.5% (8,331) were moderate
- 0.5% (669) were severe
- 97% of clients managed within DSD-plus clinics recovered
- 3% required referral to specialized care

Treatment outcomes:

- Continuity in care increased from 65% to 98%
- Viral suppression rate increased from 78% to 99%

Notably, <0.5% of clients missed doses due to ADRs and enhanced documentation of hypersensitivity reactions in client files significantly prevented ADRs.

Conclusions: This approach demonstrates the effectiveness of the DSD-plus Pharmacovigilance client-focused program in identifying, managing, and preventing ADRs, ultimately improving treatment outcomes for people living with HIV in Zambia.

This project was funded by the Health Resources and Services Administration (HRSA) under the U.S. President's Emergency Plan for AIDS Relief, as part of the Historically Black Colleges and Universities (HBCU) Global Health Consortium (GHC) Initiative.

THPEB036

Perspectives of people living with HIV (PWH) 24 months following a switch to cabotegravir and rilpivirine long-acting (CAB+RPV LA) in an observational real-world US study (BEYOND)

F. Felizarta[1], O. Alozie[2], R. Miller[3], K. Nelson[4], M. Reynolds[4], D. Richardson[4], K. Nguyen[5], P. Teichner[5], C. Garris[5]

[1]Private Practice, Bakersfield, United States, [2]Sunset West Health, El Paso, United States, [3]Cleveland Clinic, Infectious Disease, Cleveland, United States, [4]RTI Health Solutions, Research Triangle Park, United States, [5]ViiV Healthcare, Durham, United States

Background: CAB+RPV LA is the only complete long-acting regimen administered by a healthcare provider for treatment of virologically suppressed PWH. CAB+RPV LA may alleviate challenges associated with daily oral antiretroviral therapy (ART).

This study reports perspectives of PWH receiving CAB+RPV LA in real-world US healthcare settings.

Methods: This 2-year prospective observational study enrolled PWH following the decision to switch to CAB+RPV LA (monthly or every 2 months) across 27 US sites.
Participants completed surveys (at baseline [BL] before first injection and Months 6, 12 and 24 [M24]) identifying reasons for initiating CAB+RPV LA, challenges with oral ART, ART preference, HIV treatment satisfaction (HIV-TSQs, score range 0-66), and benefits of more frequent clinic visits.
Results: 308 PWH were enrolled and completed BL surveys. Median age 45 years, 83% identified as male, 39% as Black. The most common primary reasons CAB+RPV LA was initiated were pill fatigue (27% of participants), more convenient treatment option (21%), and pill adherence anxiety (17%). At BL, 49% of participants reported sometimes, often, or always hiding their prior oral ART for fear of disclosing HIV status. 195 PWH completed surveys at M24.
The proportion of PWH receiving CAB+RPV LA reporting fear of disclosure, anxiety around adherence, daily reminder of HIV, and feeling stigmatized by HIV treatment decreased from BL to M24 (Figure). At M24, most participants preferred CAB+RPV LA (95%; N=194).
Treatment satisfaction increased from BL to M24 (+6.3, p<0.0001; N=190). At M24, most participants (94%; N=188) reported ≥1 additional benefit of more frequent clinic visits (e.g., feel HIV is better controlled, more opportunities to discuss HIV treatment and/or other issues).
Conclusions: 24 months following a switch to CAB+RPV LA, PWH reported improvements in the challenges with prior oral therapy, reported a strong preference for CAB+RPV LA, had increased treatment satisfaction, and more opportunities to engage with their HIV care.

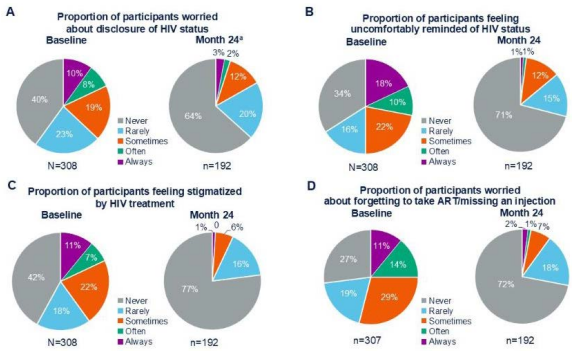

Figure. Proportion of participants (A) worried about disclosure of their HIV status, (B) Feeling reminded of their HIV status because of their treatment, (C) Feeling stigmatized by HIV treatment, and (D) Worried about forgetting to take ART/missing an injection at BL and M24.
**Month 24 proportions add up to 101% due to rounding.*
BL, baseline; M24, month 24.

THPEB037

Acceptability of long-acting injectable antiretroviral therapy among persons living with human immune-deficiency virus at the Korle Bu Teaching Hospital, Accra, Ghana

S. Fumador[1], P. Puplampu[1], I. Kyeremanteng[2], E. Amankwa[1], O. Oladele[3], V. Ganu[1]
[1]Korle Bu Teaching Hospital, Medicine and Therapeutics, Accra, Ghana, [2]Brown School, Washington University, Missouri, United States, [3]Korle Bu Teaching Hospital, Psychiatry, Accra, Ghana

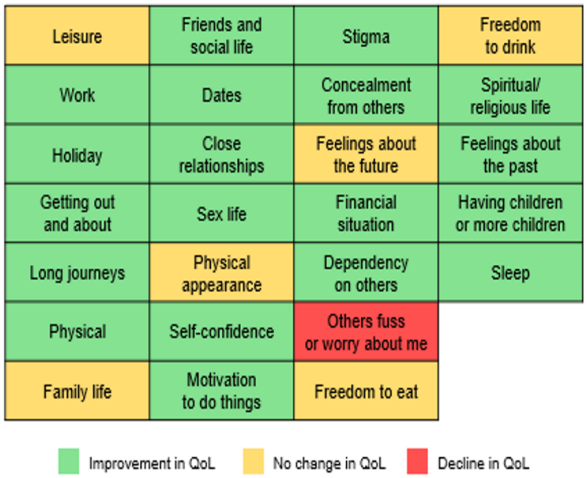
Background: A strategic approach to enhancing adherence to antiretroviral therapy (ART) is the development of long-acting injectable ART (LAI-ART). Client acceptability is however a key determinant to the success of these novel therapies, but data is lacking in Africa and Ghana.
This study assessed the knowledge of and willingness to accept LAI-ART among people living with HIV (PLHIV) attending the HIV clinic of the Korle-Bu teaching hospital.
Methods: A cross-sectional study with a quantitative approach was conducted over a four month period in 2024 among adult PLHIV on ART for at least 6-months and attending the HIV clinic of the Korle-Bu teaching hospital. Participants were recruited using a simple random sampling and data was collected via a self-administered questionnaire. Participants were initially asked about their knowledge on LAI after which education on LAI was provided and participants reassessed.
Descriptive statistics was used to summarize the demographic and clinical characteristics. Inferential analysis was performed with Fisher's exact or Chi square test and logistic regression.
Results: Three hundred and nine (309) PLHIV participated in the study. Most (71.5%) of participants were female and 46% were above 50 years. Majority (78.9%) of them were on a single-pill regimen and 80.2% were adherent on ART. 70% of participants had no prior knowledge about LAI-ART. Of those who had prior knowledge about LAI-ART (30.1%), 65.6% got the information from the hospital.
After education, 89.6% showed a preference for LAI-ART, with a preferred frequency of injections being every 6 months (67.3%). About 79% preferred a trained nurse to administer LAI-ART. However, 41% preferred self- administration of LAI-ART if trained to do so.
Thirty-two percent had fears of side effects about LAI-ART even after education, and about 72% of PLHIV were willing to pay for LAI-ART. Participants who take more than one pill a day had eight times the odds of accepting LAI-ART compared to those taking one pill a day (aOR: 8.2 95%CI: 1.1-8.4).
Conclusions: Inadequate knowledge about LAI among PLHIV was high. Education of PLHIV on LAI-ART increased their preference and need for LAI-ART.

THPEB038

Satisfaction, preference, and health-related quality of life changes using HIV-specific patient-reported outcome measures with a novel, twice-yearly administered HIV-1 treatment regimen

A. Gaur[1], J. Eron[2], O. Ogbuagu[3], K. Price[4], H. Liu[4], K. Mponponsuo[4], J. Jarrett[4], S. Shahraz[4]
[1]St. Jude Children's Research Hospital, Memphis, United States, [2]University of North Carolina, Chapel Hill, United States, [3]Yale School of Medicine, New Haven, United States, [4]Gilead Sciences, Inc., Foster City, United States

Background: The combination of lenacapavir (LEN), an approved HIV-1 capsid inhibitor, and two investigational broadly neutralizing antibodies (bNAbs), teropavimab (TAB) and zinlirvimab (ZAB), administered every 6 months (Q6M), is being evaluated in a Phase 2 open-label study (NCT05729568); we describe Week 26 (W26) patient-reported outcomes.
Methods: Virologically suppressed (HIV-1 RNA <50 copies/mL) adults with HIV-1 highly susceptible to both bNAbs receiving oral antiretroviral therapy (ART) for ≥12 months were enrolled (N=83) and randomized 2:1 to subcutaneous LEN 927 mg (with LEN oral loading) plus intravenous TAB 2550 mg and ZAB 2550 mg Q6M, or to continue baseline oral ART.
Assessments included: HIV Treatment Satisfaction Questionnaire – Status (HIVTSQ status) and – Change (HIVTSQ change), HIV Treatment Preference Questionnaire (HIVTPQ), and HIV Dependent Quality of Life (HIVDQoL) questionnaire. Analyses were conducted for participants receiving LEN, TAB, and ZAB using descriptive statistics and complete-case analysis for longitudinal comparisons.



Improvement, no change, and decline in QoL were defined as the numerical mean change from baseline to Week 26 in weighted impact scores of >0, 0, and <0, respectively, for each of the 26 domains.
LEN, lenacapavir; Q6M, every six months; QoL, quality of life; TAB, teropavimab; ZAB, zinlirvimab.

Figure. Change from baseline to week 26 in the HIV dependent quality of life questionnaire individual domain measurements for participants receiving LEN, TAB and ZAB Q6M.

Results: Participants receiving LEN, TAB and ZAB (n=53) had a mean (SD) age of 44 (13.7) years; 85% were male, 91% from the US, and 53% White. Mean (SD) HIVTSQstatus score increased from 58 (7.7) at baseline to 61 (7.3) at W26. W26 HIVTSQchange mean (SD) score was 25 (10.6), indicating improved satisfaction over baseline oral ART. At W26, 41/49 (83.7%) participants reported a preference for LEN, TAB, and ZAB on the HIVTPQ (strong, n=32; moderate, n=9), with 43/49 (87.8%) indicating it would be easier to adhere to LEN, TAB, and ZAB Q6M versus daily oral ART. HIVDQoL scores increased from baseline to W26 *(Figure)*; at baseline and W26, respectively, 42/45 (93.3%) and 44/45 (97.8%) participants reported positive (good–excellent) quality of life (QoL), with 11/45 (24.4%) and 17/45 (37.8%) reporting excellent QoL.
Conclusions: Participants switching to LEN, TAB, and ZAB Q6M reported improved treatment satisfaction and QoL by W26, with a moderate-to-strong preference for LEN, TAB, and ZAB over oral ART.

Antiretroviral therapies and clinical issues in adolescents and young adults

THPEB039

Mental health challenges and substance use associated with poor viral suppression and transition readiness among adolescents with HIV transitioning to adult care

B. Zanoni[1,2,3], T. Sibaya[4], F. Magut[4], K. Baisley[4], J. Upton[4], C. Gathers[1], V. Marconi[5,2], L. Sewnarian[4], J. Haberer[6], M. Archary[4,7]
[1]Emory University, Medicine and Pediatric Infectious Diseases, Atlanta, United States, [2]Rollins School of Public Health, Atlanta, United States, [3]Children's Healthcare of Atlanta, Atlanta, United States, [4]Africa Health Research Institute, Durban, South Africa, [5]Emory University, Infectious Diseases, Atlanta, United States, [6]Massachusetts General Hospital, Boston, United States, [7]University of Kwa-Zulu Natal, Pediatric Infectious Diseases, Durban, South Africa

Background: Adolescents with perinatally-acquired HIV (APHIV) often engage in substance use and experience mental health issues contributing to lower retention in care and viral suppression after transitioning to adult care.
Methods: We are conducting a type 1, hybrid implementation-effectiveness, stepped-wedge, cluster-randomized trial to assess the effectiveness of in-person and mHealth based delivery of an adolescent-friendly transition intervention (InTSHA-VIP) on viral suppression among APHIV aged 15-19 years in 16 clinics in urban and rural KwaZulu-Natal, South Africa.
At baseline, we evaluated depression (PHQ-9), self-esteem (Rosenberg scale), stigma (Internalized AIDS Stigma Scale), and social support (Child and Adolescent Social Support Scale). We assessed factors associated with baseline viral suppression (viral load <200 copies/ml) and transition readiness (HIV Adolescent Readiness for Transition Scale [HARTS]) using generalised estimating equa-

tions and generalised linear mixed models respectively, adjusting for age, sex, schooling, geographic location and factors with p-values less 0.2 on bivariable analysis.

Results: We enrolled 380 APHIV. At baseline, 279 (84.3%) had viral suppression and 44 (11.6%) had high transition readiness. Overall, 136 (41.2%) reported feeling depressed or sad most days of the year, 48 (14.3%) met criteria for depression, 156 (41.7%) reported using alcohol in the past 30 days, and 43 (11.3%) reported marijuana or drug use in the past 30 days. After adjustment, marijuana use and depression were both associated with reduced odds of viral suppression (adjusted odds ratio (aOR)=0.38; 95%CI=0.16,0.91; p=0.03 and aOR=0.51; 95%CI=0.27,0.96; p=0.04, respectively).

In the unadjusted analysis, higher self-esteem scores were associated with lower transition readiness (mean difference −0.02; 95%CI= −0.02,−0.01; p=0.002), and higher PHQ-9 scores were associated with higher transition readiness, although that difference was not significant (mean difference 0.03; 95%CI=−0.05,0.11; p=0.452). After adjustment, we found no evidence of association between self-esteem scores or PHQ-9 scores and transition readiness.

Conclusions: Mental health and substance use play a critical role in viral suppression for APHIV in South Africa. Studies of interventions such as InTSHA VIP addressing these issues are needed to improve viral suppression and transition readiness.

THPEB040

Treatment outcomes among children and adults who commenced third line antiretroviral therapy at Newlands Clinic in Zimbabwe in 2024: a review of clinic records

C. Chimbetete[1], A. Mandiriri[2,1], T. Mudzviti[1,3], T. Shamu[1]
[1]Newlands Clinic, Clinic, Harare, Zimbabwe, [2]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [3]University of Zimbabwe, Faculty of Medicine, Department of Pharmacy, Harare, Zimbabwe

Background: Newlands Clinic (NC) introduced the third-line ART in 2015 and has Zimbabwe's biggest third-line cohort. Zimbabwe ART guidelines lack individualized care options after third-line ART failure.

Methods: This was a records review of individuals initiated on third-line ART at NC by December 2024. We abstracted demographic and clinical data including third-line initiation dates, CD4 counts and age at third-line commencement, and the latest viral load results. We reported treatment outcomes, including the association between sex, age-group, and baseline CD4 count with viral suppression among those still in care using logistic regression.

Results: A total of 390 individuals commenced third-line ART at NC (50% female). The median baseline age and CD4 count was 39 years (IQR 23-48) and 134 cells/mm^3 (IQR 36-277), respectively. The median third-line ART duration was 3.8 years (IQR 1.9-6.4). At analysis, 296 (75.9%) were still in care, 50 (12.8%) had died, 35 (9.0%) had transferred out, and 9 (2.3%) were lost to follow-up. The crude mortality rate was 2.56/100 person-years with 20 (47.6%) deaths occurring within the first year after commencement (Figure, Left). Among those in care, 242 (81.8%) had undetectable viral loads (<50 copies/ml) while 20 (6.8%) had viral loads >1000 copies/ml. Compared to adults aged ≥25 years with an HIV viral suppression rate of 96%, children and young people (CYP) had lower suppression rates of 86% (Figure, Right). Adults were twice as likely to be suppressed (aOR 2.16, 95%CI 1.12 – 4.14, p=0.021) than CYP.

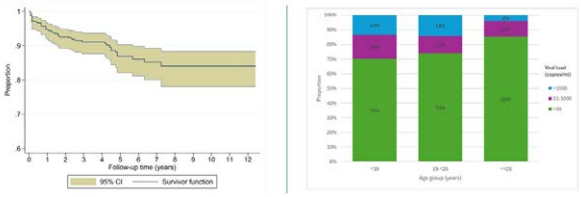


Figure: VL and mortality rates among 3rd line ART clients.

Conclusions: We report a high burden of advanced HIV disease among individuals commencing third-line ART which may explain the high mortality rates. HIV treatment programs should improve monitoring to ensure early diagnosis of second-line ART failure, especially among CYP. Individualized ART regimens are needed for patients failing third-line ART.

Antiretroviral therapies and clinical issues in neonates, infants and children

THPEB041

Virologic control near delivery and ART-adherence in a cohort of naïve and experienced pregnant people living with HIV in a PMTCT center

E. João[1], M.I. Gouvea[1,2], M.d.L. Benamor Teixeira[1,2], T. Fuller[1], E. Souza[1], C. Braga[1], M.C. Sodré[1]
[1]Hospital Federal dos Servidores do Estado, Rio de Janeiro, Brazil, [2]Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

Background: Pregnant people living with HIV (PLWH) face barriers to achieving virologic suppression near delivery. At the individual level, factors that might influence virologic suppression include antiretroviral adherence and the history exposure to ART prior to pregnancy, if any. Few studies have focused on the role of ART-experience on virologic suppression during pregnancy in the era of universal combined antiretroviral regimens.

The objective of this study was to assess virologic control and ART adherence profile including naïve and experienced pregnant PLWH at a PMTCT unit.

Methods: The primary endpoint was undetectable HIV VL (<40cp/mL) near delivery. Three regimens were used: INSTI-based, NNRTI-based, and PI-based. VL was performed at entry, quarterly, and near delivery. The groups were defined: ART-naïve (Group1), experienced who conceived in continuous use of ART (Group2) or who restarted ART during pregnancy (Group3). Genotype tests were performed for PLWH with VL > 500 cp/mL at entry.

Adherence during prenatal care at the center was defined as the percentage of days during which participants had

picked up their ART regimens in pharmacy records. Below 90% was suboptimal. Obstetric/neonatal outcomes were reported.

Results: 350 pregnant PLWH received antenatal care from 2019-2023. Median HIV VL at entry was Group1: 3.0 log10 copies, Group2: 0.0 log10 copies, and Group3: 3.5 log10 copies. The proportion who achieved virologic suppression near delivery was 89%. Virological control near delivery was Group1 122/131 (93%), Group2 155/162 (96%), and Group3 34/57 (60%). 115 had genotypic testing and resistance rates were: NRTI 10%, NNRTI 24%, PI 4%, and INSTI 0%. More than 90% of pickups were in Group1: 60.3%; Group2: 45.7%; Group3: 26.3%, respectively. There were no cases of vertical transmission. Two stillbirths occurred.

Conclusions: Most participants achieved virologic control near delivery. The group with the highest rate of ART pickups of more than 90% was ART-naïves, followed by those who conceived in use, and those who were ART experienced and restarted ART during pregnancy. Despite good overall rates of virological control achieved near delivery, there are still challenges to maintaining optimal adherence and controlling HIV VL during pregnancy in ART-experienced pregnant PLWH who restarted ART during pregnancy.

Clinical issues specific to key populations

THPEB042

TGD scorecard: addressing trans erasure in HIV clinical trials

B. Minalga[1], C. Feuer[2]
[1]Fred Hutchinson Cancer Institute, Office of HIV/AIDS Network Coordination, Seattle, United States, [2]AVAC, New York, United States

Background: Transgender and gender-diverse (TGD) people remain woefully underrepresented in HIV research. TGD communities are frequently overlooked in study design, eligibility criteria, data collection, and data reporting, resulting in their exclusion and erasure from research and limiting urgently needed opportunities to benefit from clinical advancements. To address these problematic research norms, we offer a structured framework (The TGD Scorecard) for guiding and evaluating TGD inclusion in HIV clinical trials with actionable criteria for trial design and conduct. The Scorecard was subsequently used to quantify and characterize TGD inclusion in pivotal HIV studies since the start of HIV research as supporting evidence of the need for this framework.

Methods: With input from global TGD communities, we devised a tool (Scorecard) consisting of 14 scoreable indicators to measure responsivity of HIV clinical trials to the lived realities and HIV-related needs of TGD communities. We tested the Scorecard in a retrospective, cross-sectional review of 41 randomized controlled trials. Studies were selected to represent the spectrum of groundbreaking HIV therapeutic and prevention studies enrolling participants from 1991–2023. https://avac.org/resource/no-data-no-more-scorecard-tool/

Results: Most studies did not collect or report demographic data such that participants could be identified as cisgender, transgender, and/or gender-diverse. Only 2,532 (1.4%) out of the total 178,893 participants in this analysis could be identified as TGD. Within this group, the largest proportion was made up of 2,042 (80.6%) transgender women (TGW), followed by 398 (15.7%) gender nonbinary individuals (GNB) and 92 (3.6%) transgender men (TGM). Cisgender people represent 42,905 (24.0%) of total participants, including 29,668 cisgender men and 13,237 cisgender women. The remaining 133,456 (74.6%) participants could not be categorized as TGD or cisgender due to ambiguous definitions of the study population.

Conclusions: Findings from our analysis of 41 milestone HIV clinical trials confirm TGD people remain underrepresented in HIV research, though there is a small uptick in the last 10 years. The lack of TGD representation in HIV clinical trials represents a historical erasure of TGD communities with potential public health consequences. These findings support our recommendation to utilize the Scorecard as a policy and advocacy tool to operationalize commitment to TGD representation in HIV research.

Epidemiology of HIV

THPEC043

Data-driven HIV prevention in Zambia: prioritizing sub-national high-burden areas for optimized intervention impact

M. Silondwa[1], B. Longwe[1], N. Soko[2], H. Mutale[3], M. Chilembo[1], N. Nyathi[4], M. Radebe[5], P. Haimbe[1], H. Shakwelele[1], T. Mwamba[1]
[1]Clinton Health Access Initative, Programs, Lusaka, Zambia, [2]National HIV/AIDS/STI/TB Council, Policy and Planning, Lusaka, Zambia, [3]Ministry of Health, Policy and Planning, Lusaka, Zambia, [4]Clinton Health Access Initative, Programs, Harare, Zimbabwe, [5]Clinton Health Access Initative, Programs, Johannesburg, South Africa

Background: Zambia has made significant progress in controlling the HIV epidemic through widespread HIV treatment and prevention initiatives. However, measuring the direct impact of HIV prevention, especially at local levels, presents challenges. To address this, the Clinton Health Access Initiative (CHAI) partnered with Zambia's Ministry of Health and the National AIDS Council to develop a methodology for analyzing HIV prevention data, aiming to create actionable insights for prioritizing high-impact interventions in areas of greatest need.

Description: An Excel-based data collation tool was created to streamline the collection and aggregation of epidemiological and program data, including HIV estimates, program data, and socioeconomic risk indicators from

2023 and 2024. disaggregated by age and gender. This tool enables the efficient identification of high-burden districts, allowing for data-driven prevention strategies to focus resources where they will be most effective.

Lessons learned: From 2010 to 2023, Zambia achieved a 65% reduction in new HIV incidence however, the burden remains concentrated, with 13 districts accounting for nearly half of all cases. Analysis revealed disparities in HIV incidence across age, gender, and geography, with adolescent girls and young women (AGYW) facing the highest risk. Despite representing just 11% of the population, AGYW account for 29% of new incidence. The data highlighted service gaps in high-burden districts, where access to condoms, PrEP, and VMMC services is limited. Identifying these areas has allowed for the development of tools, such as District Factsheets, that support targeted prevention efforts.

Conclusions/Next steps: The findings underscore the varied HIV incidence across Zambia, with higher rates in urban centers and among AGYW. By identifying districts with elevated incidence rates and unmet prevention needs, stakeholders can implement tailored interventions to address specific gaps. This approach promotes evidence-based methods in advancing a differentiated HIV prevention strategy across Zambia.

THPEC044

Sex differences in advanced HIV disease at presentation among people living with HIV in Latin America and the Caribbean

Y. Caro-Vega[1], J. Mejía-Castrejón[1], L. Guerrero-Torres[1], C. Cesar[2], C.P. Cortes[3], D. Machado[4], P.M. Luz[5], J. Andrade Pinto[6], M.T. Luque[7], E. Gotuzzo[8], V. Rouzier[9], J. Castilho[10], P.F. Rebeiro[10], B. Crabtree-Ramírez[1], Caribbean, Central & South American network for HIV epidemiology (CCASAnet)

[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Infectología, Mexico City, Mexico, [2]Fundación Huesped, Buenos Aires, Argentina, [3]Universidad de Chile School of Medicine & Fundación Arriarán, Santiago de Chile, Chile, [4]Escola Paulista de Medicina, Universidade Federal de São Paulo (Unifesp), Sao Paulo, Brazil, [5]Fundacao Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [6]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [7]Instituto Hondureño de Seguridad Social, Tegucigalpa, Honduras, [8]Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru, [9]Le Groupe Haïtien d'Etude du Sarcome de Kaposi et des Infections Opportunistes in Port-au-Prince (GHESKIO), Port-au Prince, Haiti, [10]Vanderbilt University Medical Center, Nashville, United States

Background: In 2024, UNAIDS reported an overall decline of 28% in AIDS-related deaths in Latin America but noted an increase among women in certain countries. Women remain underrepresented in HIV research, particularly in countries with concentrated epidemics (CE) such as most countries in Latin America.

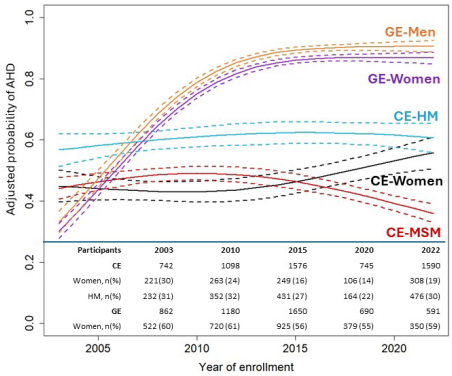
We therefore compared advanced HIV disease (AHD) at enrollment in HIV care between men and women in Latin America and the Caribbean.

Methods: Adults (≥18 years old) in the Central and South America network for HIV epidemiology (CCASAnet) enrolled between 2003 and 2022 were stratified by birth sex and HIV acquisition risk group as women, men who have sex with men (MSM), and heterosexual men (HM). We classified sites as experiencing either a generalized epidemic (GE, Haiti) or a concentrated epidemic (CE: Argentina, Brazil, Chile, Honduras, and Mexico).

We estimated the probability of AHD (defined as AIDS diagnosis or CD4<200 cells/μL) at cohort enrollment using logistic regression models, stratifying by sex/HIV acquisition risk group and CE/GE, and adjusting for age, education level, and calendar year of enrollment.

Results: Of 40,609 participants, 40% were from CE sites, where 19% were women, 60% were MSM and 21% were HM (at the GE site, 58% were women). At CE sites, the proportion of women enrolling declined from 29% in 2003 to 19% in 2022 . Median CD4 was highest for CE-MSM (335, IQR:157-526) cells/μL and lowest for CE-HM (177, IQR:58-360) cells/μL and GE-men (201, IQR:74-340) cells/μL. The adjusted probability of AHD increased among women in both epidemic settings (Figure 1).

Figure 1. Adjusted probability of Advanced HIV Disease (AHD) over time by birth sex and HIV transmission risk groups and epidemic setting.



Participants	2003	2010	2015	2020	2022
CE	742	1098	1576	745	1590
Women, n(%)	221(30)	263 (24)	249 (16)	106 (14)	308 (19)
HM, n(%)	232 (31)	352 (32)	431 (27)	164 (22)	476 (30)
GE	862	1180	1650	690	591
Women, n(%)	522 (60)	720 (61)	925 (56)	379 (55)	350 (59)

Note: Curves are predictions from multivariable logistic models of advanced HIV disease (AHD; AIDS diagnosis or CD4 <200 cells/μL) at enrollment, stratified by sex and HIV transmission risk group (Women, MSM: men who have sex with men; and HM: heterosexual men) and epidemic type (CE, concentrated epidemic, GE generalized epidemic), including year of enrollment, secondary education level, and age at enrollment

Conclusions: In CE sites, the increasing trend of AHD among women contrasts the decreasing trend among MSM. In GE, both men and women show an increase in AHD over time. Our findings support the implementation of effective interventions that increase awareness, improve HIV testing, and hasten linkage to care among women.

THPEC045

HIV incidence trends and associated risk factors among people who inject drugs in Pakistan: programmatic data from a national harm reduction intervention

M.K.A. Mazhar[1], M. Zafar[2], S.u.H. Qureshi[2], Y. Akhtar[2], L. Maher[3,4], P. Vickerman[1], A. Artenie[1,5]

[1]University of Bristol, Bristol, United Kingdom, [2]Nai Zindagi Trust, Islamabad, Pakistan, [3]Kirby Institute, UNSW, Sydney, Australia, [4]Burnet Institute, Melbourne, Australia, [5]Université de Montréal, Montreal, Canada

Background: HIV prevalence among people who inject drugs (PWID) in Pakistan is estimated to be high (38.4% in 2017), but data on HIV incidence is unavailable. We estimated HIV incidence and associated risk factors among PWID in Pakistan using nationwide programmatic data.

Methods: We used data from Nai Zindagi Trust, which provides harm-reduction services to PWID across Pakistan. All participants provided self-reported behavioural data and were tested for HIV at enrolment, with HIV-negative participants offered re-testing every 3-6 months. PWID testing HIV-negative at baseline with ≥1 follow-up test were eligible for this study.

Univariable and multivariable Cox regression analyses explored factors for HIV acquisition risk, including socio-demographic (e.g., age, gender), structural risk factors (e.g., homelessness, incarceration), and risk behaviours (e.g., syringe sharing, public injecting) at enrolment.

Results: Among 89,021 PWID enrolled between 2012-2023, 88,427 (99.3%) had valid HIV tests, with 29,327 (33.2%) testing HIV-positive at baseline. Of 59,100 HIV-negative PWID, 43,783 (74.1%) had ≥1 follow-up test and were included in the incidence analysis. At baseline, 99.5% were male, with an average age of 31.2 years, and 71.2% were heroin injectors. Over 100,797 person-years (py) of follow-up over 2012-2023, 12,151 (27.8%) PWID acquired HIV, giving an overall incidence of 12.1/100py (95%CI: 11.8–12.3). Incidence was highest in Punjab (17.5/100py; 95%CI: 17.2–17.9) and lowest in Balochistan (0.7/100py; 95%CI: 0.4–1.1). By year, incidence peaked in 2016 (19.3/100py; 95%CI: 18.3–20.3) and declined steadily thereafter, reaching 10.2/100py (95%CI: 9.6–10.7) in 2023.

In the multivariable Cox regression model, higher HIV acquisition was associated with homelessness (aHR 1.09; 95%CI: 1.03–1.15), public injecting (aHR 1.26; 95%CI: 1.16–1.37), syringe sharing (aHR 1.08; 95%CI: 1.01–1.15), and injection by street doctors (aHR 1.14; 95%CI: 1.09–1.19) at enrolment; no associations were found for other variables.

Conclusions: HIV incidence among PWID in Pakistan has a declining trend from a peak in 2016, possibly due to effective prevention services with high coverage. This study demonstrates the value of programmatic data for monitoring HIV incidence and highlights an urgent need to initiate opioid agonist treatment and potentially HIV pre-exposure prophylaxis for enhanced impact.

THPEC046

HIV seroprevalence, self-reported STIs and associated risk factors among men who have sex with men: a cross-sectional study in Rwanda, 2015

E. Shema[1], R. Ntale[1], G. Rutayisire[2], J. Greatorex[3], S.D. William Frost[3]

[1]University of Rwanda, Biomedical Laboratory Sciences, Kigali, Rwanda, [2]University of Rwanda, Kigali, Rwanda, [3]University of Cambridge, Cambridge, United Kingdom

Background: Men who have sex with men (MSM) represent a key population with elevated risks for acquiring HIV and sexually transmitted diseases (STDs) in Rwanda.

This study aimed to estimate the prevalence of HIV, other STIs, and associated risk behaviours among MSM in Rwandan urban centres to inform targeted interventions.

Methods: In this cross-sectional study, we recruited through peer referral men aged between 18 and 60 years, who reported sex with men at least once in the 12 months prior to the survey. Representativeness was increased using ‚seeds' from a variety of sources. Signed informed consent was obtained from all participants.

Data on demographics, risk behaviours, and self-reported STIs were collected through an interviewer-administered questionnaire. We screened all eligible participants for HIV using the Rwanda-approved protocol for rapid HIV detection.

Results: Among 504 participants (median age 23 years, range 18–55), 96.0% (484/504) were unmarried. A self-reported history of gonorrhoea and/or syphilis was observed in 13.0% (65/504), while 10.5% (53/504) reported a gonorrhoea diagnosis and treatment in the past 12 months. HIV prevalence was 4.8% (24/504).

A significant proportion (46.0%, 232/504) reported receiving payment for sex by a man, with 46.1% (107/232) engaging in this activity more than three times. Most participants (76.4%, 385/504) reported HIV testing in the past 12 months. Multivariate analysis revealed that receiving payment for sex was independently associated with higher odds of a past STI diagnosis (adjusted odds ratio [AOR] 3.36; 95% CI: 1.82–6.43; P<0.001) and HIV positivity (AOR 3.13; P<0.05).

Conclusions: The findings underscore the high prevalence of transactional sex and its strong association with STIs and HIV among Rwandan MSM. This study highlights the urgent need for tailored interventions, including enhanced access to HIV prevention services, regular STI screening, and targeted behaviour change programmes. Future research should focus on understanding the structural and behavioural drivers underlying the high prevalence of transactional sex in this population, as it represents a significant risk factor for STIs, including HIV.

Monitoring and population-level interventions for non-HIV outcomes

THPEC047

Neutralizing antibody titers are immune correlates of COVID-19 risk in the Ubuntu study of people with HIV in East and Southern Africa

[1]Baylor College of Medicine Children's Foundation-Uganda, Kampala, Uganda, [2]University of the Witwatersrand, SAMRC Antibody Immunity Research Unit, Faculty of Health Sciences, Johannesburg, South Africa, [3]National Institute for Communicable Diseases, National Health Laboratory Service, Johannesburg, South Africa, [4]Duke Human Vaccine Institute, Departments of Surgery and Integrative Immunobiology, Center for Human Systems Immunology, Durham, United States, [5]Fred Hutchinson Cancer Center, Vaccine and Infectious Disease Division, Seattle, United States, [6]University of Washington, Division of Allergy and Infectious Diseases, Department of Medicine, Seattle, United States, [7]University of Cape Town, Department of Medicine, Cape Town, South Africa, [8]Johns Hopkins Research Project, Blantyre, Malawi, [9]University of Washington, Department of Biostatistics, Seattle, United States, [10]University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa, [11]South African Medical Research Council, Pretoria, South Africa, [12]University of Washington, Department of Global Health, Seattle, United States, [13]Qhakaza Mbokodo Research Clinic, Ladysmith, South Africa, [14]University of KwaZulu-Natal, Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, [15]University of KwaZulu-Natal, Discipline of Public Health Medicine, School of Nursing and Public Health, Durban, South Africa, [16]National Institutes of Health, National Institute of Allergy and Infectious Diseases, Bethesda, United States, [17]Hutchinson Centre Research Institute of South Africa, Cape Town HVTN Immunology Laboratory, Cape Town, South Africa, [18]Duke University School of Medicine, Center for HIV/AIDS Vaccine Immunology, Durham, United States, [19]Fred Hutchinson Cancer Center, Public Health Sciences Division, Seattle, United States

Background: The CoVPN 3008 (Ubuntu) study, conducted in East and Southern Africa in 11,681 people with HIV (PWH) and 2321 people without HIV (PWoH), showed lower COVID-19 incidence for a hybrid immunity group (baseline SARS-CoV-2 positive, one mRNA-1273 dose) compared to a vaccine immunity group (baseline SARS-CoV-2 negative, two mRNA-1273 doses). We aimed to identify immune correlates of COVID-19 risk.

Methods: Vaccinations occurred between December 2021 and September 2022. Using case-cohort sampling, neutralizing antibody and IgG-binding antibody levels against Spike and Nucleocapsid measured at enrolment (M0) and four weeks post-final vaccination (Peak) were assessed as potential immune correlates of COVID-19. Proportional hazards models estimated hazard ratios (HR) of COVID-19 per 10-fold increase of antibody levels at M0 or Peak. A flexible nonparametric method, constrained to ensure monotone curves, estimated cumulative incidences of COVID-19 through approximately 3 and 7 months post-Peak as a function of antibody levels. All analyses adjusted for potential confounders.

Results: Antibody responses and immune correlates were similar for PWH and PWoH; results shown are pooled. For the hybrid-immunity group (n=287), all antibody markers at M0 inversely correlated with COVID-19 over 230 days post-Peak, with neutralizing antibodies the strongest and only independent correlate (HR=0.46, 95% CI 0.28-0.75, P=0.002). For the vaccine-immunity group (n=115), Peak neutralizing antibodies were an inverse correlate but only in early follow-up (HR=0.44, 0.23-0.85, P=0.015 through 92 days post-Peak; HR=1.08, 0.76-1.54, P=0.66 through 230 days post-Peak). Figure-1 shows marker distributions and COVID-19 risk by marker level.

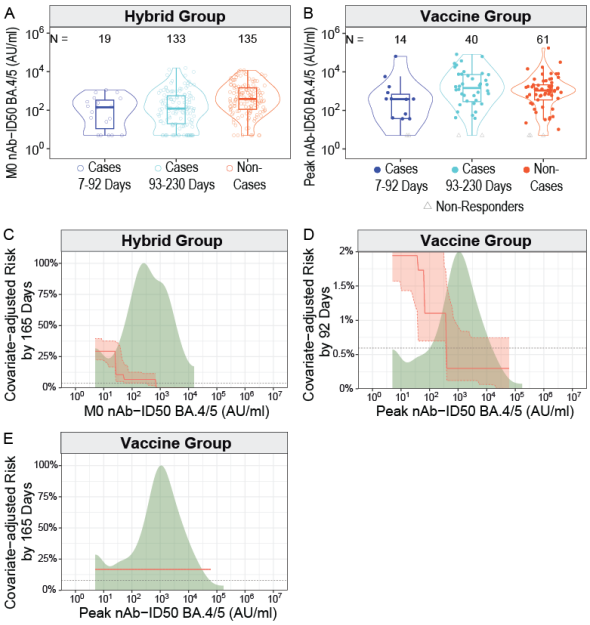

Figure-1. nAb-ID50 titer against BA.4/5 (**A**) at M0 in the Hybrid Group (N=287) and (**B**) at Peak in the Vaccine Group (N=115) by COVID-19 outcome status. Covariate-adjusted probability of COVID-19 (**C**) by 165 days for Hybrid by M0 titer; (**D**) by 92 days for Vaccine by Peak titer; (**E**) by 165 days for Vaccine by Peak titer. Titer distributions are shown. Days are post Peak. Peak, 4 weeks post last vaccine dose (M1 for Hybrid Group, M2 for Vaccine Group).

Conclusions: This study is the first to show that binding and neutralizing antibody correlates of protection apply for PWH. Moreover, this study quantifies the constrained cross-reactive protection of the ancestral-strain vaccine mRNA-1273 in a naïve population where even the highest antibody responses elicited by two doses without priming by natural SARS-CoV-2 acquisition impacted COVID-19 risk for only 4 months.

THPEC048

Distribution of HIV and viral hepatitis co-infection among people who use drugs in Rwanda

I. Tuyishime Ntaganda[1], C. Ndinda[1], T.T. Adegboyega[2]
[1]Rwanda Biomedical Centre, Kigali, Rwanda, [2]University of Rwanda, Huye, Rwanda

Background: Coinfection of HIV and viral hepatitis B & C among people who use drugs (PWUD) represents a significant public health challenge, particularly due to the shared transmission mechanisms between the two infections. Managing both HIV and viral hepatitis simultaneously is challenging, often leading to negative health outcomes.

This study aimed to estimate the prevalence of HIV and viral hepatitis B & C coinfection and identify demographic and geographic variations among PWUD in Rwanda.

Methods: A cross-sectional survey using respondent driven sampling (RDS) was conducted in November 2024, involving 1,113 adults aged 18+ from ten predetermined sites across Rwanda. Data were collected through structured interviews, which assessed sociodemographic characteristics and health tests, focusing on drug use and risky behaviors. Co-infection status was determined through laboratory tests for HIV and viral hepatitis B & C.

Results: The national coinfection rate among PWUD was 0.59% (CI: 0.33–0.85). The prevalence was higher among men (0.65%, CI: 0.0–16.42) than women (0.21%, CI: 0.0–9.24). The median age of participants was 35+ years, with the highest prevalence in the 35+ age group (0.99%, CI: 0.0–20.48), followed by those aged 25-34 (0.75%, CI: 0.0–17.78). No cases of co-infection were found in the 18–24 age group. The regional coinfection rates varied: 2.19% (CI: 0.0–30.94) in Northern Province, 0.68% (CI: 0.0–16.91) in Southern, 0.57% (CI: 0.0–15.36) in Eastern, and lower rates of 0.37% (CI: 0.0–12.3) and 0.35% (CI: 0.0–11.93) in Western and Kigali City, respectively.

Conclusions: The findings highlight the low prevalence of HIV and viral hepatitis B & C coinfection among PWUD in Rwanda, with notable regional and gender differences. Targeted, integrated healthcare services that combine prevention, testing, and treatment for both HIV and viral hepatitis are critical. Expanding harm reduction programs, addressing barriers like stigma, and enhancing surveillance are essential for improving health outcomes for this high-risk population.

Methodology to support epidemiological studies

THPEC049

A path to sustainability: differentiated service delivery models in challenged government health facilities

L. Molemane[1], J. Thabeng[1]
[1]Tebelopele Wellness Center, Programs Department, Gaborone, Botswana

Background: On June 30, 2023, the Botswana Nurses Union (BONU) announced that nurses would cease dispensing medications effective July 1, 2023, citing the Nurses & Midwives Act Cap 02 of 2005, which excludes dispensing from their professional duties. This decision posed a significant threat to Botswana's progress toward the 95-98-98 targets for HIV epidemic control, as it risked treatment interruptions for people living with HIV (PLHIV), especially in districts already facing a shortage of pharmacy personnel.

In response, Tebelopele Wellness Centers (TWC), with its established expertise in Differentiated Service Delivery (DSD) models, collaborated with the Government of Botswana (GoB) to ensure continuity of treatment in affected communities. This partnership demonstrated the effectiveness of DSD models in maintaining care delivery even during crises.

Description: The GoB, through District Health Management Teams (DHMT), assigned four facilities with limited or no pharmacy personnel and no prior external funding in two districts to TWC for support. TWC conducted facility needs assessments to establish baseline requirements and guide program implementation.

Collaborating with community-based organizations, TWC introduced two DSD models: Community Medication Refill (CMR) and Facility Fast Track Refill (FFTR). Key preparatory activities included stakeholder engagement, community sensitization, supply chain optimization, and setting up monitoring and reporting systems.

These models served as stop-gap measures to maintain treatment continuity, reduce travel burdens for PLHIV, decongest health facilities, and support adherence and retention.

Lessons learned: Among the 823 PLHIV clients receiving treatment at GoB facilities, 585 (70%) were assessed for DSD model eligibility, with 457 (78%) meeting the criteria. All eligible clients opted to participate, with 311 (68%) selecting FFTR and 146 (32%) choosing CMR. The remaining 128 (22%) were ineligible for DSD models. By October 26, 2023, when the High Court ruled for the reinstatement of nurses' dispensing duties, 238 (30%) clients were not yet due for refills or clinical visits.

Conclusions/Next steps: Scaling up DSD models for PLHIV in Botswana improves patient-centered care, enhances the quality and efficiency of treatment delivery, and reduces healthcare system costs while maintaining equivalent clinical outcomes. These models also provide a resilient mechanism to address health service disruptions and ensure continuity of care during crises.

Surveillance: Measuring the HIV pandemic

THPEC050

Predictors of mother-to-child transmission of HIV among pregnant and breastfeeding women living with HIV in Rwanda

P. Nisingizwe[1,2], D. Umutesi[1], Z. Nzeyimana[1], B. Ikuzo[1], G. N. Rwibasira[1]
[1]Rwanda Biomedical Center, Institute of HIV/AIDS Disease Prevention and Control (IHDPC), Kigali, Rwanda, [2]University of Rwanda, Kigali City, Rwanda

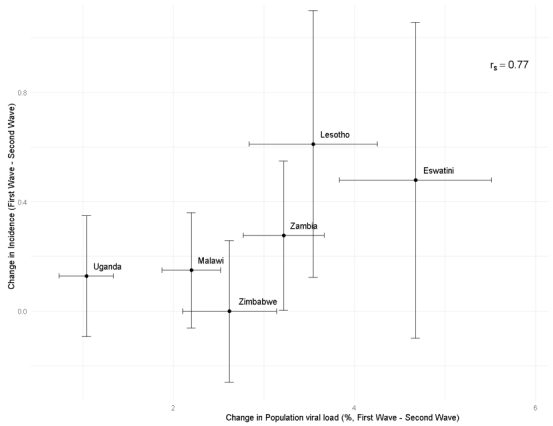
Background: Mother to Child Transmission (MTCT) has declined in Rwanda since implementation of universal coverage of Prevention of Mother to Child Transmission (PMTCT) program in all health facilities across the country. The transmission rate has been maintained below 2% for the last 10 years. However, exposed infants reamin at high risk of acquiring HIV infection from their mothers.
We assessed predictor of transmission and remaining gap to be closed toward elimination of mother to child transmission.
Methods: We conducted a retrospective cohort study to review clinical and demographic characteristics of pregnant and breastfeeding women living with HIV enrolled in PMTCT follow up, from July 2016 to June 2020 at 283 health facilities across the country. Eligible were all mothers of all ages who consulted antenatal care (ANC) living with HIV, mothers who tested positive in ANC and their infant after delivery. We used STATA 17 for data analysis. Logistic regression analysis was used to assess predictors of mother to child transmission.
Results: A total of 9,734 pair mother-infants have been enrolled and mother's mean age was 35 ± 6.56 years. About 84.25% were living with HIV before first antenatal care (ANC1) with 99.69% on ART, 15.75% tested HIV positive in ANC1 with 99.33% initiated on the ART. Among, 66(1.1%) infants were identified HIV positive during 24 months follow up. Mothers with 25 – 34 years showed a higher transmission to their infant 44% (p 0.001) and living with male partner had association with transmission at 75% (p < 0.001). In multivariate analysis, mother to child transmission was associated with being negative or with unknown HIV status in ANC1 (aOR:2,36, 95% CI: 1,31 – 4,26), having viral load > 1000 copies/ml at 6-month post-delivery (aOR:17, 95% CI: 9.71 -33) and infant birth weight below 2.5kg (aOR: 2.17 95% CI: 1.02 – 4.59).
Conclusions: Despite Rwanda has significantly reduced the MTCT rate, identified predictors still contribute to transmission. Interventions should focus on viral load suppression, providing appropriate suport to mothers with infant born small, and supporting mothers who knew their positive status in ANC. Addressing these predictors is vital for eliminating mother to child transmission.

THPEC051

Progress towards key UNAIDS targets: change in adult HIV incidence and population viral load across six African countries over a 5-year period

K. Enders[1], B. Shook-Sa[1], L. Stranix-Chibanda[2], S. Phiri[3], L.-G. Bekker[4], J. Justman[5], B. Chi[6], N. Rosenberg[7]
[1]University of North Carolina at Chapel Hill, Biostatistics, Chapel Hill, United States, [2]University of Zimbabwe, Harare, Zimbabwe, [3]Partners In Hope, Lilongwe, Malawi, [4]Desmond Tutu HIV Foundation, University of Cape Town, Cape Town, South Africa, [5]Columbia University, New York, United States, [6]University of North Carolina at Chapel Hill, Department of Obstetrics and Gynecology, Chapel Hill, United States, [7]University of North Carolina at Chapel Hill, Health Behavior, Chapel Hill, United States

Background: Population-based HIV Impact Assessment (PHIA) household surveys provide empirical estimates of HIV-1 incidence and HIV-1 population viral load. First and second wave PHIA surveys were conducted five years apart (range 4-6 years) between 2015-2017 and 2020-2021, respectively. These surveys quantify progress towards UNAIDS targets.
Methods: First and second wave PHIAs were conducted in Eswatini, Lesotho, Malawi, Uganda, Zambia, and Zimbabwe. For each country, changes in HIV-1 incidence rates and HIV-1 population viral load were estimated among individuals aged 15-59. Recent HIV-1 was classified using a cross-sectional algorithm consisting of HIV-1 limiting antigen avidity enzyme immunoassay, HIV-1 viral load, and antiretroviral detection, and was used for estimation of incidence. Population HIV-1 viral load was estimated as the proportion of all adults with detectable viral loads. The association between HIV-1 incidence and population viral load was estimated with Spearman correlation. All analyses accounted for the complex sample designs of the PHIA surveys.
Results: Both HIV-1 incidence and population viral load were higher during the first than second wave surveys; however, trends were not consistent across countries. The change in HIV-1 incidence ranged from -0.61/100PYs (95% CI: -0.12, -1.10) in Lesotho to 0.00/100PYs (95% CI: -0.26, 0.26) in Zimbabwe. The change in population viral load ranged from -4.7% (95% CI: -3.8%, -5.5%) in Eswatini to -1.0% (95% CI: -0.7%, -1.3%) in Uganda. Declines in population viral load were strongly correlated with declines in incidence (correlation coefficient=0.77).



Conclusions: Changes in HIV-1 incidence and population viral load demonstrate progress towards UNAIDS targets and were highly correlated, but progress was not uniform.

THPEC052

Trends in orphanhood incidence and prevalence among children and adolescents in Rakai, Uganda, 1995-2022

D. Malden[1], A. Khalifa[1], O. Ratmann[2], Y. Chen[2], K. Grabowski[3], L. Chang[3], F. Nalugoda[4], G. Kigozi[4], T. Lutalo[4], N. Sewankambo[5], A. Ndyanabo[4], D. Serwadda[4], P. Kreniske[1], F. Makumbi[4], R. Ssekubugu[4], J. Kagaayi[4], A. Settuba[4], H. Nakawooya[4], S. Hillis[6], J. Santelli[1]

[1]Columbia University, Department of Population and Family Health, New York City, United States, [2]Imperial College London, Department of Mathematics, London, United Kingdom, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [4]Rakai Health Sciences Program, Kalisizo, Uganda, [5]Makerere University, Kampala, Uganda, [6]University of Oxford, Global Reference Group for Children Affected by Crisis, Oxford, United Kingdom

Background: Orphans face multiple health and social consequences. HIV treatment and prevention programs have contributed to dramatic declines in the prevalence of orphanhood in sub-Saharan Africa. Less is known about declines over time in incident orphanhood and factors associated with this decline, including changing attribution to HIV infection.

Methods: We used population-based census data from 28 continuously surveyed communities in the Rakai Community Cohort Study to calculate maternal, paternal, and double orphanhood prevalence and incidence by census round (N=47,177). Orphanhood incidence trends were estimated using a non-parametric hierarchical Bayesian model. Poisson regression was used to estimate incidence rate ratios (IRR) of orphanhood by time period: 1-pre-antiretrovrial therapy (ART) (1995-2004), 2-ART rollout (2005-14), and 3-Universal ART (2015-22).

Population attributable fractions of incident orphanhood due to parent's HIV positive serostatus were estimated among those with parents tested for HIV (Maternal: 32,866; Paternal: 20,096).

Results: Prevalence and incidence of orphanhood declined over time following the introduction of ART in 2004. Prevalence among all persons aged 0-17 years declined from 27.7% in 1995 to 21.5% in 2004 to 6.3% (1 in 16 Rakai children) in 2022. Orphanhood incidence also declined sharply from 20.5 per 1000 person-years in 2003 to 5.9 in 2022 for paternal orphanhood, and from 8.55 to 2.3 per 1000 person-years for maternal orphanhood. The sharpest declines in orphanhood incidence occurred among children and adolescents with parents living with HIV.

Among those with known parental HIV status, HIV+ status was associated with almost ten times the IRR of incident orphanhood (maternal orphanhood: IRR 9.98, 95% CI: 8.58-11.60; paternal orphanhood: IRR 8.94, 95% CI: 7.96-10.10). The proportion of incident maternal and paternal orphanhood attributed to parental HIV+ status declined from 67% and 71%, respectively, during the Pre-ART period to 11%-12% during the universal ART period.

Conclusions: Orphanhood prevalence and incidence, including orphanhood cases attributed to HIV, dramatically declined following the introduction and expansion of ART in Rakai, Uganda. However, the burden of orphanhood remains considerable and demands evidence-based responses.

THPEC053

Estimating HIV incidence using a longitudinal assessment of routine community-based testing data across the WHO European Region: insights from the COBATEST Network

L. Fernàndez-López[1,2,3], M. Alarcón[1,2], G. Escaramís[1], J. Aceitón[1], L. Alonso[1,2], M. Gogishvili[1,2], J. Casabona[1,2,3], COBATEST Network Study Group

[1]Centre of Epidemiological Studies of HIV/AIDS and STI of Catalonia (CEEISCAT), Health Department, Generalitat de Catalunya, Badalona, Spain, [2]Institute for Health Science Research Germans Trias i Pujol (IGTP), Badalona, Spain, [3]CIBER Epidemiologia y Salud Publica (CIBERESP), Madrid, Spain

Background: Over the past two decades, global HIV incidence has decreased, but this decline is slowing, and in some regions, it has plateaued or risen, particularly among key populations (KPs). Monitoring changes in HIV incidence over time within these groups is essential. Nevertheless, longitudinal incidence data for KPs remains scarce due to logistical and economic challenges. Community-based testing services are vital for reaching and testing KPs. The COBATEST Network connects such services across Europe and Central Asia, sharing harmonised data. An anonymised unique identifier helps track repeat testers, enabling longitudinal data analysis. The study aimed to demonstrate the feasibility of using routine community-based testing data to calculate HIV incidence for KPs.

Methods: A retrospective longitudinal analysis was conducted on testing data collected by COBATEST Network members using the COBATEST online data collection tool during the period 2014-2023. Participants with a at least two visits and a negative-HIV test result at the first visit, or those with only one visit but a self-reported previous HIV-negative test during the study period, were included in the analysis. HIV incidence rates were calculated using person-time measures and 95% confidence intervals (CIs).

Results: Over the entire period, 38657 participants were included in the analysis, contributing 66605.73 person-years, and 447 participants seroconverted, resulting in an overall incidence of 0.67 per 100 person-years (95% CI: 0.61-0.74), ranging from 0.44 in year 2014 to 0.92 in year 2016. The estimated incidences across KP groups were as follows: 1.02 (95% CI: 0.92-1.13) for men who have sex with men (MSM), 0.27 (95% CI: 0.14-0.48) for people who inject drugs (PWID), 1.21 (95% CI: 0.98-1.45) for sex workers (SW), and 1.42 (95% CI: 1.21-1.64) for non-European migrants.

Conclusions: This study demonstrates the feasibility of using routine community-based testing data to estimate HIV incidence among key populations (KPs). The findings reveal significant variability in incidence rates, with non-European migrants, MSM, and SW facing the highest burden.
The use of anonymized unique identifiers and harmonized data collection within the COBATEST Network is a valuable approach for longitudinal monitoring. Expanding such networks and data-sharing initiatives can strengthen surveillance and inform public health responses and policy.

Figure 1. Annual infections averted.

Conclusions/Next steps: Injectable PrEP offers the opportunity to unlock impact at scale. However, securing affordable commodity costs and reducing delivery costs through less frequent clinic visits will be critical to achieving cost-effectiveness.

Modelling the HIV pandemic

THPEC054

Curbing HIV transmission in Malawi by scaling long-acting injectable PrEP: a modeling analysis

C. Banda[1], D. Telela[1], C. Chavula[1], L. Mwandira[1], T. Mwenifumbo[1], D. Resar[1], A. Gunda[1]
[1]Clinton Health Access Initiative, Infectious diseases Cluster, HIV Prevention, Lilongwe, Malawi

Background: In 2023, an estimated 72,335 people received pre-exposure prophylaxis (PrEP) in Malawi. However, there were 12,000 new HIV acquisitions that same year, highlighting persistent unmet need for prevention. Many individuals and programs face challenges with oral PrEP due to stigma and pill burden, among other issues. Long-acting PrEP products like long-acting cabotegravir (CAB-LA) and lenacapavir offer the opportunity to address many of the challenges faced with oral PrEP. This analysis modelled the costs and health outcomes of injectable PrEP scale-up in Malawi to inform decision-making.
Description: This analysis used the Goals model in Spectrum (version 6.38) to estimate the costs and health outcomes of various injectable PrEP scale-up scenarios from 2025-2040. Goals models HIV transmission by population groups based on behaviors, epidemiological factors, and the impact of interventions. Efficacy and adherence rates were assumed to be 90% and 50%, respectively, for oral PrEP, 90% and 90% for CAB-LA, and 95% and 95% for lenacapavir. In the oral PrEP scenario, current coverage rates were held constant through 2040. In the injectable PrEP scenarios, we assumed UNAIDS PrEP coverage targets were reached in 2030 (80% coverage among sex workers; 80% coverage among MSM; 50% coverage among people who inject drugs; 50% coverage among clients of sex workers; 20% among medium risk heterosexual women via linear scale-up and then maintained. The method mix was assumed to reach 70% injectable and 30% oral in 2030 via linear scale-up of injectable.
Lessons learned: The injectable PrEP scale-up scenarios would avert between 33-37K HIV acquisitions compared to constant coverage of oral PrEP from 2025-40 at USD $1,600-1,800 per acquisition averted (assuming $100 per person treated for any PrEP product).

HIV prevention research

Uptake of injectable long-acting cabotegravir pre-exposure prophylaxis among vulnerable populations in Zambia

K. Musokotwane[1], M. Mwansa[2], N. Soko[1], P. Ndemena[1], Z. Malwa[3], C. Baumhart[4,5], J. Mwanza[3], C.W. Claassen[2,5,6], L. Hachaambwa[3,6,5], L.K. Mwango[3]
[1]National AIDS Council, Lusaka, Zambia, [2]Maryland Global Initiatives Corporation Zambia, Lusaka, Zambia, [3]Ciheb Zambia, Lusaka, Zambia, [4]Institute of Human Virology, University of Maryland School of Medicine, Baltimoreunited, United States, [5]Center for International Health, Education, and Biosecurity, University of Maryland Baltimore School of Medicine, Baltimore, United States, [6]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States

Background: In Zambia long-acting Cabotegravir (CAB-LA), an injectable form of HIV pre-exposure prophylaxis (PrEP), was launched in February 2024 and is currently offered in eight of ten provinces. HIV prevalence is over two-times higher among Vulnerable populations (VPs) compared to the general population in Zambia, with female sex workers (FSW) at 45%, men who have sex men (MSM) at 21%, and people who inject drugs (PWID) at 23% according to Zambia's 2023 Biological and Behavioural Surveillance Survey.
The National AIDS Council has been increasing access to HIV prevention methods, including PrEP, for VPs across the country to reduce HIV transmission. We reviewed program data to investigate uptake of CAB-LA among VPs, as a strategy to reduce new infections in Zambia.
Methods: Using country-wide program data from the Ministry of Health DHIS Tracker for CAB-LA, we reviewed and described clients screening, uptake, and discontinuations of CAB-LA PrEP in Zambia. We collected data on sociodemographic characteristics, population categories, and uptake of CAB-LA. Deidentified and aggregated data were analyzed to determine CAB-LA uptake by VP types. Data were analyzed using R and Stata.

Results: A total of 3,221 clients were screened, and 16% (525/3,221) were VPs. Of the 525 VPs, 94% (492/525) were initiated on CAB-LA PrEP. Nearly half (47%) of the VPs were aged 25-35 with 38% (185/492) aged 16-24. Of the 492 VPs initiated, nearly two-thirds (64%) (317/492) were FSW, 29% (142/492) were MSM, and 7% (33/492) were vulnerable persons.

After the first dose, 8% (41/492) of VPs discontinued CAB-LA with 71% (29/41) of discontinuations among FSW. Muchinga Province had the highest (46%) (225/492) VPs initiated on CAB-LA. Of those initiated in Muchinga, nearly 73% (165/225) were FSW. Of the 165 FSW, 45% (75/165) were aged 25-34 and 38% (63/165) were aged 16-24 years.

Conclusions: Vulnerable Populations have an increased risk of acquiring HIV. In reducing new HIV infections among VPs, CAB-LA plays a critical role in preventing new HIV infections. VP friendly strategies should be put in place to enhance uptake and retention of CAB-LA among the VP community in Zambia.

THPEC056

A prospective cohort study assessing implant site healing, implant acceptability and PrEP preferences following removal of the tenofovir alafenamide sub-dermal implant

T.N. Gengiah[1], L. Lewis[1], I. Harkoo[1], L.E. Mansoor[1], N. Myeni[1], Q. Abdool Karim[1,2], S.S. Abdool Karim[1,2]

[1]Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, [2]Columbia University, Department of Epidemiology, Mailman School of Public Health, New York, United States

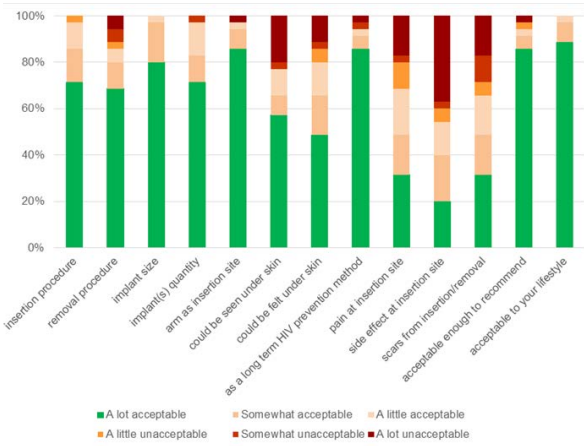
Background: The CAPRISA 018 Phase I/II trial evaluated a novel 110mg tenofovir alafenamide implant for HIV prevention in South African women over 48 weeks. This follow-up cohort study, CAPRISA 097, assessed the long-term resolution of implant site reactions (ISRs) after implant removal, while exploring implant acceptability, preferred attributes, and HIV pre-exposure prophylaxis (PrEP) preferences, to inform the design of next-generation PrEP implants by providing insights into user preferences.

Methods: Women from the CAPRISA 018 trial were followed quarterly for 12 months after implant removal. ISR prevalence was assessed at each study visit and were evaluated for severity and healing. Implant acceptability and PrEP modality preferences were assessed at enrolment, Month 6, and Month 12.

Results: In total, 35 of the 36 participants from CAPRISA 018 were enrolled in CAPRISA 097. Participant median (interquartile range [IQR]) age was 29 (23-32) years. At study entry, which occurred a median (IQR) of 9.8 (7.9-16.1) months after implant removal, all participants had ongoing scarring, 14% had ongoing hyperpigmentation, 6% had induration and 3% had hypopigmentation.

At study exit, a median of 18.9 (19.0-26.9) months after implant removal, scarring was still observed in all participants, with hyperpigmentation in two participants and induration in another. All ISRs were mild (Grade 1) throughout the study. Implant visibility, palpability and ISRs reduced implant acceptability (Figure1: Implant acceptability at enrolment).

At enrolment and month 12, the preferred PrEP modalities were a 12-monthly implant (38.2% vs 50%), a 6-monthly injectable option (29% vs 37.5%), oral (11.8% vs 6.3%) or vaginal PrEP tablets (11.8% vs 0%), a 6-monthly implant (0% vs 3.1%) and the vaginal ring (2.9% vs 0%).



Conclusions: ISRs such as scarring, hyperpigmentation, and induration while mild are persistent reducing the acceptability of the implants. Despite these drawbacks, 12-monthly subdermal implants remain the preferred choice for women who have used the TAF implant.

Bridging the gaps: enhancing pre exposure prophylaxis uptake among adolescent girls and young women through support groups on the DREAMS initiative in Kapiri Mposhi District, Central Zambia

K. Kasonde[1], J. Banda[1], P. Shitima[1], L. Chisenga[1], G. Kutola[1]

[1]Coalition Health Zambia, Technical, Kapiri Mposhi, Zambia

Background: Adolescent girls and young women (AGYW) remain disproportionately affected by the HIV epidemic, particularly in sub-Saharan Africa. Despite the availability of pre-exposure prophylaxis (PrEP) as a highly effective biomedical intervention for HIV prevention, the uptake and adherence rates among AGYW are alarmingly low. Various barriers contribute to this gap, including stigma, limited access to healthcare services, misinformation about PrEP, and socio-economic challenges.

Cultural norms and gender-based violence further exacerbate these issues, creating an environment where AGYW feel marginalized and powerless. The USAID Controlling HIV Epidemic for Key and Underserved Populations (CHEKUP II) Activity aimed to ascertain the effectiveness of PrEP peer support groups in DREAMS Sites in Kapiri Mposhi District.

Methods: Between October 2023 to September 2024, using trained biomedical mentors and connectors, the USAID Controlling HIV Epidemic for Key and Underserved Populations (CHEKUP II) Activity addressed the barrier of PrEP uptake through formation of peer support groups in Kapiri Mposhi. AGYW who had earlier accessed PrEP engaged their peers in five support groups through Focus Group Discussions. Data was collected through desk reviews, erims and DHIS2.

Results: 5,308 Adolescent Girls and Young Women in Kapiri Mposhi newly accessed PrEP against a target of 1,654 compared to 3,144 in 2023, while 7,193 continued on PrEP in 2024 reporting year compared to 2,871 in 2023. The increase in PrEP uptake and retention, signifies acceptability of the service while highlighting the significant role of peer support. Peer supporters leveraged on their lived experiences to exchange information, correct misconceptions and provided support for each other. Supportive peer networks enhanced comfort levels and encouraged PrEP uptake

Conclusions: This research underscores the importance of PrEP support groups in enhancing uptake among adolescent girls and young women. The realities of PrEP uptake among adolescents highlight the need for targeted interventions that address the unique barriers this population faces. By fostering supportive environments, educating adolescents, and improving access to healthcare, we can promote higher rates of PrEP uptake and better sexual health outcomes among young people. We recommend use of support groups to enhance PrEP uptake and retention as peers will share knowledge and support leveraging on their lived experiences.

THPEC058

Strengthening post-exposure prophylaxis uptake among sexual violence survivors through immediate access at police stations in Nigeria's Federal Capital Territory

B. Adewumi[1], M. Cain[2], U. Kanagasabai[2], S. Dahal[2], V. Adamu[1], T. Efuntoye[1], F. Omodele[1], A. Ayuba[1], D. Collins-Kalu[3], C. Ayeni[3], H. Omuh[3], C. Nwafor[3], A. Raji Ajuwon[3], A. Orisawayi[3], P. Dakum[3], F. Daggash[4]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV & Tuberculosis, Abuja, Nigeria, [2]U.S. Centers for Disease Control and Prevention, Division of Global HIV & Tuberculosis, Atlanta, United States, [3]Institute of Human Virology, Abuja, Nigeria, [4]FCT AIDS and STI Control Program, Public Health Department, Abuja, Nigeria

Background: Data on sexual violence (SV) prevalence in Nigeria is limited; however, findings from the 2014 Nigeria Violence Against Children Survey found that 24.8% of females aged 18 to 24 years experienced SV in childhood, and only 3.5% received any form of services. Initiation of post-exposure prophylaxis (PEP) to prevent HIV infection following SV is most effective when started immediately and is not recommended after 72 hours. Police stations are often entry points for SV survivors; however, lengthy processes may result in missed PEP opportunities due to delays in timely linkage to health facilities.
Using a phased approach, we introduced PEP into selected police stations in Nigeria's Federal Capital Territory to explore how to increase access to time-sensitive HIV prevention within non-health services.
Methods: Our intervention phase consisted of the provision of immediate PEP starter packs coupled with linkage to the nearest referral facility for the remainder of the PEP doses.
During two time periods (Pre-intervention: January – March 2023) and (During Intervention: July – September 2023), we evaluated routinely reported program data from 27 U.S. Centers for Disease Control and Prevention-supported health facilities for changes in the provision of SV services and PEP initiation.
We used geospatial mapping to assess the proximity of participating health facilities to police stations and changes in both SV and PEP service provision. The statistical significance of the difference in PEP uptake proportion during the two periods was determined using Wilcoxon signed rank test at 0.05 level of significance.
Results: Of the 27 health facilities, 24 were within a 5km radius of a participating police station. Total SV service provision was 114 cases, with 56x PEP initiations (pre-intervention); this increased to 218 SV cases, with 218xx PEP initiations (during intervention). Results indicate that SV service provision increased by 91.2% and PEP initiation increased by 289.3%.
Conclusions: Our findings showed promise in increasing immediate access to PEP in non-health services and highlighted the feasibility of police stations and health facilities to collaborate to address urgent health needs. There was an overall increase of PEP initiations by referral and non-designated referral facilities, possibly due to increased access at police stations.

A randomized, double-blind, controlled, phase 2 clinical trial to evaluate safety, tolerability, pharmacokinetics, and neutralization of VRC07-523LS, PGT121.414.LS, and PGDM1400LS broadly neutralizing monoclonal antibodies given intravenously in adults without HIV

H. Gelderblom[1], L. Naidoo[2], T. Torres[3], G. Vásquez[4], P. Andrew[5], M. Anderson[1], G. Broder[1], S. Chiambah[6], B. Dye[5], Y. Huang[1], J. Hural[1], M. Marzinke[7], K. Mondal[1], D. Montefiori[8], E. Piwowar-Manning[5,7], K. Seaton[9], N. Sista[5], H. Spiegel[6], J. de Dieu Tapsoba[1], M. Yacovone[6], B. Zhang[1], D. Barouch[10], L. Corey[1], P. Gilbert[1], G. Tomaras[11], C. Gay[12], G. Gray[2,13], B. Grinsztejn[14], R. Panchia[13], H. Scott[15], HVTN 206 / HPTN 114 Study Team

[1]Fred Hutchinson Cancer Center, Vaccine and Infectious Disease Division, Seattle, United States, [2]South African Medical Research Council, Cape Town, South Africa, [3]Instituto Nacional de Infectología Evandro Chagas (INI-Fiocruz), Rio de Janeiro, Brazil, [4]Via Libre – CITBM, Lima, Peru, [5]HIV Prevention Trials Network, Durham, United States, [6]National Institute of Allergy and Infectious Diseases, Division of AIDS, Rockville, United States, [7]Johns Hopkins University School of Medicine, Baltimore, United States, [8]Duke University Medical Center, Durham, United States, [9]Duke University, Center for Human Systems Immunology, Durham, United States, [10]Harvard Medical School, Boston, United States, [11]Duke University, Center for Human Systems Immunology, Departments of Surgery, Immunology, Molecular Genetics and Microbiology, Durham, United States, [12]University of North Carolina at Chapel Hill School of Medicine, Department of Medicine, Division of Infectious Diseases, UNC HIV Cure Center, Chapel Hill, United States, [1] [3]University of the Witwatersrand, Perinatal HIV Research Unit, Soweto, South Africa, [14]Instituto de Pesquisa Clinica Evandro Chagas-Fiocruz, Rio de Janeiro, Brazil, [15]San Francisco Department of Public Health, Bridge HIV, San Francisco, United States

Background: The global HIV epidemic demands innovative prevention tools to complement existing strategies. The Antibody-Mediated Prevention (AMP, HVTN703/HPTN081 & HVTN704/HPTN085) trials demonstrated the protective efficacy (PE) of a single broadly neutralizing antibody (bnAb) in participants with sensitive HIV strains, indicating the need for a combination of bnAbs to enhance PE. HVTN206/HPTN114 is the first phase 2 study to evaluate the safety, tolerability, pharmacokinetics (PK), and neutralization capacity of a triple-bnAb combination—VRC07-523LS, PGT121.414.LS, and PGDM1400LS—administered intravenously to adults without HIV.

Methods: HVTN206/HPTN114's design was informed by AMP and six subsequent phase 1 trials with next-generation bnAbs. We found that LS-modified bnAbs, individually and in combination, are safe, well-tolerated, and maintain PK and neutralization activity for at least six months. These trials showed no significant anti-drug antibody (ADA) development or interference between bnAbs, and supported fixed-dose regimens as comparable to weight-based dosing.

Results: HVTN206/HPTN114 is a randomized, double-blind, controlled trial conducted at 12 clinical sites across Brazil, Peru, South Africa, and the United States. 200 adults of all gender identities, without HIV, aged 18–65 will receive two intravenous infusions, spaced six months apart, in one of two dosing groups:

1. a lower dose (400 mg of each bnAb per infusion) or;
2. a higher dose (3200 mg of VRC07-523LS, 1600 mg of PGT121.414.LS, and 1600 mg of PGDM1400LS per infusion).

The design incorporates fixed doses to standardize administration and reduce complexity. Data collection includes adverse events, serum PK, neutralization activity, and ADA detection, with subgroup analyses based on age, gender, and weight. This design builds on prior evidence to further evaluate the triple-bnAb combination for long-acting immunoprophylaxis.

Conclusions: HVTN206/HPTN114 represents a critical step in advancing HIV prevention strategies by testing a triple-bnAb combination informed by robust evidence from the AMP efficacy trials and phase 1 trials with next-generation bnAbs, including HVTN140/HPTN101 with the same triple-bnAb combination.

This trial will inform the design of the combo-AMP efficacy trials and could establish HIV bnAbs immunoprophylaxis (passive immunization) as a biannual, long-acting option for HIV prevention, addressing key gaps in current strategies and enhancing global HIV prevention programs.

THPEC060

A competing risks duration model to study PrEP discontinuation among men having sex with men in France: The ERAS 2023 study

C. Boutet[1], M. Di Ciaccio[1,2], B. Spire[1], A. Velter[3,1], L. Sagaon Teyssier[1]

[1]Mixed Research Unit SESSTIM, Aix-Marseille-University, Inserm, IRD, Marseille, France, [2]Coalition Plus, Pantin, France, [3]Santé Publique France, Saint Maurice, France

Background: PrEP effectiveness is hindered by high discontinuation rates. Despite the wide literature about PrEP discontinuation (PD), the role of PrEP weariness (PW) remains unclear. We aimed investigating PD providing further insight about PW and accounting for different reasons for discontinuation.

Methods: The French online survey *Enquête Rapport au Sexe 2023* targeting men having sex with men (MSM) was used. The outcome was the duration between the date of first PrEP prescription and the date of PD. An accelerated failure time model was implemented. Competing risks accounted for different reasons of PD: changes in sexual behaviors (CSB, e.g. number of partners), desire to discontinue PrEP (DDP e.g. declared preference for condoms), and clinical reasons (CR, e.g. secondary effects, seroconversion, medical decision).

Demographic, socioeconomic, psycho-behavioral and geo-epidemiological factors were considered. Mpox vaccination proxied closeness with the gay community. PW was investigated by a Weibull distribution estimating the effect of time elapsed in PrEP over the probability of PD (Weibull parameter, WP) measuring duration depen-

dence: negative <1, null=1, positive >1. Acceleration factors (AF), interpreted as hazard ratios and 95% confidence intervals (95%CI) were presented.

Results: Of 23502 MSM, 4819 declared current or past PrEP use. Among them, 870 discontinued PrEP (median[IQR] duration: 10[3-21.75] months). CSB, DDP and CR explained 54.5%, 26.2% and 19.3% of PD respectively.

Younger participants with CSB (AF[95%CI]: 0.950[0.937-0.964]) were more likely to PD. Concerning DDP, residents in regions with low HIV incidence (AF[95%CI]: 2.320[1.054-5.107]), youngest and oldest participants (U-shaped effect, AF_age[95%CI]: 0.780[0.663-0.919], AF_age²[95%CI]: 1.252[1.028-1.525]) were more likely to PD. Concerning CR, PD probability increased for unemployed (AF[95%CI]: 3.513[1.615-7.645]), first PrEP prescription at hospitals after 2021 (AF[95%CI]: 4.322[1.209-15.443], versus prescription by general practitioners), in rural areas (AF[95%CI]: 2.312[1.099-4.868]) and using condoms at most recent sexual encounter (AF[95%CI]: 5.223[2.478-11.005]). Overall, the probability of PD decreased with the number of sexual partners and for those close to MSM community.

Negative duration dependence was found for the three reasons of PD (CSB_WP[95%CI]: 0.495[0.469-0.524]; DDP_WP[95%CI]: 0.590[0.554-0.628]; CR_WP[95%CI]: 0.630[0.590-0.672]) implying a probability decrease with the time elapsed using PrEP.

Conclusions: Our results suggested no PW among French MSM. However, counseling/support should target differently PrEP users according to the drivers inducing discontinuation.

THPEC061

PEPtoPrEP: descriptors and factors associated with initiating PEP and PrEP uptake post possible exposure to HIV as part of the FastPrEP study in Cape Town, South Africa

F. Bennin[1], E. Rousseau[1], P. MacDonald[1], L.-G. Bekker[1]
[1]Desmond Tutu Health Foundation, Cape Town, South Africa

Background: Initiating long-acting injectable pre-exposure prophylaxis (PrEP) in users during periods of very recent HIV sexual exposure and potential asymptomatic acute HIV acquisition should be avoided. Initiating PrEP directly after completing post-exposure prophylaxis (PEP) treatment with confirmed HIV sero-negativity in the user provides an alternative approach. This mixed-method study aimed to describe this process in community-based differentiated delivery service.

Methods: FastPrEP is an ongoing implementation science project in Cape Town, South Africa, evaluating adolescent and young people's PrEP uptake and effective PrEP use from community-based mobile clinics, primary health facilities and courier delivery service. Along with oral and Dapivirine ring, long-acting injectable cabotegravir (CAB-LA) is currently provided. Routine questions determining participant exposure to HIV in the previous 72 hours, and participant user characteristics (demographics and sexual profiles/ experiences) were introduced in May 2024 for participants (male or female, ≥ 15 years) enrolled onto FastPrEP. Descriptive statistics were used to describe user characteristics, PEP and PrEP uptake and reasons for declining PrEP initiation.

Results: From May-December 2024, 37 males and 36 females (N=73) with a mean age of 27.5 years, reported potential HIV exposure in the previous 72 hours, of which 4 (6%) acquired HIV. 81% were single with a partner and 12% knew their partners were HIV sero-positive.

Over half (56%) chose not to use condom protection, resulting in potential HIV exposure. Most of the participants (93%) were interested in taking PEP and 88% expressed interest in starting PrEP automatically after completing PEP. 93% of participants received PEP, with two thirds of these participants receiving PrEP after completing PEP. Reasons for declining PrEP included wanting PEP only and deferring the PrEP choice, and wanting more time to deliberate the decision to initiate PrEP.

Conclusions: Injectable CAB-LA PrEP is an attractive and effective prevention modality. Our data shows that offering PEP is feasible to mitigate the risk of initiating CAB-LA when a user may be seronegative but concurrently in the window period of asymptomatic acute HIV acquisition.

Further awareness and research are needed to further determine how to facilitate the uptake of PrEP after the PEP period.

THPEC062

HIV treatment outcomes following HIV acquisition on oral PrEP in Western Kenya

J. Ayieko[1], G. Orori[1], E. Wafula[2], B. Chodha[1], E. Bosek[3], B.H. Chohan[4], L. Georgetti Gomez[5], A.L. Heaps[6], L.D. Kudrick[6], A. Conroy[5], C.A. Koss[5], U.M. Parikh[6], ACTION Study Team
[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]University of California San Francisco Global Programs for Research and Training, Nairobi, Kenya, [3]University of Washington-Kenya, Nairobi, Kenya, [4]University of Washington, Seattle, United States, [5]University of California San Francisco, San Francisco, United States, [6]University of Pittsburgh, Pittsburgh, United States

Background: Kenya's oral PrEP program has been highly effective with few HIV diagnoses reported among PrEP clients since national scale-up was launched in 2017. However, up to 20% of individuals who acquire HIV on PrEP could have mutations that are associated with resistance to TDF or XTC, which could impact viral suppression on first-line ART with TDF/3TC/DTG.

Data are limited on ART outcomes following HIV acquisition on PrEP. We evaluated viral suppression on ART for 6 months following HIV acquisition among persons receiving PrEP.

Methods: ACTION (#R01AI16775) evaluates HIV treatment outcomes among individuals ≥16 years of age in western Kenya who are newly diagnosed with HIV following PrEP use in the previous 3 months.

Plasma samples collected at enrollment and 6-months post-ART initiation were tested for HIV RNA and genotyped (Sanger sequencing). Barriers to PrEP and ART adherence were collected by questionnaire.

Results: Ten individuals diagnosed with HIV while on oral PrEP (TDF/XTC) were enrolled in ACTION between 05/2023-07/2024. Participants were 21-37 years of age and 80% female. The median duration on PrEP was 275 days (range 5-1667 days) prior to HIV diagnosis. At diagnosis, median HIV RNA was 99,200 c/mL (IQR 16,200-218,000). The XTC-associated M184V mutation in HIV reverse transcriptase was detected in 2 of 8 participants with a successful genotype; none had TDF-associated mutations.

Ten individuals initiated first-line ART with TDF/3TC/DTG with a median duration to ART start of 2.5 days post-diagnosis. 9 of 10 participants, including 2 of 2 with M184V, achieved viral suppression (<200 c/ml) by 6-months follow-up.

The individual with viral non-suppression at 6 months self-reported limited to no ART adherence; barriers to accessing ART included moderate food insecurity and intimate partner violence.

Conclusions: Among individuals who acquired HIV after TDF/XTC PrEP use, most achieved viral suppression on DTG-based first-line ART, including participants with XTC-associated viral resistance. Efforts to support barriers to adherence for both PrEP and ART are needed to avert HIV acquisition and maintain viral suppression.

As long-acting PrEP modalities with potential cross-resistance to ART are rolled out, further studies are needed to monitor the effect of PrEP-selected ARV resistance on virologic outcomes on ART.

Integration of HIV services with other services, including sexual and reproductive health services

THPEC063

Postpartum family planning choices and decision-making among women living with HIV in Kigali, Rwanda

R. Ingabire[1], C. Umuhoza[1], R. Parker[2], M. Green[2], J. Nyombayire[1], A. Mazzei[2], T. Sharkey[2], A. Tichacek[2], A. Nizam[2], J. Sales[2], L. Haddad[3], P. Corso[4], S. Allen[2], E. Karita[1], K. Wall[2]

[1]Center for Family Health Research (CFHR), Kigali, Rwanda, [2]Emory University, Atlanta, United States, [3]Population Council, New York, United States, [4]Indiana University, Indianapolis, United States

Background: Postpartum family planning (PPFP) prevents unintended pregnancy and improves maternal, newborn, and family health. How to meet PPFP needs of women living with HIV (WLWH) is understudied. This study describes PPFP choices and decision-making among Rwandan WLWH.

Methods: The Center for Family Health Research implemented PPFP services in 14 Kigali public health facilities (2022-2024). PPFP informed-choice educational counseling was provided to women and partners beginning in antenatal care, and methods were provided in labor and delivery/postpartum and infant vaccination wards. Mixed-method follow-up surveys administered 9-months after PPFP uptake assessed decision-making.

Results: Among 38,226 pregnant women given PPFP educational counseling, 22,126 (58%) chose a PPFP method, of whom 324 (1.4%) were WLWH. WLWH vs HIV-negative women were more likely to choose sterilization (7% vs 3%) and the copper intrauterine device (38% vs 24%) independent of age and parity (adjusted risk odds ratio=2.0; 95% confidence interval=1.6-2.5). WLWH did not report greater PPFP-related adverse events than HIV-negative women (<1% in both groups).

Follow-up surveys among 50 WLWH and 64 HIV-negative women found WLWH were more likely ($p<0.05$) to be unmarried (30% vs 9%) and want no more children (72% vs 34%). PPFP decision-making in WLWH was more likely driven by desire for non-hormonal (20% vs 2%), highly effective (34% vs 28%), and long-term (26% vs 13%) methods. WLWH were also more likely to have continued their PPFP method at 9 months (86% vs 72%) and make independent PPFP-decisions (98% vs 31%). Among those married/cohabiting, WLWH were less likely to discuss PPFP with partners (60% vs 91%).

WLWH were also more likely to recommend peer (38% vs 17%) or home-based (58% vs 27%) PPFP educational counselling and discussed desire for HIV-tailored counselling, for example discussions of antiretroviral treatment-contraception interactions.

Conclusions: WLWH were more likely to choose highly effective, non-hormonal methods and make PPFP decisions independently, without outside influence. PPFP educational messaging should be tailored to provide information relevant to WLWH and may effectively be provided one-on-one and in non-traditional settings, in addition to clinical settings. These novel findings inform refinement of services for WLWH to increase the impact and inclusivity of PPFP programs in Rwanda.

THPEC064

Prevalence and incidence of chlamydia and gonorrhoea infections in adolescent females using long acting injectable cabotegravir as HIV pre-exposure prophylaxis in South Africa, Zimbabwe and Uganda: results from HPTN 084-01

E.H. Roos[1], D. Sharma[2], T. Peega[3], N.M. Mgodi[4], M. Bhondai-Mhuri[4], B.G. Mirembe[5], B. Kamira[5], Y. Agyei[6], B. Hanscom[2], E. Hamilton[7], L. Stranix-Chibanda[4], S. Hosek[8], S. Delany-Moretlwe[1]

[1]Wits RHI, Research, Johannesburg, South Africa, [2]Fred Hutchinson Cancer Research Centre, Seattle, United States, [3]Wits RHI, Johannesburg, South Africa, [4]University of Zimbabwe, Harare, Zimbabwe, [5]MUJHU Research Collaboration, Kampala, Uganda, [6]Johns Hopkins University, Baltimore, United States, [7]HIV Prevention Trials Network, Durham, United States, [8]Stroger Hospital of Cook County, Chicago, United States

Background: Despite the high prevalence of curable STIs in eastern and southern Africa, there are few data on prevalence, incidence and risk factors in younger ado-

lescent females. We assessed the prevalence, incidence and risk factors associated with C.trachomatis (CT) and N. Gonorrhoeae (GC) infections in female adolescents using long-acting injectable cabotegravir (LA CAB) as HIV pre-exposure prophylaxis.

Methods: HPTN 084-01 was a prospective, open label clinical safety and bridging trial of LA CAB that enrolled HIV-negative sexually active, healthy female adolescents under age 18 from South Africa, Zimbabwe and Uganda between 2020 and 2021. Urine or vaginal swabs collected at screening, week 17 and week 33 visits were tested using GeneXpert. Socio-behavioural characteristics at baseline were summarised, STI prevalence and incidence calculated, and univariate associations between characteristics and CT/GC incidence assessed.

Results: Sixty-nine participants were screened and 55 enrolled. At enrolment, 27% (15/55) were aged 12 to 15 years, 69% (38/55) had a regular partner but did not live with him, 57% (26/45) reported condomless sex, and 22% (12/55) reported transactional sex in the past month. At baseline, 33% (18/55) had CT/GC; 31% (17/55) with CT and 7% (4/55) with GC (3 had both CT and GC). Over 53.9 person-years (py) of follow-up, 10 participants had 12 diagnoses of CT (incidence rate [IR] 23 per 100 py, 95% CI 11.6-39.3) and 5 participants had 6 episodes of GC (IR 11.3 per 100 py, 95% CI 4.1-24.5).

Overall CT/GC incidence was 33.4 per 100 py (95% CI 19.8-52.7). No significant associations between socio-behavioural characteristics and CT/GC incidence were observed.

Conclusions: CT/GC prevalence and incidence was high in this population of young women, emphasising the need for STI testing and treatment to be integrated into PrEP programs in eastern and southern Africa to prevent future negative health outcomes.

Population-specific interventions for HIV prevention

THPEC065

Peer-led PrEP/PEP strategy increases biomedical HIV prevention coverage among women who engage in sex work in Southwestern Uganda: the Peers for PrEP (P4P) Pilot Study

J. Kabami[1], C. Akatukwasa[1], L. Balzer[2], R. Aruho[1], M. Ayebare[1], S. Kabageni[1], H. Atuhaire[1], S. Ankwantiriire[1], B. Beinmatsiko[1], A. Asiimwe[1], L. Georgetti Gomez[3], J. Rooney[4], M. Kamya[1,5], C. Koss[3], P4P Study Team
[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California, Berkeley, Berkeley, United States, [3]University of California, San Francisco, San Francisco, United States, [4]Gilead Sciences, Foster City, United States, [5]Makerere University, Kampala, Uganda

Background: In Uganda, HIV prevalence is 31% among women who engage in sex work (WESW); yet PrEP use is limited due to stigma and lack of flexible services at health facilities. Peer-mentors, who are leaders in the WESW community, could be a trusted source of PrEP/PEP access, but approaches to engage peers in biomedical prevention delivery have been limited.

We developed and evaluated the preliminary effectiveness of a peer-led PrEP/PEP strategy for WESW in southwestern Uganda.

Methods: Peers for PrEP (P4P; NCT06353295) is a single-arm pilot trial testing a peer-led PrEP/PEP delivery strategy for cisgender WESW recruited from bars/venues in two communities in southwestern Uganda. We developed the P4P intervention through stakeholder engagement meetings and focus groups with WESW and peers.

The intervention, delivered by trained peer-mentors at bars/venues/community settings with remote clinician support, included oral PrEP (TDF/XTC) refills, HIV self-testing (HIVST), and rapid PEP access from peer-mentors, and phone hotline for peer support.

We compared time covered by PrEP/PEP (self-reported at baseline/endline) over 6 months before and after intervention implementation.

Results: Among 140 participants, median age was 23 years (range 15-42; IQR 20-27); 69 (49%) reported alcohol use 4+ times/week; 57 (41%) reported spending 1+ night away from community in last 3 months.

Over 6 months, 137 (98%) received HIV prevention services from a peer-mentor: 126 (90%) completed HIVST; 122 (87%) received a PrEP refill; 3 (2%) received PEP. 117 (84%) participants had outcomes ascertained at endline.

Time covered by PrEP/PEP was 72.7% during the 6-month study compared to 12.5% over 6 months before the study, a difference of 60.2% (95%CI: 54.3-66.1%; p<0.0001). There were no incident HIV diagnoses. 98% of participants reported feeling comfortable with the peer-mentor; 93% preferred to access PrEP/PEP through a peer-mentor in the future.

Conclusions: In this single-arm pilot trial, the P4P intervention increased HIV prevention coverage by 5-fold compared to the 6 months before study implementation. Most women received services from a peer-mentor and reported interest in continuing peer services.

This peer-led intervention is a promising approach for further testing in a larger trial, with additional long-acting prevention choices to address remaining gaps in prevention coverage.

THPEC066

Innovative community-driven strategies for sustaining PrEP continuation: lessons from the PEPFAR community HIV prevention in Liberia

L.W. Nagbe[1], J. Toomey Garbo[1], S.M. Kpadeh[1], L.T. Gbe- Fully[1], A. Christensen[2], E.C. Ernest[3]
[1]Jhpiego Liberia, Monrovia, Liberia, [2]Jhpiego Regional, Dar es Salaam, Tanzania, the United Republic of, [3]Jhpiego Reginoal, Dar es Salaam, Tanzania, the United Republic of

Background: Pre-exposure prophylaxis (PrEP) is an essential HIV prevention strategy introduced in Africa in 2017, that significantly reduces the risk of HIV infection among high-risk populations. PrEP discontinuation after one-month is generally high; pooled data showed continu-

ation rate highest among women (73.8%), followed by men who have sex with men (72.8%), female sex workers (46.6%) and the general population (46.5%).

In Liberia, PrEP was introduced in 2022, targeting Key Populations (KPs). Liberia leveraged best practices from established PrEP programs to improve PrEP continuation amongst KPs to heighten HIV prevention effectiveness. The Liberia program addressed known continuation challenges including stigma, systemic barriers, and diverse population needs during the design and start-up phase.

Description: Liberia's community HIV prevention program, funded through PEPFAR, supported through HRSA, and administered by Jhpiego, introduced PrEP through a multifaceted, community-based and integrated client centered strategy in two counties. Between June and September 2023, Jhpiego employed human-centered design and leveraged peer educators to deliver tailored community PrEP services.

Client centered approaches included using KP led CSOs, moonlight testing, community outreach programs, and influential peer leaders like "Mammy Queens" and "Five Stars" for PrEP advocacy.

Lessons learned: Following the implementation of these strategies, focused on addressing continuation barriers, of 2,536 individuals enrolled on PrEP, 2,186 were retained at the end of September 2024-a continuation rate of 86%. Using KP specific peer-educators and champions that used tailored messages that were culturally acceptable; conducting weekly mobile phone follow-up, built trust, reduced stigma, and reinforced adherence. This represented a substantial increase in PrEP availability in Liberia, which established very low targets in previous years. Mobilizing influencers enhanced advocacy and trust in the healthcare system.

By addressing known barriers to PrEP continuation at introduction and developing a culturally relevant, community-driven PrEP program, continuation rate was high even during start-up, therefore reducing HIV transmission among KPs in Liberia.

Conclusions/Next steps: Harnessing best practices from established PrEP programs during Liberia's PrEP introduction led to high retention. Future HIV prevention initiatives should continue to learn and leverage known best practices during program design to ensure no missed HIV prevention opportunities, and increase PrEP access among KPs, particularly in resource-constrained settings.

THPEC067

Understanding PrEP uptake and use patterns in the context of a multimethod PrEP market among pregnant and breastfeeding populations in public health settings in Africa

E.P. Gwavava[1], M. Conlon[2], L. Wamala[3], M. Kiruki[4], S. Atieno[4], M. Sebiloane[5], R. Adams[5], M. Chabela[6], O. Mugurungi[7], L. Noguchi[8], P. Jeckonia[4], CATALYST Study Group

[1]Pangaea Zimbabwe, Harare, Zimbabwe, [2]FHI360, Washington DC, United States, [3]FHI360, Kampala, Uganda, [4]LVCT Health, Nairobi, Kenya, [5]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [6]Jhpiego, Maseru, Lesotho, [7]Ministry of Health & Child Care, Harare, Zimbabwe, [8]Jhpiego, Washington DC, United States

Background: HIV acquisition is higher in women during pregnancy and postpartum. Data supports safe use of oral PrEP and PrEP ring during pregnancy and breastfeeding. CATALYST, a study implemented by the PEPFAR/USAID-supported MOSAIC project, assesses selection of oral PrEP and PrEP ring among women, including pregnant and breastfeeding populations (PBFP), in five African countries. However, country policies vary on allowable PrEP ring use. Kenya and Lesotho permit ring use by PBFP, while Zimbabwe allows it during breastfeeding only. We describe uptake and use patterns among PBFP enrolled in CATALYST.

Methods: We used descriptive statistics to describe uptake, month one return, and reasons for method selection among PBFP participants between May 2023 and April 2024 and compare results with non-PBFP participants. We used logistic regression to assess the relationship of pregnancy and breastfeeding status on method uptake.

Results: Among 1,591 participants in Kenya and Lesotho, 161 (10%) were pregnant at enrollment, and 149 (93%) chose a PrEP method. Fourteen percent of pregnant participants chose PrEP ring versus 33% of non-pregnant participants (AOR=0.339, 95% CI [0.213, 0.540], p=<0.001).

Among those choosing oral PrEP, refill rates at month 1 (≤60 days) were higher for pregnant participants (45%) versus non-pregnant (25%) and comparable for PrEP ring (50% and 62%, respectively).

Among those becoming pregnant during PrEP ring use (n=23), 20 (87%) switched to oral PrEP, while three (13%) stopped PrEP. Of 2,497 participants in Kenya, Lesotho, and Zimbabwe, 355 (14%) were breastfeeding. Ninety-five percent (n=338) chose a PrEP method, 19% choosing PrEP ring versus 32% of non-breastfeeding women (AOR = 0.512, 95% CI [0.402, 0.704], p<0.001).

Refill rates at month 1 were comparable between breastfeeding and non-breastfeeding participants for oral PrEP (36% versus 31%, respectively) and PrEP ring (65% versus 62%, respectively). The most common reason for method selection among PBFP and non-PBFP was ease of use.

Conclusions: We observed high PrEP uptake among PBFP. While PBFP less frequently chose PrEP ring than non-PBFP participants, some PBFP preferred it in countries where it was permitted. Policy restrictions on PBFP PrEP ring use limit access to a multi-method PrEP market for this population vulnerable to HIV acquisition.

THPEC068

Lessons from the Harm reduction strategy for increased HIV case detection and treatment among People Who Inject Drugs under the National AIDS Control Programme in India

G. Ngaihte[1], S. Rajan[1], S.P. Bhavsar[1], S. Purohit[1], S. Verma[1]
[1]National AIDS Control Organization, Ministry of Health and Family Welfare, New Delhi, India

Background: National AIDS Control Programme (NACP) has achieved significant HIV detection among people who inject drugs (PWIDs) through harm reduction interventions provided through 398 Targeted intervention (TI) NGOs and 286 Opioid Substitution Therapy (OST) centres.
Harm reduction strategy combines health screening for HIV, HBV.HCV, TB etc. with prioritization of harms, risk reduction and prevention and treatment services.
Description: People who inject drugs have the highest HIV prevalence at 9.03 % among the high risk populations and are the main contributors to new HIV detections for 11 out of states 36 federal states/union territories in 2023-24 in India. Harm reduction services have been scaled up to reach uncovered PWIDs with screening, prevention and treatment services. In 2024-25, HIV case detection has reached 30197 at the TI NGOs and 16722 at the OST centres, of which 78 % and 93 % are linked to ART respectively.

HIV Case Detection by TI NGOs under NACP			HIV Case detection by OST under NACP		
Coverage of PWID	Total PLHIV	Total PLHIV linked to ART	Coverage of PWID	Total PLHIV	Total PLHIV linked to ART
272641	30197	23511	58648	16722	15510

This extensive HIV case detection has been achieved through a combination of outreach or mobile based screening services in the hotspots, static DIC/Clinic services, and linkage and referrals.
Lessons learned: Outreach services using peer to peer networks and community intelligence greatly amplifies the reach to uncovered PWIDs with testing and treatment services.
Targeted community based screening and mobile testing services are effective among PWIDs as they allow flexibility in approaches during outreach to suit multiple settings, reach hitherto unreached hotspots and congregation points and deliver screening services to allied service facilities such as rehabilitation centres or correctional homes etc. OST as a treatment for opioid use disorder greatly increases demand for services, helps reduce injection related harms including overdose, HIV, HBV and HCV and improves adherence to ART and chronic Hepatitis treatments. Linkage to ART remains a challenge among the PWID populations.
Conclusions/Next steps: Harm reduction strategy approach is effective for achieving 95-95-95 targets as it combines health screening for HIV, HBV.HCV, TB etc. with risk reduction, prioritization of harms, prevention and treatment for substance use disorders.
Co-located OST-ART facilities and community based ART refill groups can improve achievement of the 95-95-95 targets among PWID PLHIV populations.

HIV testing

THPEC069

Community-led approaches to reach high-profile men who have sex with men with HIV services in the central region of Ghana

J. Mensah[1], W. Kwaku Yeboah[2], S. Elliot Owusu[3]
[1]Ghana AIDS Commission, Technical Support Unit, Cape Coast, Ghana, [2]Ghana AIDS Commission, TSU, Cape Coast, Ghana, [3]Maritime PreciousLife Foundation, Takoradi, Ghana

Background: In Ghana, reaching high-risk men who have sex with men (MSM) with HIV services is hindered by persistent stigma, discrimination, and limited outreach efforts. Among MSM, high-profile individuals—such as lawyers, politicians, and business leaders—represent a particularly hard-to-reach subgroup. These individuals are often more discreet in their sexual behaviors due to their social status, making them less likely to access conventional HIV programs. To effectively engage high-profile MSM, innovative, community-led strategies are needed to overcome these barriers and provide tailored HIV prevention, testing, and treatment services.
Description: A community-led intervention was piloted from March to December 2024 in the Central Region of Ghana to improve HIV service access among high-profile MSM. The intervention used peer-led outreach and differentiated service models. Key components included:

1. Community-based outreach: Trusted peer educators engaged high-profile MSM with tailored messages, creating safe spaces for individuals to seek care without fear of exposure.
2. Utilizing sexual networks: Peer educators leveraged MSM sexual networks to provide HIV testing services (HTS) at participants' homes, offering discreet and convenient access to services. thereby ensuring confidentiality and building trust.
3. Digital engagement: Social media platforms were used to deliver HIV education and virtual consultations, extending reach beyond face-to-face interactions.
4. Leveraging local leaders: MSM leaders helped deliver culturally sensitive messages and facilitated trust within the community, ensuring the protection of people's rights.

Lessons learned: The community-led approach proved more effective in reaching high-profile MSM than conventional outreach models. Program data demonstrated notable increases in HIV service uptake and a reduction in HIV-related stigma. The intervention led to significant improvements in health outcomes, with HIV testing uptake rising from 62% to 87%, condom use increasing from 71% to 93%, and the HIV-positive yield among participants increasing from 7% to 13.6%.
Qualitative feedback from participants highlighted the importance of trust and the reduction of fear regarding discrimination, encouraging sustained engagement with healthcare services.
Conclusions/Next steps: Given the success of this model, expanding community-based testing and engagement strategies for high-profile MSM is recommended for oth-

er districts in Ghana. Scaling peer-facilitated interventions can serve as a model for improving HIV prevention and care outcomes for this key population across the country.

THPEC070

Complementing community interventions with technology to maximize tracking of HIV exposed infants (HEI) final outcome, lessons from a community HIV program in Zimbabwe

V. Mubaiwa[1,2,3], C. Kafesu[4,5,1], L. Mukwekwezeke[6,1], C. Masibhera[2], T. Tapera[7,8,9]
[1]Midlands State University, Gweru, Zimbabwe, [2]University of Zimbabwe, Harare, Zimbabwe, [3]Bindura University of Science Education, Bindura, Zimbabwe, [4]Amref International University, Nairobi, Kenya, [5]Chinhoyi University of Technology, Chinhoyi, Zimbabwe, [6]Catholic University of Zimbabwe, Harare, Zimbabwe, [7]University of Witwatersrand, Johannesburg, South Africa, [8]National University of Science and Technology, Bulawayo, Zimbabwe, [9]University of Essex, London, United Kingdom

Background: In 2023, Zimbabwe Mother to Child Transmission (MTCT) rate stood at 5.7% which is above the WHO target of 5% (Zimbabwe HIV Estimates report, 2024). This is attributable to numerous factors that include paper-based tracking of HEI resulting in missed clinical appointment dates, poor follow-up of PMTCT mothers with high viral load, delayed final PMTCT outcome testing, and high Nucleic Acid Test (NAT) result turnaround time more than 6 to 8 weeks. In bridging the gap, the Zimbabwe USAID/PEPFAR funded Orphans and Vulnerable Children (OVC) is being implemented in 25 HIV burdened districts.
Description: The project utilizes trained mentor mothers through a community case management approach to prevent HEI from seroconversion. The mentors are responsible for bi weekly home visits to support PMTCT adherence, facilitate for EID testing, regular checking developmental mile stones and provide PMTCT sessions. In April 2023, the project adopted the DHIS2 tracker capture application with an embedded Early Infant Diagnosis (EID) module to identify HEIs due for EID testing, and records dates and results for completed tests throughout the PMTCT algorithm up to outcome. The application flags pending results while signaling to project staff and mentors the priority needs for HEIs being case managed, allowing timely follow-up on pending results with the laboratories.
Lessons learned: In 2024, 3,224 HEI enrolled in the project due for the final test were identified through the DHIS2 tracker capture app. 3,127 (97%) were tested for their final PMTCT outcome by September 2024 and 3,219(99.8%) received results within two weeks reducing the turnaround time by 50%. Of those tested, 3,210(99.7%) were negative and 9 (0.3%) were positive, achieving an MTCT rate within the national target of <5%.
Conclusions/Next steps: Digital longitudinal tracking of HEI is comprehensive, timely and reliable. Coupled individual-level case management, these approaches have contributed to high outcome testing among HEI and a low MTC rate. The next phase of the project is scaling the strategy to future cohort due for their PMTCT final outcome test.

THPEC071

Preferences for HIV self-testing modalities among sexually and gender-diversity adolescents in Brazil

J.P. Azevedo Gonzaga Vieira[1], L. Magno[2], B. Oliveira Leite[2], F. Soares[2], D. Zeballos[2], L. Dezanet[3], D. Greco[4], A. Grangeiro[5], I. Dourado[2], PrEP15-19 Choices Study Group
[1]Universidade do Estado da Bahia, Departamento de Ciências da vida, Salvador, Brazil, [2]Universidade Federal da Bahia, Instituto de Saúde Coletiva, Salvador, Brazil, [3]Instituto René Rachou, Fundação Oswaldo Cruz, Belo Horizonte, Brazil, [4]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [5]Universidade de São Paulo, Faculdade de Medicina, São Paulo, Brazil

Background: HIV self-testing (HIVST) has proven instrumental in scaling-up HIV testing, decentralizing services and empowering individuals by strengthening their autonomy. HIV digital blood-based self-test (HIVDST) offers higher accuracy compared to the HIV oral fluid self-test (HIVOST) and is more recommended during the use of a Long-Acting Injectable Cabotegravir (CAB-LA) for HIV Prevention.
This study aimed to evaluate the preferences for HIV testing modalities among sexually and gender-diversity adolescents in Brazil (SGDA) in Brazil.
Methods: This cross-sectional analysis is part of the ongoing PREP15-19 choices implementation study which assesses the use of oral and CAB-LA PrEP among SGDA in three Brazilian cities. The study included a convenience sample of cisgender men who have sex with men (MSM), transgender individuals, and non-binary individuals aged 15–19 who underwent (HIVOST). Participants were required to perform a HIVDST before completing an acceptability questionnaire, in which they ranked their preferences among three HIV testing modalities: rapid testing conducted by a healthcare professional (RT), HIVOST, and HIVDST. Descriptive statistics of responses were estimated.
Results: A total of 171 individuals participated in the study. The majority were MSM (70.8%), aged 18-19 (50.3%), Black or Brown (78.4%), and high school students (66.7%). More than half (56.1%) of participants had undergone HIV testing before enrolling in the main. study. Additionally,33.6% reported being aware of the HIVDST, while 9.9% had previously used it, and 69.9% described the experience of performing this modality as easy or very easy. Regarding testing preferences, most preferred the RT (39.2%), followed by HIVDST (35.1%) and HIVOST (25.7%).
Notably, 93,6% stated they would use the HIVDST again, with the primary reason being greater confidence in blood-based results (51.5%). The fear of needles was the most commonly cited barrier (81.8%) for not wanting to repeat the use of this testing modality.
Conclusions: This study underscores that RT remains the most preferred HIV testing method among SGDA. However, a significant proportion of participants found the

HIVDST easy to use and expressed willingness to use it again citing greater confidence in its accuracy. Expanding awareness about HIVDST is essential to promote test uptake and ensure equitable access to HIV testing options.

THPEC072

Motivations for linkage to HIV services after HIV self-testing among fishermen in Kenya: a qualitative study

H. Nishimura[1], K. Agot[2], S. Gutin[3,1], P. Olugo[2], Z. Kwena[4], M. Thorpe[5], B. Ayieko[2], H. Thirumurthy[6], C. Camlin[7]
[1]University of California San Francsico, Division of Prevention Science, San Francisco, United States, [2]Impact Research and Development Organisation, Kisumu, Kenya, [3]University of California San Francsico School of Nursing, Department of Community Health Systems, San Francisco, United States, [4]Kenya Medical Research Institute, Nairobi, Kenya, [5]University of California Los Angeles, Los Angeles, United States, [6]University of Pennsylvania, Center for Health Incentives and Behavioral Economics, Philadelphia, United States, [7]University of California San Francsico, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States

Background: HIV self-testing (HIVST) is a promising strategy to increase access to testing, particularly for hard-to-reach populations like Kenyan fisherman who face barriers to clinic-based testing. This qualitative study examines motivations and barriers to HIVST and linkage to services among fishermen participating in the Owete Study, a social network-based intervention (NCT04772469).
Methods: Sixty-five in-depth interviews (IDIs) at 3-months follow-up were conducted with fishermen in Siaya County, Kenya, including 30 socially-connected men recruited as "promoters" to distribute HIVST and transport vouchers to clinics. Fishermen were purposively sampled based on age (< & ≥35 years), study arm, and community for IDIs exploring motivations for and barriers to using HIVST and linkage to services. IDIs were audio-recorded, translated/transcribed into English, then inductively coded and analyzed by 6 researchers using a framework approach.
Results: Convenience and privacy were key motivators for men's use of HIVST; fishermen valued an option that helped them avoid HIV stigma and unwanted status disclosure. Those who perceived themselves as high HIV risk due to behaviors like unprotected sex and multiple sexual partners were especially motivated to use HIVST. However, some men preferred clinic-based testing, for counseling and perceived testing accuracy.
Promoters' training highlighted the importance of knowing one's HIV status; this motivated promoters to learn their own status before encouraging others to test. Linkage to confirmatory testing was facilitated by perceived HIV risk, interest in accessing PrEP, and spousal encouragement. Study-provided transport vouchers (in the intervention arm) facilitated linkage to clinics by offsetting the costs of travel to the clinic and lost work time. Barriers to linkage included long distances to clinics, competing work priorities, and the perception that confirmatory testing was unnecessary if self-test results were negative. Gender norms which discouraged healthcare seeking and prioritized work over clinic visits unless men perceived immediate health benefits hindered linkage to HIV services.
Conclusions: HIVST is a valuable tool for increasing testing among highly mobile, at-risk populations such as fishermen, and its dissemination is enhanced through use of a social network-based approach. Interventions such as community-based services and extended testing hours may further improve timely linkage to HIV services following HIVST.

Cascades of HIV prevention, treatment and care

THPEC089

Characterizing individuals with unsuppressed viral load: a comprehensive analysis of viral load among people living with HIV enrolled in ART program in Rwanda, 2019-2024

G. N.Rwibasira[1], S. Karera[2], G. Gatete[1], B. Ikuzo[1], A. Tuyishime[1]
[1]Rwanda Biomedical Centre, National HIV program, Kigali, Rwanda, [2]ICAP at Columbia University, Mailman School of Public Health, Kigali, Rwanda

Background: Achieving viral suppression is critical for individuals enrolled in antiretroviral therapy (ART) programs to prevent disease progression and transmission of HIV. In Rwanda, despite high ART coverage, a subset of individuals remains with unsuppressed viral loads (VL). This study aims to characterize the demographic, clinical, and behavioral factors associated with unsuppressed viral load (VL) among the Rwandan population enrolled in the ART program.
Methods: This cross-sectional study analyzed data from the national database, encompassing children and adults enrolled in the ART program between January 2019 and December 2024. Unsuppressed VL was defined as ≥1000 copies/mL in the latest measurement. Advanced statistical methods were applied, including multivariable logistic regression to identify factors associated with unsuppressed VL and cluster analysis to profile high-risk subgroups. Propensity score matching was used to adjust for confounders, while multilevel modeling accounted for variations across healthcare facilities and regions
Results: The analysis inlcuded 55,557 ART-enrolled individuals , 4.21% had unsuppressed VL. Key predictors of unsuppressed VL included younger age (adjusted odds ratio [aOR]: 2.75, 95% CI: 2.55-2.96 for ages 0-24), male gender (aOR:1.19, 95% CI: 1.11-1.27), and inconsistent ART adherence (aOR: 3.40, 95% CI: 3.05-3.77). Cluster analysis identified two high-risk subgroups: younger individuals with irregular clinic attendance and older individuals with comorbidities. Multilevel modeling revealed facility-level factor, such as inadequate staffing significantly influenced viral suppression rates.

Conclusions: Unsuppressed VL in Rwanda's ART program is associated with demographic, behavioral, and systemic factors. Interventions targeting younger populations, enhancing adherence support, and addressing facility-level barriers are critical to achieving universal viral suppression.

Advanced statistical approaches revealed nuanced insights that can guide data-driven policies to optimize ART outcomes in Rwanda. Further research is needed to evaluate the impact of tailored interventions on reducing unsuppressed VL.

THPEC090

Current and prior PrEP use and associated factors among sexual and gender minorities (SGM) from Brazil, Mexico and Peru

K. Konda[1,2], T.S. Torres[3], H. Vega-Ramirez[4], J. Qquellón[2], C.F. Cáceres[2], P. Luz[3], B. Hoagland[3], C. Pimenta[3], R. Robles-Garcia[4], M. Benedetti[3], V. Veloso[3], B. Grinsztejn[3]

[1]Keck School of Medicine, University of Southern California, Department of Population and Public Health Sciences,, Los Angeles, United States, [2]Universidad Peruana Cayetano Heredia, Center for Interdisciplinary Research in Sexuality, AIDS and Society, Lima, Peru, [3]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz), Rio de Janeiro, Brazil, [4]Instituto Nacional de Psiquiatría Ramon de la Fuente Muñiz, Mexico City, Mexico

Background: Oral HIV PrEP is being scaled-up in Latin America, but uptake remains low. Herein we assessed the frequency of and factors associated with PrEP use among SGM in Brazil, Mexico and Peru.

Methods: We conducted an online survey from August-November 2024 among SGM aged 18+ years, excluding people living with HIV (PLHIV) to ask about current and prior PrEP use.

Herein we include age, country of residence, education, income, race/ethnicity, depression (PHQ-9), homonegativity, self-perceived HIV risk, HIV knowledge, number of sex partners, chemsex, and sex with PLHIV/unknown HIV-status partners in two multivariate logistic regression models exploring associations with

1. Current PrEP use (versus never) and
2. Prior PrEP use (versus current).

Regression models included socio-demographics *a priori*, removing other non-significant variables.

Results: Among 9257 non-PLHIV (Brazil: 65.5%; Mexico: 24.6%; Peru: 9.9%), 2380 (25.9%) were current and 649 (7.1%) were prior PrEP users. Current use varied significantly by country (Brazil: 32.1%; México: 19.0%; Perú: 21.7%).

Model 1: current PrEP use was associated with Brazilian residence, post-secondary education, higher income, lower homonegativity, lower self-perceived HIV-risk, higher HIV-knowledge, more sex partners, sex with PLHIV/unknown HIV-status, and recent chemsex.

Model 2: prior PrEP use was associated with: ≤secondary education, higher self-perceived HIV-risk, fewer sex partners, and fewer sex partners with PLHIV/unknown HIV-status (all aORs and 95%CIs in Table).

Characteristics	Model 1: Current PrEP use (Comparator = Never users) aOR [95% CI]*	Model 2: Prior PrEP use (Comparator = Current users) aOR [95% CI]*
Country (Ref: Brazil)		
Mexico	0.38 [0.31-0.45]	0.98 [0.72-1.34]
Peru	0.75 [0.59-0.96]	1.30 [0.90-1.88]
Post-secondary education (Ref: ≤secondary education)	1.45 [1.19-1.76]	0.53 [0.40-0.70]
Monthly income (Ref: <1 minimum wage)		
>1 to 2 minimum wage	1.02 [0.82-1.29]	0.87 [0.62-1.23]
>2-6 minimum wage	1.21 [0.99-1.48]	0.82 [0.61-1.11]
>6 minimum wage	1.39 [1.11-1.74]	0.77 [0.55-1.10]
Homonegativity	0.97 [0.96-0.97]	--
Perceived HIV risk	0.90 [0.89-0.91]	1.12 [1.10-1.15]
HIV knowledge	1.27 [1.21-1.35]	--
Chemsex	1.56 [1.37-1.78]	--
Number of sex partners (Ref: 0 or 1)		
2-5	3.75 [2.91-4.81]	0.31 [0.22-0.43]
6+	10.52 [8.16-13.55]	0.15 [0.10-0.21]
Sex with PLHIV (Ref: no)		
With 1	3.32 [2.73-4.03]	0.59 [0.45-0.79]
With 2-6	4.80 [3.45-6.67]	0.32 [0.17-0.58]
I don't know	2.62 [2.27-3.03]	0.64 [0.50-0.83]

PLHIV: People living with HIV. *Multivariate odds ratios were also adjusted for age and race. Bold text indicates a p-value<0.05.

Table: Socio-demographic and behavioral factors associated with PrEP use among SGM currently using PrEP and Prior PrEP users in Brazil, Mexico and Peru, 2024.

Conclusions: Current PrEP use was highest in Brazil where oral PrEP has been publicly available since 2018. The association of PrEP use with higher education and income, despite free availability, points to the need for increased public health communication and intervention. Behavior associations with current PrEP use point to PrEP knowledge and understanding of HIV-risk, such as a reduction in self-perceived risk and sex with PLHIV/unknown HIV-status. Differentiated PrEP services, such as mobile units and long-acting modalities, should be implemented in Latin America to increase PrEP persistence, especially among SGM with socio-economic vulnerabilities.

Social and behavioural aspects and approaches to HIV prevention and living with HIV

THPED073

Persistently low PrEP use and high unmet HIV prevention needs for PWID in the San Francisco Bay Area

E. Wilson[1], B. Suprasert[1], R. Ruiz[1], M. Tate[1], J. Francisco[1], I.R. O'Neal[1], P. Lella[1], G. Baguso[1], E. Dunne[2], G.-M. Santos[3], W. McFarland[1]
[1]San Francisco Department of Public Health, San Francisco, United States, [2]Alameda County Public Health Department, San Leandro, United States, [3]University of California, San Francisco, San Francisco, United States

Background: Among MSM in San Francisco PrEP uptake increased 56% from 2014 to 2023 and HIV diagnoses in the population dropped by half. Conversely, PrEP uptake among people who inject drugs (PWID) decreased between 2018 to 2022 from 3% to 1.5% and new HIV diagnoses remained stable.
We launched a community-recruited cohort study of PWID in San Francisco and Oakland to gauge barriers and facilitators of PrEP uptake; here we present preliminary findings from the baseline data.
Methods: PWID in San Francisco and Oakland, California were recruited using Starfish Sampling, a novel approach that combines venue- and peer referral-based recruitment. Participants completed an interviewer-administered survey followed by a rapid HIV test. Quarterly follow-up is underway using a combination of phone calls, community outreach, and drop-in hours. Participants are given $50 for enrollment and $20 for each quarterly follow-up. Data are presented on socio-demographics, drug use, and HIV risk and preventive behaviors among 491 PWID recruited from April-December 2024 who were not living with HIV at enrollment.
Results: Most PWID not living with HIV were age 30-59 years (84%), male (67%), and persons of color (58%), with 34% identifying as Black/African American. Many currently experienced homelessness (69%) and 15% had been incarcerated in the past 3 months. Over half (54%) injected daily, with methamphetamine being the most common substance used (71%), followed by heroin (50%), and fentanyl (46%). Many reported injecting with used needles (10%), exchanging sex for drugs or money (16%), and having condomless sex (81%) in the past 3 months. Majorities saw a healthcare provider in the past 3 months (62%), had tested for HIV in the past 12 months (62%), and were aware of PrEP (61%). Less than 2%of PWID had used PrEP.
Conclusions: Our data found that no progress has been made to improve PrEP uptake among PWID in the San Francisco Bay Area with negligible use for several years. Free and widely available PrEP in healthcare settings is not sufficient. HIV prevention strategies are needed that address income, housing, and substance use at a minimum, and novel delivery models in and outside clinics are urgently needed for PWID.

THPED074

Utilizing community health promoters to enhance HIV treatment adherence in Kisumu County, Kenya

J. K'Odero[1], J. Okoko[1]
[1]Health Innovations Kenya, Social Sciences, Kisumu, Kenya

Background: Kisumu County faces a critical challenge in achieving consistent HIV treatment adherence, with an adult HIV prevalence of 16.3%, significantly higher than Kenya's national average of 4.9% (Kenya HIV Estimates, 2021). Non-adherence to antiretroviral therapy (ART), reported at 30-50% in some resource-limited settings (UNAIDS, 2023), contributes to virologic failure, compromised immune health, and drug resistance. Community Health Promoters (CHPs)—local individuals trained in health education and psychosocial support—offer an effective strategy for overcoming socio-cultural barriers and improving ART adherence.
Methods: This study evaluated a CHP-led intervention targeting 500 HIV-positive individuals (aged 18–65) at risk of non-adherence (missing >20% of doses in the prior month) across seven urban and rural health facilities (Ministry of Health HIV Data, 2022). CHPs received training in adherence counseling, stigma reduction, treatment literacy, and referral pathways.
The intervention incorporated:
1. Household Visits: Weekly sessions for personalized counseling and support.
2. Treatment Reminders: SMS alerts to strengthen adherence.
3. Support Groups: Peer-led forums addressing stigma and psychosocial needs.
4. Data Reporting: Real-time challenges reported to healthcare providers.

Adherence outcomes were measured using self-reports, pharmacy refill records, and viral suppression rates (viral load <200 copies/mL). Qualitative data were gathered through focus groups and interviews with participants and stakeholders.
Results: The intervention led to substantial improvements: ART adherence increased from 65% to 88% ($p < 0.05$), while viral suppression rose from 57% to 85% ($p < 0.01$), aligning with findings in similar settings (Amollo et al., 2021). Qualitative results highlighted improved treatment literacy, reduced stigma, and enhanced trust in healthcare systems. Participants attributed these changes to consistent CHP visits and community mobilization efforts. However, logistical challenges in rural areas and the need for sustainable incentives for CHPs were noted.
Conclusions: CHPs demonstrate a transformative role in addressing barriers to ART adherence. This intervention supports WHO 95-95-95 goals by enhancing treatment literacy and viral suppression rates. Sustaining and scaling such programs requires policy-level investment and integration into existing healthcare systems. Further studies should explore long-term impacts and replication potential in other high-burden regions.

THPED075

Understanding preferences and transitioning between oral and injectable PrEP: insights from ImPrEP CAB Brasil Study

C. Pimenta[1], C. G. Mann[1], E. Carvalheira[1], C. Coutinho[1], C. Jalil[1], A. Farias[2], J. V. Madruga[3], J. N de Lima[4], M.P. G. Mourão[5], R. Zonta[6], M. Benedetti[1], R. Ismerio[1], B. Hoagland, V. G. Veloso[1], T. S. Torres[1], B. Grinsztejn[1], ImPrEP Cab Brasil Study Group

[1]Fiocruz - Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas (INI-Fiocruz), Rio de Janeiro, Brazil, [2]Centro Especializado em Diagnóstico, Assistência e Pesquisa -CEDAP, Salvador, Brazil, [3]Centro de Referência e Treinamento em DST/Aids - CRT, São Paulo, Brazil, [4]Centro de Referência em DST/Aids, Campinas, Brazil, [5]Fundação de Medicina Tropical Heitor Vieira Dourado, Manaus, Brazil, [6]Aconselhamento - CTA/Policlínica Centro, Florianópolis, Brazil

Background: Long-acting injectable PrEP may enhance PrEP coverage and protection, demonstrating potential in overcoming adherence issues associated with daily oral PrEP. We describe preferences and transitions between oral and injectable PrEP during ImPrEP CAB-Brasil study.

Methods: ImPrEP CAB-Brasil is an implementation study of same-day delivery of injectable CAB-LA PrEP for young sexual and gender minorities (SGM; 18-30 years) in PrEP public health clinics in six Brazilian cities. PrEP naïve participants were enrolled from October-2023 to October-2024 and followed for 48-weeks. Participants are allowed to switch PrEP modalities (oral or injectable CAB-LA) once. A subset of participants who switched PrEP were invited to participate in a qualitative study. Semi-structured interviews were conducted, recorded and transcribed. Conventional content analysis was performed to explore motivations and gather insights regarding individuals' choices and transition experiences between PrEP modalities.

Results: Of 1,447 young SGM enrolled, 1,200 (83%) initiated injectable PrEP and 47 (3.2%) switched PrEP regimen: 26 from CAB-LA to oral and 21 from oral to CAB-LA. Twenty interviews were conducted with participants who switched modalities. Initial preference for oral PrEP was influenced by fear of needles and pain leading individuals to avoid injectable PrEP. Prior knowledge and accessibility of information about oral PrEP made it a familiar choice.

Conversely, participants who switched from oral to injectable PrEP reported adherence difficulties due to adverse side effects such as persistent nausea and headaches or frequent forgetfulness missing doses. These participants considered that injectable PrEP provided a more practical and consistent protection.

Despite potential benefits, transitions from injectable to oral PrEP were due to adverse reactions associated with CAB-LA such as persistent pain at the injection site, fever, chills, and other systemic symptoms. The second most common reason for transitioning to oral PrEP was long term travel.

Conclusions: Oral and injectable PrEP are perceived as effective options among young SGM in Brazil. Our findings emphasize the complexity of PrEP choice dynamics and highlight the need for personalized healthcare support for transitioning between PrEP options. Understanding personal experiences and needs is crucial for optimizing PrEP delivery and ensuring successful HIV prevention outcomes and adherence to initial choice.

THPED076

Learnings from community pilot implementation of MaPeers&Me digital application for HIV and drug harm reduction response among female sex workers who use/inject drugs in Abia State, Nigeria

D.C. Vena[1], J.C. Aseme[1]

[1]Greater Women Initiative for Health and Right, Public Health Programs, Port-Harcourt, Nigeria

Background: In the Generation Z era, digital applications remains a powerful tool for transforming health services among young people hence Greater Women Initiative for Health and Right through the sex workers' community introduced the MaPeers&Me App. This innovative application facilitated onsite peer-to-peer navigation, provided digital appointment reminders, tracked medication adherence through drug consistency charts, and ensured anonymous service uptake in addressing long-term in-person HIV stigma.

The program's objectives include optimizing service delivery strategies, promoting a status-neutral approach to healthcare, and establishing a supportive digital community-based services for FSWUIDs.

Description: The MaPeers&Me App, a community-driven digital application, was developed and launched in January 2024 and remained operational through December 2024. Its primary goal was to enhance access to HIV prevention, care, and harm reduction services.

As a community-owned initiative, the app prioritized relevance, usability, and trust by integrating community participation, robust digital infrastructure, and partnerships with healthcare providers for its effectiveness.

Key activities conducted include co-creation socialization, digital peer navigators mentoring, peer-led healthcare connections, socializing harm reduction concepts through the app, creating HIV prevention social hubs, issuing appointment reminders, tracking drug adherence, and promoting U=U (Undetectable = Untransmittable) messaging.

Lessons learned: Key Findings and Outcomes:

- Over 74% of FSWUIDs reported better access to harm reduction and HIV services.
- Visits to One Stop Shop facilities rose by 48% among FSWUIDs, driven by consistent social engagement facilitated through the app.
- 88% of users felt empowered to seek services without fear of judgment, while drug adherence tracking charts improved consistency for 65% of users.

Lessons Learned:

- Actively involving the sex workers' community in the app's design and implementation ensured it was relevant, user-friendly, and trust while anonymous service uptake options effectively addressed fears of stigma/discrimination.

Best Practices:

- Combining digital tools with peer-led support created robust community network that tackled both structural and individual barriers faced by FSWUIDs.

Conclusions/Next steps: In summary, MaPeers&Me App pilot implementation showed the importance of community-driven and technology-enhanced programming in improving HIV and harm reduction services and the need for continued investment in innovative service delivery models for HIV response among FSWUID and key population at large.

THPED077

HIV Viewpoints: survey on the experiences of people living with HIV around the world

X. Guillaume[1], R. Barkins[2], M. Dams[3], N. Eland[4], M. Owino[5], C. Saucedo[6], Y.-C. Lu[7], A. Omri[1], A. Moussallem[1], L. Callaghan[8], M. Bogart[8], C. Kim[8], M. Dunbar[8]
[1]Oracle Life Sciences, Paris, France, [2]To Restore, Unite, Support, and Transform, Los Angeles, United States, [3]Aidshilfe NRW e.V, Cologne, Germany, [4]Emthonjeni Counselling & Training, Cape Town, South Africa, [5]York University, Toronto, Canada, [6]Agenda LGBT A.C., Mexico City, Mexico, [7]We As One Association, -, Taiwan, Province of China, [8]Gilead Sciences, Inc., Foster City, United States

Background: The experiences of people with HIV (PWH) differ significantly throughout the world and it is important to understand these experiences to enhance engagement in care and improve long-term treatment success.
Methods: A 45-minute, cross-sectional, online survey was co-developed by investigators and community advocates from 11 countries (Canada, France, Germany, Italy, Japan, Mexico, South Africa, Spain, Taiwan, United Kingdom, United States) and translated into local languages. The survey evaluated experiences of PWH across the care continuum. Participants ≥18y were recruited through patient databases, patient panels, advocacy groups, and physician referrals.
Results: Among 2307 participants, 96% were currently or had been on antiretroviral therapy (ART); 74% were taking 1 single-tablet oral daily ART. Treatment was initiated >30 days after diagnosis for 37% of participants (23% of those diagnosed <10 years ago and 55% of those diagnosed ≥10 years ago), primarily due to physician recommendation based on CD4 count, fear of potential side effects, and needing time to accept diagnosis.

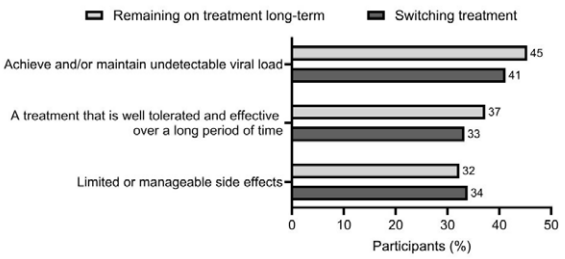

Figure 1. Top 3 treatment features (selected by ≥25% of participants) that would be most important in remaining on HIV treatment long term or switching HIV treatment.

Adherence difficulties were experienced by 14% of participants taking oral ART and 16% taking injectable ART. Features of HIV treatment identified as most important for staying on treatment long-term and for switching are shown in *Figure 1.*
Median HIV Treatment Satisfaction Questionnaire status version score was 51/60 overall and was numerically higher for those on bictegravir/emtricitabine/tenofovir alafenamide and those on treatment ≥10 years *(Table 1).*

Participants, n	HIVTSQ score, median
Overall, n=2128	51.0
Bictegravir/emtricitabine/tenofovir alafenamide, n=585	54.0
All oral regimens excluding bictegravir/emtricitabine/tenofovir alafenamide, n=1387	50.0
All regimens excluding bictegravir/emtricitabine/tenofovir alafenamide, n=1544	50.0
Participants on treatment ≥10 years, n=901	54.0
Participants on treatment <10 years, n=1227	50.0

Table 1. HIVTSQ Scores by Subgroup.

Conclusions: Participants reported high levels of ART satisfaction and identified treatment effectiveness, side effects, and long-term safety as top considerations for remaining on or switching HIV medication. The substantial proportion of participants reporting delayed treatment highlights opportunities to support/improve rapid initiation.

THPED078

Household HIV competence and illness identity in HIV: insights from a cluster randomized control trial baseline study

L. Campbell[1], N. Sematlane[2,1], L. Knight[3,2], C. Masquillier[1,4], E. Wouters[1]
[1]University of Antwerp, Department of Sociology, Antwerpen, Belgium, [2]University of the Western Cape, School of Public Health, Bellville, South Africa, [3]University of Cape Town, School of Public Health, Cape Town, South Africa, [4]University of Antwerp, Family Medicine and Population Health – FAMPOP, Antwerpen, Belgium

Background: Illness identity in HIV; the extent to which HIV is integrated into a sense of self, can have a significant impact on health outcomes of people living with HIV. Incorporating HIV into a sense of self and identity can be influenced by the social context within which HIV is experienced. We hypothesized that when households are HIV competent, this can have a significant influence over the dimensions of illness identity; engulfment, rejection, acceptance and enrichment.
The study therefore aimed to explore the association between household HIV competence and illness identity in HIV.
Methods: Data for the current study was drawn from the baseline phase of the Sinako cluster randomized control trial. The Sinako study was set in five sub-districts of the Cape Metro health district in the Western Cape, South Africa. A total of 316 adults living with HIV, aged 18 to 65 (M_{age} = 35.49; 83% women) completed questionnaires eval-

uating the four illness identity dimensions; rejection, acceptance, engulfment, and enrichment and household HIV competence. Multiple regression with robust standard errors were conducted to assess associations between household HIV competence and illness identity, with the dependent variables engulfment, rejection, acceptance and enrichment regressed onto the independent variable household HIV competence while simultaneously controlling for gender, age and illness duration.

Results: We found evidence of an association between household HIV competence and the acceptance and rejection dimensions of illness identity in HIV. Higher household HIV competence levels were related higher acceptance and lower rejection scores. We found no evidence of an association between household HIV competence and enrichment nor household HIV competence and engulfment.

Conclusions: The degree to which households are HIV competent may have important ramifications for acceptance and or rejection in HIV. The findings of the current study thus suggest the crucial role of household HIV competence in illness identity in HIV, with important implications for support for people living with HIV, implementation of HIV programs and intervention research.

THPED079

Trauma-informed decision-making in HIV post-exposure prophylaxis: insights from sexual assault survivors' experiences

T. Porter[1], P. Fernandez[2], L. Webb[3], J. Anderson[3], J. Draughon Moret[2]

[1]UC San Diego Health System, Herbert Wertheim School of Public Health & Human Longevity Science, La Jolla, United States, [2]University of California, Davis, Betty Irene Moore School of Nursing, Sacramento, United States, [3]University of Arkansas for Medical Sciences, College of Nursing, Little Rock, United States

Background: Sexual assault survivors are at increased risk of HIV, yet decision-making around HIV post-exposure prophylaxis (PEP) remains complex. This study explores the factors influencing PEP acceptance or declination in sexual assault care, highlighting trauma-informed approaches, health disparities, and systemic barriers. Trauma-informed approaches require providers to acknowledge and accommodate the influence of previous trauma on participants' attitudes, beliefs, feelings, and behaviors. Making decisions following a sexual assault can be challenging for participants. Exploring participants' experiences with healthcare visits can offer insight into HIV prevention strategies.

Methods: Semi-structured interviews captured participants' experiences with healthcare providers, understanding of HIV PEP, and reasons for their decisions. Data were analyzed to identify themes highlighting barriers, facilitators, and systemic inequities in PEP access and adherence.

Results: This qualitative study included 42 sexual assault survivors seeking care within the 72-hour PEP window. Survivors cited prevention as a motivator, emphasizing trust in providers and clear communication. A participant shared, "I trusted what they said...if I took it within 48 hours, it would work" (African American female, insured). Barriers included fear of side effects, financial constraints, and perceived low risk of HIV exposure. A participant noted, "The cost wasn't feasible, and I couldn't use my parents' credit card without them knowing" (Hispanic female, uninsured).

Participants who felt coerced by providers described heightened trauma. For example, one stated, "They said, 'You need to take this or you'll get AIDS and die,' and I just wanted to leave" (White female, insured).

Theme	Quote	Demographics
Stigma and Fear	"It felt like taking the medication meant admitting to something shameful, even though I didn't do anything wrong."	Black female, insured
Stigma and Fear	"It was pretty scary 'cause there was a lot of folks around... I didn't want everyone knowing my business."	White female, employed, insured
Stigma and Fear	"In the beginning, I wanted to keep it private... I didn't want anybody to know because I was embarrassed."	White female, employed, insured
Provider Influence	"The doctor said, 'If you don't take this, you'll get HIV,' and it made me feel like I was dirty or already infected."	White female, insured
Provider Influence	"They just said just follow what the specialist says, because if you don't, you could catch something that you might not know how to handle."	White male, employed, insured
Provider Influence	"I guess I mean more extensive details and information... I don't even know what it really was treating."	White male, employed, insured
Perception of Risk	"I've never been with someone who uses drugs or prostitutes, so I didn't think it was something I had to worry about."	Hispanic female, employed
Perception of Risk	"He told me he had a family and kids, so I thought he wasn't the type to give me anything."	White female, insured

Table 1: Key Themes in HIV PEP Decision-Making.

Conclusions: Findings underscore the need for trauma-informed, survivor-centered care to improve PEP uptake and reduce disparities. Addressing systemic barriers such as cost and improving provider communication can empower survivors to make informed decisions.

These insights inform differentiated HIV prevention strategies that prioritize equity and respect survivors' autonomy, contributing to improved care protocols and public health outcomes.

THPED080

Trends in HIV testing and risk behaviors among adolescent boys and young men in Kenya: a pseudo-longitudinal analysis

S. Ndwiga[1], T. Nyoni[2], K. Malama[3]
[1]University of Washington, Global Health, Nairobi, Kenya, [2]Dalhousie University, School of Social Work, Nova Costia, Canada, [3]McGill University, Ingram School of Nursing, Montreal, Canada

Background: Adolescents and young men (ABYM) in sub-Saharan Africa (SSA) face a face significant HIV risk, yet prevention efforts are often hindered by limited data disaggregation and tailored interventions.
This study investigates trends in HIV testing, awareness, and risk behaviors among ABYM in Kenya using data from the 2014 and 2022 Kenya Demographic and Health Surveys (DHS).
Methods: This pseudo-longitudinal study analyzed data from 2014 and 2022 DHS sub-samples of ABYM aged 15–24 years. Key variables included socio-demographics, HIV testing history, awareness of HIV prevention strategies, and behaviors that influence HIV acquisition. Descriptive statistics were used to compare trends, while logistic regression identified factors associated with HIV testing and condom use across survey years.
Results: Data from 4,657 participants in 2014 and 5,455 in 2022 revealed a decline in HIV testing rates among ABYM. Testing prevalence dropped from 72.1% (young men) and 39.9% (adolescents) in 2014 to 44.5% and 27.9%, respectively, in 2022 ($p<0.001$). Condom use during the most recent sexual encounter also decreased but remained higher among young men (2014: 88.0%; 2022: 85.7%) compared to adolescents (2014: 79.7%; 2022: 77.4%).
Key predictors of HIV testing and condom use were consistent across survey years. Young men were significantly more likely to test for HIV compared to adolescents (2022: aOR = 3.49, 95% CI: 3.07–3.96; $p < 0.001$; 2014: aOR = 3.12, 95% CI: 2.73–3.58; $p < 0.001$). Education emerged as a critical factor, with higher education strongly associated with HIV testing and condom use. In 2022, individuals with higher education were nearly 7 times more likely to test for HIV (aOR = 6.72; 95% CI: 3.81–11.87; $p < 0.001$). Media exposure, particularly watching television, became an increasingly significant predictor of HIV testing in 2022 (aOR = 1.35; 95% CI: 1.15–1.59; $p < 0.001$).
Conclusions: Declining HIV testing rates among ABYM in Kenya, despite high awareness, highlight the need for targeted interventions. Tailored interventions focusing on adolescents, leveraging education, and integrating media-driven outreach are essential to mitigate HIV risk and close testing gaps in this population.

THPED081

Intimate partner violence and determinants of HIV seroconversion among female caregivers in KwaZulu-Natal, South Africa: insights from the Asenze Cohort longitudinal study

C. Ferraris[1], R. Gruver[2], G. George[3], L. Davidson[2], C. Desmond[4], A. Santoro[1], J. Knox[1]
[1]New York State Psychiatric Institute, HIV Center for Clinical and Behavioral Studies, New York, United States, [2]Columbia University, Department of Epidemiology, Mailman School of Public Health, New York, United States, [3]University of KwaZulu-Natal, Health Economics and HIV and AIDS Research Division, Durban, South Africa, [4]University of KwaZulu-Natal, Center for Rural Health, Durban, South Africa

Background: HIV disproportionately affects women in South Africa, with intimate partner violence (IPV) being a key contributor to HIV acquisition. While most research has focused on pregnant women and adolescent girls, caregiving women remain understudied, and few studies have examined multiple IPV types or their associations with HIV seroconversion.
This study examines longitudinal associations between IPV exposure and HIV seroconversion among caregiving women in KwaZulu-Natal, South Africa.
Methods: Data were drawn from the Asenze Study, involving 580 female caregivers followed over three waves. Participants underwent HIV testing or self-reported status at baseline (Wave 1 [W1]; 2008-2010) and follow-up (Wave 3 [W3]; 2019-2021), completing measures of IPV, sociodemographics, mental health, and alcohol use at W1. IPV types included physical, sexual, and threatening violence from current or other partners. Analyses compared women living with HIV (WLHIV) versus HIV-negative at W1 and women who seroconverted by W3 versus those remaining HIV-negative, using chi-square and t-tests.
Results: At W1, the mean age of participants was 34.8 years, with WLHIV significantly younger than HIV-negative women (32.4 vs. 35.6 years, $p = 0.003$). No significant differences were found in education or household assets between groups. Overall, 42% reported experiencing any IPV at W1. WLHIV were more likely to report threatening IPV (34% vs. 23%, $p=0.005$) and experiencing multiple IPV types (32% vs. 23%, $p = 0.029$). Of the participants HIV-negative at W1, 75% (n = 322) remained HIV-negative by W3, while 22% (n = 93) seroconverted. This resulted in 42% of the overall sample (n = 242/580) being WLHIV and 56% (n = 322) remaining HIV-negative by W3. At W3, there were no significant differences in baseline (W1) IPV exposure between women who seroconverted and those remaining HIV-negative. Women who seroconverted were younger (28.2 vs. 37.8 years, $p >0.001$) and more likely to report hazardous drinking (13% vs. 3%, $p<0.001$).
Conclusions: HIV seroconversion was high in this sample, even in a South African province with scaled-up ART and PrEP access, suggesting women are not fully benefiting. Multiple types of IPV were prevalent. The lack of association between baseline IPV and seroconversion suggests additional sociobehavioral and structural factors drive HIV acquisition.

Social, cultural, political, legal, environmental and structural determinants of health in different contexts

THPED082

Associations of multilevel social determinants of health with HIV care continuum outcomes among persons in HIV care in Baltimore, Maryland, United States

L. Zalla[1], J. Jones[2], R. Moore[2], O. Falade-Nwulia[2], J. Keruly[2], L. Snow[2], A. Fojo[2], C. Lesko[1]

[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins School of Medicine, Baltimore, United States

Background: Studies of how social determinants of health (SDoH) affect HIV care continuum outcomes are often limited to individual-level or contextual SDoH. We examined the associations of multilevel SDoH with care outcomes in a longitudinal clinical cohort in the United States.

Methods: We included Johns Hopkins HIV Clinical Cohort participants alive and in care on December 31, 2022. We captured 5-year histories of income, housing stability, incarceration, insurance type, and residential address geocoded to census block groups (i.e., neighborhoods), which we used to measure residential mobility and area socioeconomic deprivation.

We estimated associations of each SDoH with the probabilities of death, missing a scheduled visit, not having a viral load (VL) measurement, and having a non-suppressed VL result (HIV-1 RNA >200 copies/mL) in 2023.

Results: Of 1,764 participants, 2.2% died, 46.0% missed a scheduled visit, 9.9% did not have a VL measurement, and 7.5% had a non-suppressed VL result in 2023. Adverse SDoH were strongly associated with death, missed visits, and non-suppressed VL (Table).

		Probability of Death		Probability of Missing Scheduled Visit(s)		Probability of Not Having a Viral Measurement		Probability of a Non-Suppressed Viral Load Result	
	N (%)	%	Difference (95% CI)	%	Difference (95% CI)	%	Difference (95% CI)	%	Difference (95% CI)
Income									
>300% Federal Poverty Level	568 (32.2)	1.1	ref.	23.6	ref.	13.2	ref.	4.5	ref.
≤300% Federal Poverty Level	1,196 (67.8)	2.7	1.6 (0.4, 2.9)	56.6	33.0 (28.5, 37.5)	8.3	-4.9 (-8.1, -1.7)	8.8	4.4 (1.9, 6.9)
Housing Status									
Stable	1,595 (90.4)	2.0	ref.	43.6	ref.	9.8	ref.	6.4	ref.
Unstable	169 (9.6)	3.6	1.5 (-1.3, 4.4)	68.1	24.4 (17.0, 31.9)	10.7	0.9 (-4.0, 5.7)	17.9	11.5 (5.6, 17.7)
Mobility									
≤1 Moves in Past 5 Years	1,321 (74.9)	2.3	ref.	41.3	ref.	9.0	ref.	6.1	ref.
≥2 Moves in Past 2 Years	443 (25.1)	1.8	0.5 (-1.0, 1.9)	60.1	18.8 (13.5, 24.1)	12.4	3.4 (0, 6.8)	11.9	5.8 (2.3, 9.3)
Area Deprivation									
80% Least-Deprived	533 (30.2)	0.9	ref.	28.7	ref.	8.8	ref.	4.5	ref.
20% Most-Deprived	1,231 (69.8)	2.7	1.7 (0.5, 3.0)	53.5	24.8 (20.0, 29.5)	10.3	1.5 (-1.5, 4.5)	8.8	4.3 (1.8, 6.8)

Table.

For example, participants with a 5-year history of low income were 33 percentage points more likely to miss a scheduled visit (95% CI 28.5, 37.5), and those with a history of unstable housing were 11.5 percentage points more likely to have a non-suppressed VL result (95% CI 5.6, 17.7). Low income and residing in a socioeconomically deprived neighborhood were independently associated with poor outcomes: e.g., the probability of missing a scheduled visit was 20.4 percentage points higher among low-income residents of the most-deprived vs. less-deprived neighborhoods, and 12.5 percentage points higher among high-income residents of the most-deprived vs. less-deprived neighborhoods.

Conclusions: Both individual-level and contextual SDoH are strongly associated with HIV care continuum outcomes in a large urban cohort in the United States. Multilevel interventions may be needed to achieve target levels of viral suppression, especially in structurally resource-deprived communities.

THPED083

The role of law enforcement in reducing HIV and HCV risk among PWUDs in Rwanda

N. Kabanyana[1], S. Murindanyi[1], D. Ndagijimana[1], L. Ngabonzima[1], J.P. Ayingoma[1], B. Ikuzo[2]

[1]Rwanda NGOs Forum on HIV/AIDS & Health Promotion. (RNGOF on HIV/AIDS & HP), Kigali, Rwanda, [2]Rwanda Biomedical Centre, Kigali, Rwanda

Background: People who use drugs (PWUDs) are at high risk of acquiring Human Immunodeficiency Virus (HIV) and hepatitis C virus (HCV) due to behaviors such as needle sharing and unprotected sex. Law enforcement practices significantly influence harm reduction efforts by shaping access to prevention services and play a key role in shaping the health outcomes of PWUDs.

This study evaluates the role of law enforcement in mitigating HIV and HCV risks among PWUDs in Rwanda, emphasizing the importance of collaborative, harm-reduction approaches.

Methods: A cross-sectional study was conducted using survey data in 2024 from 1,114 PWUDs self-reported users in 10 districts of Rwanda. Participants were recruited through respondent-driven sampling (RDS). Multivariable logistic regression using key variables like police confiscation injection equipment in 12 months, needle needle-sharing frequency in the last month, HIV test consent, ever tested for HIV, ever tested for HCV, HIV status, HCV status was used to assess the association between law enforcement practices, reduced HIV/HCV risk behaviors and improved health outcomes among PWUDs.

Results: Punitive law enforcement, such as arrests and equipment confiscation, drives higher-risk behaviors and increased needle sharing (aOR 1.89, 95% CI 1.31-2.73, p = 0.002), highlighting its adverse health impact. However, positive law enforcement, such as harm reduction services, significantly reduces risky behaviors among PWUDs (adjusted odds ratio [aOR] 0.42, 95% CI 0.28-0.62, p < 0.001) and increased HIV testing uptake (aOR 2.15, 95% CI 1.67-2.76, p < 0.001).

Conclusions: The findings show that law enforcement, public health, and harm reduction can significantly reduce HIV and HCV risk behaviors among PWUDs. Law enforcement should prioritize harm reduction approaches, such as referring individuals to health services instead of confiscating injecting equipment. Programs addressing needs among PWUDs can indirectly reduce risky behaviors by improving access to clean equipment and healthcare.

THPED084

Social determinants of mental health outcomes among refugee adolescents and youth living with HIV in refugee settlements in Uganda: a cross-sectional analysis

N. Tutlam[1], S. Kizito[1], P. Nabunya[1], M. Naseh[1], I. Nabbosa[2], I. Kwesiga[2], P. Namatovu[2], O. Sensoy Bahar[1], N. Nakasujja[3], F. Ssewamala[1]
[1]Washington University in St. Louis, Brown School, University City, United States, [2]International Center for Child Health and Development Field Office, Masaka, Uganda, [3]Makerere University, School of Medicine, College of Health Sciences, Kampala, Uganda

Background: Although the prevalence of mental disorders is high among conflict-affected populations, the extent to which social determinants impact the mental health of conflict-affected youth living with HIV is not well studied. Uganda is the top refugee receiving country in sub-Saharan Africa (SSA), currently hosting nearly 1.8 million refugees. Many of these refugees come from countries mired in protracted armed conflicts.
Given the complex interplay between conflict, HIV and mental disorders, the objective of this study was to investigate how social determinants impact the mental health of conflict-affected youth living with HIV in Uganda.
Methods: We analyzed cross-sectional data from a two-year cluster randomized clinical trial (RCT) among youth (ages 13 – 30). The youth were recruited between July and December 2023 from 20 health centers in three refugee settlements. We summarized the descriptive statistics using frequencies and percentages for the categorical variables and means and standard deviations for the continuous variables.
To examine the association between the selected predictors and the mental health outcomes, we fitted a separate mixed-effects linear regression model for each outcome including depression, hopelessness, and PTSD. Based on the structure of the data where the participants were clustered in health clinics, there was more than one source of variance in the outcomes—that is, participant level and clinic level variance.
Results: HIV-related stigma (β = 0.04, 0.01 – 0.07; p = 0.012) and PTSD (β = 0.29, 0.16 – 0.43; p = <0.001) were associated with increased depressive symptoms. Similarly, unemployment (β = 2.39, 0.65 – 4.13; p 0.007), HIV-related stigma (β = 0.20, 0.09 – 0.31; 0.001) and PTSD (β = 1.55, 0.84 – 2.26; p < 0.001) were associated with hopelessness. Good physical health (β = -0.53, -1.00 – 0.06; *p* = 0.028) and school enrollment (β = -0.94, -1.3 – 0.50; *p* <0.001) were associated with lower PTSD symptoms.
Conclusions: This study found that social determinants including school enrollment, double orphanhood, HIV-related stigma, poor physical health, and poverty related factors like unemployment are important predictors of poor mental health among refugee youth living with HIV, underscoring the need for multilevel approaches to address these challenges.

Community-engaged/participatory social science-based interventions

THPED085

Perspectives of partners and families on the psychosocial impacts of analytical treatment interruptions in HIV cure research in Durban, South Africa

K. Dong[1,2,3], M.W. Ngcobo[4], D. Mthimkhulu[4], N. Langa[4], A. Zulu[4], L. Maphalala[5], V. Pillay[5], M. Mthembu[6], W. Tran[7], R. Lau[7], A. Miall[5], D. Mindry[8], A. Ahmed[7], T. Ndung'u[9,10,11], K. Dube[7]
[1]Harvard Medical School, Medicine, Boston, United States, [2]Massachusetts General Hospital, Infectious Disease, Boston, United States, [3]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [4]Integration of TB in Education and Care for HIV/AIDS, Pietermaritzburg, South Africa, [5]Females Rising through Education, Support and Health, Durban, South Africa, [6]University of KwaZulu-Natal, School of Applied Human Sciences, Durba, South Africa, [7]University of California San Diego School of Medicine, Division of Infectious Diseases and Global Public Health, La Jolla, United States, [8]University of California Global Health Institute, San Francisco, United States, [9]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, [10]Africa Health Research Institute, Durban, South Africa, [11]University College London, Division of Infection and Immunity, London, United Kingdom

Background: Analytical treatment interruptions (ATIs) are a critical component of HIV cure trials, permitting assessment of interventions designed to induce ART-free virologic control. However, ATIs pose risks related to viral rebound and psychosocial impacts that extend beyond trial participants to members of their support network. Partners and family members provide ATI trial participants with much needed emotional and practical support, yet their ATI experience is rarely considered.
This study assessed the experience of partners and family members of ATI trial participants in HIV high-prevalence KwaZulu-Natal, South Africa.
Methods: We conducted a qualitative study between February 2023 and April 2024, interviewing ten partners and family members of young women enrolled in an ATI-inclusive HIV cure trial at the Females Rising through Education, Support, and Health (FRESH) site in Durban, South Africa. Interviewees were contacted after consent from ATI participants.

We transcribed, translated, and analyzed in-depth interviews using conventional content analysis, guided by principles of community-based participatory research and relational theory.

Results: Five male partners (two living with HIV and three without), and five family members (two sisters, two mothers, and one cousin) completed in-depth interviews. Hope from advancement of HIV cure science was countered by concerns about viral rebound risks, emotional strain, and stigma. A desire for clear trial information and provision of psychosocial support was conveyed.

Strengthened communication and emotional bonds were reported as relational benefits from the ATI. Partners without HIV valued access to pre-exposure prophylaxis (PrEP) but reported inconsistent use. Partners with HIV also experienced ATI-related stress. Family members advocated for open dialogue but felt ill-equipped to explaining ATIs within their communities.

Conclusions: This study provides unique insights into the experiences of partners and family members of participants enrolled in an ATI-inclusive HIV cure trial. Understanding the extent of ATI impact beyond trial participants is an ethical responsibility. Inconsistent PrEP use underscored the need for additional support and acceptable partner protection options.

Incorporating relational considerations into ATI-inclusive protocols acknowledges both cultural context and the important role of trial participants' existing support networks. Broader participant-considerations may prove invaluable toward improving ATI-trial uptake, retention, risk mitigation and success.

THPED086

Transforming paediatric HIV care in Tanzania: a community-centered and data-driven success story of advocacy

S. Shilagwa[1], F. Luwole[2], E. Kafuku[1], A. Mchangi[1], J. Raphael[1]
[1]Focus for the Future Generation, Dar es Salaam, Tanzania, the United Republic of, [2]COMPASS Tanzania, Dar es Salaam, Tanzania, the United Republic of

Background: An innovative community-led monitoring (CLM) initiative in Tanzania, implemented across nine PEPFAR-supported regions, is transforming pediatric HIV care by integrating communities into the healthcare process. The program engages 11 community-led organizations to identify and address key barriers such as pediatric ARV shortages, delays in early infant diagnosis (EID), malnutrition, and inconsistent follow-up care for children living with HIV (CLWHIV). By leveraging data collected directly from the communities, the initiative enhances the quality and accessibility of pediatric HIV services.

This community-centered, data-driven approach builds a sustainable, tailored response that reshapes pediatric HIV care and improves the overall healthcare delivery for CLWHIV.

Description: From October 2023 to September 2024, the program actively engaged 80 parents and caregivers of CLWHIV as community monitors. These individuals received training to identify gaps in care, such as ARV shortages, delays in EID, insufficient nutritional counseling, and inadequate psychosocial support.

Targeted interventions included strengthening supply chain management to reduce ARV stockouts, deploying additional EID machines to shorten result turnaround times from 50 to 14 days, delivering nutritional counseling to 620 caregivers, and forming psychosocial support groups for 310 participants. These efforts, guided by real-time data, significantly enhanced service delivery and care outcomes.

Lessons learned: The results underscore the effectiveness of community-driven solutions. ARV shortages were reduced by 85%, ensuring consistent treatment availability in 90% of facilities. Faster EID processing enabled quicker treatment initiation, while nutritional counseling improved caregivers' practices and health outcomes for CLWHIV. Psychosocial support groups increased treatment adherence rates by 25% and reduced stigma within families and communities. These achievements provide a replicable and scalable model for improving pediatric HIV care.

Conclusions/Next steps: This initiative demonstrates that empowering communities and effectively leveraging data can drive transformative change. Expanding the CLM model nationwide, coupled with continued investments in supply chain systems and caregiver support, is essential for sustaining progress.

This success story offers a blueprint for integrating community engagement into policy frameworks, fostering collaboration, and advancing healthcare equity for CLWHIV across Tanzania.

THPED087

Empowering traditional health practitioners to address HIV/AIDS, TB, and STIs: a community-driven training and engagement model

B. Rambono[1], S. Nduku[1], N. Tshuma[2], T.M. Ndhlovu[2]
[1]Civil Society Forum, Tradiotional Health Practitioner Sector, Mthatha, South Africa, [2]Best Health Solutions, Public Health, Johannesburg, South Africa

Background: Traditional Health Practitioners (THPs) play a crucial role in providing primary healthcare support in rural communities, where access to formal healthcare services is often limited. However, many THPs lack adequate training to address critical health challenges such as HIV/AIDS, TB, and STIs.

This initiative aimed to develop and evaluate a tailored, community-driven training model to equip THPs with essential knowledge and practical tools. The inclusion of THPs who are TB survivors as peer educators aimed to reduce stigma and foster supportive healthcare environments.

Description: Conducted over a 12-month period across 15 rural communities with high TB and HIV prevalence, the intervention employed a participatory approach involving dialogue-based workshops and mentorship sessions. A total of 203 THPs were engaged through structured training modules covering TB, HIV, STIs prevention, treatment and management.

Pre and post-training assessments were conducted to evaluate changes in knowledge, attitudes, and practices, while qualitative data was collected through in-depth interviews and focus group discussions.

The training modules incorporated culturally relevant content and were co-designed with healthcare professionals and community stakeholders to ensure alignment with public health objectives.

Lessons learned: The intervention led to a 63% increase in THPs' knowledge scores, with 92% of participants demonstrating improved confidence in discussing and managing TB and HIV-related cases. Stigma reduction efforts were successful, as evidenced by a 77% increase in THPs' willingness to disclose their TB status and encourage healthcare clients to seek formal care.

Additionally, 81% of THPs reported integrating the acquired knowledge into their daily practice, leading to improved healthcare clients' counseling on holistic health support, including nutrition and mental health. Peer-led sessions emerged as a critical factor in enhancing trust and engagement.

Conclusions/Next steps: The community-driven training model has demonstrated significant success in equipping THPs with the necessary skills to address major health challenges within their communities. Scaling this model to other regions could enhance the role of THPs in the healthcare continuum and further strengthen community resilience.

Future efforts should focus on integrating digital learning platforms and developing advanced modules tailored to evolving community health needs.

THPED088

Empowering key populations: the impact of kp-led civil society organizations on health access, stigma reduction and community resilience in Kitui, Kenya

N. Ndone[1], P. Eshikumo[2], J. Kioko[2], E. Ekisa[1], J. Gachoki[1], M. Makau[3], P. Nzioki[1], R. Ombura[3], N. Mutuku[4], S. Wafula[5]
[1]Ciheb Kenya, Kitui, Kenya, [2]Ciheb Kenya, Machakos, Kenya, [3]County Department of Health, Kitui County, Kenya, [4]Kitui Innovators -KP Led CSO, Kitui County, Kenya, [5]Ciheb Kenya, Nairobi, Kenya

Background: Key populations (KPs), including female sex workers and men who have sex with men are disproportionately affected by HIV/AIDS due to systemic marginalization that limits their access to health and social services. Community-led approaches including Key Population-led Civil Society Organizations (KP-led CSOs), are recommended in advocating for rights and empowering the KP community to access HIV prevention services and control the HIV/AIDs epidemic. We describe involvement of KP-led CSOs and its impact on reach, retention, and uptake of HIV prevention services.

Description: In collaboration with the County Health Management team, we engaged KP-led CSOs in Kitui County to scale-up reach of new (yet to be reached) KPs, uptake of HIV of pre-exposure prophylaxis (PrEP), and retention in HIV prevention services. The CSOs were actively involved in engagement of peer-educators and management of the peer education and outreach activities through strengthening structural and behavioral interventions, aimed at mobilizing their community to access HIV prevention services including PrEP at the KP- friendly drop-in centers.

We compared before (October 2021 – September 2022), and after/during (October 2022 to September 2023) periods to identify significant changes associated with involvement of CSOs.

Lessons learned: The total number of KPs newly reached increased from 776 (383 FSWs and 393 MSM) before engagement to 1727 (735 FSWs and 992 MSM). Retention rates significantly improved among both typologies: from 39% to 79% among FSWs ($t(11) = 15.67$, $p < 0.001$) and from 45% to 67% among MSM ($t(11) = 9.45$, $p < 0.001$).PrEP uptake among newly reached MSM increased significantly from 21% to 67% ($t(11) = 3.988$, $p = 0.002$), whereas no significant change was observed in PrEP uptake among newly reached FSWs. The mean number of FSWs reached increased from 31 to 61 post-CSO engagement, showing statistical significance ($t(11) = 2.305$, $p = 0.042$).

However, there was no significant change in the mean number of MSM reached before and after CSO involvement

Conclusions/Next steps: Meaningful engagement of KP-led CSOs through collaborative capacity building positively impacts reach, service uptake, and retention of KP in HIV prevention service

THPED092

Effectiveness of the Buddy system on treatment outcomes and viral load suppression among children and young people living with HIV (CYPLHIV) aged 15-24 years at Mpilo Centre of Excellence

P.S. Dube[1], S. Nyathi[1], D. Moyo[1], P. Siqo[2], S. Chiomvu[2], T. Matare[3], A. Mpofu[4], B. Madzima[4], F. Dube[5]
[1]National AIDS Council Zimbabwe, Bulawayo, Zimbabwe, [2]Million Memory Project Zimbabwe, Bulawayo, Zimbabwe, [3]Ministry of Health and Child Care, Harare, Zimbabwe, [4]National AIDS Council Zimbabwe, Harare, Zimbabwe, [5]National AIDS Council Zimbabwe, Communications, Harare, Zimbabwe

Background: Records review at Mpilo Centre of Excellence revealed poor ART outcomes and low viral load suppression (VLS) in 2021 among Children and Young People living with HIV (CYPLHIV) aged 15-24 years. CYPLHIV experienced high defaulter and/or lost to follow up rates and low levels of returnees to care. Ministry of Health and Child Care, National AIDS Council and AHF Zimbabwe in partnership with the Million Memory Project Zimbabwe in designed and implemented a peer-led intervention, Buddy System, from 2022 to 2023 to improve treatment outcomes and VLS among CYPLHIV.

Description: Million Memory Project Zimbabwe (MMPZ) introduced a programming approach guided by the ecological model concept with a particular bias to Peer-Led Interventions including the buddy system to support monitoring of viral load suppression among children and

young people living with HIV aged 10 - 28 years in Mpilo Hospital. The MMPZ initiative sought to enhance health outcomes for children and young people by delivering comprehensive healthcare and support services.
This approach involves the participation of everyone in the child's life, fostering a responsive and supportive environment. The system supported the care for CYPLHIV through peer training, peer-led support groups, Youth Friendly Room, health education and resources, community outreach, defaulter tracking, experiential learning and self-care.
Lessons learned: Peer-led interventions were youth friendly and effective in improving treatment outcomes and viral suppression outcomes among CALHIV at Mpilo Centre of Excellence. Retention in care among CYPLHIV improved; with a significant increase in proportion of active patients in care from 89% (2,653) in 2021 to 97% (3,304) in 2023 ($\chi 2$ =170.9, p=0.00). Viral load suppression significantly improved from 83% (1,925) in 2021 to 88% (2,529) in 2023 ($\chi 2$ =22.0, p=0.00). CYPLHIV who participated in the interventions felt more motivated to take their medication, attend clinic appointments, disclose their status to others, and adopt a healthy lifestyle.
The participants reported that peer supporters played a significant role in providing emotional support, encouraging them to adhere to medication, and helping to address stigma and discrimination they encountered.
Conclusions/Next steps: The best practice showed a need to scale up and prioritise peer led interventions to other health facilities in Zimbabwe.

THPED094

Leveraging Community-Led Monitoring (CLM) to enhance HIV service delivery and accountability in Nigeria

F.J. Medayese[1], A. Ibrahim[2], N. Ugbenyen[2], J. Atusue[2], M.O. Edoh[2], O.J. Obeten[1], E. Iwolode[2], O. Adebayo[3], T. Adetiba[3], O. Olupitan[3], A. Agbaje[3], H.B. Raji[3], K. Tsujii[4], M. Zamzu[4]
[1]Network of People Living with HIV/AIDS in Nigeira, Monitoring and Evaluation, Abuja, Nigeria, [2]Network of People Living with HIV/AIDS in Nigeria, Programs, Abuja, Nigeria, [3]Global Fund N-THRIP, Institute of Human Virology, Nigeria (IHVN)., Programs, Abuja, Nigeria, [4]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Programs, Geneva, Switzerland

Background: Achieving the goal of ending HIV and AIDS by 2030 requires community involvement in holding health systems accountable. Community-Led Monitoring (CLM), an intervention under Nigeria's Global Fund GC7 grant and led by the Network of People Living with HIV/AIDS in Nigeria (NEPWHAN), which empowers the communities across 13 States in Nigeria to assess and monitor service delivery, identify gaps, and advocate for actionable solutions. CLM leverages routine data collected at the community level, translates these data into actionable insights to inform policies, practices among implementing partners, aiming to improve the quality-of-service delivery.
Description: A cross-sectional descriptive study was conducted from January to June 2024 in 13 states where NEPWHAN implements CLM. Quantitative data were collected using the community iMonitor mobile application, while qualitative data was from focus group discussions. Quantitative data from the app were analyzed using IBM SPSS Statistics 23 while qualitative data was analyzed using inductive thematic analysis.
Lessons learned: A total of 17,657 responses were recorded from the app and 6 focus group discussion sessions with 6 participants each were conducted across the 13 states. 81.9% (14,478), 10% (1766) and 8% (1413) of the responses were from People Living with HIV (PLHIV), Key Population; and adolescent and young persons (AYP) respectively. The top three challenges reported from the app were access to mental health services 8459 (47.9%), access to legal services 7926 (44.8%) and stock-out of condoms and lubricants 938 (5.3%) The qualitative data focused on 4 themes which are barriers to treatment, quality of care, availability of commodities, gender and human rights. Major challenges included lack of nutritional support, stock-out of condoms and lubricants, and lack of access to mental health and legal services.
Conclusions/Next steps: Community Led monitoring as an intervention is a critical tool for improving person-centered care and service quality for PLHIV, the key and vulnerable population. Addressing the identified issues through targeted interventions and engaging policymakers with actionable data is essential in achieving epidemic control and ending AIDS by 2030.

THPED095

Strengthening links: open days and guided tours for adolescents and young women (AGYW), the community, and healthcare providers

E.N.A.L. Kimou[1], D. Doulo[1], E. Irié[1], M.E.A. Kouassi[1]
[1]OGRADIE, Abidjan, Côte d'Ivoire

Background: Inadequate preparation on sexuality, gender norms, and reproductive health makes Adolescents Girls and Young Women (AGYW) vulnerable to abuse, unwanted pregnancies, and Sexually Transmitted Infections (STIs), including HIV. Individuals aged 15-24 account for 45% of new HIV infections, primarily due to lack of information about available healthcare services.
Since 2018, OGRADIE, supported by USAID/PEPFAR through the DREAMS Soungourou Farima project, has implemented open days and guided tours in healthcare centers in the districts of Cocody-Bingerville to strengthen access to information and foster connections between AGYW and healthcare providers.
Description: Three months after the start of Comprehensive Sexual Education (CSE) sessions, which aim to provide AGYW with information on sexuality, sexual rights, and reproductive health, open days and guided tours are organized in safe spaces and healthcare facilities. During open days, Mentors, Ambassadors, and Facilitators run stands to present the various DREAMS program interventions and address the concerns of AGYW ,s parents and guardians.

During the guided tours, Mentors and Supervisors accompany AGYW through health centers, where medical staff present the services available. These visits allow AGYW to become familiar with healthcare services and build trust with healthcare providers.

Lessons learned: From 2018 to September 2024, 81,577 AGYW identified by the project benefitted from the social asset-building program. Analysis showed that over 80% of AGYW accessed healthcare services based on their needs. A total of 92,374 AGYW were referred to these services, contributing to a reduction in risk behaviors, stigma within the community, and healthcare settings. The relationships between AGYW and healthcare providers have been strengthened, leading to better care for AGYW.

Conclusions/Next steps: These initiatives strengthen relationships between AGYW, healthcare providers, and the community, while reducing health risks. By September 2025, the project aims to reach 38,010 AGYW. To ensure maximum coverage, the next steps include geographic expansion and intensifying awareness campaigns.

THPED097

Acceptability of a peer-led STI screening model among females using PrEP at a peri-urban public health facility in South Western Uganda

C.H. Namugerwa[1], A. Kazibwe[1], A. Mijumbi[1], M. Etukoit[1], A. Napyo[2], G. Mirembe[3], A. Kiiza[4], M. Kyohairwe[5]
[1]The AIDS Support Organization, Health and Research, Kampala, Uganda, [2]Kabale University, Health and Research, Kabale, Uganda, [3]Bufunda HC III, Health, Ibanda, Uganda, [4]Bufunda HC III, Laboratory, Ibanda, Uganda, [5]Bufunda HC III, Peer to Peer Leader, Ibanda, Uganda

Background: Screening and management of sexually transmitted infections is an integral component of a person-centered HIV prevention program. The ministry of health recommends provision of routine syndromic screening for and timely linkage to STIs treatment within PrEP services. STI screening coverage was less than 14.2% at a health center due to several barriers. We describe a mixed methods study to assess the acceptability of peer-led STI screening intervention among female PrEP users.

Methods: We piloted a peer-led STI screening intervention among female PrEP users at a peri-urban public health facility in South Western Uganda. The facility focal person identified and oriented five peer leaders on syndromic STI screening and linkage for management. We conducted individual structured and semi-structured interviews based on the theoretical framework for acceptability. We used systematic random sampling recruit peer beneficiaries for individual interviews and purposive sampling to enroll peer leaders and facility health-workers for qualitative inquiry. Participant language, time preferences were considered in scheduling interviews. We used summarized quantitative data as medians and frequencies; and conducted thematic analysis for qualitative responses. We obtained ethical approval for the study.

Results: A total of 120 Peers were reached by the peer leaders. Of these beneficiaries, 78, all female of the age range 18 to 24 years (62.9%). We also received responses from 06 health facility staff and all PrEP service providers for the qualitative inquiry. Of the screened 90/122 (62.5%) reported this was their first time being screened for STI, 70/122 (58.33%) had symptoms for more than a month without care. 112/120 (93.33%) perceived intervention would have positive effects.

It was noted 51/120 (42.5%) of the respondents opted for self-medication of suspected STI without confirmed diagnosis/prescription. 98/120 (81.67%) responded that the model is highly acceptable, 22/120 (18.33%) found it somewhat acceptable, there was no disagreement with the intervention being acceptable to the community. 120 peers were in support of integrating STI screening into their PrEP services.

Conclusions: Peer-led STI screening is acceptable among female PrEP users. This model can be used to increase coverage of STI screening and timely management. We recommend additional studies to evaluate the effectiveness and cost-effectiveness of the model.

THPED098

Advanced HIV disease among Vulnerable populations living with HIV accessing HIV services at 2 wellness centers in Livingstone

C. Kunda[1], V. Kaputa[1], O.N. Chilyabanyama[2], B. Baumhart[3,4], J. Mwanza[1], L.K. Mwango[1]
[1]Ciheb Zambia, Lusaka, Zambia, [2]Maryland Global Initiative Corporation -Zambia, Lusaka, Zambia, [3]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [4]Center for International Health, Education, and Biosecurity, Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States

Background: Advanced HIV Disease (AHD) remains a significant public health concern in Zambia with the overall prevalence among people living with HIV at 7.0% (CI: 5.7–8.5%) in 2021. Vulnerable Populations (VPs) face heightened risk of AHD due to stigma, criminalization, and limited access to health services. Defined by a CD4 count <200 cells/μL or the presence of opportunistic infections (WHO stage 3 or 4) AHD increases morbidity and mortality among VPs.

We analyzed routinely collected data on CD4 counts among newly identified HIV-positive individuals and clients re-engaging in HIV care.

Methods: Retrospective review of clinical records from Mahatima Gandhi and Maramba KP Wellness Centers was conducted from January through December 2024. The population included VPs newly diagnosed with HIV or re-engaging in care after prior disengagement.

We summarized the data using frequencies and relative frequencies. A chi-square test was used to test for association between AHD and social demographic characteristics. Statistical significance was set at p-value 0.05 and all data analysis was conducted using Stata version 18.

Results: A total of 261 VPs had valid CD4 count results recorded with median 253 (IQR :75-490) cells per cubic millimeter; 164 (62.8%) were female. Most KP living with HIV, were aged between 25 and 35 years 190 (72.8%), and the

majority (62%) of KP clients were treated at Maramba facility. There were 97 (37.2%) female sex workers (FSW), 94 (36%) and men who have sex with men (MSM), 44 (16.9%) people who inject drugs, and 26 (10%) vulnerable persons.

The prevalence of AHD among KP in Livingstone district was estimated at 40.6% (95% CI 34.6% - 46.84%). Prevalence of AHD was higher at Maramba facility (54%) compared to Mahatma Gandhi (18.2%) with a p-value of <0.001. The occurrence of AHD was not related to sex, age, or VPs type.

Conclusions: The high prevalence of AHD among VPs in Livingstone highlights persistent health challenges. These findings emphasize the importance of addressing structural barriers and optimizing care for vulnerable populations. Strengthening access to early HIV diagnosis, comprehensive care, tailored support services for VPs is critical to reducing AHD-related morbidity and mortality.

Key populations and other vulnerable populations: Behavioural, social, cultural, structural and multilevel issues, contexts and interventions

THPED099

Prevalence of Mpox virus among men who have sex with other men in Kenya

E. Pascal Mwore[1], J. Zech[2], J. Walimbwa[1], S. Wambua[3]
[1]Ishtar, Research, Nairobi, Kenya, [2]ICAP University of Columbia, Research, New York, United States, [3]Key Populations Consortium, Research, Nairobi, Kenya

Background: Mpox virus, a zoonotic disease caused by the monkeypox virus, has seen a global resurgence in recent years, particularly affecting men who have sex with men (MSM). In Kenya, where MSM communities face social stigma and barriers to healthcare, there is limited data on the prevalence of mpox virus. This study aimed to determine the prevalence of mpox virus among MSM in major Kenyan cities (Nairobi, Mombasa, and Kisumu) and to explore associated risk factors.

Methods: A cross-sectional study was conducted between July and November 2024 in Nairobi, Mombasa, and Kisumu. A total of 500 MSM were recruited through community-based organizations. Participants were surveyed about sociodemographic characteristics, sexual behaviors, and prior healthcare access. Blood and lesion samples were collected and tested for mpox virus using PCR and serological assays. Descriptive statistics, chi-square tests, and logistic regression were applied to determine prevalence and associated factors.

Results: Of the 500 MSM participants, 6.4% (32/500) tested positive for active mpox virus infection. The prevalence varied by city: Nairobi (7.8%), Mombasa (5.1%), and Kisumu (4.3%). The median age of participants was 30 years (range 18-55 years). High-risk sexual behaviors, such as multiple sexual partners (OR=2.45, p<0.05) and unprotected anal sex (OR=3.12, p<0.01), were significantly associated with higher odds of infection. A history of recent travel or contact with known cases of mpox was reported by 12% of those infected. No significant difference in prevalence was found based on HIV status or condom use.

Conclusions: The study reveals a concerning prevalence of mpox virus among MSM in urban centers of Kenya, with sexual behaviors and recent exposure playing key roles in transmission.

These findings highlight the need for targeted public health interventions, including education, testing, and vaccination programs, to mitigate the spread of mpox among at-risk populations in Kenya. Further research is necessary to understand the full scope of mpox in this community and its relationship with other sexually transmitted infections.

THPED100

Developing a comprehensive framework to address chemsex and HIV in Southeast Asia: insights from a regional forum

R.K.J. Tan[1], J. Kidd[2], H. Kiri[3], S. Sok[4], P.B. Thanh[5], N. Phanuphak[6], P. Serkpookiaw[6], P. Panpet[7]
[1]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [2]Columbia University, New York, United States, [3]KHANA Association, Phnom Penh, Cambodia, [4]Men's Health Cambodia, Phnom Penh, Cambodia, [5]Light House, Ho Chi Minh City, Viet Nam, [6]Institute of HIV Research and Innovation, Bangkok, Thailand, [7]MPLUS Foundation, Chiang Mai, Thailand

Background: Chemsex or sexualized drug use in many Asian countries is driving HIV transmission, among key populations (KPs). Programs have been ineffective or ill-equipped to provide HIV services to this group because of stigma and discrimination against people who engage in chemsex, punitive drug policies, and a lack of engagement with this population in designing services.

There is an urgent need for consensus on interventions and components of a comprehensive package of chemsex harm reduction and HIV services, particularly tailored to the needs of KPs who are already stigmatized and in settings where increasingly punitive approaches to drug policy are taking root.

Description: In May 2024, we convened a forum of 20 participants from Thailand, Cambodia, Vietnam, and Singapore. Participants included representatives from community-based organizations, healthcare providers, policymakers, government officials, and academic researchers. They discussed research evidence and data from successful programs reaching chemsex users and providing HIV services.

Lessons learned: Participants agreed on a comprehensive framework to guide chemsex harm reduction and HIV interventions, addressing gaps in prior models that paid limited attention to the unique needs of transgender women in chemsex contexts. The framework emphasizes intersectional stigma and gender-specific approaches for men who have sex with men, transgender women,

and young KPs. With principles of being people-centered, gender-affirming, inclusive, and sex-positive, it integrates substance-related harm reduction, sexual health, social and legal aspects, and mental health, while prioritizing broader outcomes, including improved overall well-being.

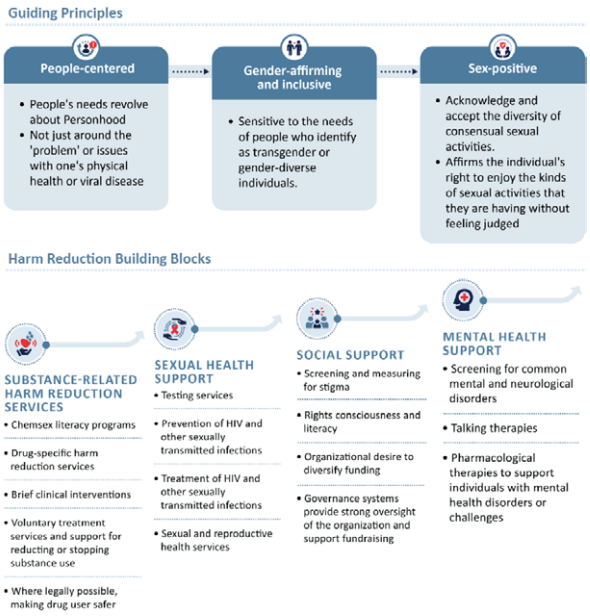

Figure 1. Lessons Learned from Regional Forum on Chemsex Interventions.

Conclusions/Next steps: We believe that this comprehensive framework, constructed from an inclusive forum, should guide on-going programming, capacity building, and policy efforts towards the health of chemsex users. We advocate for improvements in the policy environment around chemsex, inclusive program design processes, and more resources to expand people-centered services at the community level.

THPED101

Harnessing technology to address HIV prevention, treatment, and unplanned pregnancies in Kenya, Uganda and South Africa

M. Nhamo- Murire[1], H. Essendi[2], S. Malaba[2], N.A. Donjon[3], L. Wanaswa[2], P. Mookane[1], M. Luyiga[4], B. Renard[3]
[1]Tiko Africa, Global Operations, Johannesburg, South Africa, [2]Tiko Africa, Global Operations, Nairobi, Kenya, [3]Tiko Africa, Global Operations, Cape Town, South Africa, [4]Tiko Africa, Global Operations, Kampala, Uganda

Background: Adolescent girls and young women (AGYW) in sub-Saharan Africa, aged 15-24, remain highly vulnerable to both HIV acquisition and unplanned pregnancies. In 2022, AGYW represented 50% of unplanned pregnancies and 67% of new HIV infections. Addressing HIV prevention and reducing unplanned pregnancies among AGYW is crucial to eliminating both challenges. Achieving the UN 95-95-95 targets by 2030 requires innovative approaches to tackle HIV and unplanned pregnancies remain an unmet need. Tiko Africa uses technology to identify and connect AGYW with youth-friendly, stigma-free sexual and reproductive health services tailored to their needs.

Description: In collaboration with the Ministries of Health in South Africa, Kenya, and Uganda, Tiko Africa partners with community-based organisations to identify AGYW facing barriers to accessing sexual and reproductive health (SRH) services and who are at risk of HIV acquisition and unplanned pregnancies due to multi-dimensional poverty. These community-based organisations work within an ecosystem that includes both public and private retailers, as well as mobilizers, to create an enabling environment for delivering tailored SRH services to AGYW. Through the Tiko mobile platform, AGYW are enrolled and linked to care. The digital platform provides AGYW with the option to access stigma free services and fully subsidized services at both public and private health facilities. Real-time data is collected via dashboards, supporting program implementation and ongoing improvements.
Lessons learned: Between January 2023 and December 2024, Tiko Africa delivered a total of 2,378,717 services to AGYW. Of these, 23.8% (565,651) were related to contraceptive services, and 23.1% (548,438) were HIV testing services. Among those tested, 7% (17,284) were on antiretroviral therapy (ART), while 4.8% (26,446) began taking pre-exposure prophylaxis (PrEP) during this period.
Conclusions/Next steps: The Tiko platform has shown that integrating sexual and reproductive health (SRH) services across various health facilities empowers young people to access stigma-free, discreet services. This approach has been instrumental in preventing unplanned pregnancies and reducing HIV acquisition among AGYW. By offering a range of tailored, confidential services, the platform has provided AGYW with the support they need to make informed choices about their health, ultimately averting pregnancy and contributing to HIV prevention.

THPED103

Stigma and healthcare access among African, Caribbean, and Black refugee and migrant women affected with HIV in Canada

J. Kamanzi[1], S. Richter[2,2]
[1]University of Calgary, Social Work, Calgary, Canada, [2]University of Saskatchewan, Nursing, Saskatoon, Canada

Background: HIV remains a significant public health concern worldwide, with marginalized populations, including African, Caribbean, and Black (ACB) immigrant and refugee women, disproportionately affected. According to the 2021 Canadian Census, immigrants and refugees account for 23% of the total population. In Canada, the majority of those affected are women and these women face a unique set of challenges in accessing health services, including social stigma, discrimination, and cultural barriers. These factors often deter them from seeking the care they need, contributing to poorer health outcomes.
The study also aims to identify strategies to improve health care access and reduce stigma for this population.
Methods: A qualitative, focused ethnographic study using an intersectionality framework was conducted between August 2022 and December 2024. Data were col-

lected through in-depth interviews with 14 participants, including refugee and migrant women affected with HIV, healthcare providers, and community leaders. Participants were selected using purposive sampling and were required to be comfortable communicating in English and/or French. Ethical approval was granted by the Behavioral Research Ethics Board (Beh-REB, #: 3232) at the University of Saskatchewan, on August 30, 2022.

Results: Key findings revealed that stigma and discrimination were the primary barriers to accessing healthcare. Participants reported feeling isolated, rejected, and fearful of disclosing their HIV status due to both HIV-related stigma and racism. Misinformation about HIV, both in within the community and within the healthcare system, exacerbated these challenges. Language barriers further hindered women's ability to access care. Despite these obstacles, some participants emphasized the importance of community-driven efforts to fight stigma, such as reframing language around HIV and fostering peer mentoring.

Conclusions: This study highlights the complex barriers that ACB immigrant and refugee women who are affected with HIV face in accessing healthcare in Canada. To improve healthcare outcomes for this population, a multifaceted approach is necessary, including reducing stigma, addressing misinformation, improving cultural competency in healthcare settings, strengthening peer mentoring and support systems, and providing language support. By adopting these strategies, healthcare systems can ensure better access to care and support for these women, ultimately improving their health and quality of life.

Mental health and well-being interventions, programmes and models

THPED104

Innovations in mental health and well-being in HIV care: addressing mental health and substance use disorders among displaced women and youth living with HIV in Nakivale Refugee Settlement, south-western Uganda

U. Muhumuza[1], M. Naturinda[2], E.S. Abay[3], Z. Nahumuza[4]
[1]Africa CDC, Kampala, Uganda, [2]Kampala International University, Kampala, Uganda, [3]Africa CDC, Addis Ababa, Ethiopia, [4]International University of Africa, Khartoum, Sudan, the

Background: The mental health and substance use challenges of displaced populations living with HIV are well-documented. However, few studies focus on integrating culturally tailored, community-led interventions to simultaneously address these issues while improving HIV care outcomes. This study uniquely investigates the intersection of mental health, substance use disorders (SUD), and HIV care among women and youth in Nakivale Refugee Settlement. By leveraging community-led approaches rooted in trauma-informed care and peer support, this research brings new insights into replicable and sustainable interventions tailored to refugee contexts, aiming to bridge gaps in mental health support and HIV service delivery in resource-limited settings.

Methods: A mixed-methods observational study was conducted from February 2023 to April 2024 in Nakivale Refugee Settlement, which hosts refugees displaced by violence in the Democratic Republic of Congo and climate-related events. A sample of 300 women (aged 15–49) and youth (aged 15–24) living with HIV was selected using stratified random sampling.

Quantitative data was collected through structured interviews, mental health assessments (PHQ-9, GAD-7), and substance use screenings. Qualitative data was gathered via focus group discussions and key informant interviews with healthcare providers.

Results: The prevalence of mental health conditions and SUD among participants was striking: 45% of women and 35% of youth reported moderate to severe depressive symptoms; 50% exhibited PTSD symptoms; and 40% of women and 30% of youth experienced generalized anxiety disorder. SUD was also significant, with 20% engaging in alcohol use (10% meeting criteria for alcohol dependence) and 15% of youth using cannabis or other drugs. Interventions yielded promising results. A community-led mental health program reduced depressive symptoms by 35% and PTSD symptoms by 25%. Trauma-informed harm reduction strategies decreased alcohol dependence by 20%. A youth-led peer counseling initiative reduced substance use by 15% while fostering resilience and improved coping mechanisms.

Conclusions: This study demonstrates the transformative potential of integrating culturally adapted, community-led mental health and harm reduction programs into HIV care for displaced populations. Unlike prior research, it highlights the role of refugee health workers and youth leaders in delivering scalable and replicable interventions that simultaneously improve mental health and HIV outcomes.

THPED105

Insights from 2024 baseline assessment of mental health and psychosocial support interventions in selected USAID supported sites in Niger State, Nigeria

M. Ekerette[1], O. Atibioke[2], A. Olutola[3], A. Etsetowaghan[3], S. Idris[3], M. Rufai[1], B. Adebobola[4], T. Ileri[5], F. Agbo[6], P. Gado[7], O. Oyelaran[8], D. Ogundehin[9], A. Idemudia[9]
[1]Centre for Clinical Care and Clinical Research Nigeria, Care and Support, Minna, Nigeria, [2]Association for Reproductive and Family Health, Clinical Services, Abuja, Nigeria, [3]Centre for Clinical Care and Clinical Research Nigeria, Clinical Services, Abuja, Nigeria, [4]National AIDS, Sexually Transmitted Infections Control and Hepatitis Programme, Abuja, Nigeria, [5]National Agency for Control of AIDs, Director General, Abuja, Nigeria, [6]National Agency for Control of AIDs, Director, Abuja, Nigeria, [7]United States Agency for International Development, AOR, Abuja, Nigeria, [8]United States Agency for International Development, Head of Office, Abuja, Nigeria, [9]United States Agency for International Development, HAT Team, Abuja, Nigeria

Background: HIV and tuberculosis (TB) remain significant public health challenges in Sub-Saharan Africa, particularly in Nigeria, where mental health disorders such as depression and anxiety exacerbate poor adherence to antiretroviral therapy (ART) and directly observed treatment (DOT). However, mental health services remain inadequately integrated into health care.
This baseline assessment evaluated the availability of mental health infrastructure in selected facilities in Niger State, aligning with Nigeria's national mental health policies.
Methods: A cross-sectional survey design was employed, with cluster sampling used to select six USAID supported facilities representing three clusters in Niger State. Purposive sampling was applied to select two facilities in each cluster with the highest number of ART clients. A mixed-methods approach was used to collect both quantitative data through an assessment checklist and service utilization records, and qualitative data via key informant interviews (KII) with heads of ART, DOT, and Mental Health units as primary respondents. Quantitative data were analyzed using STRATA to derive percentages while thematic analysis was used to generate themes of the qualitative data.
Results: The findings revealed significant gaps in the integration and delivery of mental health services in secondary healthcare facilities. Only 31% of facilities have incorporated mental health services, and the same percentage of providers have received relevant training, signalling skills gap. Budgetary support is negligible, with only 6% of facilities receiving mental health budgets, while partnerships with mental health institutions exist in 12% of cases. Documentation of mental health activities is present in only 25% of facilities. Thematic analysis further underscores systemic issues, including poor integration of mental health into TB/HIV care, absence of referral systems, and limited technical expertise among service providers.
Conclusions: This assessment serves as a novel findings of current mental health provisions in the state and further highlights the critical need for integrated mental health services in TB/HIV care. These gaps also point to a need for enhanced policy advocacy, increased funding, capacity building, improved service delivery frameworks, and robust monitoring and evaluation of systems to address the challenges in providing quality mental health care in these selected facilities of the state.

THPED106

Co-existing depression and post-traumatic stress disorders in people living with HIV in Zimbabwe – a mixed-methods study

M.A. Abas[1], M. Akiba[1], T. Bere[2], C. O'Cleirigh[3], S. Lewis[4], W. Mangezi[2]
[1]King's College London, Centre for Global Mental Health, London, United Kingdom, [2]University of Zimbabwe, Mental Health Department, Harare, Zimbabwe, [3]Massachusetts General Hospital, Behavioral Medicine Program, Department of Psychiatry, Boston, United States, [4]King's College London, London, United Kingdom

Background: Progress in mental health care for people living with HIV (PLWH) has largely focused on depression. However, many individuals with HIV and depression have also experienced severe trauma and may have co-occurring post-traumatic stress disorder (PTSD). Despite this, little is known about the impact of trauma on the health of PLWH in high HIV-burden countries like Zimbabwe, or whether people with both PTSD and depression benefit from non-trauma-focused psychological interventions commonly used in primary health care, such as problem-solving therapy.
Methods: We studied 484 participants receiving HIV care in Mashonaland, Zimbabwe from 2018 - 2024. All had at least mild depressive symptoms (PHQ-9) and were being assessed for potential enrolment in a clinical trial addressing depression in PLWH. We assessed depression, trauma exposure, PTSD, and antiretroviral therapy (ART) adherence. Associations were examined using linear or logistic regression. Additionally, 24 participants with comorbid PTSD and depression who had received six sessions of a psychological intervention (called TENDAI, based on problem-solving therapy) were interviewed in-depth. Qualitative data were analysed using thematic analysis.
Results: Over 98% of participants with mild depression had experienced at least one severe lifetime trauma, and one-third had PTSD. Being assaulted and having more traumatic events were significantly associated with risk of PTSD. PTSD severity was linked to poorer ART adherence, even after adjusting for depression ($p<0.01$). Religious and spiritual attitudes, economic stress, and family influence shaped participants' views of the way the trauma had changed them. Many said that despair after trauma had caused them to become non-adherent. Participants overall found the TENDAI therapy very helpful in addressing mental health symptoms, but some aspects of the therapy inadvertently reinforced unhelpful PTSD-related coping mechanisms.

Conclusions: We found a high burden of trauma and PTSD among PLWH with depression in Zimbabwe. More research is needed to understand the social and cultural factors linking trauma exposure with mental health in this population. Non-trauma-focused, brief therapies can support recovery in PLWH with depression and PTSD, but adaptations may be necessary to prevent aggravating unhelpful coping behaviours which are characteristic of PTSD.

Gender, sexuality and sexual cultures: Meanings, identities, norms and interventions

THPED107

Sexual health and perceptions of "time left" among older people with HIV in Ukraine: implications for HIV care

J. Rozanova[1], I. Zaviryukha[2], O. Zeziulin[2], V. Earnshaw[3], L. Grau[4], A. Deac[5], I. Kharandiuk[2], S. Shenoi[1]

[1]Yale University, Internal Medicine, New Haven, United States, [2]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [3]University of Delaware, Human Development and Family Sciences, Newark, United States, [4]Yale University, Center for Interdisciplinary Research on AIDS, New Haven, United States, [5]University of East London, London, United Kingdom

Background: The sexual lives of older people including older people with HIV (OPWH), defined as 50+ years, is a persistent social and medical taboo. As clinicians avoid discussing risky sexual behaviors and testing older clients for STI, many OPWH present at diagnosis with advanced disease: in Ukraine, that included over 1/3 of OPWH, resulting in 3-11 times higher mortality than among HIV-negative age-peers.

Population mobility in humanitarian setting may increase risky sexual behaviors including among OPWH, leading to further HIV transmission.

Understanding OPWHs' perceptions of their sexual life and behaviors are essential for successfully reaching 95-95-95 HIV prevention and treatment goals and curbing the HIV epidemic.

Methods: We analyzed data from 30 qualitative interviews and 8 focus group discussions with OPWH about their experiences of diagnosis and living with HIV; and 15 qualitative interviews and 6 FGDs with HIV care providers about working with their OPWH clients.

Data were collected in Ukraine from 2019-2024, audio-recorded and transcribed verbatim, coded, and thematically analyzed using constant comparison method.

Results: Across OPWH and clinicians' accounts, four themes were discerned:

a. "Time left", whereby OPWH perceived their biological, professional, and social life may continue, but their sexual life was over. This translated into withdrawal from existing sexual relationships and shunning new relationships, to avoid HIV disclosure with an anticipated stigmatizing reaction;

b. "Internalized stigma" whereby OPWH considered themselves as less desirable than non-OPWH age-peers;

c. "Anticipated stigma", with heterosexual and LGBTQ male and female OPWH avoiding ageist discrimination from current and prospective partners by withdrawing from sexual life, and;

d. "U=U is a sexual renaissance vehicle" for OPWH whose romantic self resurrects through successful HIV treatment.

While the humanitarian context increased the vulnerability of new relationships, an active sexual life was important for OPWH, and its possibility provided inspiration.

Conclusions: HIV providers may combat ageism by routinely discussing sexual health among HIV treatment goals with OPWH clients and emphasizing the value of achieving viral suppression for safe and happy romantic and sexual relationships. Using real-life older persons narratives may be a powerful tool for edifying ART-naïve OPWH and broadening their notion of 'time left'.

THPED108

Bridging the gap: leveraging peer mentorship and community engagement to enhance health-seeking behavior among adolescent boys and young men in Zimbabwe

W. Chikanya[1], O. Mukorera[1], T. Mushove[1], S. Mugudubi[1]

[1]ZiCHIRe, Health, Harare, Zimbabwe

Background: Adolescent boys and young men (ABYM) in Zimbabwe face significant challenges in accessing sexual and reproductive health rights (SRHR) services, especially in urban and peri-urban areas like Harare Metropolitan and Marondera District.

Despite comprising 20.16% of Zimbabwe's population, ABYM are often excluded from SRHR programming, resulting in low engagement and retention in HIV care (ZIMPHIA, 2020; ZIMSTAT, 2022). According to UNAIDS (2023), stigma, harmful gender norms, and limited youth-friendly services disproportionately affect ABYM, hindering their access to HIV and SRHR services.

The Brotha2Brotha (B2B) program addresses these gaps through mentorship, SRHR education, GBV prevention, drug abuse awareness, promoting positive masculinity and health-seeking behaviors.

Methods: Data on health service uptake, session exposure, and mentorship outcomes were collected using DHIS2 and analyzed through descriptive statistics to measure program impact. Qualitative data were gathered through focus group discussions and in-depth interviews. Thematic analysis was employed to analyze qualitative data, providing deeper insights into mentee experiences and program effectiveness. Study participants include 5,969 adolescent boys and young men (ABYM) aged 15-24 across Harare and Marondera to represent a population at high risk of HIV, GBV, and substance use. A risk assessment tool was employed to inform the recruitment process, ensuring the inclusion of participants most vulnerable to these challenges.

Results: The results shows that 99.45% was achieved regarding recruitment and 95% session exposure rates. Referrals resulted in 58.4% redeemed health services, with 96% of diagnosed HIV-positive mentees initiated on ART. Additionally, 362,384 condoms were distributed, and HIVST training improved HIV testing accessibility, achieving a 75% testing rate for targeted ABYM. Community initiatives reached over 7,500 people, raising awareness of drug use and SRHR. Program outcomes included increased health service uptake, reduced stigma around HIV, and development of peer role models.

Conclusions: B2B program successfully enhanced health-seeking behavior and SRHR awareness among ABYM in Zimbabwe, addressing critical gaps in HIV prevention and care. The program's sustainability plan, include trained mentors, purchased tablets installed with DHIS2 for data collection and community hubs, ensures long-term impact and scalability, demonstrating its potential as a model for similar contexts.

Implementation research to scale up prevention

THPEE093

Online PrEP and PEP delivery in Kenya: qualitative insights on client and provider barriers and facilitators to using a novel e-pharmacy telehealth model

P. Okello[1], N. Thuo[1], A. Saravis[2], D. Mwai[1], P. Naik[2], C. Kiptinness[1], T. Kareithi[1], M.L. Mugambi[2], S.D. Roche[3], M. Sharma[2], K.F. Ortbald[3], K. Ngure[4]
[1]Partners in Health Research and Development, Center for Clinical Research, Kenya Medical Research Institute, Nairobi, Kenya, [2]University of Washington, Washington, United States, [3]Public Health Science Division, Fred Hutch, United States, [4]School of Public Health, Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Background: Online delivery of HIV pre- and post-exposure (PrEP/PEP) has the potential to mitigate barriers to clinic-based services, but its implementation in Africa is still nascent. As part of the ePrEP Kenya Pilot, we interviewed clients and providers who obtained or delivered PrEP/PEP via a novel online delivery model to identify barriers, facilitators, and recommendations.

Methods: The delivery model leveraged a telehealth-enhanced version of an existing e-pharmacy platform. Adults (18+) based in Nairobi and Mombasa Counties completed initial PrEP/PEP eligibility screening with a remote clinician via telehealth; were courier-delivered an HIV self-test (HIVST) by a pharmaceutical technologist ("pharm tech") who could, if desired, assist with testing; uploaded a photo of the HIVST result for remote clinician review; and received a 1-month drug supply.

Clients paid nothing for the telehealth consultation or PrEP/PEP drugs but the equivalent of ~$2.00 USD for the HIVST and ~$1.50 USD for courier delivery. Near study endline, Kenyan social scientists conducted in-depth interviews with purposively sampled clients and with the study's remote clinicians and pharm techs.

Our thematic analysis of verbatim interview transcripts was informed by the Consolidated Framework for Implementation Research.

Results: From March to November 2023, we interviewed 30 clients—10 PEP clients, 10 PrEP clients who refilled ≥1 time, and 10 PrEP clients who never refilled—3 remote clinicians, and 6 pharm techs. Among clients, 53% (16/30) were female, and the median age was 27 years (IQR 25-30). Overall, participants liked the delivery model.

Facilitators to getting/delivering PrEP/PEP included factors supportive of client motivation (e.g., good privacy; fast, reliable delivery) and of client and provider capability (e.g., easy-to-use platform; high quality training) and opportunity (e.g., long delivery hours; dedicated time for delivery).

Client barriers included cost; platform requirements (e.g., smartphone); limited delivery area; and misunderstanding the courier deliverer/pharm tech's role. Pharm techs reported logistical barriers (e.g., delivery delays due to poor road infrastructure). Key recommendations included reducing client costs; expanding delivery area and hours; and establishing alternative delivery options (e.g., package lockers).

Conclusions: Online PrEP/PEP delivery is a promising differentiated service delivery option. Additional implementation strategies should be considered to address identified barriers.

THPEE096

Health care provider experiences after 12 months of implementing cabotegravir long-acting injectable PrEP (CAB LA) for Black women: EBONI study results

Z. Tims-Cook[1], K.L. Nelson[2], H. Kwakwa[3], R. Hsu[4], R.K. Scott[5], A. Dyson[2], N. Badhoniya[6], K. Sutton[2], D. Sutherland-Phillips[2], C. Bonner[7], N. Mack[7], D. Chowdhury[8], M. Aboud[2], P. Budnik[9], K. Brown[2], A. de Ruiter[9], D. Merrill[2], T. Evans[2], M. Czarnogorski[2], N. Pilgrim[2]
[1]Faebris Medical & Community Education, Atlanta, United States, [2]ViiV Healthcare, Durham, United States, [3]Newlands Health, Philadelphia, United States, [4]AIDS Healthcare Foundation, NYU Langone Medical Center, New York City, United States, [5]Medstar Washington Hospital Center, Washington, D.C., United States, [6]GSK, Brentford, United Kingdom, [7]RTI International, Durham, United States, [8]RTI International, Rockville, United States, [9]ViiV Healthcare, London, United Kingdom

Background: Black women (BW) make up ~50% of new HIV diagnoses among women in the US (CDC, 2021). EBONI, the first industry led implementation study evaluating CAB-LA for PrEP in BW among women's health (WH), primary care (PC) and infectious disease (ID) clinics in the US, used a gender aligned approach.

We present health care providers' (HCPs) implementation outcomes and ancillary health benefits after 12 months of CAB-LA use in their clinics.

Methods: From September 2022 to September 2024, 72 staff-study participants (SSPs) (11= WH, 20= PC, 41= ID) from 15 clinics completed surveys on implementing CAB-LA for BW that were analyzed using descriptive statistics. Interviews were completed with SSPs (N=43) at M12.

Results: Most HCPs (55.6%) were cisgender females, 43.1% were Black, and 13.9% were Hispanic, with a mean age of 43.5 years. HCPs rated CAB-LA highly appropriate for BW (mean=4.5/5, SD=0.62), acceptable (mean=4.5/5, SD=0.57), and feasible (mean=4.4/5, SD=0.57).

Clinic capacity to accommodate >25 patients on CAB-LA tripled from BL to M12 (15% vs. 54%) without increasing number of trained staff (4.8 vs. 5.2) or weekly staff time (40.9% vs. 37.5% reporting <=40% FTE).

HCPs reported high use (>50% among clinics with access) of these resources: clinic readiness for CAB-LA checklist, guide for CAB LA initiation and administration, CAB-LA acquisition tracker and CAB-LA injection video. HCPs reported high use of these strategies: using flexible scheduling (e.g. drop-in), training on providing PrEP to BW, partnering with pharmacies to acquire CAB-LA and other medication access supports. Consequently, over 85% of HCPs found implementing CAB-LA into their workflow easy (75%) or "neither easy or difficult" (13%).

HCPs noted benefits of bi-monthly visits for CAB-LA injections, including additional STI screenings (73.2%), screening for comorbidities (46.5%), and providing other health/psychological care (35.2%).

Conclusions: Within a year, clinic capacity to provide CAB-LA tripled without staffing changes. CAB-LA can be seamlessly integrated into various clinics to expand PrEP access for BW by using implementation resources (e.g., clinic assessment tools) and strategies (e.g., flexible appointments). HCPs in WH, PC, and ID clinics found CAB-LA highly suitable for BW, with bi-monthly visits offering ancillary health benefits.

THPEE113

Unveiling disparities through intensified case finding: transformative insights from HIV-TB cascade analysis across 12 states in India

S. Kandaswamy[1], S. Pandey[2], S. Agarwal[3], M. Pancholi[4]
[1]Hindustan Latex Family Planning Promotion Trust, Monitoring and Evaluation, Noida, India, [2]Hindustan Latex Family Planning Promotion Trust, Director, Noida, India, [3]Hindustan Latex Family Planning Promotion Trust, Cheif Executive Officer, Noida, India, [4]Hindustan Latex Family Planning Promotion Trust, Project Lead, Noida, India

Background: Tuberculosis (TB) is the leading cause of mortality among individuals receiving HIV care, with 10.5% of all TB deaths in India attributed to HIV-associated TB. Resource-limited regions face challenges in accessing timely screening and treatment, exacerbating the dual burden of HIV and TB. Project SSHAKTI, under the Global Fund, implemented an intensified case finding (ICF) model across 12 Indian states (Apr-Dec 2024) to enhance TB detection and treatment among individuals diagnosed with HIV.

Methods: A cross-sectional study analyzed data from 82,299 individuals receiving HIV care who were screened for TB at 74 Care and Support Centres (CSCs) across 12 states. Screening efforts were community-led, with peer volunteers playing a vital role in identifying individuals suspected of having TB and ensuring referrals to diagnostic centres for evaluation and treatment. Standard diagnostic protocols were employed to confirm TB cases, including symptom screening, chest X-rays, sputum microscopy, and GeneXpert.

A cascade approach tracked referrals, testing, and anti-TB treatment (ATT) initiation. State-level and demographic data were analyzed using chi-square tests ($p < 0.05$) to assess correlations between TB diagnosis and key factors.

Results: Of 4,232 presumptive cases (5.14%), 96% were tested, and 241 cases (5.93%) were diagnosed as TB-positive. Delhi reported the highest positivity rate (11%), while Uttar Pradesh, with the largest cohort, had a lower positivity rate (3%). Referral adherence was over 97%, with 99% ATT linkage overall, although Bihar showed a 1% gap. Nagaland identified 13% presumptive cases but had a low 46% diagnosis-to-treatment linkage, indicating the need for stronger follow-ups. TB positivity was significantly higher among male adults and children under 15 (chi-square = 12.71, $p = 0.013$). Variability in suspected TB rates, from 1% in Assam to 13% in Nagaland, highlighted disparities in healthcare outreach and infrastructure.

Conclusions: Project SSHAKTI's ICF model effectively scaled TB detection and treatment among PLHIV. Community-led initiatives were instrumental in achieving high referral and testing rates. Addressing systemic barriers in states like Odisha and Sikkim through improved infrastructure, training, and follow-up systems is critical. Investing in predictive modelling, real-time data integration, and tailored interventions can significantly accelerate progress toward HIV-TB elimination.

THPEE114

AI-driven enhancements in PrEP care delivery

M. Blasingame[1], H. Patani[2], G. Palmeri[1], S. Warmuth[1], R. Bastani[1], W. Engeran-Cordova[2], S. Tuyisenge[2]
[1]Healthvana, Los Angeles, United States, [2]AIDS Healthcare Foundation, Los Angeles, United States

Background: Health disparities in HIV prevention persist despite advancements in PrEP (pre-exposure prophylaxis) care. High-needs populations require awareness and access to PrEP, while healthcare systems face resource constraints. To address these challenges, we implemented Healthvana's Conversational AI tool at AIDS Healthcare Foundation (AHF) Wellness Centers, hypothesizing that AI interaction improves client awareness, PrEP initiation, adherence, and retention, while reducing staff workload.

This study evaluates the AI tool's impact on the PrEP Care Continuum, providing actionable insights into its role in advancing public health outcomes.

Methods: We analyzed client interactions with Healthvana's AI tool from January to December 2024. Metrics aligned with the PrEP Care Continuum—awareness, initia-

tion, adherence, and retention—were evaluated. Statistical comparisons were made between AI-interacting and non-interacting cohorts using odds ratios.
Demographic stratification included sex and other demographic variables where available. Specific metrics such as viewed results, appointment completion, and follow up visits were calculated. Staff workload was assessed by monitoring trends in AI-handled versus human-handled messages.
Results: Clients interacting with AI were 2.5 times more likely to view their results (65% vs. 45%, OR=2.3). PrEP initiation rates tripled with AI engagement (17% vs. 6%, OR=3.0). Appointment adherence improved from 58% to 68% with AI reminders opened (OR=1.5). Follow up visit rates doubled (52% vs. 35%, OR=2.0), highlighting improved retention. Demographic analysis revealed consistent benefits across all groups. AI-driven conversations predominantly discussed PrEP (28% of entries), demonstrating high levels of awareness. Staff burden was reduced, with 40% of incoming client messages routed to AI, enabling human resources to focus on complex tasks.
Conclusions: The findings highlight the transformative potential of AI in HIV prevention care. By enhancing client awareness, increasing PrEP initiations, improving adherence, and doubling retention rates, Healthvana's AI tool addresses critical gaps in the PrEP Care Continuum. Furthermore, the tool alleviates healthcare system constraints by reducing staff workload. These results advocate for broader implementation of AI in healthcare to optimize public health outcomes and resource efficiency.

THPEE115

PrEP awareness, offers, and uptake among pregnant women who tested negative for HIV in South Africa

N. Mutanda[1], A. Huber[1], I. Mokhele[1], V. Ntjikelane[1], S. Rosen[1,2], S. Pascoe[1]
[1]Health Economics and Epidemiology Research Office, Wits Health Consortium, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, Johannesburg, South Africa, [2]Boston University, School of Public Health, Massachusetts, United States

Background: Women's risk of contracting HIV increases considerably during and after pregnancy and childbirth. Oral pre-exposure prophylaxis (PrEP) is available to pregnant women in most primary healthcare clinics in South Africa, but access and uptake of PrEP during pregnancy is unclear.
Methods: Between 16/04/2024 and 11/10/2024, we conducted the third round of the AMBIT SENTINEL survey at 24 primary healthcare clinics in Eastern Cape, Kwazulu-Natal, Mpumalanga, and Gauteng provinces of South Africa. Up to 10 adults (ages 18+) seeking HIV testing services (HTS) during antenatal care at each clinic were sequentially enrolled. Participants who tested negative for HIV were asked about their experiences with HTS, including whether they were screened for and offered PrEP, accepted it when offered, and reasons for accepting or rejecting the offer.
Results: 213 (median age 26 years) pregnant women who tested negative for HIV were enrolled. 98% had tested for HIV before the current test, with 64% reporting ≥3 previous tests. 81% were aware of PrEP as a prevention method, with nurses and counsellors being primary sources of information. Only 44% (75/172) had been offered PrEP during their previous negative HIV tests, however. 68% (51/75) had accepted PrEP at the time.
Almost half of the participants (47%, 100/213) reported being asked about HIV transmission risk on the survey day; 31% (66/213) reported that PrEP itself was discussed with them. Of these, 44% (29/66) were offered PrEP and 72% (21/29) of those offered PrEP accepted it. Common reasons for accepting PrEP included protecting themselves and their baby from HIV. Reasons for rejecting PrEP included side effects from previous PrEP use and a preference for other prevention methods like condoms.
Conclusions: PrEP awareness is high among pregnant women testing negative for HIV. Although PrEP is being integrated into routine HTS in antenatal care, a positive step toward HIV prevention, only 14% of ANC clients in this study offered PrEP. Three quarters who were offered it accepted the offer. Enhancing consistency of providers discussing and offering PrEP is essential to improve actual uptake.

THPEE116

High initiation of pre-exposure prophylaxis (PrEP) among clients following STI diagnosis in Mazowe district, Zimbabwe from October 2023 through September 2024

P. Moyo[1], E. Molande[1], J. Murungu[1], S. Nyakuwa[1], G. Gonese[2], B. Makunike[2], C. Hera[2], E. Chidovi[2], T.A. Sola[2], H.J. Cham[3], T. Mharadze[3], K. Thomson[4]
[1]Pangaea Zimbabwe, Harare, Zimbabwe, [2]Zimbabwe Technical Assistance Training & Education Center for Health, Harare, Zimbabwe, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB (DGHT), Harare, Zimbabwe, [4]International Training and Education Center for Health (I-TECH), University of Washington, Washington, United States

Background: Clients testing positive for sexually transmitted diseases (STIs) are at heightened risk of HIV acquisition. Integration of STI screening, HIV testing (HTS), and Pre-Exposure Prophylaxis (PrEP) screening and counselling has potential for identifying and linking at-risk individuals to PrEP. Gaps persist in leveraging STI diagnosis for same-day HTS and PrEP referral and active linkage (connecting and ensuring client gets the service) among STI-positive HIV-negative clients.
Description: From October 2023-September 2024, we trained healthcare workers (HCWs) at 17 HIV supported facilities in an HIV high-incidence district on strengthening HIV testing for clients treated for STIs using the revised Zimbabwe Ministry of Health and Child Care STI register. The register includes a column to document HIV testing information and administration of the PrEP screening tool. All STI clients testing HIV-negative are PrEP eligible under this tool, including other risk factors. Intensive

in-person monthly monitoring support visits to facilities were conducted from April 2024 to ensure implementation with fidelity.

Lessons learned: Intensified in-person monthly monitoring support to facilities on STI register and PrEP screening tool use improved same-day HIV testing and PrEP referral and linkage resulting in a surge in PrEP initiations during the six months of late-implementation (April to September 2024). Out of 6,036 clients who tested positive for STIs from October 2023-September 2024, 4,210 (69.7%) received HIV testing. Of those tested, 4,069 (96%) were HIV-negative (2,212 54% from October-March (early-implementation) and 1,857 (46%) from April-September, realizing a 3.3% positivity rate. All STI clients testing HIV-negative received PrEP counseling, with 1,279 (30.4%) initiating PrEP. Large PrEP initiation gains were made among STI clients specifically. PrEP uptake increased by 124% from 371–832 in early-implementation to late-implementation period.

Conclusions/Next steps: STI diagnosis can serve as an entry point for PrEP counselling, highlighting the importance of integrating PrEP services into STI service delivery. HCW capacitation, support and tailored screening tools can facilitate same-day PrEP counselling among STI-positive HIV negative clients.

Results confirm the importance of optimizing PrEP uptake among STI clients, ultimately reducing HIV incidence in this high-risk group. Adhering to automatic PrEP eligibility for STI-positive clients could further increase coverage in this high-risk group.

THPEE117

Understanding how preferences for self- versus provider-screening of HIV risk are associated with reported behaviors among clients accessing pharmacy-based HIV prevention services

P. Banerjee[1], S.D. Roche[2], V. Omollo[3], T. Kareithi[4], P. Ong'wen[5], L. Juma[3], C. Kiptinness[4], P. Otieno[3], M. Anyona[5], M. Asewe[3], B. Rono[3], E. Gichuru[4], K. Harkey[2], R. C. Malen[2], J. Odoyo[3], A. Meisner[2], D. Were[5], E. Bukusi[3], K. Ngure[6], K. F. Ortblad[2]

[1]University of Washington, Seattle, United States, [2]Fred Hutch Cancer Center, Seattle, United States, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Partners in Health and Research Development, Nairobi, Kenya, [5]Jhpiego, Nairobi, Kenya, [6]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Background: Private community pharmacies often serve as a first access point for sexual and reproductive health products and could be leveraged to identify individuals who could benefit from HIV pre- and post-exposure prophylaxis (PrEP and PEP). We aimed to understand how pharmacy clients' preferences for self- versus provider-screening of HIV risk—the first step of engaging clients in pharmacy-based prevention services—are associated with various reported behaviors.

Methods: In the Pharm PrEP cRCT (NCT05842122)—a 60-pharmacy cluster-randomized controlled trial testing different models of pharmacy PrEP/PEP delivery in Kenya—all interested clients (16+) were screened for PrEP/PEP eligibility, including behaviors associated with HIV risk in the past 6 months and 72 hours. Clients could opt for self- or provider-screening of HIV risk. Clients who opted for self-screening used a portable tablet to select behaviors from a list that providers later reviewed; clients who opted for provider-screening answered questions with a provider in a private room.

We used Chi-square tests to determine if there were any statistically significant ($p<0.05$) differences in the demographics and reported behaviors correlated with HIV risk among clients who opted for self- versus provider-screening.

Results: From June 2023-December 2024, 3,944 clients enrolled among which 46% (1,815/3,944) opted for self-screening. Compared to clients who opted for provider-screening, a significantly greater proportion of those who opted for self-screening were female (48% vs. 44%) and in school (25% vs. 18%). Almost all reported behaviors associated with HIV risk in the past 6 months were significantly more prevalent among clients who opted for self- vs. provider screening, with some of the largest differences being in reported inconsistent condom use (81% vs. 59%), multiple sexual partners (55% vs. 42%), and engagement in transactional sex (15% vs. 5%).

There were no significant differences in reported behaviors associated with HIV risk in the past 72 hours between clients who opted for self- vs. provider-screening.

Conclusions: Self-screening of HIV risk offers a client-centered approach to enhance PrEP/PEP delivery, accommodating diverse disclosure preferences and encouraging open reporting of behaviors. Integrating a self-screening option into pharmacy-based HIV prevention programs could increase engagement and efficiency.

THPEE118

Implementation considerations for long-acting injectable PrEP rollout among female sex workers in South Africa: a qualitative analysis guided by the Consolidated Framework for Implementation Research

E. McNeilly[1], C. Comins[2], V. Chen[2], C. Singh[3], N. Dladla[3], N. Matenjwa[3], A. Abdulrahman[2], J. Steingo[3], M. Mcingana[3], J.G. Rosen[4,5,6], A. Rao[2], S. Baral[2], S. Schwartz[2], H. Hausler[3,7], K. Rucinski[1]

[1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]TB HIV Care, Cape Town, South Africa, [4]Brown University Warren Alpert Medical School, Medicine, Providence, United States, [5]Rhode Island Hospital, General Internal Medicine, Providence, United States, [6]Brown University School of Public Health, Epidemiology, Providence, United States, [7]University of Pretoria, Family Medicine, Pretoria, South Africa

Background: Female sex workers (FSW) in South Africa are disproportionately impacted by HIV, and daily oral PrEP initiation and continuation rates remain low. Long-acting injectable PrEP (LAI-PrEP) may alleviate adherence challenges associated with oral PrEP; however, LAI-PrEP

remains largely unavailable in South Africa. Exploring the contextual determinants of LAI-PrEP's implementation among FSW is essential before national rollout.

Methods: In May-June 2024, 44 adult FSW not living with HIV and served from two TB HIV Care FSW program sites, eThekwini and Ehlanzeni, participated in in-depth interviews (n=24) and focus group discussions (n=2).

Additional interviews were conducted with providers (n=4). Semi-structured guides, based on the Consolidated Framework for Implementation (CFIR) 2.0, elicited multilevel implementation determinants, including implementer and FSW contexts—mapped to CFIR domains and constructs through team-based, deductive thematic analysis.

Results: We identified LAI-PrEP implementation determinants across all five CFIR domains (Figure). Many FSW expressed LAI-PrEP needs and demand, citing advantages over oral PrEP such as greater privacy and reduced stress attributed to daily pill-taking. Many FSW suggested bundling other health services (e.g., family planning, STI testing), using mobile vans for delivery, and proactively communicating potential side effects to enhance LAI-PrEP's accessibility and acceptability.

Providers emphasized concerns about local conditions (e.g., supply chain), cold chain maintenance, training requirements, and overburdened staff, but highlighted the need for LAI-PrEP and its compatibility with their existing HIV prevention services.

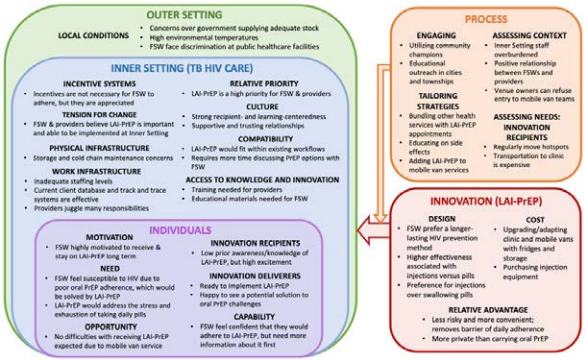

Figure. Key themes identified from IDIs and FGDs with FSWs and providers mapped to CFIR domains and constructs.

Conclusions: Findings demonstrate LAI-PrEP's potential to improve FSW health and well-being by circumventing onerous daily pill burdens. These results also provide insights into strategies to overcome potential barriers such as the need for integration with other health services, education, and program site infrastructure modifications.

Characterizing key implementation determinants within a large FSW program in South Africa can guide the tailoring of delivery strategies to optimize both the effectiveness and equity of LAI-PrEP rollout in South Africa.

THPEE119

Staying on PrEP: what matters most – delivery channel, cost, and quality of outreach

D. Kumar[1], V. Armugam[1], R. Kumar[1], S.C. Ghosh[1], J.H. Thakker[2], R.S. Baba[2], A.K. Reddy[2], A. Singh[2], A.K. Srikrishnan[1], S. Mehta[3], S. Solomon[2]

[1]YR Gaitonde Center for AIDS Research and Education (YRGCARE), India, Chennai, India, [2]Johns Hopkins University School of Medicine, Infectious Disease, Baltimore, United States, [3]The Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: In 2021, India's National Program in India released the Technical Guidelines for PrEP, outlining various delivery modes. The PEPFAR-USAID-funded Project ACCELERATE implemented several channels for delivering PrEP, including clinic-based services for trans individuals, community site-based delivery, an online platform based, outreach via dating and social media apps, and helpdesk models. Both free and subsidized PrEP options were provided, with costs of less than 7 USD/bottle of Tenofovir alafenamide fumarate and 10 USD/bottle of Tenofovir disoproxil fumarate.

Methods: Eligible clients, as per National Guidelines, were recruited across various delivery modes. Online consultations and necessary diagnostic tests were conducted prior to PrEP dispensing. Counseling services, both at trans-clinics and online, were provided to support PrEP literacy, retention and safe sex practices. Data collected through the online platform (www.safezindagi.in) during September 2021- September 2024 was analysed to understand client preferences regarding delivery channel, cost and quality of outreach.

Univariate analysis was used to examine the association between outreach source and PrEP initiation and retention. Cox regression survival analysis assessed retention levels.

Results: A total of 3,640 participants were enrolled, with a median age of 28 years. Of these, 60.9% were male, 18.4% female, and 20.7% transgender, while 49.3% were MSM, and 16.7% were serodiscordant couples.

Among 98.3% eligible PrEP clients, 92.7% initiated PrEP and 53% remained on PrEP for over six months. PrEP continuation rates were 86%, 67% and 42% at 1, 3, and 6 months, respectively (X^2=408.41, p<0.001). Of MSM clients, 32.4% registered by self through the online platform, and 46% via social media/dating apps.

Among serodiscordant couples, 46.6% preferred picking up PrEP from a community site. Additionally, 88.7% preferred subsidized PrEP through self-registration and community site pick-up. Of paid PrEP users, 55.6% continued for more than six months, compared to 43.3% of those using free PrEP.

Conclusions: Online PrEP delivery and pick-up from community sites, combined with subsidized PrEP options are highly acceptable and likely to enrol new users. Outreach via virtual counselors is particularly effective in improving both retention and initiation.

These findings provide valuable insights for scaling up PrEP with multiple delivery options, ensuring broader access and adherence.

THPEE120

Retention patterns of clients on long-acting injectable cabotegravir (CAB-LA) and oral pre-exposure prophylaxis (PrEP) in Zambia: a comparative analysis

A.P. Ndhlovu[1], J. Musangulule[1], L. Cicciò[1], L. Kawanga[1], M. Nyumbu[1], S. Hartchard[1], M. Musonda[2], D. Mwamba[2], J. Posner[3]

[1]John Snow Inc, USAID District Coverage of Health Services, Lusaka, Zambia, [2]United States Embassy/Zambia Mission, Lusaka, Zambia, [3]John Snow Inc, Boston, United States

Background: Long-acting cabotegravir (CAB-LA) represents a significant advancement in HIV prevention, offering an alternative to oral pre-exposure prophylaxis (PrEP). USAID DISCOVER-Health, implemented by JSI, implements both CAB-LA and oral PrEP in Zambia.

This analysis compares continuity rates between both sets of clients, providing insights into the performance of CAB-LA.

Description: This retrospective cohort analysis evaluated retention rates for clients initiated on CAB-LA and oral PrEP at six health facilities in Kitwe and Chibombo districts. CAB-LA clients initiated from February to November 2024, including those transitioning from oral PrEP, were monitored at subsequent injection intervals of 1,2,3,5,7 and 9 months from initiation. Those initiated on oral PrEP at the same facilities in the past 18 months were monitored at their subsequent drug refills at 1,3,6 and 9 months from initiation. Continuity was measured as the proportion of clients who attended their scheduled visits at the specified time points relative to the total number expected to attend, based on the elapsed time since initiation.

Lessons learned: By November 2024, 1,470 clients had received CAB-LA (females 60%; median age 29 years), while 6,399 were initiated on oral PrEP (females 57%; median age 27 years). For CAB-LA clients' continuity: 79% were still on treatment at 1 month; 63% at 3 months; 47% at 5 months; 28% at 7 months, 10% at 9 months. For oral PrEP clients continuity; 53% at 1 month; 42% at 3 months; 30% at 6 months, 9% at 9 months.

Conclusions/Next steps: CAB-LA seems to have better continuity rates in the early stages when compared to oral PrEP, however those rates become similar after 9 months from initiation. Although, further data and monitoring at follow-up points are required to corroborate these findings and tailor strategies for retention to both prevention methods.

THPEE121

HIV self-test kit implementation in community PrEP program reduces human resources and PrEP's waiting list

M. Meulbroek[1], F. Pérez Tejera[1], A. Dalmau-Bueno[1], À. Rivero[2,3], J. Saz[1], J. Fernández[2,3], J.M. Cabrera[2,3], H. Taboada[1], J. Reguant[2,3], M. Łucejko[2,3], J. Calderon[2,3], A. Mendoza[2,3], F. Cabellero[2,3], A. Brusov[1], J. Bosch[2,3], G. Marazzi[1], E. Muñoz[1], C. Espinoza[1], D.M. Jacobs[1], G. Ferrer[1], I. López[1], L. Barrios[1], M. Artacho[1], W. Roa[1], J. Puig[2], E. Negredo[2], R. Mansilla[4], J. Colom[4], F. Pujol[1]

[1]Projecte dels NOMS-Hispanosida, Barcelona, Spain, [2]Hospital Germans Trias i Pujol, Badalona, Spain, [3]BCN Checkpoint, Barcelona, Spain, [4]Departament de Salut, Catalunya, Barcelona, Spain

Background: Barriers of access to PrEP created long waiting lists in Spain since its approval at the end of 2019. One of the reasons were three-monthly check-up visits and the lack of budget for Health Care Personnel (HCP). The community clinic BCN Checkpoint for MSM and Transgender Women studied the feasibility of implementation of HIV self-test kits every six months to reduce yearly visits with HCP.

Description: Inclusion criteria:

1. <50 years;
2. >1 year on PrEP with quarterly check-ups;
3. FG >70 in last two tests;
4. Good adherence; and
5. Agree to replace one biannual blood test for an HIV self-test.

PrEP participants were then invited for a "PrEP express-visit", which included an HIV self-test kit, self-sampling for other STIs and medication. Photo of HIV result was sent by e-mail to the nurse team for control and archive. Before implementation an acceptability survey was performed. From April 2021 till December 2024 data were collected from Standard and Express visits, average time of both visits, labor and material costs, reduction of the waiting list and costs of HIV self-test kits.

Lessons learned: Of the acceptability study 80.4% of participants expressed the HIV self-test was easy to perform and 92.9% easy to interpretate. A total of 43,532 HIV tests were performed to 4,937 persons during the study period and 2,810 persons received a "PrEP express-visit" (56.9%) with a total of 11,247 (25.8%) visits (allowing 9,471 additional visits compared to no-implementation).

Given the limited human and infra-structural resources, the implementation of the HIV self-test has provided slots for more check-up visits to an accumulated number of 820 persons, which represented an increase of 30.1% of capacity at the last quarter of the study period.

Although new PrEP users came partly from those falling out of the program, the majority were incorporated due to implementation of HIV self-test kits.

Conclusions/Next steps: The introduction and implementation of HIV self-test kits in the PrEP program of the community clinic has shown a high level of user's acceptability, has achieved reduction of the waiting list and improve PrEP access to more persons at risk, and less workload for HCP.

THPEE122

Insights from 6 Years of oral PrEP in Brazil: who are we missing in the path?

B. Brittes Kamiensky[1], T. Benoliel Rocha[2], T. Cherem Morelli[2], F.A. Paula de França[2], M. Camelo Madeira de Moura[1], I. Ornelas Pereira[1], J. Boullosa Alonso Neto[1], A. Olhovetchi Kalichman[1], D. Barreira Cravo Neto[1]
[1]Ministry of Health of Brazil, Department of Surveillance of HIV, Tuberculosis, Viral Hepatitis and Sexually Transmitted Infections, Brasilia, Brazil, [2]Ministry of Health of Brazil, Brasilia, Brazil

Background: Oral HIV prevention (PrEP) with tenofovir/emtricitabine (TDF/FTC) has been available in Brazil, free of charge, through the public health system (SUS) since 2018. It can be prescribed for individuals aged 15 or older and weighing ≥ 35 kg at substantial risk of HIV. High rates of PrEP discontinuation have been observed in Brazil.
Our objective was to estimate and describe the factors associated with PrEP discontinuation.
Methods: National data from Drug Logistic Control System (SICLOM) for the years 2018 to 2023 were analyzed. Discontinuation was defined as having at least one dispensation in the last 12 months but without a valid dispensation (pills dispensed plus 40%) on the database closure date for that year. A binary logistic regression model identified sociodemographic factors associated with discontinuation. Significant predictors were selected through stepwise analysis (p-value inclusion <0.05), and odds ratios (OR) were calculated to assess their associations with discontinuation.
Results: Of 149,023 PrEP users, 76% were MSM, 9.53% cisgender women, 63% aged 25–39, and 66% had over 12 years of education. By 2023, 48.3% discontinued PrEP. Figure 1 highlights the probability of discontinuation was higher among cisgender women, individuals with lower education, and residents of the North region. Older individuals were progressively less likely to discontinue PrEP compared to younger users.
Notably, individuals with unregistered or ignored education levels were 17 times more likely to discontinue compared to those with >12 years of education (OR: 17.3, 95% CI: 4.0–75.1).

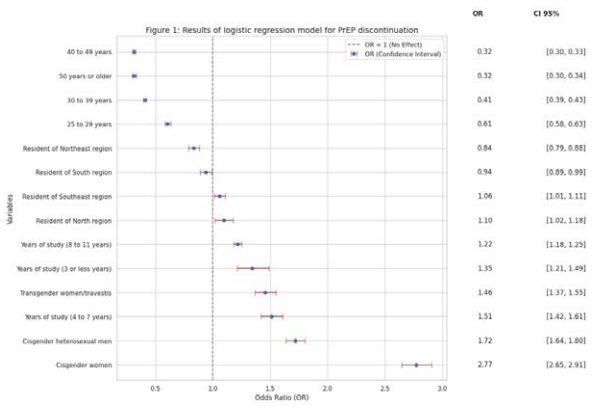

Figure 1.

Conclusions: Identifying the profile of PrEP users who discontinue is necessary for targeted interventions to support PrEP use. Barriers such as stigma and socio-economic challenges remain, particularly for the most vulnerable groups. Providing access to tailored HIV prevention strategies that address specific needs and circumstances is essential. Injectable PrEP could be a viable option, and further investigations should explore the feasibility of alternative PrEP modalities.

Implementation research to scale up treatment

THPEE123

Favorable impact of community ART dispensation on reintegration into care, retention, interruption in treatment and viral load suppression among persons with HIV in Zambézia Province, Mozambique (June 2021–September 2023)

J.A. Tique[1], C. Belo[1], Z. Yu[2], C. Cabsela[1], E. Graves[3], J. Matsimbe[1], E. Ntasis[1], G. Amorim[2], C.W. Wester[4], C.M. Audet[5], C. De Schacht[1]
[1]Centro pela Saúde Global (C-Saúde), Maputo, Mozambique, [2]Vanderbilt University Medical Center, Department of Biostatistics, Nashville, United States, [3]Vanderbilt Institute for Global Health, Nashville, United States, [4]Vanderbilt University Medical Center, Department of Medicine, Nashville, United States, [5]Vanderbilt University Medical Center, Department of Health Policy, Nashville, United States

Background: Community antiretroviral therapy dispensation (cARTd) was introduced in Mozambique during the COVID-19 pandemic to minimize interruptions in treatment. Clinical officers and community volunteers were trained to dispense ART at clients' homes, provide adherence counseling, and guide clients to return to health facilities (HF). We evaluated cARTd's impact on reintegration into HIV care, retention in care, interruption in treatment (IIT), and viral load suppression (VLS) in Zambézia Province.
Methods: We conducted a retrospective cohort analysis using data extracted from electronic medical records in all 68 HF where cARTd is being implemented in Zambézia Province (June 2021–September 2023). We compared cARTd-eligible clients (missed scheduled appointments by 7–59 days) that received cARTd to non-recipients (clients not being visited). Outcomes were: time to first ART dispensation post-eligibility (T1), time from last scheduled pick-up after first ART dispensation post-eligibility until return to HF (T2), retention in care (having an ART dispensation <60 days after last scheduled date), IIT (missing a scheduled appointment by >59 days), and VLS (<1,000 copies/mL) rates. Descriptive statistics and multivariable regression models adjusted for demographic and clinical factors were used to evaluate cARTd effect.
Results: Compared to non-cARTd recipients (n=101790; 41.7%), cARTd recipients (n=142,371; 58.3%) were older (mean age 34.1 vs. 32.0 years), more often male (39.0% vs. 27.1%), and resided in rural locales (80.2% vs. 78.1%).

In the 12 months before eligibility, cARTd recipients had a higher proportion of IIT (31.5% vs 17.4%) and similar viral suppression rates (88.0% vs 88.8%), compared to non-recipients. T1 (32 vs. 34 days; Hazard Ratio[HR]=1.06, p<0.001), and T2 (-10 vs. -5 days; HR=1.14, p<0.001) were shorter for cARTd recipients. During the first-year post-return, IIT decreased (21.8% vs. 11.2%), retention rates were higher (79.7% vs. 76.1%; odds ratio[OR]=1.2, p<0.001), and VLS rates remained slightly lower among cARTd recipients (90.5% vs. 94.5%; OR=0.5, p<0.001).

Conclusions: Prior to eligibility, cARTd recipients had more interruptions in therapy. Post-cARTd, they returned faster to HF, had better retention and comparable VLS rates compared to non-recipients. Community participatory approaches/models may improve HIV-related health outcomes, particularly during crises (e.g., pandemics, major climate-related events), when access to care is further constrained.

THPEE124

Towards client-centered HIV care for older adults: a study of preferences and unmet needs in Uganda

A. Lawino[1], N. Kasunumba[1], I. Ddumba[2], S. Namukose[1], O. Apok[1], P. Erem[1], T. Nsubuga Nyombi[2], A. Angwech[1], M. Bernard Etukoit[1], J. Calnan[2]

[1]The AIDS Support Organization, Health, Gulu, Uganda, [2]USAID, Health and HIV, Kampala, Uganda

Background: With the scale-up of antiretroviral therapy (ART), the population of older adults living with HIV (PLHIV) continues to grow. In Uganda, the healthcare system is challenged to adapt its service delivery models to address the unique needs of PLHIV aged 65 and above.

This study assessed the preferred differentiated service delivery (DSD) models, unmet health needs, and their association with clinical outcomes to guide client-centered care model design.

Methods: A cross-sectional study was conducted from July to September 2023 across 47 public health facilities in Northern Uganda, involving 1,173 PLHIV aged 65 years and older. Structured interviews captured demographics, DSD model preferences, health needs, and barriers to care.

Clinical outcomes, including ART adherence and viral suppression, were extracted from electronic medical records. Descriptive and inferential analyses were performed to identify trends and associations.

Results: Participants were predominantly aged 65–69 (51%), female (62%), widowed (48%), and rural residents (72%). While 84% were enrolled in their preferred DSD models, Community Drug Distribution Points (CDDP) were the most preferred (52%), followed by Fast Track Drug Refill (FTDR, 29%), Community Client-Led ART Delivery (CCLAD, 8%), and Facility-Based Individual Management (FBIM, 8%). Among participants not enrolled in their preferred models, CDDP was the top alternative (66%), followed by CCLAD (12%) and home-based services (12%). Mobility limitations, sensory impairments, and co-morbidities such as hypertension and arthritis influenced preferences. Unmet health needs, reported by 17% of participants, primarily related to hypertension, chronic pain, and sensory impairments. Barriers to ART adherence, reported by 16%, included food insecurity, forgetfulness, and limited transportation access. Furthermore, 26% of participants reported insufficient information on coping with aging and chronic conditions. Despite 90% achieving viral suppression, adherence challenges were linked to unmet needs and misalignment with preferred DSD models.

Conclusions: The findings highlight the need for tailored HIV care models for older adults living with HIV, integrating services for co-morbidities and addressing logistical barriers. Community-centered and home-based DSD models show promise for improving satisfaction and health outcomes. Adapting Uganda's healthcare delivery framework to the unique needs of aging PLHIV will enhance care quality and equity for this growing population.

THPEE125

Integrated mobile health intervention to improve medication adherence and outcomes among people living with HIV/AIDS and co-infected with tuberculosis at care centers in parts of South-Eastern Nigeria

U. Chukwuocha[1], C. Osuoha[1]

[1]Federal University of Technology, Public Health, Owerri, Nigeria

Background: Medication adherence is critical for achieving optimal treatment outcomes in people living with HIV/AIDS co-infected with tuberculosis (TB). Poor adherence increases the risks of treatment failure, drug resistance, and mortality. Mobile health (mHealth) technologies has shown promising solutions to improve adherence by leveraging tools such as SMS reminders, phone calls, and video support and this stresses the need to evaluate the effectiveness of an integrated mHealth intervention in improving medication adherence and clinical outcomes.

This study aimed to determine the effectiveness of an integrated mobile health intervention to improve medication adherence among People Living with HIV/AIDS and co-infected with Tuberculosis at Care Centers in South-Eastern Nigeria.

Methods: About 700 consenting male and female participants were randomly slected from three care centers in Imo State, South-Eastern Nigeria for the study. They were further randomized into five groups: SMS, Telephone call, Video, Integrated mHealth which involved simultaneous utilization of SMS, Telephone call and Video, as well as the Control group without any mhealth intervention but the usual clinical practice.

The intervention included medication reminders, adherence monitoring, and appointment notifications tailored to the group assignment. Data on medication adherence were collected at baseline and six months post-intervention using validated scales and questionnaires.

Outcomes such as CD4 counts, Viral load, and body mass index (BMI) were determined using standard methods. Statistical analyses included Chi-square tests, logistic regression, and multivariate analyses.

Results: Of the 646 participants evaluated at baseline, 618 completed the study. Post-intervention medication adherence improved significantly across all mHealth groups, with the integrated mHealth group showing the highest adherence (baseline: 65.1%; post-intervention: 76.2%, p<0.0001).
Appointment adherence also increased notably in the integrated mHealth group (baseline: 19.4%; post-intervention: 83.4%). Viral load suppression was significant (mean: 3922.2 to 386.6 copies/mL, p<0.0001), with improvements in CD4 counts and body mass index (BMI).
Conclusions: Integrated mHealth interventions significantly enhanced medication adherence and clinical outcomes in HIV/AIDS-TB co-infected individuals.
This study demonstrates the need for combining multiple mHealth tools for comprehensive care, offering evidence for policy implementation and future scaling in resource-limited settings.

THPEE126

Institutionalization of Quality Improvement projects to improve ART service delivery in Rwanda

I. Angeline[1,2]
[1]ICAP Global Health/Rwanda Program, HIV, Kigali, Rwanda, [2]Rwanda Biomedical Center, HIV/AIDS Disease Prevention and Control, Kigali, Rwanda

Background: The Rwanda Health Sector Strategic Plan IV prioritizes the institutionalization of Quality Improvement (QI) to enhance the quality of healthcare service delivery. QI has been instrumental in advancing HIV care and treatment in Rwanda. Since September 2022, the Rwanda Biomedical Center (RBC), with ICAP's technical support, initiated implementation of a national QI system within the HIV program.
This abstract presents strategies, outcomes, and lessons learned from QI implementation at 10 high-volume health facilities (>1000 PLHIV in care) across Rwanda, focusing on client enrollment in less-intensive model (LIM) to enhance Differentiated Service Delivery (DSD).
Description: Since 2022, ICAP supported RBC to scale-up QI program across 109 HFs using Plan-Do-Study-Act model to enhance ART service delivery. At the 10 targeted HFs barriers to quality ART service delivery included high staff workloads, incomplete viral load (VL) documentation, client readiness issues, and inadequate adherence support, which hindered effective client categorization into DSD.
To address the gaps, interventions included establishing QI teams, reorganizing workflows, improving VL documentation and monitoring, providing targeted training and mentorships on DSD flowcharts, and strengthening adherence counseling.
These strategies aimed at systematically improving ART services delivery, ensure client consent, increase client enrollment in LIM, and improve VL suppression.
Lessons learned: The initiative demonstrated that implementing the QI program improved healthcare outcomes. Client enrollment in the LIM increased from 35% at baseline in July 2022 to 88% after 18 months, surpassing the national standard of 85%. Strategic interventions, including establishing QI teams, enhanced data management and visualization, mentorships and customized training, experience-sharing platforms, optimized work organization, setting self-driven targets, and continuous monitoring, proved instrumental in addressing site-specific challenges and driving performance improvements. It also highlighted the value of data-driven, decision-making and stakeholder engagement in achieving sustainable results.
Conclusions/Next steps: Adopting QI processes enhanced the quality of differentiated ART service delivery, strengthened client-centered care, and improved enrollment in differentiated ART delivery models.
Establishment of QI committees fostered a culture of continuous improvement, enabling early problem identification and timely response.
Leveraging successful projects as models for broader applications offers valuable insights and frameworks for scaling up QI initiatives across the healthcare continuum.

THPEE127

Welcome back package: supporting people living with HIV in reengaging with care in Mozambique

R. Mussane[1], M. Barrios[1], P. Luvrencio[1], F. De Bock[1], L. Vilanculos[2], E. Paunde[3], J. Sabado[2], A. Flores[4], P. Isaakidis[4]
[1]Médecins Sans Frontières (MSF), Beira, Mozambique, [2]Munhava Health Center, Beira, Mozambique, [3]National HIV/AIDS Program (PNC ITS-HIV/SIDA), Ministério da Saúde (MISAU), Maputo, Mozambique, [4]Médecins Sans Frontières (MSF), Cape Town, South Africa

Background: Negative attitudes and behaviours among healthcare staff, such as rude and judgmental treatment, are significant barriers to HIV care engagement in Mozambique. Fear of mistreatment often discourages clients from returning to care, leading them to seek services elsewhere, which exacerbates the crisis in HIV care continuity.
To address these challenges, MSF implemented the Welcome Back Package (WBP) in Beira, Mozambique, to support PLHIV facing difficulties with adherence, retention, and re-engagement. The WBP aims to equip healthcare workers with the skills and attitudes to provide non-judgmental, supportive care, foster trust and encourage PLHIV to resume treatment.
Description: The WBP pilot was launched in May 2022 at Munhava Health Center (HC). It consists of three key components:
1. Triage/Identification,
2. Patient Support, and;
3. Clinical Management.
The program targeted disengaged individuals and a diverse range of healthcare. Core activities focused on transforming attitudes through training, collaboration, strengthening reintegration processes, and conducting client satisfaction surveys.
Lessons learned: The WBP has re-engaged around 141 individuals in care by 2024, contributing to increase the number of active ART clients in this HC. During the pilot

implemented in 2022, there was an increase of 32.4% of increased in active ART clients and a 70.2% reduction in LTFU compared to the previous year.

A notable cultural shift emerged among healthcare workers, who began to recognize and acknowledge their previous limited understanding of PLHIV. This transformation was mirrored by HIV care recipients.

In turn, patients advocated for the program, recommending its expansion to other HCs and attesting to its role in reducing fear, foster trust, and encourage return to care.

The WBP's impact extends beyond individual stories, enhancing PLHIVs' care and satisfaction, attracting the attention of national-level stakeholders.

Conclusions/Next steps: The WBP program highlights the importance of supportive, person-centred approaches in addressing barriers to HIV care retention. Its success has gained traction from Mozambique's National HIV Program, with plans of nationwide scaling.

A (comprehensive) toolkit is being developeed to guide implementation, training, and monitoring efforts. The WBP pilot illustrates the potential for broader adoption in high-burden HIV settings, offering a humane and impactful approach, ultimately improving HIV care.

Global and national financing, economic evaluation and sustainability

Shifting dynamics and expenditure patterns of HIV and AIDS funding in Lagos State: a description of trends and variations across different funding sources (2018-2023)

O.T. Ogungbade[1], A. Adesina[2], M. Okeneye[2], F.B. Animashaun[3], O. Fisher[4], C. Umeh[5], M. Omololuoye[6], B. Ochonye[7], K. Green[8], O. Durosinmi-Etti[9], O. Kanu-Oji[10], J.P. Mbah[11], O. Adegbite[12], D. Ogundehin[13], O. Igboelina[13]

[1]West Africa Center for Public Health and Development (WACPHD), an affiliate of the Institute of Global Public Health, University of Manitoba, Winnipeg, Canada, Strategic Information, Ikeja, Nigeria, [2]John Snow Research and Training Institute (JSI), Private and Private Partnership, Ikeja, Nigeria, [3]Lagos State Agency for the Control of AIDS (LSACA), Chief Executive Officer, Ikeja, Nigeria, [4]Lagos State Agency for the Control of AIDS (LSACA), Project Director, Ikeja, Nigeria, [5]Heartland Alliance LTD/GTE (HALG), Chief of Party, ACE6 Project, Ikeja, Nigeria, [6]Heartland Alliance LTD/GTE (HALG), Technical Director/Deputy Chief of Party, ACE6 Project, Ikeja, Nigeria, [7]Heartland Alliance LTD/GTE (HALG), Chief Executive Officer, Ikeja, Nigeria, [8]West Africa Center for Public Health and Development (WACPHD), an affiliate of the Institute of Global Public Health, University of Manitoba, Winnipeg, Canada, Country Director, Abuja, Nigeria, [9]John Snow Research and Training Institute (JSI), Private and Private Partnership, Abuja, Nigeria, [10]Heartland Alliance LTD/GTE (HALG), Director of Strategic Information, ACE6 Project, Ikeja, Nigeria, [11]Heartland Alliance LTD/GTE (HALG), Associate Director – PCT, ACE6 Project, Ikeja, Nigeria, [12]Heartland Alliance LTD/GTE (HALG), M&E Manager, ACE6 Project, Ikeja, Nigeria, [13]USAID, HIV/AIDS, Abuja, Nigeria

Background: Despite global health efforts, major gaps persist in the fight against HIV/AIDS, especially in resource-limited settings such as Lagos State, Nigeria. Achieving the UNAIDS 95-95-95 goals for 2025 and SDG-3 by 2030 may increasingly become uncertain for the State in the face of perennial healthcare challenges.

This study assessed trends in public funding, evaluated funding contributions for care and treatment, and determined private sector involvement in HIV/AIDS programmes in Lagos State from 2018 to 2023.

Methods: The study used a retrospective assessment of HIV and AIDS funding in Lagos State from 2018 to 2023, employing the State AIDS Spending Assessment (SASA) system. Data collection involved both top-down and bottom-up approaches, capturing financial flows from sources to service providers. The top-down approach used donor and government reports, while the bottom-up approach gathered data from service providers. A new aspect was the inclusion of out-of-pocket expenses. Data was collected from policy documents, budgetary information, and stakeholders, using an adapted SASA questionnaire. Validation occurred in three stages, ensuring accuracy through verification, institutional review, and stakeholder feedback.

Results: The analysis of HIV and AIDS expenditure in Lagos State from 2018 to 2023 revealed notable disparities among funding sources. International contributions ranged from 74.69% in 2018 to 86.95% in 2023. Public contributions declined from 24.95% in 2018 to 12.34% in 2023, and private funding peaked at 1.57% in 2021 and was as low as 0.12% in 2019. Out-of-pocket expenditure was introduced in 2022 (0.1%) and increased slightly in 2023 (0.2%). In care and treatment, international sources provided 47.53%, public (1.06%), and private (9.59%). Human resource funding comprised 78.66% public, 7.7% international, and 35.29% private. Prevention funding was 14.22% international, 32.95% private, and 3.96% public. Programme management was funded 11.97% internationally, 15.89% publicly, and 14.51% privately.
Overall, international funds accounted for 78.69%, public for 20.61%, and private for 0.69% of total expenditure.
Conclusions: The study highlighted the critical need for sustainable HIV/AIDS financing in Lagos State by increasing domestic resource mobilization, fostering private sector engagement, and enhancing public investment in direct care and treatment while reducing reliance on international aid through integrating HIV services into broader health systems.

THPEE130

Market shaping and innovative financing for sustained dual HIV/syphilis rapid diagnostic tests commodity procurement

A.T. Bashorun[1], O. Fasawe[2], O.A. Ijaodola[1], M. Mobolaji-Bello[1], C. Nwafor[2], L. Bwala[2], E. Neenwi[2], A. Storey[3]
[1]National AIDS, STI and Viral Hepatitis Control Programme, Abuja, Nigeria, [2]Clinton Health Access Initiative, Abuja, Nigeria, [3]Clinton Health Access Initiative, Boston, United States

Background: Over 8 million pregnancies occur annually in Nigeria and antenatal care coverage is 64%. HIV and syphilis prevalence in ANC is 1.4% and 0.7% respectively. Adequate and consistent supply of diagnostic and treatment commodities is key to achieving the UNAIDS 95-95-95 cascade targets. In 2019, the WHO updated the HTS Consolidated Guidelines, releasing a policy brief recommending the use of the dual HIV/syphilis test within ANC settings. Despite WHO's recommendation, country-level adoption was limited as the only available WHO-prequalified supplier was 45% more expensive than the existing first line global funded procured single HIV RDT. With dwindling donor resources, securing government and partner resources for large scale procurement of the more expensive dual RDTs was hindering scale up.
Description: CHAI commenced market shaping efforts to attain significant price reduction for the dual HIV/syphilis RDTs by supporting additional manufacturers from India and South Korea to complete WHO-PQ. CHAI's business case culminated in a volume guarantee facilitated by MedAccess UK with one of the suppliers, reducing the price of dual HIV/syphilis RDTs for public procurement at $0.95, from $1.50 previously.
Lessons learned: Three dual HIV/syphilis RDT manufacturers have achieved WHO-PQ. increased competition within the dual HIV/syphilis RDT market, coupled with significant price reductions realized a 36% cost saving when compared to procurement of single RDTs for both diseases. The Government of Nigeria, through state and donor resources, has sustained large volume procurement of the dual HIV/syphilis RDT with 4.2 million tests procured in 2021, 1.08 million in 2022, 4.4 million 2023 and 4.3 million in 2024.
Conclusions/Next steps: Continued market intelligence and visibility into the dual HIV/syphilis RDT market enabled MOH and partners to make cost-effective financing decisions for large volume procurements.
Lessons learned from this successful market shaping endeavor will remain crucial as more countries continue to adopt and roll out emerging diagnostic solutions.

Health systems, health systems strengthening and partnerships

THPEE131

Resilience of HIV services in the face of climate-related disasters: assessing system readiness and community adaptation in Kigoma, Tanzania

C. Komba[1], N. Nacopha[2]
[1]Network of Young People Living with HIV, Young Engagement, Dar Es Salaam, Tanzania, the United Republic of, [2]National Council of People Living with HIV, Young Engagement, Dar es Salaam, The United Republic of Tanzania

Background: Tanzania has experienced increasing climate-related disasters, including floods and landslides, particularly between December 2023 and June 2024. Kigoma, located along Lake Tanganyika's eastern shore, is one of the most affected regions, with recurring floods disrupting health services, livelihoods, and infrastructure.
These disasters disproportionately affect adolescents and young people, particularly those living with HIV, by hindering access to essential HIV prevention and treatment services.
Methods: A mixed-methods approach was employed to assess system readiness and resilience in Kigoma. Ten young people were trained to understand the purpose of the research, the data collection tools, and the data collection processes. Each enumerator collected data from at least 30 respondents over two weeks. Quantitative data were collected from 367 respondents, including people living with HIV (PLHIV), non-PLHIV community members, and healthcare providers.
Additionally, qualitative data were gathered through eight focus group discussions with 10 participants in each group, involving PLHIV, non-PLHIV, healthcare workers, and local government authorities. Desk reviews of na-

tional frameworks complemented the primary data collection. The findings were validated through stakeholder consultations.

Results: The study revealed that most respondents lacked awareness of strategies, laws, or disaster preparedness mechanisms related to HIV service continuity. Government and agency assistance during disasters was minimal, leaving communities unprepared to handle the health challenges that arose. A significant proportion of respondents experienced severe health challenges, including disruptions in medication adherence. Among PLHIV surveyed, 53% failed to access ART refills during the disaster period, leading to deteriorated health outcomes. Of those who missed ART refills, 67% experienced an increase in their viral load, moving from undetectable to detectable levels.

Conclusions: Climate-related disasters significantly threaten the continuity of HIV services in Kigoma. This emphasizes the need for urgent action to integrate HIV service continuity strategies into national disaster preparedness frameworks. Enhancing community-led initiatives and strengthening health system capacities is crucial to mitigating future disruptions. These findings will inform advocacy efforts and policy development to ensure sustained access to HIV services during disasters.

THPEE132

Transitioning adolescents and young people living with HIV to adult care through rolling out a transition tool checklist: experiences from Zimbabwe in 2024

A. Sellberg[1], N. Willis[1], V. Chitiyo[1], M. Kapurura[1], T.B. Guri[1], S. Masaila[1], P. Mugobheri[1], R. Matewe[2], A. Ingwani[3], J. Nyakura[3], T. Moyo[3], T. Apollo[3], M. Mawodzeke[1]
[1]Zvandiri, Harare, Zimbabwe, [2]Swiss Agency for Development and Cooperation, Harare, Zimbabwe, [3]Ministry of Health and Child Care, Harare, Zimbabwe

Background: Over 190,000 Adolescents and Young People Living with HIV (AYPLHIV) will transition from adolescence to adulthood within the Zimbabwean health system over the next ten years. Therefore, there is an increasing call for differentiated services, and programs that support the transition of Adolescents and Young People living with HIV (AYPLHIV) from paediatric care to adult self-care management service.

Description: Zimbabwean Ministry of Health and Child Care (MoHCC) designed a transition checklist to support adolescents with age-appropriate knowledge and self-care milestones in HIV care. The checklist is in the Zimbabwean Operational Service Delivery Manual (OSDM) 2022, and MoHCC coordinated with Zvandiri (peer-to-peer counselling and support programme) in rolling out the checklist. In February 2024, MoHCC and Zvandiri conducted virtual training for 65 Health Care Workers (HCWs) and 10 Zvandiri staff. The checklist was administered electronically using OpenDataKit (ODK) by HCWs and Community Adolescent Treatment Supporters (CATS) during facility-based ART refill days, and in the community. Transition checklist outcomes were analysed descriptively using excel.

Lessons learned: Between March-December 2024, 5961/7791 (77%) AYPLHIV (median age 11, IQR 3 years, 56% females) were screened using the checklist across 18 districts in Zimbabwe. 96% (5719/5961) were aware of their HIV status, 92% (5475/5961) had a suppressed viral load and 93% (5524/5961) were able to independently take their medication.

Main challenges were noted among areas such as substance abuse and sexual and reproductive health as only 74% (4383/5961) were said to be free from substance abuse; 70% (4190/5961) were aware of risk factors of STIs and HIV transmission and 69% (4105/5961) were aware of how to prevent mother to child transmission (PMTCT). AYPLHIV with knowledge or self-care capacity gaps were linked to relevant services by CATS and/or HCWs.

Conclusions/Next steps: Many AYPLHIV are assumed to be knowledgeable and self-care as they move through the health system. However, with the help of the transition checklist, community cadres and HCWs can easily identify knowledge and capacity gaps and provide tailored services, ensuring smooth transition to adult care and optimal outcomes. There is need to follow up on the identified gaps, as Ministry continues to roll out the transition tool.

THPEE134

A roadmap to scale up person-centred care in the HIV response: recommendations from a global consensus process

L. Golob[1], E.L. Williams[1], M. Bras[1], B. Clifton[2], N. Ford[3], E. Geng[4], K.E. Green[5], R. Janamnuaysook[6], I. Katz[7], L. Mworeko[8], R.A. Olete[9,10], C. Pinto[3], R. Rajasuriar[11], K. Sikombe[12], D.H. Tan[13], B. Grinsztejn[14]
[1]International AIDS Society, HIV Programmes & Advocacy, Geneva, Switzerland, [2]National Association of People with HIV Australia, Newtown, Australia, [3]World Health Organization (WHO), Department of HIV, Hepatitis and STIs, Geneva, Switzerland, [4]Washington University School of Medicine in St. Louis, St. Louis, United States, [5]PATH, Geneva, Switzerland, [6]Institute of HIV Research and Innovation, Bangkok, Thailand, [7]President's Emergency Plan for AIDS Relief, Bureau of Global Health Security and Diplomacy, Washington D.C., United States, [8]International Community of Women Living with HIV Eastern Africa, Kampala, Uganda, [9]Sustained Health Initiatives of the Philippines Inc, Mandaluyong City, Philippines, the, [10]National Cheng Kung University, Department of Public Health, Tainan City, Taiwan, Province of China, [11]University of Malaya, Centre of Excellence for Research in AIDS, Kuala Lumpur, Malaysia, [12]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [13]St. Michael's Hospital, Division of Infectious Diseases, Toronto, Canada, [14]Fiocruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil

Background: WHO global normative guidance recommends person-centred care (PCC) approaches to reduce HIV-related mortality and morbidity and improve quality of life (QoL). However, consensus on and endorsement of key PCC elements and guidance on how different stake-

holders can realize PCC principles at the health systems, service delivery and individual client-healthcare worker (HCW) levels are lacking. We conducted a global consensus-building process to define core PCC elements and develop recommendations for implementation at scale.

Methods: We conducted five stakeholder consultations (34-43 participants each) between July 2022-July 2023, a three-round Delphi survey from March-July 2024 (49 participants) and an extensive review of the literature.

Participants represented all world regions and diverse actors (including clients, HCW, policymakers and researchers). Adjustments to statements and recommendations were made in Delphi Rounds 1 and 2 with final voting in Round 3.

Results: Emerging consultation themes provided the basis for survey statements in five categories: context/participation; relationships/empowerment; complex clinical needs/integration; health systems/universal health coverage (UHC); and HCW competencies. All Round 3 statements achieved over 90% agreement, with recommendations reaching at least 95% agreement.

An effective primary healthcare system, which prioritizes individual health and well-being and adapts to evolving needs, was recognized as foundational for PCC. Additional core elements (100% agreement) included: HCW responsibility to create safe/inclusive/stigma-free spaces; prioritize community leadership, including in care provision by trained and compensated peers and community HCWs; power sharing in client-HCW relationships, reinforced by HCW training and client literacy; use of appropriate digital technology to increase engagement; and cross-disciplinary collaboration to address different health issues in an integrated manner.

Recommendations included: policymakers setting national targets for self-reported QoL; strengthening integrated primary healthcare; researchers prioritizing community-academic partnerships; HCWs routinely assessing client-reported outcomes.

Conclusions: Our findings outline a roadmap with roles and actions for different stakeholders to realize the full potential of PCC. Jointly, there is a need to foster a culture that hears all voices in the care team, including clients, community, all HCW cadres and caregivers.

At a systems level, it will be crucial to integrate HIV into primary healthcare and align with the UHC agenda for increased investment in inclusive and responsive healthcare for all.

THPEE135

Using stakeholder engagement to improve gender based violence cascade among women and girls aged 15-59 years in Bukedi Subregion, Eastern Uganda

S. Ebiot[1], R. Barusya[1], K. Katulege[2], R. Jjuuko[3], W. Akobye[4], J. Bakyawa[5], A. Mugume[5], D. Kiragga[6], H. Akello[7], O. Nasio[8], S. Okurut[7], D. Naikambo[9]

[1]USAID Local Partner Health Services- Eastern (USAID LPHS-E), HIV Prevention, Mbale, Uganda, [2]USAID Local Partner Health Services- Eastern (USAID LPHS-E), Care and Treatment/Prevention, Mbale, Uganda, [3]Baylor foundation -Uganda, Quality Improvement, Kampala, Uganda, [4]USAID Local Partner Health Services- Eastern (USAID LPHS-E), Care and Treatment/Prevention/Administration, Mbale, Uganda, [5]USAID Local Partner Health Services- Eastern (USAID LPHS-E), Administration, Mbale, Uganda, [6]Baylor foundation -Uganda, Administration, Kampala, Uganda, [7]Pallisa District Local Government, Uganda, Care and Treatment/Prevention/Administration, Pallisa, Uganda, [8]Budaka District Local Government, Uganda, Care and Treatment/Prevention/Administration, Budaka, Uganda, [9]Butaleja District Local Government, Uganda, Care and Treatment/Prevention/Administration, Butaleja, Uganda

Background: In Uganda, 95% of women have experienced gender-based violence (GBV). By September-2022, Pallisa, Butaleja, and Budaka districts in Bukedi sub-region registered 88% (4,620/5,238) GBV survivors among women 15-59 years, but none of these survivors was eligible for post-exposure prophylaxis (PEP) due to reporting more than 72-hours after the assault to the health facility, linked to social stigma, fear of revenge, confidentiality concerns, and cultural acceptability of violence, resulting in an increased risk of HIV acquisition.

We set out to improve timely reporting of SGBV within 72-hours through stakeholder engagement, thereby improving the PEP eligibility and uptake for HIV prevention.

Description: Since 2022, with district local governments' support, we identified key stakeholders in GBV prevention and management, including GBV focal persons, community development officers (CDOs), local council one chairpersons (LC1s), Village Health Teams (VHTs), police, religious and cultural leaders.

The team jointly conducted community dialogues at sub-county level, and group discussions at village level. The VHTs and LC1s sensitized the community and identified survivors of GBV at village level. Identified GBV cases were referred to the CDO, police or health facility for management.

Trainings and mentorships for 33 supported sites were conducted to equip CDOs, police and health workers with knowledge and skills to manage, document and report GBV survivors.

Data was reported on the performance indicator reference sheet monthly and was quarterly reviewed by stakeholders.

Lessons learned: With stakeholder engagement, the number of women 15-59 years that reported as GBV survivors increased by 80% from 4,620 in 2022 to 8,299 in 2024. The implication was that more women were seeking help from LC1s, police, CDO and health facility when experiencing violence, compared to the baseline.
PEP eligibility in the same period improved from zero to 103. Of the 103 eligible survivors, 73% (75/103) were initiated on PEP and 40% (40/75) completed.
Conclusions/Next steps: The stakeholder engagement efforts led to a significant increase in reported GBV survivors, indicating improved help-seeking behavior among women. We therefore recommend engagement of higher government authorities to influence policy changes that address SGBV, especially among women and continued stakeholder engagement and community sensitization on GBV.

THPEE136

Integrating GBV services in HIV prevention programs targeting AGYW in Eswatini

G. Ndlovu[1], L. Malaza-Dlamini[1], O. Hlungwani[1], H. Mkhatshwa[1], M. Maseko[1]
[1]World Vision Eswatini, Integrated Health, Mbabane, Eswatini

Background: Gender based violence (GBV) continues to be the driver of HIV in Eswatini. Reporting of violence is low due to existing gender norms and pervasive culture of family secrets. World Vision Eswatini is implementing a Global Fund supported project in 14 constituencies in the four regions of Eswatini. WVE is delivering a combination HIV Prevention package aimed at halting the spread of HIV and reversing its impact in Eswatini.
The primary objective is to deliver comprehensive and layered HIV prevention package with high impact HIV services. GBV integration is aimed at addressing SGBV as a driver of HIV, enhance knowledge, increase reporting of violence cases and create a safe environment for AGYW aged 10-24 years.
Description: Integration of GBV services entailed training of project staff and 128 community cadre trained on GBV and LIVES. A gender-transformative approach was undertaken to engage communities on GBV focusing on gender norms, power dynamics, GBV-HIV nexus, challenging harmful masculinity and promoting equitable gender norms. In July – December 2023, two GBV Case Workers, through small groups and mass sessions, reached 324 community leaders and gatekeepers, and 439 ABYM aged 10 – 24 years. As a result, 35 AGYW who experienced sexual violence accessed services. SGBV prevention efforts were upscaled in the January – June 2024 period, reaching 382 community leaders, 614 members of the community, 350 caregivers of AGYW, and 263 ABYM. This resulted in 106 AGYW who experienced GBV accessing post-GBV services, a 203% increase from the previous period.
Lessons learned: Gender transformative engagement of communities on GBV as a driver of HIV should address power imbalances, increase AGYW's knowledge of GBV and on reporting pathways. It should equip caregivers with knowledge on HIV and GBV risks faced by AGYW and knowledge of protective and health services; and at community level, equip community members, leaders and ABYM with knowledge on SGBV root causes, address harmful gender norms and promote equitable gender attitudes.
Conclusions/Next steps: Upscale GBV prevention and response interventions targeting community leaders, caregivers, and ABYM for increased knowledge of SGBV and reporting of suspected cases. Investment in human resources and wrap-around services to improve access to comprehensive post-GBV services.

Integration of HIV services with other health and support services

THPEE137

Breaking the chain of tuberculosis transmission in high-risk groups through efficient program implementation

M. Bajehson[1], M. Tukur[1], G. Zephaniah[2], M. Said[3], H. Baffa[3], A. Zarewa[4], U. Bashir[5], A. Labaran[6], O. Chukwuogo[7], O. Bethrand[7]
[1]KNCV Nigeria, Programs, Kano, Nigeria, [2]KNCV Nigeria, Strategic Information, Kano, Nigeria, [3]KNCV Nigeria, GF-GC7, Kano, Nigeria, [4]Kano State Ministry of Health, Department of Public Health, Kano, Nigeria, [5]Kano State Agency for Control of AIDS, Kano, Nigeria, [6]Kano State Ministry of Health, Kano, Nigeria, [7]KNCV Nigeria, Abuja, Nigeria

Background: The blunderbuss approach to Tuberculosis (TB) program implementation has been the norm in Nigeria. The 2019 Nigeria HIV/AIDS indicator impact survey reported a prevalence rate of 0.6% in Kano, the most populous state in Nigeria.
KNCV Nigeria with donor funding implements TB care and treatment interventions, for the first time, we are intentionally targeting risk groups to generate evidence for programmatic decision making while improving treatment coverage.
Description: TB LON project is a five-year USAID funded grant implemented in Nigeria since March 2020. KNCV Nigeria designed activities spanning facility and community-based implementation approaches. At high volume facilities we institute mandatory TB screening services at ART clinics and other service delivery points using adhoc staff to improve coverage. At communities, outreaches targeting brothels and correctional facilities were conducted along with house-to-house TB screening campaigns involving community patent medicine vendors.
Reports were collected weekly, monthly and quarterly. Outreach data for 2022 from 3 brothels with host local government area (LGA), with outreach data for 2023 from 3 correctional facilities with host LGA and facility screening data from nine ART and out-patient clinics was cleaned and analysed using SPSS v20.

Lessons learned: A total of 558 female sex workers (FSW), 4,784 male inmates and 41,489 persons living with HIV (PLHIV) were screened for TB. TB yield among person's found presumptive for TB in these risk groups was 28.7% in FSW, 30.2% among inmates and 13.8% in PLHIVs representing the highest absolute value of 663 co-infected clients. The risk ratio, RR = 2.41, 95% CI [1.66, 3.50]; 2.16, 95% CI [1.73, 2.69]; 1.95, 95% CI [1.78, 2.14] respectively. The number needed to test (NNT) for a TB case was 21 for FSW, 7 for PLHIV and 3 for Inmates.
Conclusions/Next steps: TB yield was noticeably higher than that of the general population and not intentionally targeting these risk groups while programming could result in missed TB clients. Need to collaborate better with widened scope to include such risk groups as people who inject drugs is recommended. Findings and HIV testing limitations encountered have helped inform modified approaches in ongoing interventions on the project which are scalable nationwide.

THPEE138

Sustainable health financing for marginalized groups: Nepal's free health insurance model for PLHIV

A.B. Rai[1], D.R. Joshi[2], U. Shrestha[1], A.P. Poudyal[1], S. Bhatta[3], S. Paudel[2], M.R. Pant[2]
[1]AIDS Healthcare Foundation (AHF), Nepal Country Office, Monitoring and Evaluation Department, Lalitpur, Nepal, [2]AIDS Healthcare Foundation (AHF), Nepal Country Office, Program and Management Department, Lalitpur, Nepal, [3]AIDS Healthcare Foundation (AHF), Nepal Country Office, Program, Administration and Management Department, Lalitpur, Nepal

Background: Nepal introduced its Health Insurance scheme in 2016 to reduce financial barriers to healthcare and improve access to quality services for all citizens. In 2019, a free Health Insurance scheme for People Living with HIV (PLHIV) and their families was launched. However, the uptake was limited, with only 21% of PLHIV enrolled by 2021 at the 16 ART centers collaborating with the AIDS Healthcare Foundation (AHF) Nepal.
The primary barrier identified was the stigma and discrimination associated with HIV status disclosure during registration at local ward offices. By 2024, AHF Nepal was supporting 60.4% of the 25,728 PLHIV receiving antiretroviral treatment (ART) in Nepal.
Description: To address these challenges, AHF Nepal initiated a collaborative effort with the Health Insurance Board to modify the registration process, incorporating ART centers as the primary site for insurance registration. Peer Educators were enlisted to support PLHIV during the process, reducing the stigma associated with enrollment. ART centers, where PLHIV have already disclosed their HIV status, were identified as a more suitable environment for integration.
Lessons learned: This strategic shift led to a significant increase in enrollment: by 2022, the registration rate increased to 53%, 82% by 2023 and by 2024, it reached 88%. The results suggest that embedding the health insurance registration process within ART services, where individuals are already receiving care and have disclosed their HIV status, improved enrollment rates significantly.
The study demonstrates that merely offering free health insurance is not enough for high enrollment rates. Stigma and the need for a supportive environment are key factors. ART centers, with their established patient trust and privacy, offer an effective setting for registration.
Conclusions/Next steps: The integration of health insurance registration within ART centers, with continuous support from peer educators and other community-based interventions, has proven to be an effective strategy for increasing enrollment among PLHIV.

THPEE139

The health impact of increasing cervical cancer screening for women living with HIV in twelve PEPFAR focus countries

J. Sherwood[1], B. Honermann[1], A. Sayas[1], E. Lankiewicz[1], G. Millett[1], A. Sohn[2]
[1]amfAR The Foundation for AIDS Research, Public Policy Office, Washington DC, United States, [2]amfAR The Foundation for AIDS Research, TREAT Asia, Bangkok, Thailand

Background: Cervical cancer is the most common cancer and cause of cancer-related death in women living with HIV (WLHIV) globally. The President's Emergency Plan for AIDS Relief's (PEPFAR) has invested over 168 million USD for cervical cancer screening and treatment in 12 countries through its "Go Further" campaign. However, the majority of WLHIV remain unreached by these interventions.
This analysis examines the impact of expanding cervical cancer screening to all WLHIV in PEPFAR treatment programs in "Go Further" countries.
Methods: This secondary analysis connects program data from PEPFAR's Monitoring, Evaluation, and Reporting (MER) Datasets (2022-2024) with data from the peer-reviewed literature to generate models for cervical cancer screening, treatment, and progression in the 12 countries. Models apply known case detection and pre-cancer treatment rates from 2024 MER data to the total number of "unscreened" WLHIV (no cervical cancer screening in the past three years) on PEPFAR-supported HIV treatment.
Models estimate the impact of reaching full screening coverage for this group on the detection of precancerous lesions, progression to high-grade squamous intraepithelial lesions (HSIL), and invasive cervical cancer (ICC).
Results: From 2022-2024, PEPFAR supported cervical cancer screening for 24.6% (6,854,607) of WLHIV on HIV treatment in "Go Further" countries (range: Namibia 11.8%, Tanzania 33.0%). Of these, 5.0% (340,653) of WLHIV screened positive for precancerous lesions (range: Kenya 1.6%, Namibia 12.3%) and 87.7% received treatment (range: Kenya 69.7%, Mozambique 94.1%).
If all WLHIV on PEPFAR-supported HIV treatment in these countries were screened for cervical cancer, the program could detect an additional 1,273,983 precancerous lesions (range: Botswana 11,189, Mozambique 517,074) and treat an additional 1,138,701 WLHIV (range: Botswana 9,043, Mo-

zambique 499,593). This investment would prevent an estimated 627,933 HSIL (range: Botswana 5,515, Mozambique 254,861) and avert 244,894 ICC cases (range: Botswana 2,151, Mozambique 99,396).

Conclusions: Improving cervical cancer screening among WLHIV in PEPFAR treatment programs would have a long-term impact on cervical cancer rates. Screening WLHIV for cervical cancer at PEPFAR sites integrates services for high-risk populations and capitalizes on pre-existing PEPFAR infrastructure. Increased investments to expand screening and treatment of precancerous lesions at PEPFAR sites are needed to reach adequate population coverage.

THPEE140

Unmet need for health and welfare services and treatment adherence in people living with HIV in the UK

A. Williamson[1], F. Lampe[2], A. Aghaizu[3], A. Pelchen-Matthews[2], A. Sparrowhawk[4], J. Sewell[2], V. Delpech[3], T. Fernandez[5], S. Taylor[6,7], C. Kelly[3], H. Kitt[3], A. Rodger[2], M. Kall[3], C. Smith[2], Positive Voices 2022 Study Group

[1]Guy's and St Thomas' NHS Foundation Trust, Harrison Wing, London, United Kingdom, [2]University College London, London, United Kingdom, [3]UK Health Security Agency, London, United Kingdom, [4]Terrence Higgins Trust, London, United Kingdom, [5]Royal Free Hospital, London, United Kingdom, [6]Birmingham Heartlands Hospital, Birmingham, United Kingdom, [7]University of Birmingham, Birmingham, United Kingdom

Background: Despite accessible HIV care in the UK, not all people with HIV are able to consistently take their anti-retroviral treatment (ART) as prescribed ('non-adherence'). Unmet wider health/social needs may hinder ability to fully engage with treatment.

Methods: Positive Voices 2022 surveyed people accessing HIV care at 101 clinics across the UK. We included all participants receiving ART who answered relevant questions (n=3,953; 85.5% of respondents).

Participants were asked about services needed in the past year, choosing from the following options grouped into four categories:

1. *Lifestyle management:* weight management, smoking cessation, alcohol counselling.
2. *Mental health:* psychology, stress/isolation, sex/relationship advice.
3. *Drug services:* drug counselling, chemsex support, detox.
4. *Welfare:* housing, meals, childcare, employment/benefits/financial advice, legal/immigration.

Responses were classified into three levels:

i. No service needs in this category ('no needs');

ii. 1+ service need in this category, all needs met ('met need(s)');

iii. 1+ service need in this category, 1+ need not met ('unmet need(s)').

Treatment non-adherence was defined as answering 'yes' or 'don't know' to the question: 'In the past 3 months, have you ever missed your HIV treatment for 2 or more days at a time?'.

Results: 2365 (59.8%) were gay, bisexual and other men who have sex with men, 938 (23.7%) women. 765 (19.4%) were Black African; median (IQR) age 53 (44-60). 362 (9.2%) reported non-adherence.

The proportion of respondents reporting unmet need(s) were 4.7% (drug services), 22.6% (welfare), 23.1% (lifestyle), and 30.3% (mental health). In demographic-adjusted analyses, 'unmet need(s)' for all four categories significantly associated with non-adherence, compared to no needs. Met need(s) for mental health and drug services had significant but weaker associations with non-adherence.

		Total N	Reported ART non-adherence (%)	Non-adherence aOR (95% CI)
		3,953	**362 (9.2%)**	
Lifestyle management	No needs	2,603	190 (7.3%)	1.00 (ref)
	Met need(s)	437	41 (9.4%)	1.33 (0.92, 1.90)
	Unmet need(s)	913	131 (14.3%)	2.00 (1.57, 2.54)
Mental health/ relationships	No needs	2,255	127 (5.6%)	1.00 (ref)
	Met need(s)	502	57 (11.4%)	1.86 (1.33, 2.61)
	Unmet need(s)	1,196	178 (14.9%)	2.61 (2.04, 3.33)
Drug services	No needs	3,680	295 (8.0%)	1.00 (ref)
	Met need(s)	91	16 (17.6%)	2.07 (1.18, 3.64)
	Unmet need(s)	182	51 (28.0%)	4.07 (2.85, 5.81)
Welfare	No needs	2,653	178 (6.7%)	1.00 (ref)
	Met need(s)	406	37 (9.1%)	1.31 (0.90, 1.91)
	Unmet need(s)	894	147 (16.4%)	2.50 (1.96, 3.18)

Each model displays the results from a logistic regression model, adjusted for age, gender, ethnicity, sexuality and year of HIV diagnosis; aOR=adjusted odds ratio; CI=confidence interval.

Table. Association between health/welfare service needs and non-adherence to ART.

Conclusions: Health/welfare service needs associated with ART non-adherence. Associations were stronger with unmet needs; care providers should proactively assess needs and offer support to improve ART adherence.

THPEE141

Cardiovascular risk profiles and signs of vascular damage in people living with HIV on ART in rural Lesotho: findings from the PRECARIF study

M.A. Makhele[1], A. Klicpera[1], F. Chammartin[1], J.A. Brown[1], B. Letuma[2], M. Majonothane[2], N.D. Labhardt[1]

[1]University of Basel, Division of Clinical Epidemiology, Basel, Switzerland, [2]Solidarmed, Butha Buthe, Lesotho

Background: The introduction of antiretroviral therapy (ART) has improved the life expectancy of people living with HIV (PLHIV) across Africa. As individuals on ART age, the burden of cardiovascular diseases (CVDs) has gained increasing importance.

The PRECARIF study aimed to assess the prevalence of cardiovascular risk factors and early signs of vascular damage among PLHIV receiving ART in rural Lesotho.

Methods: This cross-sectional study included adults aged ≥18 years attending routine ART visits at five healthcare facilities in rural Lesotho. Participants were assessed for cardiovascular risk factors such as elevated blood pressure (systolic BP ≥140 mmHg and/or diastolic BP ≥90 mmHg), diabetes mellitus (random blood glucose ≥5.6 mmol/L and HbA1c ≥6.5%), dyslipidemia (total cholesterol ≥5.2 mmol/L, LDL-C ≥4.1 mmol/L, or HDL-C <1.0 mmol/L in men and <1.3 mmol/L in women), high BMI (≥25 kg/m²), and tobacco use. Vascular damage was evaluated using the ankle-brachial index (ABI), fundoscopy for retinopathy, and ultrasound of carotid and femoral intima-media thickness (IMT). Pathologic ABI was defined as <0.9, retinopathy as abnormal blood vessels in the retina, and abnormal IMT as >0.9 mm.

Results: Among 343 participants 227/343 (66%) female, the median age was 50 years (IQR:18). Elevated BP was observed in 221/343 (64%), elevated blood glucose in 32/343(9%), dyslipidemia in 24/343 (7%), and an elevated BMI in 215/343 (63%); 88/343 (26%) reported use of tobacco. The number of participants with zero, one, or two or more cardiovascular risk factors was 39/343 (11%), 103/343 (30%), and 201/343 (59%), respectively. Ultrasound revealed abnormal IMT in 31/343 (9%) participants for carotid and 20/343 (6%) for femoral arteries.

Retinopathy was present in 44/343 (13%), while 63/343 (18%) had a pathologic ABI and 120/343 (35%) had renal impairment. Overall, 90/343 (26%) exhibited at least one marker of vascular damage.

Conclusions: A high proportion of PLHIV on ART in rural Lesotho had one or more cardiovascular risk factors, and 26% displayed evidence of vascular damage. These findings underscore the need for integrated approaches to CVD prevention and management within HIV care programs in resource-limited settings.

Innovations in data collection, monitoring and evaluation

THPEE143

Dorsal Slit conventional and Shang Ring device Voluntary Medical Male Circumcision methods: post operative outcome, Jhpiego's Project DOLO 2023-2024, Malawi Experience

G. Menego[1], S. Shire[2], G. Ngwinja[1], D. Nkombezi[3], W. Msungama[4], Z. Mwandi[5], J. Van't Pad Bosch[6]
[1]Jhpiego Corporation, Clinical, Lilongwe, Malawi, [2]Jhpiego Corporation, MER, Lilongwe, Malawi, [3]Jhpiego Corporation, Demand Creation, Lilongwe, Malawi, [4]CDC, Biomedical, Lilongwe, Malawi, [5]Jhpiego Corporation, Clinical, Nairobi, Malawi, [6]Jhpiego Corporation, Management, Lilongwe, Malawi

Background: The Project DOLO, through United States Centers for Disease Control and Prevention (CDC) funding, has supported the Ministry of Health (MOH) to roll out Voluntary Medical Male Circumcision (VMMC) services in the Lilongwe district since 2020. Dorsal Slit (DS) and the Shang Ring (SR) Device are the two preferred methods approved by the VMMC program. World Health Organization (WHO) guidelines recommend scheduled follow-up to ensure good wound care during the healing process.

Description: We analyzed data for the period January 2023 through September 2024 to understand the total number of clients who received VMMC services; those who were able to be followed up on the scheduled days; those who experienced moderate or severe adverse events (AEs); the method used for VMMC service; and diagnosis of AE.

Lessons learned: A total of 132,754 men received this HIV prevention service/intervention during the period under review. Of the total, 86,710 (65%) were circumcised using the SR device while 46,044 (35%) received services by the DS method. All clients, for the two methods, were followed at least once within 14 days.

During follow up, 6 (0.0045%) of the total circumcised clients were diagnosed with moderate AEs. This is within the program's acceptable 0.5% rate. Of all the moderate AE cases, 5 (83%) were diagnosed with moderate bleeding post operation and 1 (17%) with moderate infection post operation. The rate for moderate AE for SR and DS was 0.001% and 0.01% respectively.

Further, of the total with bleeding, 4 (80%) were circumcised through the DS method while 1 (20%) through the SR device. No intraoperative and severe adverse events were reported.

Conclusions/Next steps: This analysis demonstrated that men who are circumcised by the SR device have lower AE rate of 0.001% compared to 0.01% for DS method. Promoting use of SR could drastically reduce AE rates in VMMC.

THPEE144

Role of community led monitoring (CLM) as a quality assurance tool for improving coordination of HIV viral load monitoring services under the TASCQ program in Southern Zimbabwe

S. Mukungwa[1], T. Makoni[1], C. Mademutsa[1], A. Nhapi[1], W. Mukuwapasi[1], L. Muremba[1], E. Dhodho[2], K. Takarinda[2]
[1]Zimbabwe National Network of People living with HIV, Harare, Zimbabwe, [2]Organization of Public Health Interventions, Harare, Zimbabwe

Background: Viral load monitoring is a critical aspect of managing viral conditions, especially HIV, for tracking of treatment efficacy and client outcomes. However, access to viral load testing remains a significant barrier in many low-resource settings. Traditional viral load monitoring often faces challenges such as accessibility, cost, and timely data collection.

Community-led monitoring (CLM) offers a potential alternative, integrating local knowledge and resources to enhance viral load surveillance.

Description: To improve viral load surveillance community tailored adaptation strategies were implored in October 2023-August 2024. We engaged and trained 315 Community HIV/AIDS Support Agents (CHASAs) to collect Client Satisfactions Survey (CSS) that are embedded viral load indicators using digital tools in CommCare.

Data were collected from a cohort of HIV-positive individuals enrolled in Target Accelerate Sustain Quality Care (TASQC) program across several rural health centres in 4 Southern Zimbabwe provinces namely Matabeleland South, Masvingo, Bulawayo and Harare.

The CHASAs were then used as vital links to facilitate referrals, appointment scheduling, and follow-up care via Differentiated Service Delivery (DSD) models, which are central to community systems strengthening initiatives.

Lessons learned: The program conducted over 53,000 CSS to identify barriers in HIV services, including tracking of viral load indicators. The data was instrumental in enhancing quality improvement strategies localised at

each facility. Has enhanced quality improvement led to improvements in viral load monitoring, with the percentage of recipients without valid viral load results decreasing from 22% in March 2024 to 19% in June 2024 and 17% by September 2024.195 issues relating to viral load were identified and102 (52.3%) were resolved. CLM data has improved program planning and informed strategies for decentralized viral load testing facilitating localised viral load sample collection through DSDs, complimenting health systems and lab efforts to facilitating a more client-centred service delivery.

Conclusions/Next steps: CLM remains a vital tool for health systems monitoring and surveillance. Augmenting CLM, routine quality improvement efforts with periodic catch-up quality improvement campaigns increases program performance.

Looking ahead, scaling up CLM initiatives and better integrating community-led data into decision-making processes will be critical to driving equity and impact in the HIV response addressing barriers to achieving the final 95% of the 95-95-95 targets.

THPEE145

Using continuous quality improvement approach to improve HIV viral suppression among children and adolescents living with HIV in a National Teaching Referral Hospital in Kenya

R. Wairimu[1], K. Mutai[2], B. Anudo[2], D. Nyamweya[2], N. Opiyo[2], S. Wahome[2]

[1]Kenyatta National Hospital, Comprehensive Care Center, Nairobi, Kenya, [2]Kenyatta National Hospital, Nairobi, Kenya

Background: HIV viral suppression is the ultimate goal of ART programs globally with UNAIDS setting the target at 95% to be achieved by 2030. Program data in Kenya shows progress toward achieving global goals, especially in the adult population. However, HIV viral suppression among children and adolescents living with HIV (CALHIV) is sub-optimal despite their vulnerability to the adverse effects of advanced HIV disease.

We initiated a continuous quality improvement (CQI) activity aimed at enhancing HIV viral load suppression and improving the quality of care for CALHIV.

Methods: This analysis included CALHIV on ART follow-up at the Kenyatta National Hospital in Kenya from Oct 2022 to Sept 2024. High HIV viral load was defined as VL results ≥200 copies per mL of blood. Program reports were reviewed at baseline and a fish-bone analysis was done to identify barriers and opportunities for VL suppression in CALHIV. Plan-Do-Study-Act (PDSA) model was used to institute changes in healthcare processes.

The interventions tested included school holiday clinic scheduling, caregivers' training for drug adherence, family clinics for holistic support, and virtual sessions. A rigorous monitoring system was implemented for timely review of milestones and modification of interventions. Monthly analysis of outcomes and VL suppression rates were presented using proportions and 95% confidence intervals.

Results: A cohort of 496 CALHIV were active on ART in the period. The age distribution was 0-9 years, 87 (18%); 10-14 years, 113 (23%) and 15 to 19 years, 296 (60%). There was a notable improvement in HIV viral suppression from 86.6% (95% CI 83.5-89.1%) at baseline to 92.3% (95% CI 89.6-94.4%) at the evaluation phase. The high viremia cohort reduced by 55% in the period from 76 clients at baseline to 39 clients at the evaluation phase. Timely completion of enhanced adherence counseling (EAC) sessions improved from 20.8% (95% CI 9.2-40.5%) at baseline to 75.7% (95% CI 64.8-84.6%).

Conclusions: Several inherent challenges related to systems and processes hinder successful management of high viremia among CALHIV. Quality improvement approaches are very effective in addressing the hindrances, improving the quality of services, and achieving VL suppression in this vulnerable population.

THPEE146

Spatial autocorrelation and hotspot analysis of infants turning HIV positives between 2-12 months of age across districts in Uganda: a review of FY22-24 PEPFAR DATIM data

A. Lutaaya[1], D. Kasozi[2], C. Kavuma[3], E. Birabwa[2]

[1]US DOD/WRAIR Uganda, Strategic information, Kampala, Uganda, [2]US DOD/WRAIR Uganda, Public Health Specialist, Kampala, Uganda, [3]CDC Uganda, DSI, Kampala, Uganda

Background: Mother-to-child transmission (MTCT) of HIV, particularly during breastfeeding, remains a significant public health challenge in Uganda. Despite ongoing efforts, some HIV-exposed infants test positive between 2–12 months.

This study employs spatial analysis to identify clusters of HIV-positive infants within this age group, aiming to guide targeted interventions and improve health outcomes.

Methods: We conducted spatial analyses to assess clustering and identify districts with high counts of infants with HIV aged 2–12 months in Uganda. Data were sourced from PEPFAR DATIM for fiscal years 2022 to 2024 at the district level.

For each fiscal year, global Moran's I was used to measure overall spatial autocorrelation, while Anselin Local Moran's I (Cluster and Outlier Analysis) refined the identification of local spatial patterns, revealing districts with significant clusters and spatial outliers. Analyses were performed using ArcGIS software, with the number of HIV-positive infants as the key variable.

Results: The Spatial Autocorrelation analysis revealed positive spatial autocorrelation for HIV-positive infants across districts in fiscal years 2022 (Moran's Index = 0.2269, z-score = 7.0409), 2023 (Moran's Index = 0.2329, z-score = 6.8370), and 2024 (Moran's Index = 0.2917, z-score = 8.0498), all statistically significant (p-value < 0.001), indicating a non-random distribution of HIV-positive infants.

The cluster and outlier analysis identified persistent hotspots (HH) of HIV-positive infants, alongside shifting patterns of outliers (HL and LH) and significant cold spots (LL) in certain regions, highlighting areas for targeted interventions and resource allocation.

Conclusions: This study demonstrates a non-random spatial distribution of HIV-positive infants aged 2–12 months, with hotspots predominantly located in districts where HIV prevalence among individuals aged 15–49 exceeds the national average of 5.1% in 2024, particularly around Uganda's capital. These findings underscore the urgent need for targeted, region-specific interventions to accelerate the elimination of MTCT of HIV in Uganda. Future research should explore the underlying factors contributing to these spatial patterns and evaluate the effectiveness of interventions implemented in identified hotspot areas

Leveraging BERT-based machine learning for HIV sequence analysis: insights into genetic diversity and coreceptor utilization

N. Patel[1], W. Dampier[1,2,3], M. Nonnemacher[1,2,4], B. Wigdahl[1,2,5]
[1]Drexel University College of Medicine, Department of Microbiology and Immunology, Philadelphia, United States, [2]Drexel University College of Medicine, Center for Molecular Virology and Gene Therapy, Institute for Molecular Medicine and Infectious Disease, Philadelphia, United States, [3]Drexel University College of Medicine, School of Biomedical Engineering, Science and Health Systems, Philadelphia, United States, [4]Thomas Jefferson University, Sidney Kimmel Cancer Center, Philadelphia, United States, [5]Drexel University College of Medicine, Center for Clinical and Translational Medicine, Institute for Molecular Medicine and Infectious Disease, Philadelphia, United States

Background: HIV's genetic variability poses challenges for treatment and necessitates innovative solutions to predict resistance and coreceptor usage. This study leverages Bidirectional Encoder Representations from Transformers (BERT)-based models for comprehensive HIV sequence analysis, uncovering patterns in genetic diversity and coreceptor localization (CCR5 and CXCR4). A Python library was developed to support diverse sequence formats, enabling clustering, labeling, and feature extraction, and integrating fine-tuned BERT models with HIV-specific datasets.
By employing cost-effective methods like Nanopore sequencing, this approach bridges research and clinical applications, advancing therapeutic strategies through whole-genome sequence analysis.
Methods: A Python library was developed to process sequence file formats like BAM, SAM, FASTQ, and GenBank. The library integrates pre-trained transformer models from AIRI, such as gena-lm-bigbird-base-sparse-t2t, originally trained on telomere-to-telomere sequences. These models were fine-tuned with HIV-specific data from the Los Alamos Database to predict localization to CCR5 or CXCR4 surface proteins.
Fine-tuned models generated numerical embeddings for novel HIV sequences, representing genomic patterns. These embeddings were analyzed using a random forest classifier to predict coreceptor localization. Evaluations included an 80/20 train-validation split, clustering analyses, and balancing CCR5- and CXCR4-labeled sequences. The library supports end-to-end analysis, bridging foundational research and clinical applications.
Results: The fine-tuned Big Bird BERT model achieved an accuracy of 72.5%. The confusion matrix showed a sensitivity of 67.4% for CCR5, a specificity of 57.1% for CXCR4, a precision of 59.7% for CCR5 predictions, and a precision of 64.0% for CXCR4 predictions. While t-SNE clustering revealed no discernable trends, the Python library was rigorously tested with industry-standard practices to ensure reliability, scalability, and robust performance for HIV sequence analysis.
Conclusions: This Python library enables efficient HIV sequence analysis, processing diverse file formats and integrating fine-tuned BERT models for coreceptor localization. Employing practices like version control, automated testing, and scalability ensures robustness. Future work will address computational limitations, refine classification accuracy, and perform end-to-end analysis for broader HIV research applications.

EP0002

Blood brain barrier pericytes as novel brain HIV reservoir

M. Toborek[1]
[1]University of Miami Miller School of Medicine, Biochemistry and Molecular Biology, Miami, United States

Background: HIV latency constitutes a formidable problem within the HIV life cycle, marked by the virus integration into host DNA as metabolically inactive proviruses evade both pharmacological therapies and the host immune system detection. While subtherapeutic levels of antiretroviral drugs in the brain and the extended lifespan of several CNS cell types contribute to the generation of CNS reservoirs, the mechanisms that regulate the formation and maintenance of these reservoirs are poorly understood. This represents a substantial gap of knowledge, hindering progress toward an HIV cure and effective treatment of HIV-associated neurological disorders. Our research focused on the hypothesis that blood-brain barrier (BBB) pericytes are a previously unrecognized HIV-1 target and reservoir in the brain.
Methods: We analyzed brain capillaries isolated from brains of people who lived with HIV and cultured pericytes infected with HIV by RNA scope to determine HIV RNA and DNA. In addition, we used a novel HIV reporter, named HIVGKO, a dual fluorescent reporter that allows for identification of cells at different stages in HIV infection. The molecular signatures of actively infected pericytes and their latently infected counterparts within the same culture were assessed using fluorescence cell sorting, RNA isolation, and RNA sequencing.
Results: We identified for the first time latently infected pericytes in the brain of virally suppressed individual with HAND. Moreover, we determined several distinct molecular signatures when comparing latent, active, and uninfected populations of BBB pericytes. Among the most distinct pathways between latent and active infected pericytes are estrogen receptor signaling, mitochondrial dysfunction, and the sirtuin signaling pathway.
Conclusions: These findings are the first evidence that BBB pericytes can create a previously unrecognized HIV reservoir in the brain. Moreover, they provide key insights into the molecular signatures affecting HIV infection of BBB pericytes and may help to develop future targets for the treatment of HIV at the neurovascular unit.

EP0003

Extending the utility of standardized HIV-1 mRNA models with the HIV Informatics Suite

A.R. Gener[1]
[1]*Independent, Los Angeles, United States*

Background: Despite advances in HIV biology, a major challenge remains in tracking and integrating information across the HIV DNA, RNA, and Protein landscapes. A significant gap has been the lack of standardized models for HIV mRNA, which limits research and therapeutic development. Considering this, I developed the **HIV-1 mRNA Atlas v1.0** by comparing internal and publicly available long-read sequencing data. However, the full potential of this resource remains underutilized. To further bridge these gaps, I developed tools and resources to enable researchers to perform comprehensive analyses in the HIV mRNA space.
Methods: In December 2024, I developed use cases for working with HIV mRNA into minimal prompts with Claude 3.5 Sonnet. I wrote tools in Python 3, and organized the tools into publicly accessible GitHub repositories, with accompanying documentation and examples to guide users. To ensure quality, I tested early "alpha" tool versions using known data and expected results. Only tools that produced accurate and reliable results were released as "beta" versions for broader use.
Results: The HIV Informatics Suite, available at the landing page: **https://github.com/GenerGener/HIV_Informatics_Suite_START_HERE**, provides tools and resources for making and/or using HIV mRNA models (see **Table 1**). Example outputs include modified reference genomes and annotations from LANL HIV Sequence Database or US NCBI RefSeq as projected mRNA model sets. Users can input their own HIV assemblies to generate customized model sets for downstream applications.

Table 1: HIV Informatics Suite tools

Tool/resource name	Tool/resouce type	Function	Output	Status	Related tools/resources
Gnothios	Tool	Viral genotyping from assembly or raw reads; Detect target admixture; If admixture present, enable assembly deconvolution; Recombinant breakpoint analysis.	FASTA, metadata	Alpha	
AtlasAnnotator	Tool	Project annotations from Atlas v1.0 onto output from AtlasMaker.	GenBank, BED, GFF	Alpha	HIV-1 M B NL4-3 mRNA Atlas v1
AtlasMaker	Tool	A species-agnostic method for reference-guided mRNA modeling.	multiFASTA	Beta	HIV-1 M B NL4-3 mRNA Atlas v1; AtlasMatcher
AtlasMatcher	Tool	Determine the extent to which a user's cDNA matches a given model set. It is designed with HIV-1 in mind, but may be abbreacted for other genomic loci.	metadata	Alpha	HIV-1 M B NL4-3 mRNA Atlas v1; AtlasMaker
External HIV datasets	Resource/Knowledge base	This repo will include notes on external datasets with HIV signal. It does not contain private or identifiable patient information.	documentation	Alpha	
HIV_Profiler	Tool	Leverage 5' UTR and unique splice junctions to track changes in HIV mRNA expression from subgenomic HIV mRNAs.	Read counts	Alpha	UTR_Maker
HIV-1 M B NL4-3 mRNA Atlas v1	Resource/Knowledge base	Standardized mRNA models of HIV-1 M B NL4-3 from GenBank:MZ242719.1-MZ242757.1.	GenBank, FASTA, GFF, blat	Fully released*	HIV Informatics Suite
ONT_homopolymer_screen	Tool	Identify regions in nucleic acid sequences that may contribute toward sequencing artifacts.	metadata	Beta	
ParameterSweeper	*In silico* experiment	Minimap2, BWA optimizer pilots* on public datasets.	metadata	Alpha	Gnothios, AtlasMaker, AtlasMatcher, HIV_Profiler, SpliceChecker, UTR_Checker
SpliceChecker	Tool	Compare input cDNA sequences to standard or user-supplied HIV mRNA models.	metadata	Alpha	HIV-1 M B NL4-3 mRNA Atlas v1; UTR_Checker
UTR_Checker	Tool	Assess for U3-R-U5 presence in user-provided HIV sequences.	metadata	Beta	HIV-1 M B NL4-3 mRNA Atlas v1
UTR_Maker	Tool	Make 5' and 3' UTRs from annotated cDNA mRNA transcript models.	FASTA	Beta	HIV-1 M B NL4-3 mRNA Atlas v1; HIV_Profiler

ONT: Oxford Nanopore. UCSC: University of California Santa Cruz. UTR: Untranslated Region. U3: U3 region. R: R Repeat. U5: U5 region. "Repo": Github repository
*Full release dates (YYYY-MM-DD): GenBank models and annotations on 2021-11-08; UCSC Genome Browser on 2022-09-20 (ORFs) and 2022-09-21 (mRNAs); Github (initial commit on 2022-09-20).

Conclusions: The HIV Informatics Suite is an evolving set of open-source and computer operating system-agnostic bioinformatic resources designed to maximize information extraction from HIV sequencing experiments. Many Suite tools are adaptable for studying endogenous host loci, broadening their applicability. By offering standardized mRNA models, the Suite supports ongoing HIV research and clinical efforts, bridging existing gaps until longer sequencing methods are more widely adopted. Active development ensures the Suite's continued relevance to the HIV research community.

EP0004

Don't forget about HIV-2: a cross-sectional descriptive study in Santo Domingo, Dominican Republic

J. Adames Sánchez[1], H.J. Lora-Rodríguez[2], R. Salas Yaliney[1], C. Morillo Reinoso[1], M. Muñoz[1], R. Paulino-Ramirez[2]
[1]*Centro de Orientación e Investigación Integral (COIN), Santo Domingo, Dominican Republic, the,* [2]*Universidad Iberoamericana (UNIBE), Instituto de Medicina Tropical & Salud Global, Santo Domingo, Dominican Republic, the*

Background: HIV-2 and HIV-1/HIV-2 remain understudied in Latin America and the Caribbean (LAC) due to limited surveillance. Most research is from West Africa, where HIV-2 prevalence is 3%. This study estimates HIV-2 prevalence in the Dominican Republic (DR), a regional migration and tourism hub, to inform surveillance and clinical management strategies.
Methods: A cross-sectional study was conducted at a private HIV primary care clinic in Santo Domingo between June and July 2024. A total of 118 people with HIV (PWH) were recruited based on clinic attendance. Eligibility criteria included a confirmed HIV diagnosis and informed consent. Demographic data, key population classification, and recent CD4+ count and viral load were extracted from medical records. HIV-1 and HIV-2 serostatus was assessed using the CTK Biotech HIV 1/2 Ab Plus Combo Rapid Test, a lateral flow immunoassay with 100% reported sensitivity and specificity.
No confirmatory molecular testing was performed. Descriptive analyses were conducted to estimate HIV-2 prevalence and associated clinical parameters.
Results: Of the 118 PWH, 68 (57.63%) were biological males, and 73.73% were under 46 years old. The majority (67.8%) had been diagnosed for over two years, and 94 (79.66%) had viral loads <20 copies/mL. CD4+ counts >200 cells/mm³ were observed in 105 (88.98%). Key populations included immigrants (12.71%), sex workers (5.93%), MSM (21.19%), people who use drugs (6.78%), and individuals with no identifiable risk factors (53.39%).
Rapid testing detected HIV-2 antibodies in 3 (2.54%) participants and HIV-1/HIV-2 circulation in 8 (6.78%). Among these, 5 (45.45%) were biological females, and 6 (54.55%) had viral loads <20 copies/mL.
Conclusions: The 9.3% prevalence of HIV-2 and HIV-1/HIV-2 in this cohort suggests ongoing circulation in the DR. Given the absence of molecular confirmatory testing, these findings underscore the urgent need for expanded epidemiological surveillance, multi-center studies, and molecular diagnostics to improve case identification, clinical management, and public health interventions.
Strengthened monitoring of HIV-2 is essential to track viral evolution, optimize treatment protocols, and inform prevention strategies in LAC.
This study highlights the necessity for regional collaboration and investment in molecular epidemiology to address emerging HIV diversity in the Caribbean.

EP0005

Drug resistance associated polymorphisms in the HIV-1C RNase H and RT connection domains in treatment naïve individuals in Botswana

B.J.L. Zuze[1,2], W.T. Choga[1], N.O. Moraka[1,2], O.T. Choga[1], L. Bhebhe[1], T. Phuthego[2], M. Mokomane[2], S. Moyo[1,3,2], S. Gaseitsiwe[1,3]

[1]Botswana Harvard Health Partnership, Research Laboratory, Gaborone, Botswana, [2]University of Botswana, Gaborone, Botswana, [3]Harvard T.H. Chan School of Public Health, Boston, United States

Background: The reverse transcriptase (RT) connection (RT conn) and the RNase H domains in the RT region of HIV-1 subtype C (HIV-1C) is understudied, especially in Botswana, though research indicates that mutations in these domains can increase RT inhibitor (RTI) resistance. We sought to assess the mutation profile of RNase H and RT conn domains of HIV-1 C sequences from treatment naïve (TN) individuals in Botswana.

Methods: We surveyed previously reported RT conn and RNase H resistance associated polymorphisms (RAPs) from literature and Stanford HIV database using sequences from Botswana. These included sequences from the Los Alamos HIV database, focusing on those sequenced before 2002, prior to the rollout of RTIs. We also included HIV-1C sequences from treatment naïve individuals enrolled in a HIV-1 population-based cohort between 2013-2018, the Botswana Combination Prevention Project (BCPP). Fisher's Exact test was used to compare proportions of RAPs within the two time points.

Results: A total of 1,336 sequences from Botswana were analyzed, with 1,260 (94.3%) from the BCPP (post-2002) and 76 (5.7%) previously deposited on Los Alamos HIV database (pre-2002). In total, 764 (57.2%) polymorphisms were observed, of which 99/764 (13.0%) were significant. Polymorphisms significantly higher pre-2002 of clinical significance included L491A (5.3%, 1.1%) and K527C (1.3%, 0.1%). Polymorphisms significantly higher post-2002 of clinical significance included Q334D (5.3%, 14.8%), E339K (0.0%, 4.7%), E478K (0.0%, 6.3%), L491P (15.8%, 25.9%), R549K (0.0%, 12.1%), D549N (0.0%, 5.6%) and K527R (1.3%, 7.4%).
Other amino acid changes at position 335, such as G335Y and G335N, were significantly different between the time points, but were present at lower frequencies (G335Y: 1.3%, 0.1%; G335N: 0.0%, 4.8%) ($p < 0.05$).

Conclusions: We report a high prevalence of RAPs within the RNase H and RT conn domains of ART naïve individuals, from which the key polymorphisms were higher post RTI roll out in Botswana.
Further studies on the impact of RT conn and RNase H RAPs are warranted to understand their impact on pre-treatment RTI resistance.

EP0006

Understanding the evolution of HIV-1 in Ghana: subtype distribution and drug resistance challenges

P. Appiah[1], M. Adusei-Poku[1], B. Musah Obeng[2], R. Osei-Yeboah[3], G. Gbassana[4], S. Agyemang[5], L. Mac-Ankrah[6], I. Jamfaru[7], M. Seshie[1], I.K. Sraku[1], S. Ankamah[8], K.O. Duedu[9], K. Sagoe[1]

[1]University of Ghana Medical School, Department of Medical Microbiology, Accra, Ghana, [2]University of New South Wales, Immunovirology & Pathogenesis Program, Kirby Institute, Wales, Australia, [3]University of Edinburgh, Centre for Global Health, Usher Institute,, Edinburgh, United Kingdom, [4]University of Liberia, Department of Laboratory Medicine, A. M. Dogliotti School of Medicine, Monrovia, Liberia, [5]Yemaachi Biotechnology, Accra, Ghana, [6]University of health and Allied Sciences, Department of Microbiology and Immunology, School of Medicine, Accra, Ghana, [7]School of Medicine, University of health and Allied Sciences, Department of Microbiology and Immunology, Accra, Ghana, [8]University of Ghana, University of Ghana Library System, Accra, Ghana, [9]Birmingham City University, College of Life Sciences, Birmingham, United Kingdom

Background: Since the roll-out of antiretroviral therapy (ART), there has been significant reduction in HIV-1 related mortality and morbidity. However, limited surveillance on HIV-1 drug resistance and subtype diversity which impacts therapy have been carried out to assess the subtype population and their correlation with drug resistant mutations (DRMs) against the treatment regimen used in Ghana.
Thus, this systematic review synthesized and assessed data from 1986 to 2024 on subtype diversity and their correlation with DRM among persons living with HIV-1 in Ghana.

Methods: We searched PubMed, Scopus, Cochrane CENTRAL, CINAHL Complete, Web of Science, and Google Scholar for cross-sectional and longitudinal studies reporting on HIV-1 subtype diversity, drug resistance or both among individuals in Ghana published between 1st January 1986 to 24th July 2024 and reviewed according to PRISMA guidelines. The protocol for this review is registered with PROSPERO (CRD42024529606).

Results: A total of 2472 studies were screened, 28 were selected for full-text review, and 18 were included. The overall sample size was 2001. The majority of the HIV-1 subtypes were CRF02_AG (68.9%), A (3.9%), G (3.5%), 06_cpx (3.3%), B (2.1%), C (0.6%), CRF09_cpx (0.6%) and other recombinants forms. Subtypes D and K had only one occurrence in all the studies. Thirty DRM (majority; K20I/V (18.2%), M36I/K/T/V (15.4%) and H69K (15.1%)) were found in Protease Inhibitors, 20 (majority; K103N/R (20.5%), V179E/I/F/A (9.0%), A98G/S (8.6%) and V90I (8.2%) in the nucleoside reverse transcriptase inhibitors, 20 (majority M184V/I (31.6%), T215A/Y/F/S/I (13.0), and M41L (11.9%) non-nucleoside reverse transcriptase inhibitors, and 5 (5163R, L74I/M, E157Q, T97A and D232N) Integrase strand transfer inhibitors. Only two studies analyzed sequences for DRMs from the integrase gene.

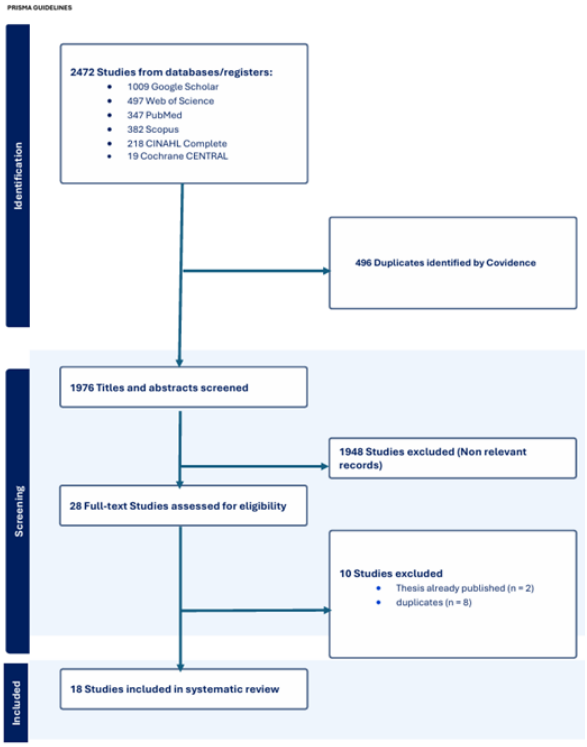

Figure. PRISMA guidelines.

Conclusions: Assessing HIV-1 subtype and DRM highlights the need for continued surveillance which is critical for a more targeted clinical and public health management of HIV based on the Ghanaian HIV infection landscape.

EP0007

Correlation of some haemostatic indices with immune status of persons living with HIV on treatment and those not on treatment and HIV negative individuals

C.O. Okeke[1], C.S. Okoye[2], G.I. Amilo[1], C.M. Okeke[3]
[1]Nnamdi Azikiwe University, Haematology and Blood Transfusion Science, Awka, Nigeria, [2]Nnamdi Azikiwe University Teaching Hospital, Medical Laboratory Science, Nnewi, Nigeria, [3]Nnamdi Azikiwe University Teaching Hospital, Family Medicine, Nnewi, Nigeria

Background: Human immunodeficiency virus (HIV) has been associated with haemostatic derangement which may be linked to the immune and treatment status of persons living with HIV (PLWH). Cluster of differentiation-4 (CD4) count has been applied as a prognostic marker of immune status in persons living with HIV.
This cross-sectional study was designed to correlate CD4 count with the levels of some haemostatic indices in PLWH on antiretroviral treatment (ART), those that are yet to start treatment (non-ART) and HIV negative individuals. This was aimed to ascertain the correlation between immune status and haemostatic derangements as well as the link between anti-retroviral treatment and haemostatic complications in PLWH.
Methods: The study included 180 age matched adult participants (18-65 years) comprising 80 PLWH on ART, 40 PLWH not on ART and 60 HIV negative control participants. Protein C and S were measured using Enzyme linked Immunosorbent assay (ELISA) method, Euglobulin clot lysis time (ECLT) by the manual method, CD4 count by flow cytometry using BD FACS count machine. Statistical package for Social Science version 25 was used for data analysis.
Results: Protein C and Protein S levels were significantly lower in PLWH (ART and non-ART) compared to HIV negative participants. Conversely Euglobulin lysis time was significantly increased in PLWH on ART and non-ART compared to HIV negative subjects. The CD4 count was significantly higher in HIV negative compared to HIV ART and non-ART and higher in HIV ART compared with non-ART. A significant positive correlation exists between CD4 count and protein C as well as Protein S and a significant negative correlation between CD4 count and ECLT.
Conclusions: HIV acquisition leads to impaired coagulation inhibition (depicted by a decreased Protein C and S levels) and impaired fibrinolysis (represented by an increased ECLT) that may predispose individuals to thrombotic complications. The positive correlation between CD4 count with Protein C and S and negative correlation with ECLT implies that a positive response to therapy (increased CD4 count and stronger immune status) is accompanied by a concurrent reduction in the risk of thrombotic complications. This indicates a favourable prospect of antiretroviral therapy in resolving derangement with timely therapeutic intervention.

EP0008

Monocytes of elite controllers of HIV-1 show altered metabolic profiles

N. Rallón[1], C. Restrepo[1], S. Nistal[2], A. Al-Hayani[3], A. Cabello[3], I. Carrillo[3], L. Prieto[3], M. Górgolas[3], J.C. López[4], A. Muñoz[5], V. Estrada[5], M. Fernández[6], H. Santos-Oliveira[7], A. García[7], J.M. Benito[1]

[1]Universidad Autónoma de Madrid (IIS-FJD, UAM), Hospital Universitario Rey Juan Carlos, Móstoles, HIV and Viral Hepatitis Research Laboratory, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Madrid, Spain, [2]Hospital Universitario Rey Juan Carlos, Móstoles, Madrid, Spain, [3]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [4]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [5]Hospital Clínico Universitario San Carlos, Madrid, Spain, [6]Centro de Metabolómica y Bioanálisis (CEMBIO), Facultad de Farmacia, Universidad San Pablo-CEU, CEU Universities, Urbanización Montepríncipe, Departamento de Ciencias Médicas Básicas, Facultad de Medicina, Universidad San Pablo-CEU, CEU Universities, Urbanización Montepríncipe, Boadilla del Monte, Spain, [7]Centro de Metabolómica y Bioanálisis (CEMBIO), Facultad de Farmacia, Universidad San Pablo-CEU, CEU Universities, Urbanización Montepríncipe, Boadilla del Monte, Spain

Background: Elite controllers (EC) are a group of people living with HIV (PLWH) able to control HIV replication without antiretroviral therapy and have been proposed as a model of functional HIV cure. However, despite viral control EC have increased incidence of different morbid conditions, some of them associated with monocyte activation. We have characterized the metabolic profile of monocytes in EC compared to non-controllers PLWH with or without ART.

Methods: 40 participants were included: 10 EC, 20 non-controllers PLWH, 10 of them on-ART(onART) and 10 off-ART(offART), and 10 uninfected controls (UC) as reference. Monocytes were purified using immunomagnetic separation with purities greater than 95%. Untargeted metabolomics of monocyte extracts was performed using gas chromatography coupled to time-of-flight mass spectrometry (GC-QTOF/MS). MetaboAnalyst 6.0 software was used for bioinformatics analysis of data.

Hierarchical clustering of the normalized abundances of annotated metabolites was represented using heatmaps of Z-score values, and the significance of differences in individual metabolite abundances was tested by ANOVA. Enrichment of metabolite sets was performed using the Metabolite Set Enrichment Analysis tool from MetaboAnalyst 6.0.

Results: 54 different metabolites were detected in monocyte extracts. Interestingly, EC was the group with the highest perturbation (taking UC group as reference) in the metabolomics profile, followed by onART and offART groups. EC showed increases in the majority of metabolites, some of them reaching statistical significance ($p<0.05$): tyrosine, proline, alanine, serine, UDP-N-acetylglucosamine and α-hydroxyglutaric acid.

Moreover, some metabolites were specifically associated to EC phenotype (increased in EC compared to all other groups), among them xylitol and hydroxyproline, for which anti-viral properties have been shown. The enrichment analysis showed several enriched metabolite sets in EC compared to UC ($p<0.05$), among them: a) phenylalanine, tyrosine and tryptophan biosynthesis, b) alanine, aspartate and glutamate metabolism, c) butanoate metabolism. All these metabolic pathways have been related to immune activation and to different morbid conditions.

Conclusions: Our results suggest the existence of an exacerbated metabolism in monocytes of PLWH EC, biased towards metabolic pathways involved in inflammation and associated with different pathological conditions, supporting that in EC monocytes have a significant role in the occurrence of these phenomena.

EP0009

Impaired immune reconstitution in PLWH: the role of CD4⁺ T cell-associated NKG2D ligands, CD4⁺ T cell subsets imbalance, and immune function deficiency

Q. Xu[1,2], Q. Zhang[3], P. Xu[1,2], T. Zhang[1,2], H. Wu[1,2], X. Zhang[1,2], C. Moog[4,2,5], B. Su[1,2]

[1]Beijing Youan Hospital, Capital Medical Unversity, Beijing Key Laboratory for HIV/AIDS Research, Clinical and Research Center for Infectious Diseases, Beijing, China, [2]Beijing Youan Hospital, Capital Medical University, Sino-French Joint Laboratory for HIV/AIDS Research, Sino-French Joint Laboratory for Research on Humoral Immune Response to HIV Infection, Beijing, China, [3]Third People's Hospital of Shenzhen, National Clinical Research Center for Infectious Diseases, Department of Immunity and Infectious Diseases, Shenzhen, China, [4]Institut National de la Santé et de la Recherche Médicale (INSERM) UMR_S 1109, Université de Strasbourg, Laboratoire d'ImmunoRhumatologie Moléculaire, Strasbourg, France, [5]Vaccine Research Institute (VRI), Créteil, France

Background: Our previous research indicated that early activation of $CD56^{dim}CD16^{dim/-}$NK cells plays an important role in the recovery of CD4⁺T cells in immunological nonresponders (INRs) after ART.

This study mainly focuses on the profiles of cell receptors and their relative ligands for NK cells and CD4⁺T cells exhibited on INRs in order to analyze the impact of differential immune status on immune reconstitution in PLWH receiving ART.

Methods: This study included 66 PLWH who had been on ART for 4 years, comprising 32 INRs. Using flow cytometry, we examined the expression of cell receptors and ligands for NK cells and CD4⁺T cells in PBMCs, as well as the differentiation of CD4⁺T cells.

Results: The expression of NKG2D ligands, including MICA/B and ULBP2-5, on CD4+T cells in INRs is elevated prior to ART. The expression of CD95 on MICA/B⁺CD4⁺T cells and ULBP2-5⁺CD4⁺T cells was higher in INRs before ART compared to IRs. The percentages of CD95 expression on MICA/B⁺CD4⁺T cells and on ULBP2-5⁺CD4⁺T cells before ART were negatively correlated with CD4⁺T cell counts and ΔCD4. An imbalance persists in the CD4⁺Tcm and CD4⁺Temra subsets in PLWH, no matter before and after ART. CD4⁺T cells

exhibit elevated levels of activation, proliferation, exhaustion, and apoptosis prior to ART initiation. However, CD4⁺T cell activation and proliferation normalize post-ART, while apoptosis and exhaustion levels remain significantly elevated. Regardless of ART, the anti-apoptotic capacity of CD4⁺T cells in PLWH is still lower than that of healthy people.
Before ART, the frequency of CD31 expression on CD4⁺Tn cells in INRs is lower than that in IRs and healthy people. Following ART, the amounts of CD31⁺Tn from CD4⁺T cells remain impaired in PLWH compared to healthy people.
Conclusions: The upregulation of elated ligands for the NKG2D receptor on CD4⁺ T cells in INRs leads to increased susceptibility of CD4⁺ T cells to NK cell-mediated killing. CD95 plays an important role in poor recovery of CD4+ T cells co-expressing NKG2D-related ligands. The imbalance in CD4⁺Tcm and CD4+Temra subset impaired CD31 expression on naive CD4⁺ T cells in INRs is associated with poor immune reconstitution outcomes.

EP0010

P-Selectin Glycoprotein Ligand (PSGL)-1 expression on CD4+ T-cells in people living with HIV: contributing factors and impact on cell behaviour

S. Zaongo[1], Y. Chen[1]
[1]Chongqing Public Health Medical Center, Department of Infectious Diseases, Chongqing, China

Background: P-Selectin Glycoprotein Ligand (PSGL)-1 acts as an HIV restriction factor and may also mediate the transmission of HIV to negative cells. We aimed to explore PSGL-1 expression on CD4+ T-cells in people living with HIV, the potential factors contributing to PSGL-1 expression, and the impact of PSGL-1 expression on CD4+ T-cells.
Methods: Flow cytometry was used to determine PSGL-1 expression on CD4+ T-cells, proportions of CD4+ T-cell-platelet aggregates, and expression of markers of cell exhaustion (PD-1), survival (BCL-2), and death (Caspase-3) in HIV-negative and HIV-positive individuals. ELISA kits were used to determine the levels of interleukin (IL)-12, interferon-gamma (IFN-γ), lipopolysaccharides (LPS), and beta (β)-glucan.
Results: A total of 117 participants (26 HIV negative, 52 ART-treated, and 39 ART-naïve) were enrolled. ART-treated individuals with CD4+ T-cells <200 cells/μl had a significantly higher level of PSGL-1 expression on their CD4+ T-cells compared to HIV-negative controls and ART-treated individuals with CD4+ T-cells ≥200 cells/μl. ART-naïve individuals with CD4+ T-cells <200 cells/μl had a significantly higher level of PSGL-1 expression compared to ART-naïve individuals with CD4+ T-cells ≥200 cells/μl. The proportions of CD4+ T-cell-platelet aggregates corresponded with the PSGL-1 expression on CD4+ T-cells, with ART-treated individuals with CD4+ T-cells <200 cells/μl having significantly higher proportions of CD4+ T-cell-platelet aggregates compared to negative controls and ART-treated individuals with CD4+ T-cells ≥200 cells/μl, and ART-naïve individuals with CD4+ T-cells < 200 cells/μl having significantly higher proportions of CD4+ T-cell-platelet aggregates compared to negative controls and ART-naïve individuals with CD4+ T-cells≥200 cells/μl. PSGL-1 expression was significantly and positively correlated with levels of IFN-γ , IL-12, LPS, and β-glucan in ART-treated individuals, whereas no significant correlations were observed in ART-naïve individuals. ART-treated individuals with CD4+ T-cells <200 cells/μl showed significantly higher proportions of Caspase-3 and PD-1, and significantly lower proportions of BCL-2 compared to those with CD4+ T-cells ≥200 cells/μl.
Conclusions: Our results showed that PSGL-1 expression on CD4+ T-cells varied in people living with HIV depending on their ART status and immunological status, and that systematic inflammation contributed to PSGL-1 expression on CD4+ T-cells, which resulted in cell exhaustion and death

EP0011

Differential immunopathogenesis between the small and large intestine in PLWH

M. Marin[1], O. Asowata[1], K. Gopee[1], S. Mfusi[1], S. Nyquist[2], H. Baharlou[3], K. Hu[3], P. Mthabela[4], K. Chetty[4], L. Madziwa[4], F. Karim[4], M. Vukani[5], S. Kader[6], F. Madela[5], A. Harman[3], A. Leslie[1], A.K. Shalek[2], H. Kløverpris[1]
[1]Africa Health Research Institute (AHRI), Durban, South Africa, [2]Institute for Medical Engineering and Science, Department of Chemistry, MIT, Boston, United States, [3]The Westmead Institute for Medical Research, Sydney, Australia, [4]Africa Health Research Institute, Basic and Translational Science, Durban, South Africa, [5]Inkosi Albert Luthuli Central Hospital, Division Upper Gastrointestinal Tract and Colorectal Surgery, Durban, South Africa, [6]Dr Pixley Ka Isaka Seme Memorial Hospital, Durban, South Africa

Background: HIV infection impairs gut homeostasis in people with HIV (PLWH) and is associated with immunopathology and comorbidities. However, the differential impact between the small and large intestines remains poorly defined.
Methods: We recruited 373 gastrointestinal-indicated participants from high HIV-endemic areas in South Africa for small and large intestinal mucosal and matched blood sampling. We performed flow—and mass cytometry (CyTOF), bulk RNA sequencing of tissue-resident memory (TRM) populations and spatial mucosal profiling, to study differential impacts between the small and large intestines from PLWH.
In addition, a 40-plex MSD assay correlated blood factors with T-cell dynamics in tissue.
Results: Tissue-resident memory (TRM) like (CD69⁺CD103⁺) and HIV susceptible (CCR5⁺) CD4⁺T-cells were enriched in duodenum compared to the colon with selective depletion of duodenal TRM CD4 T-cells in PLWH. Transcriptional profiles of remaining duodenal TRM CD4 T-cells revealed downregulation of pro-inflammatory genes (IL-2/6/8 and GM-CSF), reduction of integrin-signaling (TGFβ) and upregulation of IL-17 pathways in PLWH. Limited gene alterations were observed in the colon.
Conversely, TRM-like CD8+ T-cells were enriched in the duodenum and colon. Duodenal TRM-like CD8+ T-cells in PLWH exhibited increased activation (CD3ζ), strong cyto-

lytic function (GZMK), and elevated interferon and inflammatory responses compared to uninfected controls and blood. In PLWH, the blood CD4:CD8 ratio was positively correlated with markers of immune activation (RAGE, MIP-1β, IFNγ) and vitamin D, while negatively correlated with pro-inflammatory cytokines (TNFα, IL-17, IL-6, IL-5, IL-13) and lipid metabolism (triglycerides, LBP).
In contrast, the duodenal CD4:CD8 ratio in PLWH correlated positively with pro-inflammatory and regulatory cytokines (MIP-1β, TARC, IL-8-LA, IL-1α, IL-2, IL-10, IL-15) and the gut epithelial integrity markers (FABP2).
Conclusions: Our findings reveal selective depletion and dysfunction of integrin-expressing CD4 TRM cells in the duodenum, paired with increased cytolytic CD8 TRM activity, a pattern not found in colon. These findings underscore the compartmentalized HIV immunopathogenesis in the gut, emphasizing the need for targeted therapeutic strategies to restore gut homeostasis in PLWH.
Additionally, our results suggest that soluble markers in blood could serve as non-invasive indicators of duodenal gut pathology, potentially offering a potential tool for monitoring gut-related immune dysfunction.

EP0012

Tenascin C: a new player for HIV replication?

C. Moog[1], A. Karl[1], L. Risch[1], Z. Deng[2], T. Decoville[1], G. Laumond[1], B. Su[2], M. Cavarelli[3], G. Orend[1]
[1]INSERM U1109, Institute of Virology, University of Strasbourg, Strasbourg, France, [2]Capital Medical University, Beijing Youan Hospital, Beijing, China, [3]CEA, Laboratoire d'Immunologie et Infectiologie, IDMIT, Fontenay aux Roses, France

Background: The extracellular matrix molecule Tenascin-C (TNC) is naturally induced upon tissue injury, playing a role as danger associated molecular pattern (DAMP) molecule in response to pathogens and tissue repair.
On the contrary, during chronic inflammation stages, TNC may play a detrimental role by maintaining cytokine induction and high TGF-b production.
Noteworthy, TNC was proposed to be induced during virus acquisition but its role in HIV is so far poorly investigated. Our project aims to characterize the effects of TNC on HIV-1 replication using novel TNC targeting tools.
Methods: A) The concentration of TNC in sera from cohorts of people living with HIV (acute infection, ART with or without immune recovery (IR) and controller cohorts) was measured by ELISA.
B) The effect of TNC on HIV-1 replication was investigated *in vitro* on peripheral blood mononuclear cells (PBMC).
In parallel, T cell activation and cytokine release was defined by flow cytometry.
Results: We found that A) the concentration of TNC was significantly increased in the cohort of ART treated without IR and decreased in HIV controllers compared to the non-HIV infected group.
These results suggest a modulation of TNC induction according to disease evolution and outcome. B) HIV replication in PBMC was increased in the presence of TNC. This augmentation was associated with increased TGF-b concentration and CCR5 expression on CD4 T cells suggesting that the immunomodulatory effects of TNC promote HIV replication.
Conclusions: Our results suggest, that upon HIV acquisition, TNC is induced and its presence may interfere with HIV replication by activating immunity on one side and inflammation on the other side. As a component of the extracellular matrix, future experiments should investigate the roles of TNC on HIV replication within the tissue microenvironment, and in particular in a context of cell-to-cell HIV transmission. As a new HIV target, TNC will open novel opportunities for HIV disease management by interfering with the TNC immune-modulatory properties.

EP0013

Modeling HIV-1 Clade C SHIV-C109 viral pathogenesis and antiretroviral therapeutic responses in humanized mice

E. Barnett[1], D. Bose[2], S. Kaginkar[1], L. Remling-Mulder[1], F. Villinger[2], R. Akkina[1]
[1]Colorado State University, Microbiology, Immunology and Pathology, Fort Collins, United States, [2]University of Louisiana at Lafayette, New Iberia Research Center, New Iberia, United States

Background: Since NHP models do not support infection with HIV, Simian-Human Immunodeficiency Viruses (SHIVs) provide a good alternative for vaccine and cure studies. These hybrid viruses incorporating HIV viral envelopes and/or accessory genes into the SIV backbone are commonly used. Most SHIV studies thus far focused on HIV-1 clade B. HIV-1 clade C has been significantly understudied despite its predominance in low-resource regions outside of North America.
To address this deficiency, here we evaluated SHIV-C109 virus infection dynamics and anti-retroviral therapy (ART) responses in a dual-purpose hu-HSC humanized mouse model permissive for both HIVs and SIVs.
Methods: The clade C SHIV-C109 hybrid virus used here was created by combining the SHIVHXBc2 P3.2 backbone with an R5-tropic HIV-1 Clade C envelope sequence. Multiple hu-mice cohorts were inoculated i/p with SHIV-C109 and monitored for a prolonged period to determine the persistence of viremia by qRT-PCR and potential CD4 helper T cell decline by flowcytometry.
We also evaluated the efficacy of anti-retroviral therapy on this virus using the hu-mouse model as a prelude to translate this to the NHP model. Infected mice were administered with a combinatorial ART consisting of bictegravir, emtricitabine, and tenofovir alafenamide via drug incorporated diet.
Results: Our results showed that hu-mice could be readily infected by SHIV-C109 with viremia seen within a week. Persistent viremia lasted for >45 weeks. RNAscope analysis infected mouse tissues confirmed disseminated viral infection as seen in in lymphoid organs spleen and lymph nodes. CD4 T cell depletion was also seen during the chronic phase of infection mimicking the key aspect of HIV infection. With ART, viral suppression was achieved in all treated mice for several weeks.

However, there was a slow viral rebound during the later part of treatment period indicating generation of viral drug resistance.
Conclusions: The data from above on SHIV-C109 viral infection in the hu-HSC mouse model showed the potential for its use in pre-clinical in vivo research on understudied HIV-1 clade C viruses. Importantly, cure studies on both HIV and SIV including their variant strains can be performed in the same animal model for effective comparisons.

EP0014

Cytokines profiling, HIV-1 DNA Levels and viral-replication among antiretroviral treatment-experienced adolescents in Cameroon: paving the way toward pediatric HIV functional cure

[1]Chantal Biya International Reference Centre for Research on HIV/AIDS Prevention and Management (CIRCB), Virology, Yaounde, Cameroon, [2]University of Rome Tor Vergata, Experimental Medicine, Rome, Italy, [3]UniCamillus - Saint Camillus International University of Health Sciences, Rome, Italy, [4]Essos Hospital Centre, Pediatrics, Yaounde, Cameroon, [5]Weill Cornell Medicine Graduate School of Medical Sciences, New York, United States, [6]Department of Pediatrics, Johns Hopkins University School of Medicine, Maryland, United States, [7]Africa Health Research Institute (AHRI), Durban, South Africa, [8]National Institute of Communicable Diseases and The University of Witwatersrand, Johannesburg, South Africa, [9]Bambino Gesu Pediatric Hospital, Rome, Italy

Background: Antiretroviral therapy (ART) leads to viral control, but the persistence of inflammation might contribute to long-term complications. This study investigates the inflammatory profile of adolescents living with perinatal HIV-1 (ALpHIV), its association with viral replication and proviral HIV-DNA.
Methods: A study was conducted in the cohort of ALpHIV within health-facilities of Yaoundé-Cameroon from 2018-2019. Plasma viral load (VL) was measured by RT-PCR at three time-points over 18 months and participants were classified as persistently non-viremic (PersNV) with VL<50 copies/mL, persistently-viremic (persV) with VL≥50 copies/mL and fluctuating VL (Fluct-VL with VL that significantly varies) over the timepoints.
At the final time-point (T3), total proviral HIV-DNA levels were assessed by droplet digital PCR and some relevant cytokines (IL-1β, IL-4 and CCL3) were measured by ELISA and their concentrations calculated at 450nm optical density.
Results: Overall, 37 ALpHIV were enrolled (55.3% female, median [IQR] age 13 [12-16] years). Throughout the three time-points, 19/38 (50.0%) were persV, 10/38 (26.31%) were with Fluct-VL and 8/38 (21.05%) PersNV. The median [IQR] VL at T3 was 4.05 [3.49-5.35] log copies/mL among PersV versus 2.33 [1.79-4.85] log copies/mL among Fluct-VL, p=0.188. Overall, the median [IQR] concentration of total proviral HIV-DNA was 2.72 [2.46-3.14] log(copies/mL) with no significant difference between the three groups. IL-4 and IL-1β levels were elevated (>10 pg/mL) in PersNV-participants compared to others (p=0.023 and p<0.01, respectively).
However, a moderate negative correlation was found only between IL-1β and VL (r= -0.48; p=0.012). CCL3 levels were higher in participants with Fluct-VL compared to others (p=0.042) with an apparent higher concentration (>15 pg/mL) in ALHIV with larger HIV-DNA size (>2.72 log copies/mL), p=0.692. Moreover, IL-4 and IL-1β levels did not differ according to HIV-DNA levels (p=0.558 and p=0.657, respectively).
Conclusions: The higher levels of IL-4 and IL-1β in PersNV underscores their potentials as pro-inflammatory markers of optimal control of viral replication, indicating ART-effectiveness. The possible role of CCL3 in Fluct-VL requires a wider investigation of its effect on viral replication.
Furthermore, the lack of association between these cytokines and proviral HIV-DNA levels calls for a broader profiling of biomarkers contributing to pediatric HIV reservoir control toward a functional cure.

EP0015

Baseline Torque Teno Virus viral load as a biomarker of HIV reservoir dynamics and inflammatory status in people with HIV following one year of antiretroviral therapy

N. Ducasa[1], J.S. Schilling[1], C. Monzani[1], M. Acevedo[1], D. Giannone[1], M.B. Vecchione[1], M.I. Figueroa[2], A. Gun[2], P. Cahn[2], M. Biglione[1], G. Turk[1], Y. Ghiglione[1], F. Quiroga[1]
[1]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS) - Facultad de Medicina - Universidad de Buenos Aires, Ciudad autónoma de Buenos Aires, Argentina, [2]Fundación Huésped, Buenos Aires, Argentina

Background: Torque Teno Virus (TTV), a non-pathogenic single-stranded DNA virus from the Anelloviridae family, is found in up to 90% of the population. TTV viral load (VL) increases with immunosuppression, making it a potential marker of immune status. This study aimed to evaluate TTV as a biomarker in people with HIV (PWH).
Methods: We enrolled 28 ART-naïve PWH with detectable HIV VL. Blood samples were collected prior to antiretroviral treatment (pre-ART) and one year post-ART. TTV VL was quantified using a SYBR Green qPCR assay with a detection limit of 1.11 log10 copies/mL. HIV VL and CD4+ T cell counts were determined. Total and integrated HIV-DNA, and cell-associated viral RNA were measured by qPCR, while soluble markers (IP-10, IL-8, IL-1β, TNF-α, IL-10, IFN-γ, IL-6) were assessed by ELISA. Data analysis utilized non-parametric statistics.
Results: Pre-ART TTV VL was significantly higher than one-year post-ART (Pre-ART log10 VL median: 6.68 and post-ART log10 VL median: 5.70, respectivily; p=0.003) and it was markedly elevated at both time points compared

to healthy donors (HD) (HD log10 VL median: 4.1 p<0.0001 and p=0.0003, respectively). Pre-ART, TTV VL inversely correlated with CD4 count (p=0.045, r=-0.3328), and directly correlated with HIV VL (p=0.034, r=0.3565) and IL-6 levels (p=0.019, r=0.4166).
Furthermore, pre-ART TTV VL correlated with total HIV DNA (p=0.023, r: 0.4023), HIV-integrated DNA (p=0.041, r: 0.3985), and HIV RNA levels (p=0.008, r=0.5353). Post-ART, these correlations were no longer detected, indicating a potential restoration of immune competence. Pre-ART TTV VL was significantly associated with ΔHIV-integrated DNA (post-ART minus pre-ART) (p=0.015, r=0.4714) and correlated with IL-6 levels one-year post-ART (p=0.024, r=0.3840).
Conclusions: We developed a robust method to quantify TTV VL and observed improved control of TTV replication after ART initiation. TTV levels positively correlated with critical parameters associated with HIV infection, and he assessment of TTV VL prior to the initiation of ART emerged as a promising marker of HIV reservoir dynamics and the degree of immunocompromise. These findings highlight the potential of TTV VL as a cost-effective biomarker for monitoring HIV reservoirs, inflammatory status, immune recovery, and treatment outcomes in PWH.

EP0016

Plasma exosome cysteine-cysteine chemokine receptor 5 levels of persons living with HIV on antiretroviral therapy in university of Abuja teaching hospital, Nigeria

S.S. Awala[1], A. Ibrahim[2], J. Abubakar Bala[3], A. Abbas Anzaku[1]
[1]Institute of Human Virology, Nigeria, Clinical Laboratory, Abuja, Nigeria, [2]Bayero University Kano, Clinical Laboratory, Kano, Nigeria, [3]Bayero University Kano, Medical Laboratory Science, Kano, Nigeria

Background: Exosomes can activate resting HIV-acquired CD4+ T lymphocytes, which could reactivate the virus. Hence, this study investigates the relationship between exosome CCR5 levels and viral load among persons on antiretroviral therapy attending a clinic at the University of Abuja Teaching Hospital, Nigeria.
Methods: In this cross-sectional study, we enrolled a cohort of PLHIV on ART for three months. After ethics approval, consented participants were screened using a standardized structured semi-interviewer-based assessment. Viral load quantification was performed using the Reverse transcriptase-polymerase chain reaction (RT-PCR) technique with a conventional PCR platform while the ELISA Sandwich technique was used to quantify plasma exosomes. Specimens were classified into two groups based on plasma RNA viral load results (non-suppressed (≥1000 copies/ml) and suppressed (≤20 copies/ml)) and plasma exosomes were isolated. Pearson correlation was used to measure the association between plasma exosome CCR5 levels and viral load. All statistical analysis was done using SPSS (IBM) v26.
Results: Of the 384 participants screened, the overall non-suppression (≥1000 copies/ml) VL was 10.1% (95% CI: 0.7–19.5), and suppression (≤20 copies/ml) VL was 89.8% (95% CI: 86.7–92.8). The Mean plasma exosome levels were 1.13(±2.97) and 0.19(±0.015) for the non-suppressed and suppressed VL groups respectively (p=0.057). Plasma exosome levels were significantly associated with viral load among the non-suppressed VL group (p=0.044), with females having a greater percentage 69.2% compared to males 30.8%. The largest age groups among women with non-suppression VL group were 25–34 and 35–44 while the males had the highest in the 35–44 age group.
Conclusions: This study showed a significant association between plasma exosome CCR5 and viral load. The high percentage of women among the non-suppressed VL group within the childbearing age indicates a threat to the prevention of mother-to-child transmission (PMTCT) efforts.

EP0017

HIV gut pathology in the absence of GI disease is focused in the upper small intestine in PWH from South Africa

K. Gopee[1], M. Marin[1,2], S. Mfusi[1], F.S. Abdool[1,2], M. Ghanizada[3], A. Langhave[3], P. Mthabela[1], L. Madziwa[1], K. Chetty[1], M. Hoque[4], S. Kader[5], F. Madela[6], H. Kløverpris[1,2,3]
[1]Africa Health Research Institute, Durban, South Africa, [2]University of KwaZulu-Natal, Durban, South Africa, [3]University of Copenhagen, Copenhagen, Denmark, [4]Kwadabeka Community Health Centre, Durban, South Africa, [5]Dr Pixley Ka Isaka Seme Memorial Hospital, Durban, South Africa, [6]Inkosi Albert Luthuli Central Hospital, Durban, South Africa

Background: The gastrointestinal (GI) tract exists in a dynamic homeostatic equilibrium that is disrupted in people with HIV (PWH) despite antiretroviral treatment (ART). Most GI studies in PWH focus on Caucasian populations presenting with GI complications and who live in distinct environments to Sub-Saharan African populations representing the majority of PWH.
Here, we present the first longitudinal research-elected intestinal biopsy cohort from populations living in areas with high HIV prevalence to study HIV gut pathology.
Methods: Participants from rural and urban areas in KwaZulu-Natal, South Africa, were enrolled into three groups without prior GI complications: HIV-negative controls (NC, n=12), suppressed HIV (PWSH, n=23), and viremic HIV (PWVH, n=17) for both colonoscopy and endoscopy procedures to sample matched duodenum, ileum, and colon biopsies along with blood samples that were compared with our GI indicated cohort.
Results: First, we compared NCs from the clinically indicated GI cohort to our research elected cohort and found elevated blood inflammatory (hsCRP) and metabolic (triglycerides and HbA1c) markers, consistent with clinical GI status. While blood CD4% levels were similar, CD4 T-cell levels in the duodenum and colon were significantly lower in NCs with GI indication (p<0.0001 and p=0.0273), who also showed increased intestinal crypt proliferation (Ki-67). In PWSH, significant CD4 T-cell depletion was observed within the duodenum, but not in colon and ileum. Longitudinal follow up after 6-9 months showed no CD4 T-cell restoration in the GI tract, despite ART. Duodenal

CD4 T-cells exhibited a high abundance of tissue-resident memory (TRM)-like (CD69+CD103+) and HIV-susceptible (CCR5+) phenotype in NCs but were significantly lower in PLWH. Plasma cytokine analysis revealed elevated pro-inflammatory cytokines (IL-12, IP-10 and RAGE) in PWSH, indicating chronic immune activation. IFN-γ levels negatively correlated with duodenal CD4 T-cell levels. Additionally, HIV-p24 protein was detected in the duodenum and colon of PWSH, implicating these sites as potential viral reservoir.

Conclusions: Our research elected longitudinal gut biopsy cohort in South Africa show cross-compartment specific CD4 T-cell depletion in the GI tract despite normal CD4 T-cell counts in the blood during suppressive ART. These findings reveal distinct intestinal immune reconstitution mechanisms, underscoring the need for targeted GI interventions to restore immune function.

EP0018

Incidence and metabolomic signatures of preeclampsia in Zambian women

L. Kamulaza[1], C. Mulenga[1], T. Pokaprakarn[2], Y. Sebastiao[2], J. Sakala[1], N. Sindano[1], K. Rittenhouse[2], K. De Paris[2], J. Stringer[2]
[1]UNC Global Projects Zambia, LLC, Lusaka, Zambia, [2]UNC, Chapel Hill, United States

Background: Preeclampsia (PE) represents a major pregnancy complication, accounting for approximately 14% of maternal deaths and between 10-25% of perinatal deaths globally. The exact biological pathway resulting in PE remain largely undefined.

To answer this question and how HIV may alter these pathways, we performed a multi-omics analysis using longitudinally collected specimens from pregnant Zambian women.

Methods: Plasma samples of 1,237 pregnant women without HIV and 1,105 women living with HIV collected throughout pregnancy (32 wks GA) were collected from a prospective antenatal cohort in Lusaka, Zambia and analyzed by Sapient for metabolomic signatures.

To identify early biomarkers of PE, specimens were grouped by gestational age: <20 weeks GA versus 20 weeks GA. Metabolite detection and intensity were compared between all cases (PE) and non-cases and stratified by HIV status. Significance was determined as FDR<0.1. Enrichment and pathway analysis of significant metabolites was performed using MetaboAnalyst.

Results: Plasma samples of 1,237 pregnant women without HIV and 1,105 women with HIV collected throughout pregnancy (32 wks GA) were collected from a prospective antenatal cohort in Lusaka, Zambia and analyzed by Sapient for metabolomic signatures. To identify early biomarkers of PE, specimens were grouped by gestational age: <20 weeks GA versus 20 weeks GA.

Metabolite detection and intensity were compared between all cases (PE) and non-cases and stratified by HIV status. Significance was determined as FDR<0.1. Enrichment and pathway analysis of significant metabolites was performed using MetaboAnalyst.

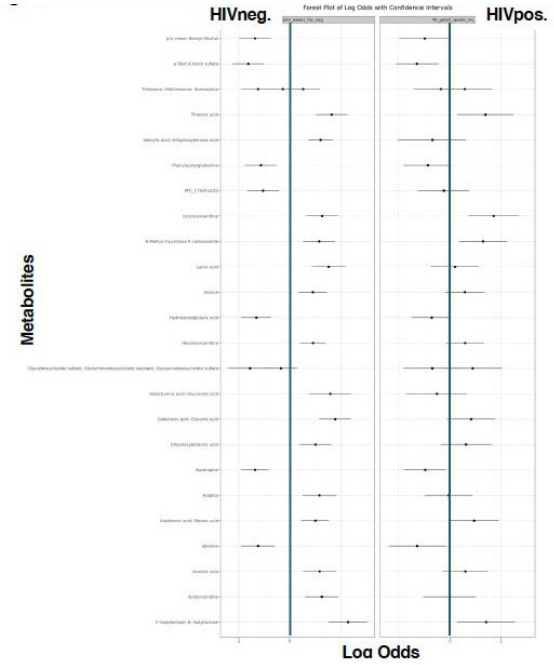

Figure 1. Plasma metabolites associated with preeclampsia.

Conclusions: Women with PE exhibit differences in the plasma metabolome compared to women without PE. These metabolomic differences did not appear to be impacted by HIV status, despite the fact that PE was less frequent in women with HIV compared to women without HIV. Additional data of the plasma proteome are being analyzed to complement metabolome data and gain more conclusive insights into the mechanisms underlying PE.

EP0019

Preterm birth outcomes in Zambian women are associated with distinct plasma metabolomic signatures, which vary by HIV status

C. Mulenga[1,2], L. Kamulaza[1], J. Sakala[1], T. Pokaprakarn[3], Y. Sebastiao[3], N. Sindano[1], M. Kasaro[1], K. Rittenhouse[3], K. De Paris[3], J. Stringer[3]
[1]UNC Global Projects Zambia, LLC, Lusaka, Zambia, [2]Levy, Mwanawasa Medical University, Lusaka, Zambia, [3]UNC, Chapel Hill, United States

Background: Globally, over 10% of pregnancies result in preterm birth (PTB), a leading cause of neonatal mortality. Surviving infants often face lifelong health challenges. The role of HIV in PTB remains controversial. PTB has a multifactorial etiology, with two-thirds occurring spontaneously. Understanding the biological mechanisms underlying PTB is critical for identifying diagnostic biomarkers and designing intervention strategies.

Methods: Longitudinally collected plasma samples of Zambian pregnant women without HIV (WHIVneg; (n=968) and with HIV (WHIVpos; n=1,017) underwent an untargeted metabolome analysis (Sapient). Specimens were grouped in 4-week intervals starting at 20wks gestational age (GA). Metabolites were compared between women with term versus PTB (<37wks GA) in the total co-

hort (n= 1,986), and in sub-cohorts stratified by HIV. Significance was defined as FDR<0.1. Enrichment and pathway analysis of significant metabolites was performed using MetaboAnalysist.

Results: PTB occurred in 6.3% of women, independent of HIV status. Full cohort analysis in specimens collected at 24-28 or after 32wks GA identified 2 or 8 metabolites positively associated with PTB, respectively, and 1 metabolite with negative association. Only three metabolites were annotated, preventing pathway analysis.

Sub-cohort analysis revealed significant metabolites only in specimens 32wks GA. A positive association with PTB was observed for 9 metabolites in WHIVpos compared to 175 metabolites in WHIVneg, with only 2 shared metabolites. Metabolites negatively associated with PTB (>200) were only detected in WHIVneg. The top 3 pathways associated with PTB in WHIVpos were distinct from WHIVneg. However, enrichment analysis identified several metabolites groups common to WHIVpos and WHIVneg (Figure 1).

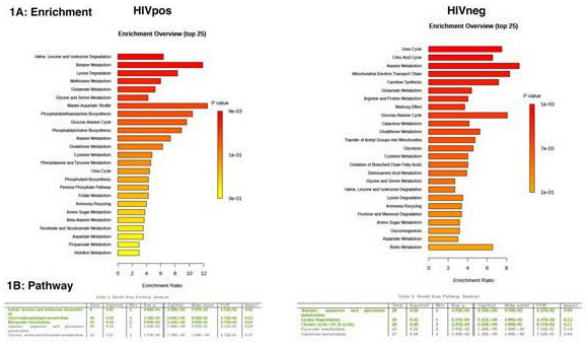

Figure 1. Metabolomic plasma signatures associated with preterm birth outcome.

Conclusions: In our Zambian cohort, metabolomic markers of PTB were only detected 32wks GA, limiting their utility as early diagnostic biomarkers. The metabolome analysis implies that there are shared and unique mechanisms leading to PTB in WHIVpos or WHIVneg.

Host immune responses

EP0020

Assessment of the level of CD4+ FOXP3+ regulatory T cells and immune status of people living with HIV under antiretroviral therapy at the Nakuru Level 5 Hospital, Kenya

B. Nyamweya[1], G. Maina[2], I. Orina[3]

[1]National AIDS and STI control programme, Nairobi, Kenya, [2]Kenyatta University, Medical Laboratory Science, Nairobi, Kenya, [3]Technical University of Kenya, Health Sciences, Nairobi, Kenya

Background: Regulatory T cells are widely recognized as capable of suppressing the activation, proliferation, and function of a wide variety of immune effector cells. Tregs are activated to modulate immune responses to avoid over-reactive immunity. However, there is limited information on Treg cells expression in people living with HIV. The aim of this study was to evaluate the level of CD4 + T cells, Plasma HIV RNA and Regulatory T cells in people living with HIV under Antiretroviral Therapy attending Nakuru Level 5 Hospital, Kenya.

Methods: Participants were people living with HIV under ART attending the hospital for routine viral load examination. Among 90 people living with HIV appointed for viral load from April to July 2022, 51 of them were selected randomly. 15 non-HIV volunteers were also included in this study as controls. Peripheral venous blood samples were collected in EDTA tubes for Treg cells analysis, viral load and CD4 cell count exams.

The quantification of CD4 + T-cells was performed through Becton Dickinson FACScount. Plasma HIV RNA level was measured by a quantitative real-time polymerase chain reaction. The phenotyping was performed on fresh whole blood using conjugated monoclonal antibodies to CD3, CD4 and FoxP3. The analyses were performed with FACScalibur and FlowJo software

Results: There was a moderate but significant inverse association between CD4 cell count and viral load ($r = -0.506$, $p < 0.001$). The frequency of Treg cells was evaluated and the results showed that the percentage of CD4 + FoxP3+ Treg cells was statistically significant high in people living with HIV comparing with that of non-HIV controls ($p = 0.023$).

All the participants in stage I, II and III demonstrated significantly higher levels of CD4 +FoxP3+ Treg cells compared to non-HIV controls. people living with HIV in clinical stage III presented a high level of Treg cells compared to people living with HIV in other clinical stages.

Conclusions: The increasing of Treg cells in the advanced phase of HIV infection may suggest the relationship between Treg cells and HIV disease progression. Also, the manipulation of Tregs in people living with HIV can possibly be used in improving their immunological status.

EP0021

Correlating immunoglobulin profiles in cervicovaginal mucus with HIV transmission and microenvironmental factors

M. Akiso[1,2], I. Abook[1], M. Mureithi[1,2], J. Kombo[2], P. Koi[1], J. Musando[2], R. Chirchir[2], M.D. Raven[3], A.M. Carias[3], T.J. Hope[3]
[1]University of Nairobi, Department of Medical Microbiology and Immunology, Nairobi, Kenya, [2]University of Nairobi, KAVI Institute of Clinical Research, Nairobi, Kenya, [3]Northwestern University, Feinberg School of Medicine, Cell and Developmental Biology Department, Chicago, United States

Background: There is inadequate knowledge on the correlations of the different immunoglobulin isotypes and subclasses with the cervicovaginal mucus (CVM) microenvironment and the possible implications in HIV-1 transmission. We aimed to correlate immunoglobulin profiles in human CVM from adult women in Kenya with CVM microenvironment and to the diffusivity of HIV-1 virions in the CVM. Our study provides a unique perspective on the interplay between immunoglobulin profiles, cervicovaginal mucus microenvironment, and HIV-1 transmission.
Methods: Blood and CVM samples from 139 adult women aged between 18 and 50 years were collected using a softcup. Antibody isotypes/subclasses, and cytokines were measured using Luminex assay. Bacterial vaginosis was diagnosed by Gram staining and classified by Nugent scoring technique. Serum estrogen and progesterone levels were measured using chemiluminescent emission assay. Diffusivity of HIV-1 virions was assessed with an established protocol at KAVI-ICR. Statistical tests were done on graph pad prism software.
Results: IgG2 levels were the highest in the human CVM samples. Five samples had elevated levels of IgA of which, 2 were both BV and HIV positive, 1 BV positive and 1 BV intermediate. IgG3 levels were elevated in 3 samples 2 of which were HIV positive. There were significant positive correlations between the Nugent scores with IgA and IgM levels. BV positive samples had significantly lower IgG1 levels compared to intermediate and BV negative samples with a significant negative correlation between Nugent scores and the IgG1 levels.
There was no difference in the antibody levels based on contraceptive usage neither was there a correlation between the antibody levels and the levels of estradiol and progesterone. IgG1 had a negative correlation while the other antibodies had a positive correlation with most of the tested cytokines. IgG1 levels had a negative correlation with the mobility of R9Bal.
Conclusions: Our results suggest a protective role of IgA in BV and IgG3 in HIV-1 infection. BV-associated inflammation and degradative enzymes may degrade IgG1. Our findings provide insights to inform targeted HIV-1 and other STIs prevention strategies.
These valuable insights are particularly relevant to populations in Kenya and other regions with high HIV prevalence, where tailored interventions are urgently needed.

EP0022

Long term Elite Control of HIV-1 infection exhibit a deep perturbation of monocyte homeostasis

J.M. Benito[1], D. Jiménez-Carretero[2], J. Valentín-Quiroga[3], I. Mahillo[4], J.M. Ligos[5], C. Restrepo[1], A. Cabello[6], E. López-Collazo[3], F. Sánchez-Cabo[2], M. Górgolas[6], N. Rallón[1]
[1]HIV and Viral Hepatitis Research Laboratory, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Universidad Autónoma de Madrid (IIS-FJD, UAM), Hospital Universitario Rey Juan Carlos, Móstoles, Madrid, Spain, [2]Unidad de Bioinformática, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, [3]Grupo de Respuesta Inmune Innata, IdiPAZ, Hospital Universitario La Paz, Madrid, Spain, [4]Universidad Autónoma de Madrid (IIS-FJD, UAM), Department of Statistics, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Madrid, Spain, [5]Cytek Biosciences, Inc., Fremont, California, United States, [6]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Background: Elite controllers (EC) are an exceptional group of PLWH able to control HIV replication without ART. However, despite viral control, EC have increased incidence of different morbid conditions, among them cardiovascular disease that has been associated with monocyte activation.
We have performed an in-deep phenotypic analysis of monocytes in a cohort of long-term EC (LTEC) compared to non-controller patients with ART-mediated control of HIV replication.
Methods: 57 participants were included: 22 LTEC, 15 non-controllers PLWH on ART (ART), and 20 uninfected controls (UC) as reference. Monocyte phenotype was analysed by spectral flow cytometry using a panel of 10 different markers.
Data were analysed using:
a) FCSExpress to define different subsets of monocytes (according to CD14 and CD56 markers) and expression level of 8 different markers of monocyte function;
b) R software for unsupervised multidimensional analysis, including batch correction, dimensionality reduction, and clustering analysis.
Results: LTEC and ART groups were matched for age, CD4 counts and years since diagnosis. Three different approaches were used to characterize the phenotypic profile of monocytes:
1. levels of monocyte subsets (classical, intermediate and non-classical monocytes);
2. levels of expression of 8 different markers of monocyte function;
3. levels of monocyte clusters defined by dimensionality reduction (56 different clusters).
ART group presented a monocyte phenotypic profile very similar to that of UC group. In contrast, LTEC presented statistically significant alterations of monocyte phenotype:
a. increased level of intermediate and decreased level of classical monocytes;
b. altered expression of markers of monocyte function by the different monocyte subsets;

c. alteration in 16 different monocyte clusters (12 decreased and 4 increased).
Many of these alterations were also observed when comparing LTEC and ART groups.
Conclusions: Our results show that while spontaneous control of HIV is a benefit for EC PLWH, it may have an associated cost reflected in a deep perturbation of monocyte phenotype what could be a compelling argument to consider treating this population.
Also the differences observed in the monocyte phenotype according to the mechanism of HIV control could be associated to the incidence of different morbidities between EC and PLWH on ART.

EP0023

HLA class I and II alleles that associate with virologic and immunologic control in antiretroviral therapy-naïve South Africans living with HIV-1

S. Loubser[1], N. Gentle[2], L. Murray[3], M. Paximadis[2], Z. Waja[4], R. Chaisson[5], N. Martinson[4], O. Ebrahim[6], C. Tiemessen[1]
[1]National Institute for Communicable Diseases, Centre for HIV and STIs, Johannesburg, South Africa, [2]University of the Witwatersrand, School of Molecular and Cell Biology, Johannesburg, South Africa, [3]University of the Witwatersrand, Department of Internal Medicine, Johannesburg, South Africa, [4]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [5]Johns Hopkins University Center for AIDS Research, Baltimore, United States, [6]University of the Witwatersrand, School of Clinical Medicine, Johannesburg, South Africa

Background: Allelic variants of HLA genes modulate virologic/immunologic control of HIV-1 disease progression. Protective/deleterious alleles can be identified in select groups of untreated HIV-1 controllers including elite controllers (ECs) and viraemic controllers (VCs), who maintain CD4 counts >350 cells/µl and viral load (VL) <50 copies/ml or <2,000 copies/ml, respectively. High VL long-term non-progressors (HVL-LTNPs) maintain CD4 counts >350 cells/µl, but have a VL >10,000 copies/ml.
Alleles associated with HIV-1 disease progression can be determined in these groups by comparison to progressors with CD4 counts <200 cells/µl and VL >10,000 copies/ml.
Methods: Most studies report on HLA class I alleles that mediate antiviral CD8 T-cell responses and neglect CD4 T-helper responses mediated by HLA class II alleles.
We compared the frequencies of both HLA class I (*A*, *B*, *C*) and -II (*DPB1*, *DQB1*, *DRB1*) alleles in ECs (n=31), VCs (n=38), HVL-LTNPs (n=12) and progressors (n=99) to identify genetic associations with virologic/immunologic control in black South Africans living with HIV-1.
Sequence-based typing methods were used for HLA genotyping. Allele frequencies were determined by direct counting. Significant statistical differences between groups were calculated by Fisher's exact test (p<0.05).
Results: Compared to progressors, known protective alleles *B*57:03:01* and *DQB1*06:09:01* were found in ECs. Known *B*81:01:01* and additional protective alleles *A*26:01:01*, *DPB1*34:01:01* and *DQB1*04:02:01* and a known deleterious allele, *B*53:01:01*, were found in VCs. *C*04:01:01* and *DQB1*03:02:01* were protective in HVL-LTNPs.
When ECs and VCs were combined into a total virologic controller group, known alleles *B*57:03:01* and *B*39:10:01* and additional alleles *C*12:03:01*, *C*17:01:01* and *DQB1*04:02*:01 were protective, while *A*29:02:01*, *B*07:02:01*, *C*07:02:01*, *C*07:06:01* and *DRB1*12:01:01* were deleterious.
When ECs, VCs and HVL-LTNPs were combined into a total immunologic controller group, known allele *B*57:03:01* and additional alleles *B*42:01:01*, *C*04:01:01*, *DQB1*04:02:01* and *DRB1*03:02:01* were protective, while *A*23:01:01*, *B*07:02:01*, *B*44:03:02*, *C*07:02:01* and *C*07:06:01* were deleterious.
Conclusions: This analysis identifies HLA alleles associated with virologic/immunologic control of HIV-1 disease progression in select controller groups (ECs, VCs, HVL-LTNPs) compared to progressors in therapy-naïve South Africans living with HIV-1.
We confirm previous associations identified by others and add new associations that includes HLA class II alleles. These data can inform prevention/cure strategies in HIV-1 disease.

EP0024

Dynamics of virus-specific immune responses in latent HTLV-1 asymptomatic carriers

T.W. Asigbee[1], M. Nakamura-Hoshi[1], N. Kuse[1,2,3], H. Ishii[1], K. Ishikawa[1], A. Kawana-Tachikawa[1,2], E. Horibe[4], M. Nakashima[4], Y. Yamano[4], K. Uchimaru[5,6], T. Matano[1,2,6]
[1]National Institute of Infectious Diseases, AIDS Research Center, Tokyo, Japan, [2]Kumamoto University, Graduate School of Medical Sciences and Joint Research Center for Human Retrovirus Infection, Kumamoto, Japan, [3]National Institute of Infectious Diseases, Research Center for Drug and Vaccine Development, Tokyo, Japan, [4]St. Marianna University School of Medicine, Department of Rare Disease Research, Kawasaki, Japan, [5]University of Tokyo, Department of Computational Biology and Medical Sciences, Graduate School of Frontier Sciences, Tokyo, Japan, [6]University of Tokyo, Institute of Medical Science, Tokyo, Japan

Background: Human T-cell leukemia virus type-1 (HTLV-1) induces chronic, long-term persistent infections and can cause serious diseases, including adult T-cell leukemia. In the asymptomatic carrier phase of infection, substantial proviruses are detected in lymphocytes. However, HTLV-1 viral replication is controlled and HTLV-1 production is poor. Virus-host immune interaction has not been fully elucidated.
This study investigated the relationship between HTLV-1 proviral loads and virus-specific immune responses in asymptomatic carriers.
Methods: Seventy-seven asymptomatic carriers seeking medical care at the Institute of Medical Science Health Facility, University of Tokyo, Japan, were enrolled. Virus-specific antibodies were evaluated by line immunoassay and by measurement of syncytia inhibition. Peripheral blood mononuclear cells (PBMCs) were employed to assess T-cell responses through flow cytometric analysis.

Results: Neutralizing antibody responses were significantly higher in individuals with higher anti-Env SU (gp46) antibody levels and positively correlated with proviral loads. Overnight *ex vivo* culture of PBMCs resulted in detectable HTLV-1 Gag antigen (p19) expression in $CD4^+$ T cells and interferon-γ (IFN-γ) induction in $CD8^+$ T cells. Frequencies of these p19-expressing $CD4^+$ T cells and non-specific IFN-γ-induced $CD8^+$ T cells were positively correlated with proviral loads, respectively. Tax-specific $CD8^+$ T-cell frequencies were not associated with proviral loads but inversely correlated with the ratios of p19-expressing $CD4^+$ T-cell frequencies to proviral loads, implying involvement of Tax-specific $CD8^+$ T cells in the control of HTLV-1 replication.

Conclusions: Our results implicate Tax-specific $CD8^+$ T cells in the control of HTLV-1 replication. This study provides insights into the elucidation of the virus-host immune interaction in latent HTLV-1 infection.

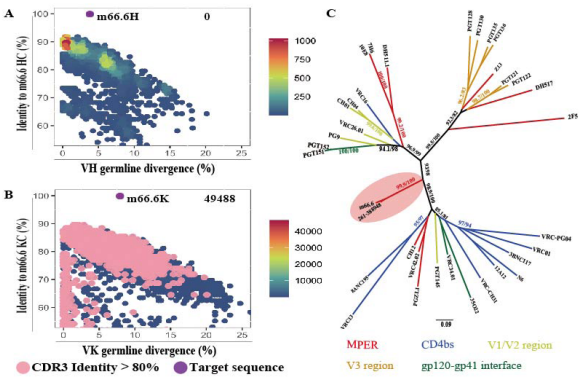
EP0025

Identification of HIV-1 MPER-specific antibody from the BCR repertoire of a HIV elite neutralizer

Q. Li[1], W. Ni[1], H. Li[1], Y. Hao[1], L. Ren[1], Y. Shao[1], Z. Wang[1]
[1]National Center for AIDS/STD Control and Prevention, China CDC, Beijing, China

Background: To identify HIV-1 MPER-directed neutralizing antibody from BCR repertoire of an elite neutralizer and study the neutralization activity of the antibody.

Methods: BCR repertoire of an elite neutralizer CBJC261 was obtained by 5'RACE-PCR and non-bias next-generation sequencing. The heavy chain and light chain of m66.6-like antibody was screened by two-dimensional identity/divergence analysis from the repertoire. Then the antibody was expressed by transfection of heavy chain and light chain expression plasmids into 293F cells and purified using protein A column. The binding activity and neutralizing activity of produced antibody was measured with ELISA and pseudotyped virus-based neutralization, respectively.



CBJC261 Antibody library characteristics.
A-B. Two-dimensional identity/divergence analysis of CBJC261 antibody, Color represents sequence density;
C. Maximum likelihood (ML) tree of HC variable regions of bnAbs, colored by Env epitope.

Results: Antibody 261-388948 was screened from the BCR library of donor CBJC261 . This antibody shares IGHV 5-51 and IGKV 1-39 with another 2F5-like MPER bNAb m66.6, but presents a lower somatic hyper-mutation rate (0.35% for V_H and 1.34% for V_L). The amino acid identities of V_H and V_L between 261-388948 and m66.6 are 90.8% and 90.42%, respectively. 261-388948 showed a MPER-directed neutralizing activity, and cross-matching of heavy chain and light chain between 261-388948 and m66.6 produced antibodies with enhanced neutralization activity.

Neutralization of HIV-1 pseudoviruses by antibodies.

Conclusions: In this study, an MPER-directed neutralizing antibody 261-388948 was obtained by BCR library screening. 261-388948 has lower somatic hyper-mutation rates, meaning lower neutralizing activity but easier induction capability.

This study may be instructive for the study of MPER-specific bNAbs evolution and provide clues for future vaccine design.

EP0026

Incremental epitope breadth and depth changes in HIV-1 specific CD8 T-cell responses to primary subtype-C HIV-1 natural infections associated with better CD4-count and viral-load outcomes in antiretroviral therapy naïve individuals.

C. Michelo[1], J.A. Dale[2], A. Fiore-Gartland[3], P. Hayes[4], M.A. Price[5], S.C. Francis[5], P. Maenetje[5], M. Kuteesa[5], W. Kilembe[1], E. Hunter[6]
[1]Center for Family Health Research Zambia, Laboratory, Lusaka, Zambia, [2]Imperial College London, London, United Kingdom, [3]Fred Hutchinson Cancer Research Center, Seattle WA, United States, [4]Imperial College London, London, United Kingdom, [5]International AIDS vaccine initiative, New York, United States, [6]Emory Vaccine Center, Atlanta, United States

Background: Host factors in people living with HIV (PLWHIV) with different rates of disease progression have provided important clues for vaccine design. The comparative characterisation of HIV-1 specific CD8 T-cell responses in PLWHIV with relatively better disease outcomes is crucial in determining effective HIV-specific immune responses. Such characterisations can inform innovative vaccine strategies aimed at improving the weak protection offered by current HIV vaccines.

In this study, we set to characterise CD8 T-cell responses in natural infection that can be attributed to better disease outcomes.

Methods: PBMCs were isolated from blood samples collected with written consent from PLWHIV after primary HIV-1 subtype-C infection and ART naïve at sampling times. Using IFN-γ ELISPOT, we assessed CD8 T-cell sample responses to HIV-1 subtype-C gag antigen peptides multivalently complemented to capture major epitope variants in circulating viral strains within the sampling population.

We compared the epitope breadth and depth of HIV-1 specific responses using same individual samples (n=15) collected at 3-6mon and 9-12mon post estimated date of infection.

Results: We analysed for CD8 T-cell response magnitudes above a pre-specified positive-response threshold of ≥ 38 SFU/10^6 cells. Significant high T-cell responses were observed with 3-6mon samples (mean SFU/10^6 cells ± SD; 874.01±1204.10 vs 474.34±469.90) accompanied by the identification of more epitope/variants with 3-6mon sample responses (mean breadth and depth: 5 vs 4 and 11 vs 9). However, CD4 counts, an indicator of immune function and status, was averagely similar between the two comparator sampling time points.

Further analysis showed a differential loss (n=10) and gain (n=5) in antigen specific CD8 T-cell from 3-6mon to 9-12mon sampling times. A gain in antigen specific CD8 T-cell responses was further indicated with improved CD4 and VL measures at 9-12mon (3-6mon to 9-12mon, mean±SD comparisons, CD4 counts: 531.80±229.59 to 677.90±99.27 compared to 718.90±256.75 to 592.90±165.37; Log10 VL: 4.30±0.46 to 3.60±0.57 compared to 3.61±0.67 to 3.97±0.35).

Conclusions: These results offer critical insight into strategic development of prime-boost T-cell vaccine regimen on the induction of high response magnitudes with an augmented boost that effectively administrates additional epitopes with the initial priming antigenic determinants.

Understanding and targeting persistent HIV reservoirs

EP0027

Latent reservoir size in virologically suppressed people living with HIV is associated with age and HIV subtype

D. Attoh[1], C. Bortey[1], A. Twumasi Boateng[1,2], E.M.K. Kanda[1], E. Adjei-Gati[3], P.C. Odartey Lamptey[3], J. Atanniba[1], K. Addo[1], C.Z.-Y. Abana[1], J. Aboagye[1,4], H. Lamptey[3], E.Y. Bonney[1], G. Boateng Kyei[1,4,2]

[1]Noguchi Memorial Institute for Medical Research, Virology, Accra, Ghana, [2]Washington University in Saint Louis, Division of Biology and Biomedical sciences, Saint Louis, United States, [3]Noguchi Memorial Institute for Medical Research, Immunology, Accra, Ghana, [4]University of Ghana Medical Center, Legon, Medical and Scientific Research Center, Accra, Ghana

Background: HIV latent reservoirs persist despite suppressive ART, posing a major barrier to cure efforts. These reservoirs contain both intact and defective proviruses, with a fraction capable of reactivating upon ART interruption. Accurately quantifying reservoir size, particularly in non-B subtypes, is crucial for advancing cure strategies.

In this study, we measured unspliced cell-associated HIV RNA to assess transcriptionally active reservoirs in virologically suppressed people living with HIV (PLWH) in Ghana.

Methods: This quantitative study was conducted in a cohort of adults living with HIV who are on ART, with most achieving viral suppression. Whole blood samples were collected from 170 PLWH across three major hospitals in Accra, Ghana. Total nucleic acid was extracted from peripheral blood mononuclear cells (PBMCs), followed by DNase treatment to isolate HIV RNA. The HIV reservoir size was assessed using the cell-associated RNA technique, with reverse transcriptase quantitative polymerase chain reaction (RT-qPCR) employed to quantify unspliced RNA copies. Data analysis was performed using Microsoft Excel and GraphPad.

Results: For unspliced RNA, a larger reservoir was observed in individuals aged (³40) 40 years and older, whereas the opposite was true for proviral DNA (p = 0.012, 0.002). No significant difference was found in the unspliced reservoir size between females and males compared to their proviral reservoir (P = 0.15, 0.80). Individuals with the CRF02_AG subtype exhibited no significant difference in unspliced reservoir size compared to those with HIV subtype B.(0.070). However, a significant difference was noted in the proviral reservoir size, with those harboring CRF02_AG subtypes showing a higher reservoir size.

Conclusions: Age and HIV subtype influence reservoir size, with older individuals showing a higher unspliced RNA reservoir and CRF02_AG having a larger proviral reservoir. These findings underscore the need for age- and subtype-specific approaches in HIV cure strategies. Further studies should explore the mechanisms driving these differences.

EP0028

Increasing uptake of siRNA delivery vehicles in cells of the HIV latent reservoir through antibody conjugation

E. Agbosu[1], Z. Cao[2], S. Ledger[1], A. Kelleher[1,3], J. Wen[2], C. Ahlenstiel[1,3]

[1]Kirby Institute, University of New South Wales, Sydney, Australia, [2]UCLA AIDS Institute, David Geffen School of Medicine, Los Angeles, United States, [3]RNA Institute, University of New South Wales, Sydney, Australia

Background: The latent viral reservoir is a major barrier to an HIV cure. The reservoir persists for the lifetime of the host, is inaccessible to antiretroviral therapy and can re-activate when therapy is interrupted. One approach to tackle this is by using RNA therapeutics to keep the latent viruses permanently suppressed. However, the reservoir involves multiple cell types, including CD4+ T cells, macrophages and brain cells, and are located in multiple tissues and organs throughout the body. Thus, any treatment or cure strategy aimed at the latent reservoir will require specific strategies to direct them to the target cells.

To address this, we aim to improve the targeted delivery of polymer nanocapsules (capable of carrying RNA therapeutics) to CD4+ cells, macrophages, astrocytes and microglia by antibody coupling.

Methods: Ten surface receptors were assessed as targets: four CD4+ T cell, three macrophage and three astrocyte and microglia receptors. Antibodies to these receptors were tagged with azide groups and reacted with dibenzocyclooctyne-tagged fluorescent nanocapsules via copper-free click chemistry. The antibody-tagged nanocapsules were added to peripheral blood mononuclear cells (PBMCs) or monocyte-derived macrophages from healthy donors or human astrocyte (SVG) and microglia (HMC3) cell lines and analysed by flow cytometry for uptake, cell viability and surface receptor expression. *In vivo* biodistribution of two lead candidate targets was assessed in healthy BALB-c mice.

Results: Increased uptake of all antibody-conjugated nanocapsules was observed compared to unconjugated nanocapsules, with no significant effect on cell viability or surface receptor expression. One CD4+ T cell targeting antibody showed targeting potential, with increased uptake in CD4+ cells two times more than other cell types in PBMCs. Two targets doubled uptake in microglia compared to other targets.

Greater biodistribution with improved target cells binding was reported for targeted nanocapsules, observed in heart, liver, spleen, lung, kidney and brain of mice compared to unconjugated nanocapsules, which accumulated in liver and kidneys.

Conclusions: These preliminary results show that antibody targeting increases nanocapsules uptake in CD4+ cells, macrophages and brain cells, while reducing non-specific delivery. This will be highly advantageous in delivery of RNA therapeutics as an HIV cure block and lock strategy for maintaining HIV latency.

Novel treatment and prevention strategies, vaccines and immunotherapies

EP0029

GRP78-CAR-T cells display HIV-specific cytolytic activity in vitro

U. Sili[1,2], D. Ayala-Gomez[1], E. McMahon[3], U. Thanekar[4], A. Bosque[3], P. Velasquez[4], M. Keller[1], R. Cruz[1], C. Bollard[1]

[1]Children's National Medical Center, Center for Cancer and Immunology Research, Washington, DC, United States, [2]Marmara University School of Medicine, Department of Infectious Diseases and Clinical Microbiology, Istanbul, Türkiye, [3]The George Washington University School of Medicine and Health Sciences, Department of Microbiology, Immunology and Tropical Medicine, Washington, DC, United States, [4]St. Jude Children's Research Hospital, Department of Bone Marrow Transplantation and Cellular Therapy, Memphis, TN, United States

Background: Evidence suggests that HIV-specific T cell responses are essential for HIV control and potentially also for cure strategies. We posited that chimeric antigen receptor (CAR)-T cell therapies, which have shown promise in cancer, might also serve as a potent therapeutic approach for HIV. Glucose-regulated protein 78 (GRP78) is the main regulator of endoplasmic reticulum (ER) stress response triggered by unfolded polypeptides. HIV replication induces ER stress, thereby upregulating GRP78 on the cell surface.

Hence, we hypothesized that CAR-T with GRP78 recognition domain (PEP42) would lead to the selective elimination of HIV-infected cells in vitro.

Methods: T-cells from three donors were transduced with an SFG retroviral vector to generate GRP78-CAR-T (1x-CAR-T). As control, T cells were transduced with a GRP78-CAR construct lacking the CD28.CD3ζ signaling domain (Δ-CAR-T). Cytolytic activity was assessed against HIV-1 (NL4-3) infected autologous CD4 (+) T cells in co-culture. Targets were labelled with a fluorescent dye for flow-cytometric distinction. The cytolytic activity of the 1x-CAR-T cells was determined by comparing the percentage of p24 (+) target cells to the no-effector and Δ-CAR-T cell added groups. Free PEP-42 ligand was added to see competitive blockage of target recognition for further demonstration of specificity.

Results: Expansion rates for 1x- and Δ-CAR-T were 28±10.6 (mean±SD) and 28.3±16 fold, respectively (p=0.978). CAR expression for 1x- and Δ-CAR-T were 78%±26% and 67.7%±21.1%, respectively (p=0.623). After overnight co-culture, the percentage of p24 (+) fraction was 14%±5.2%, 3.3%±1.6%, and 11.3%±2.6% in no-effector, 1x-, and Δ-CAR-T cell added groups, respectively.

When normalized according to the no-effector added group, these percentages corresponded to 70%±27% and 14%±16.5% cytolytic activity by the 1x- and Δ-CAR-T cell groups, respectively (p=0.022). Moreover, adding free peptide reduced cytolysis to 15.6%±20.3% by the 1x- effectors (p=0.033).

Conclusions: Cell surface GRP78 increases during active HIV replication. Here, we show p24-specific cytolytic activity of GRP78-CAR-T cells in vitro. Future work will include in vivo and IND-enabling studies.
In sum, these results suggest that the development of novel CAR-T cell targeting the HIV reservoir via cell surface ER stress molecules could contribute to HIV cure efforts.

EP0030

Exploring the synergistic potential of Atripla® in mitigating the combined effects of protein malnutrition and chronic alcohol intake on rat epididymis

T. Nyirenda[1,2,3], A. Abdulkadir[2], L.R. Sena[2], J.V. Feliu[4], K. Erlwanger[5], E.F. Mbajiorgu[2]
[1]Khalifa University, Department of Biological Sciences, Faculty of Medicine and Health Sciences, Abu Dhabi, United Arab Emirates, the, [2]University of the Witwatersrand, Division of Histology and Embryology, School of Anatomical Sciences, Faculty of Health Sciences, Johannesburg, South Africa, [3]Midlands State University, Department of Physiology, Faculty of Medicine and Health Sciences, Gweru, Zimbabwe, [4]National University of Science and Technology, Anatomy and Physiology, Bulawayo, Zimbabwe, [5]University of the Witwatersrand, School of Physiology, Faculty of Health Sciences, Johannesburg, South Africa

Background: HIV/AIDS, alcoholism and protein malnutrition are significant public health challenges that continue to coexist in resource-poor African regions. Both chronic alcohol use and protein-deficient diets are established male infertility agents, raising concerns about their combined effects on reproductive health of people on antiretroviral treatment.
This study investigated the *in-vivo* effects of Atripla® and ethanol co-administration in the epididymis of protein malnourished rats.
Methods: Sixty-four adult male Sprague-Dawley rats were randomised into two diet groups: normal protein (NP, 23%) and low protein (LP, 6%) groups. Each diet group was further divided into four sub-groups (eight rats each). Under both normal and low protein diet groups, the first group served as control (NPC, LPC) receiving distilled water only.
The second group received Atripla® (ATp) only [NPATp, LPATp], the third group received ethanol (E) only [NPE, LPE] and the fourth group received both ATp and E (NPEATp, LPEATp). Atripla® (27.5 mg/kg body weight per rat) was administered orally once-daily using gelatine. 6% ethanol in distilled water was provided *ad libitum* to respective groups.
After ninety days of treatment, the rats were euthanized and epididymides harvested for histology. Qualitative and quantitative analyses for morphometry and androgen receptor immunoreactivity (AR-ir) were conducted.
Results: Inflammatory infiltrates, fibrosis and sparse luminal sperm concentration were observed in all treatment groups relative to the study control group (NPC). Incidence and severity in tissue alterations was higher among LP compared to NP groups with alterations being mild, moderate and severe in LPATp, LPATpE and LPE groups respectively. Group LPE had significantly reduced epididymal tubular diameter and epithelial height values relative to NPC and LPC ($P<0.001$), while all morphometric values for NPATp and NPATpE, LPATp, LPEATp groups were comparable to group NPC.
Weak and significantly reduced AR-ir was recorded in LP treated groups compared to NP treated groups though LPATp and LPATpE groups had values higher than LPE ($P<0.05$, ANOVA).
Conclusions: Atripla®, ethanol and/or protein malnutrition are risks for epididymal tissue derangements. However, the effect of Atripla® was mild and protective of the impact of ethanol and protein malnutrition. This shows success of single-pill therapy in mitigating adverse effects and warrants further investigation.

EP0031

Development and characterization of a novel HIV vaccine candidate using SpyTag/SpyCatcher technology to decorate virus-like particles displaying native-like Env trimers

B.M. Akis Yildirim[1], I.d. Moral-Sanchez[2], R.W. Sanders[2], S. Biswas[1], T. Hanke[1]
[1]Oxford University, The Jenner Institute, Oxford, United Kingdom, [2]Amsterdam UMC, Amsterdam, The Netherlands

Background: Despite decades of effort, an effective HIV vaccine has yet to be developed. Recent advances in structure-based antigen design and protein engineering have opened up new possibilities for vaccine development. In this study, a novel candidate for an HIV vaccine is explored that employs virus-like particles (VLPs) made up of hepatitis B surface antigen (HBsAg) decorated with HIV envelope (Env) single-chain trimers.
The innovative use of SpyTag/SpyCatcher technology allows antigens to attach covalently to VLPs, which can increase immunogenicity.
Methods: We developed a VLP-based vaccine by fusing SpyCatcher to HBsAg and SpyTag to HIV Env in single-chain triple tandem trimers (TTT) configuration, in which three Env protomers are genetically linked in a single open reading frame and express as native-like trimers. Recombinant proteins were expressed in Expi293 cells and purified via GNL chromatography. VLP assembly and Env trimer coating were verified by Western blotting, negative-stain electron microscopy.
Antigenicity will be tested against a panel of commonly used bnAbs, and immunogenicity studies will be initially conducted in BALB/c mice.
Results: Stable VLPs displaying HIV Env trimers were produced and characterized. Electron microscopy demonstrated particles in ~50 nm in diameter, displaying Env spikes that are clearly visible. Western blot confirmed the covalent attachment of Env trimers to HBsAg VLPs using the SpyTag/SpyCatcher interaction. The binding and neutralizing activity of sera elicited in the BALB/c mice will be presented.

Conclusions: This study provides a promising approach for HIV vaccine design by combining the immunogenicity of VLPs with the structural integrity of native-like Env trimers. This novel HIV vaccine candidate using SpyTag/SpyCatcher technology to coat virus-like particles displaying native-like Env trimers will be co-administered with the T-cell HIVconsvX vaccine candidate for induction of combined antibody and killer T-cell immune responses.

EP0032

Combining generative AI, machine learning, and structure-based drug design to develop potent HIV-1 reverse transcriptase inhibitors

D. Bodun[1], A. Owolade[2]
[1]Covenant University, Chemistry, Ado/Ota, Nigeria, [2]Obafemi Awolowo University, Pharmacy, Ile, Ife, Nigeria

Background: The era of generative AI in drug design is here, and in this study, we applied a generative AI model to design potential non-nucleoside inhibitors of HIV-1 reverse transcriptase (RT). RT is a critical enzyme in the HIV replication cycle, responsible for converting viral RNA into DNA, a process essential for the virus to integrate into the host genome. Inhibiting RT is vital for stopping viral replication and limiting the disease progression. However, drug resistance has highlighted the need for new and effective inhibitors.
Methods: Using the REINVENT prior model, we fine-tuned it with classified RT inhibitors (pIC50 > 7.0) from ChEMBL, generating over 10,000 novel compounds. These compounds underwent rigorous filtering, including classification by a Message Passing Neural Network (MPNN), PAINS filtering, pharmacophore modeling, structure-based screening (HTVS, SP, XP), MMGBSA scoring, and ADMET prediction.
Results: We identified five top-performing compounds (Compound 2877, Compound 1142, Compound 780, Compound 960, and Compound 63), which demonstrated superior docking scores (≤ -13.372 kcal/mol) and binding free energies (MMGBSA dG Bind ≤ -77.48 kcal/mol) compared to the co-crystallized reference ligand (-8.424 kcal/mol). ADMET predictions revealed that these compounds were non-carcinogenic, highly drug-like (QED), and had better synthetic accessibility (SAScore) than the reference ligand.

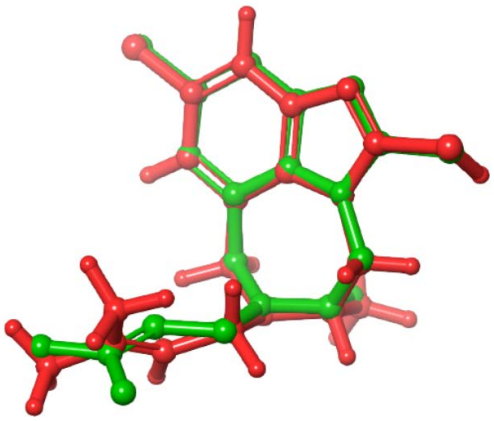

Figure 1: Redocking of the cocrystallized ligand by Glide (RMSD > 2.0).

Title	Fitness	docking score (kcal/mol)	MMGBSA dG Bind (kcal/mol)
Compound 2877	1.616	-13.372	-77.48
Compound 1142	1.981	-13.155	-67.01
Compound 780	1.733	-13.137	-69.2
Compound 960	1.299	-13.106	-76.49
Compound 63	1.636	-13.103	-69.54
Cocrystallized ligand	2.734	-8.424	-75.39

Table 1: Docking, Fitness and MMGBSA scores of the top compounds and reference.

Conclusions: These findings suggest that the identified compounds are promising candidates for further *in vitro* validation to confirm their inhibitory activity, selectivity against HIV-related proteins, and therapeutic potential. This study highlights the transformative role of AI-driven drug discovery in addressing HIV drug resistance.

EP0033

Silver nanoparticles capped with Sutherlandia frutescens showed anti-HIV, anti-bacterial and non-cytotoxicity in different human cell lines

W. Mkhwanazi[1], N. Mkhwanazi[1], S. Olojede[2]
[1]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, [2]University of KwaZulu-Natal, Nanotechnology Platforms, Discipline of Clinical Anatomy, Durban, South Africa

Background: This research aimed to evaluate the cytotoxicity and antiviral potential of green-synthesized silver nanoparticles (AgNPs) capped with Sutherlandia frutescens in various human cell lines and their antibacterial activity against gram-positive bacteria.
The study aimed to investigate the potential of these nanoparticles as an alternative therapeutic strategy for HIV-1 treatment, addressing concerns related to drug resistance, toxicity, and the persistence of viral reservoirs.
Methods: Silver nanoparticles were synthesized using a plant extract of Sutherlandia frutescens. The morphological, structural, and functional properties of the synthesized nanoparticles were characterized by UV spectroscopy, SEM,TEM, XRD, and FTIR spectroscopy. Cytotoxicity and cell viability of the SF-AgNPs, Sutherlandia frutescens plant extract, and silver nanoparticles (chemically synthesized) were assessed using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay across multiple human cell lines (Astrocytes, HepG2, 293T and TZM-bl). The antiviral activity of the SF-AgNPs was evaluated using a luciferase assay on HIV-1 cells. The minimal inhibitory concentration (MIC) of SF-AgNP was determined against Staphylococcus aureus and Staphylococcus epidermidis.
Results: The synthesized silver nanoparticles exhibited a round and spherical shape with an average size of 24nm (TEM) with an absorbance peak at 520 nm (UV-Vis). The biosynthesized silver nanoparticles were surface stabilized by polyphenolic compounds (FTIR). SF-AgNPs maintained more than 80% of cell viability across the TZM-bl, 293T, HepG2 cell line except for astrocytes, with 63.9%. SF-AgNPs demonstrated low cytotoxicity with CC50 of 10.94 µg/ml (TZM-bl), 1.476 µg/ml (293T), 0.0793 µg/ml (As-

trocytes), 0.07179 µg/ml (HepG2). The SF-AgNPs exhibited 100% inhibition of HIV-1 at the highest concentration tested (972 µg/mL) in vitro with an IC50 of 0.2142 µg/mL. The SF-AgNPs exhibited effective activity against Staphylococcus epidermidis (MIC = 7.59 µg/mL) and Staphylococcus aureus (MIC = 15.18 µg/mL).

Conclusions: Silver nanoparticles capped with Sutherlandia frutescens showed potent antiviral activity against HIV owing to the phytochemicals present in the Sutherlandia frutescens. These nanoparticles were also potent against gram-positive bacteria Staphylococcus aureus and Staphylococcus epidermidis.

The findings indicate that integrating bioactive compounds from Sutherlandia frutescens into silver nanoparticles presented a promising therapeutic strategy for HIV treatment as it exhibited significant, dose-dependent antiviral activity against HIV-1. Therefore, it demonstrates potential as an effective alternative to current antiretroviral therapies.

EP0034

Safety profile of candidate HIV vaccines across clinical trial phases: a systematic review of global trajectory

V. Ayeni[1,2], C. Agbo[3,2], S. Azumara[3,2], L. Ejike[3,2], C. Nwankwo[3,2], S. Gabriel[4,2], O. Goodness[3,2], M. Hassan[5,2], J.C. Onyehalu[3,2], F. Igwezeke[3,2], A.E. Nkieh-Nyak[6,2], N. Chukwuka[3,2], C. Idabor[3,2], A. Isah[3,2]

[1]Babcock University, Ilishan-Remo, Nigeria, [2]Person-Centered HIV Research Team, Enugu, Nigeria, [3]University of Nigeria, Nsukka, Clinical Pharmacy and Pharmacy Management, Enugu, Nigeria, [4]Nnamdi Azikiwe University, Awka, Nigeria, [5]NSIA Diagnostic Centre, Kano, Nigeria, [6]University of Douala, Douala, Cameroon

Background: Despite the widespread use of antiretroviral therapies, approximately 1.3 million people acquired HIV in 2023. Several HIV prevention strategies exist; however, the development of vaccines remains a critical tool in the global HIV response. To guide future vaccine development and regulatory approvals, a thorough assessment of the safety profile of the current vaccine candidates across clinical trial phases is important.

This systematic review examines the safety profile of HIV vaccine candidates in various clinical trials to determine their safety profiles.

Methods: An extensive literature search was conducted across multiple databases including, Google Scholar, PubMed, Web of Science and Scopus using appropriate keywords and Boolean operators. The articles were screened for eligibility and only clinical trials involving HIV-negative individuals were included. Quality of studies was assessed using the Newcastle-Ottawa scale and the results were synthesized narratively.

Results: Out of the 3,515 studies identified by the databases, 113 published between 1991 to 2024 met the eligibility criteria and were included in the study. The studies were majorly Phase I clinical trials (81 studies out of 113). Across the included studies, the age range of participants varied but 47 studies involved those within 18-60 years, with a nearly equal gender distribution. Notably, 97 studies reported positive immunogenicity outcomes with robust antibody and T-cell responses. Most studies (109/113) reported mild to moderate adverse effects such as pain, tenderness and swelling. Minor side effects such as fever, headache, fatigue, nausea, myalgia and malaise, resolving within hours to few weeks, were also frequently reported across the trials.

Some serious side effects such as atrial fibrillation, epilepsy, cancer, vitiligo, syncope, were reported in 20 studies, with some leading to the affected participants' withdrawal from the study, and even death. However, there is insufficient evidence that directly attributes these serious side effects to the vaccine candidates.

Conclusions: HIV vaccine candidates have demonstrated a favourable safety profile as adverse events were predominantly mild and moderate. Serious adverse events were rare and without a direct linkage to the vaccine. With the significant immunogenicity demonstrated, the vaccine is a promising tool for revolutionizing HIV prevention and requires further research.

EP0035

Toward an HIV cure: a review of the transformative potential of CRISPR/Cas9 in the quest for HIV cure

O. Fagbolade[1], D. Odediran[1], A.-R. Makinde[1]

[1]University of Ilorin, Medicine, Ilorin, Nigeria

Background: By 2020, around 38 million people worldwide were living with HIV. Despite advances in treatment, there are still no vaccines or cures for the disease. Antiretroviral therapy (ART) has been effective in reducing HIV-related illness and death but cannot eliminate latent HIV reservoirs. These reservoirs can reactivate if therapy is stopped, making HIV a lifelong condition.

Gene-editing technologies like CRISPR/Cas9 offer a groundbreaking approach to HIV treatment by directly targeting and removing proviral DNA. This method works by creating double-strand breaks in the DNA to disrupt viral genes. Early research targeting the HIV-1 LTR region has shown encouraging results in reducing viral replication.

This review discusses the latest advancements in using CRISPR/Cas9 for HIV therapy, its potential to achieve a functional cure, and the key challenges and future directions for this technology.

Methods: A Comprehensive literature review was conducted, focusing on studies and clinical trials published between 2015 and 2024 that used CRISPR/Cas9 for HIV treatment. Databases such as PubMed, Google Scholar, and Scopus were searched using keywords like "CRISPR/Cas9," "HIV cure," "gene editing," and "proviral excision."

Studies were analyzed across in vitro, in vivo, and human clinical trials, focusing on mechanisms, outcomes, and challenges.

Results: CRISPR/Cas9 has shown promising results in HIV-1 research:

- **In Vitro Studies:** The technology successfully targeted and removed HIV-1 proviral DNA from affected human cells, disrupting key viral genes and significantly reducing viral replication.

- **In Vivo Studies:** Humanized mouse models demonstrated effective removal of integrated HIV-1 DNA, leading to reduced viral loads. Studies in non-human primates further supported its potential for clinical use.
- **Human Clinical Trials:** Early trials of EBT-101, a CRISPR-based therapy, showed that it was safe and well-tolerated. However, viral rebound after discontinuing ART emphasized the need for further optimization.

While CRISPR/Cas9 shows potential, challenges include delivery systems, off-target effects, viral diversity, and immune responses.

Conclusions: CRISPR/Cas9 presents a promising pathway for eradicating HIV-1 by targeting and excising proviral DNA. Yet, challenges like delivery efficiency, unintended genetic changes, and the variability of the virus need to be addressed. Continued research and innovation will be crucial to overcoming these barriers and achieving a functional HIV cure.

Emerging patterns of drug resistance in HIV-1 subtypes to integrase strand transfer inhibitors at Arthur Davison Children's Hospital, Ndola, Zambia

D. Chisompola[1], T. Banda[1], H. Lumano[2], M. Munyangabe[1], M. Chakopo[1]
[1]Arthur Davinson Children's Hospital, Pathology Laboratory, Ndola, Zambia, [2]USAID Zambia Integrated HIV and Health Project, Laboratory Services, Ndola, Zambia

Background: Understanding the prevalence of HIV-1 subtypes and their associated drug resistance mutations is essential for optimizing antiretroviral therapy (ART) and enhancing treatment and prevention outcomes. Zambia is among the first countries in sub-Saharan Africa to introduce Cabotegravir (CAB-LA), a long-acting Integrase Strand Transfer Inhibitor (INSTI), for HIV prevention.

The study aimed to determine the distribution of HIV-1 subtypes and the prevalence of resistance-associated mutations to INSTIs in the Zambian population among individuals living with HIV and receiving ART.

Methods: This cross-sectional study enrolled 210 participants living with HIV suspected of treatment failure whose samples were referred to Arthur Davison Children's Hospital in Ndola, Zambia, for drug resistance testing between January 2022 and December 2024. Subtype and resistance mutation analyses were conducted using the Stanford University HIV Drug Resistance Database. Statistical analyses were performed using SPSS version 22.

Results: Among the 210 participants, 126 (60%) successfully amplified for analysis. Of these, 98.41% were classified as HIV-1 subtype C, while subtypes A1 and F were each detected in 0.79% of cases. The median age of participants was 35 years, with females comprising the majority (58%). Resistance mutations were identified with varying prevalence. The most common mutation was E138K (15.9%), followed by G118R (12.7%) and T66A/I/T (7.9%). Additional mutations observed included R263K/R (6.3%), E157Q (6.3%), S147G (4.8%), H51Y (3.2%), T97A (3.2%), G140A (2.4%), N155H (2.4%), E92Q (1.6%), Q148K (1.6%), L74M (1.6%), T122N (0.8%), and S153CG (0.8%).

Conclusions: This study highlights the predominance of HIV-1 subtype C among participants, consistent with regional epidemiological trends. The high prevalence of resistance-associated mutations, particularly E138K and G118R, underscores the need for routine resistance testing to guide ART decisions.

The detection of multiple mutations suggests potential challenges in managing treatment failure, emphasizing the importance of continuous surveillance and tailored therapeutic strategies to mitigate the impact of drug resistance on treatment outcomes.

EP0037

Safety and acceptability of synthetic HIV DNA plasmid vaccine delivery via intradermal electroporation

S. Hendricks[1], B. Furch[2], A. Takalani[3], O. Hyrien[4], N. McCloskey[2], M. Malefo[3], L. Proulx-Burns[2], V. Bailey[3], C. Duplessis[5], S. Heath[6], A. Sherman[7], S. Kassim[8], N. Naicker[9], F. Laher[10]
[1]Hutchinson Centre Research Institute of South Africa, HIV Vaccine Trial Network Leadership Operations Centre South Africa, Johannesburg, South Africa, [2]Fred Hutchinson Cancer Center, Vaccine and Infectious Disease Division, Seattle, United States, [3]Hutchinson Center Research Institute of South Africa, Vaccine and Infectious Disease Division, HIV Vaccine Trial Network Leadership Operations Centre South Africa, Johannesburg, South Africa, [4]Fred Hutchinson Cancer Center, Biostatistics, Bioinformatics, and Epidemiology Program, Vaccine and Infectious Disease Division, Seattle, United States, [5]National Institutes of Health, National Institute of Allergy and Infectious Diseases, Bethesda, United States, [6]University of Alabama, Birmingham, United States, [7]Harvard Medical School, Brigham and Women's Hospital, Division of Infectious Diseases, Boston, United States, [8]University of Cape Town, The Desmond Tutu HIV Centre, Cape Town, South Africa, [9]University of KwaZulu-Natal, Centre for the AIDS Programme in Research of South Africa, Durban, South Africa, [10]University of Witwatersrand, Perinatal HIV Research Unit, Faculty of Health Sciences, Johannesburg, South Africa

Background: Skin is an alternative vaccine administration site to muscle. An electrical pulse applied after injecting into skin, called intradermal electroporation (ID-EP), facilitates entry through temporary pores in cell membranes. Safety and acceptability of HIV DNA plasmid vaccines administered with ID-EP was evaluated.

Methods: HVTN 305, phase 1 open-label randomized trial conducted at six sites in South Africa and USA, enrolled adults without HIV. At months 0, 1, and 3, participants received two bilateral intradermal vaccinations of INO-6172 (synthetic DNAs encoding the GT8 nanoparticle and Interleukin-12) at 0.5mg in group 1 (n=10) or 2mg in groups 2 (n=18) and 3 (n=18), followed by ID-EP using Inovio CELLECTRA 2000 device.

Group 3 also received 100mcg Trimer 4571 (BG505 DS-SOSIP.664 gp140 Envelope protein) intramuscularly (IM), adjuvanted with 5mcg 3M-052 AF / 500mcg alum at months 3 and 6. Solicited adverse events (AEs) were reported within 14 days, unsolicited AEs within 30 days, serious AEs (SAEs), adverse events of special interest (AESIs) and medically attended adverse events (MAAEs) until month 18. 26 South African participants completed EP acceptability questionnaires at vaccination timepoints.

Results: We enrolled 46 participants, median age 25 years (IQR=9), 61% males. No AEs were fatal or life threatening. Severe solicited AEs included fatigue n=6 (13%), headache n=6 (13%), myalgia n=4 (9%), pain n=3 (7%), chills n=3 (7%), and arthralgia n=2 (4%). Twenty-six participants (57%) reported unsolicited AEs, 12/26 were MAAEs, 2/26 (8%) graded moderate and related to study product (decreased neutrophils and loss of appetite). One (4%) severe unrelated AE (increased creatinine) was noted (Table).

No SAEs or AESIs were reported. Among 26 participants who answered questionnaires, 1 was excluded due to study product discontinuation, 23/25 (88%) indicated willingness to repeat EP, 24/25 (96%) indicated acceptable anxiety levels, and 23/25 (92%) reported acceptable skin reactions.

Participants who reported unsolicited AEs regardless of relationship to study product	Group 1 (n=10)	Group 2 (n=18)	Group 3 (n=18)	Total (n=46)
All	5 (50%)	8 (44%)	13 (72%)	26 (57%)
Mild	0 (0%)	2 (11%)	3 (17%)	5 (11%)
Moderate	5 (50%)	6 (33%)	9 (50%)	20 (43%)
Severe	0	0	1 (6%)	1 (2%)
Potentially life-threatening or fatal	0	0	0	0

Table. Participant summary of reported unsolicited AEs.

Conclusions: HIV DNA plasmid vaccine delivery via ID-EP was generally safe and South African participants found it acceptable. Immunogenicity evaluations are ongoing.

EP0038

The impact of drug transporters and genital inflammation on oral PrEP in HIV negative South African women

N. Zondo[1,2], P. Sobia[1,2], A. Sivro[1,2,3], S. Ngcapu[1,2], L.E. Mansoor[1,4], S. Mahomed[1], K. Asare[1], L. Lewis[1], V. Ramsuran[1,2], D. Archary[1,2]

[1]CAPRISA, Mucosal Immunology, Durban, South Africa, [2]University of KwaZulu-Natal, Medical Microbiology, Durban, South Africa, [3]JC Wilt Infectious Disease Research Centre National Microbiology Laboratory, Public Health Agency of Canada, Winnipeg, Canada, [4]University of KwaZulu-Natal, School of Nursing and Public Health, Durban, South Africa

Background: In sub-Saharan Africa new HIV infections occur mostly in adolescent girls and young women. Previously tested antiretroviral drugs as different pre-exposure prophylaxis (PrEP) formulations have shown inconsistent levels of protection against HIV infections in African women. Besides adherence, biological factors such as drug transporter proteins are increasingly recognized as key modulators of oral PrEP levels and effectiveness. Drug transporter expression has been significantly correlated to varied PrEP levels *in-vitro* in different tissues.

Additionally, inflammation has be identified as a further modifier of drug transporter expression possibly affecting PrEP levels.

Methods: We, therefore, aimed to determine possible concordance between drug transporter mRNA expression in the female genital tract (FGT) and blood of N=45 South African women (from CAPRISA Clinical Research Sites) taking oral PrEP-Truvada® [a combination of tenofovir-diphosphate (TFV-DP) and emtricitabine] over 6 months for HIV prevention.

Additionally, we determined associations between drug transporter mRNA expression, genital inflammation and blood-TFV-DP. The mRNA expression of four efflux drug transporters P-gp; MATE-1; MRP-2; MRP-4 and two influx drug transporters OAT-1 and OAT-3 relevant in HIV were determined by qRT-PCR. Multiplexed technology was used to measure 27 cytokines/chemokines to define genital inflammation.

Results: Significant correlations (positive) of mRNA expression for P-gp, MATE-1, MRP-2, and MRP-4 were observed between the FGT and blood at 3 and 6 months post-PrEP initiation ($p<0.05$). For OAT-1 however, significant correlations (positive) were observed pre- and post-PrEP initiation ($p<0.05$).

Linear-mixed models showed moderate associations between FGT cytokines and drug transporter mRNA expression, with a positive relationship observed between MIP-1β concentration and MATE-1 mRNA expression. PLS-DA likewise showed that in women with genital inflammation, consistently higher mRNA expression of MATE-1 was observed compared to women without genital inflammation. No significant associations were observed between drug transporter mRNA expression and blood-TFV-DP.

Conclusions: Our results suggest that drug transporter mRNA expression may be similarly affected in the FGT and blood with PrEP exposure. Furthermore, genital inflammation may alter efflux or influx drug transporter mRNA expression, thereby modifying PrEP levels.

Collectively, our data may be used to better understand biological factors that may affect or undermine PrEP efficacy in African women who remain vulnerable to HIV.

HIV-associated viruses, co-infections and co-morbidities

HIV drives altered levels of exosome-carried onco-ncrnas from people living with HIV and cancer

A. Ureta[1], C. Restrepo[1], M. Pedregal[2], H. Callata[2], S. Nistal[3], A. Velastegui[3], E. Caviedes[4], H. Peinado[5], M. Gómez[6], F. Sánchez-Cabo[6], M. García-Gil[7], A. Cabello[2], V. Estrada[8], M. Górgolas[2], J. García-Foncillas[9], J.M. Benito[1], N. Rallón[1]
[1]HIV and Viral Hepatitis Research Laboratory, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Universidad Autónoma de Madrid (IIS-FJD, UAM), Madrid, Spain; Hospital Universitario Rey Juan Carlos, Móstoles, Spain, Madrid, Spain, [2]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, Madrid, Spain, [3]Hospital Universitario Rey Juan Carlos, Móstoles, Spain, Móstoles, Spain, [4]Hospital Universitario Infanta Elena, Valdemoro, Spain, [5]Microenvironment & Metastasis Group, Molecular Oncology Program, Spanish National Cancer Research Centre (CNIO), Madrid, Spain, [6]Unidad de Bioinformática, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, [7]Spanish National Microscopy Centre (ICTS-CNME), Universidad Complutense de Madrid, Spain, Madrid, Spain, [8]Internal Medicine Unit, Hospital Clínico San Carlos, Madrid, Spain, [9]Department of Oncology and Cancer Institute, Fundacion Jimenez Diaz University Hospital, Autonomous University, Madrid, Spain

Background: Non-coding RNAs (nc-RNAs) are important regulators of gene expression that can be carried by extracellular vesicles (exosomes) and influence the progression of diseases such as HIV infection and non-AIDS defining cancer (NADCs). However, there is still unclear the potential role of the cargo profile of exosomal ncRNAs (exo-ncRNAs) in people living with both HIV and NADCs.
Methods: The transcriptomic landscape of plasma exo-ncRNAs was profiled by RNA sequencing (RNAseq) in 60 participants: 15 with HIV infection and NADCs (HIVNADC group), 15 with HIV only (HIV group), 15 with NADC only (NADC group), and 15 healthy control participants without HIV or cancer (HC group).
All HIV participants were under cART. Plasma exosomes were isolated by size exclusion chromatography and visualized and quantified by electron microscopy and nanotracking particle analysis. RNAseq was performed by NSG (NEBNext Multiplex small RNA library PrepSet, Illumina). RNAseq reads were aligned and quantified using RSEM and EdgeR software. Exo-ncRNAS were considered up or down- regulated if log2 fold-change (log2FC) >1 and <-1 respectively, in the pairwise comparison between study groups.
Results: All groups were matched in age, gender, CD4 T-cell count, time since cancer diagnosis and HIV diagnosis, and time on cART. The differentially expressed (DE) plasma exo-ncRNAs between pairwise comparison groups showed that the HIVNADC group had upregulation of SNORD3A (small nucleolar RNA) compared to the NADC group, (log2FC=3.62).
Additionally, when discriminating by cancer type, exo-miR-451a (micro-RNA) was upregulated in the HIVNADC brain cancer group compared to the NADC brain cancer group (log2FC=9.78). In contrast, the exo- miR-451a was downregulated in the NADC brain cancer group compared to the HIV group (log2FC=-11.27).
Interestingly, both SNORD3A and miR-451a ncRNAs have previously been suggested to play diverse roles in cancer development and progression.
Conclusions: The upregulation of exosome-derived SNORD3A and miR-451a (described as tumorigenic) in people living with both HIV and cancer suggests that HIV infection may play an important role in the dysregulation of "onco-ncRNAs" influencing a worse outcome in those patients with NADCs.

EP0040

Effect of HIV on and IL18 on osteoclastogenesis: implications for low bone density in people living with HIV

L. Jeena[1], H. Knowles[2], S. Rowland-Jones[1], A.Y.Y. Hsieh[1]
[1]Oxford Centre for Immuno-oncology, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [2]Botnar Institute for Musculoskeletal Sciences, Nuffield Department of Orthopaedics, Rheumatology & Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Background: Adolescents living with HIV (ALWH) experience low bone density, increasing long-term fracture risk. We previously showed elevated inflammation in ALWH, with IL18 associated with increased bone density. This study investigates whether HIV affects osteoclast differentiation *in vitro* and if IL18 mitigates this effect.
Methods: CD14+ monocytes from healthy human donors were stimulated with receptor activator of nuclear factor-kB ligand (RANK-L) and macrophage colony stimulating factor (MCSF) for nine days. Cells were infected with vesicular stomatitis virus-g (VSV-g)-pseudotyped NL4.3 HIV, MOI=1 and stimulated with IL18 or TNFα (positive control) at 10ng/ml or 50ng/ml. Osteoclastogenesis was assessed by tartrate-resistant acid phosphatase staining, defining osteoclasts as cells with ≥3 nuclei. Flow cytometry measured early (CD9 and RANK) and mature (CD51/61 and CD63) osteoclast surface receptors. Early HIV infection of monocytes (day one) *vs.* late infection of committed osteoclasts (day six) were compared and the IL18-effect analyzed using paired Wilcoxon signed-rank tests.
Results: HIV reduced osteoclast numbers by mean±SD 0.77±0.23-fold (p=0.004) and 0.33±0.31-fold (p=0.005) with early and late infection, respectively. Early infection increased mature osteoclasts 4.01±2.15-fold (p=0.031) but had no effect on early osteoclasts compared to late infection. Larger osteoclasts were observed in late infection compared to early (Figure 1).
IL18 (10ng/ml) increased mature osteoclasts by 1.50±0.54-fold (p=0.044) in uninfected cells, which was greater than the TNFα effect (10ng/ml) (1.13±0.30-fold, p=0.636). In HIV-infected cells, IL18 showed dose-dependent trends of increasing osteoclast numbers (10ng/ml: 1.76±1.71-

fold (p=0.052); 50ng/ml: 2.57±3.24-fold (p=0.074)), which was also observed in the mature osteoclast phenotype (10ng/ml: 1.12±0.23-fold (p=0.124); 50ng/ml: 1.07±0.44-fold (p=0.402)) compared to non-IL18-stimulated HIV-infected cells.

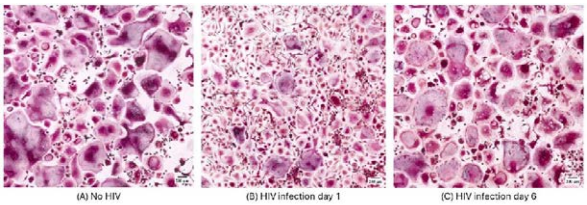

Figure 1: Representative image of osteoclast differentiation with different days of infection compared to no infection. CD14+ monocytes cultured with M-CSF and RANKL cytokines every 3 days for 9 days. Tartrate-resistant acid phosphatase staining of osteoclasts under different conditions (A) no HIV infection (B) HIV infection on day 1 for 24 hours (C) HIV infection on day 6 for 72 hours. MOI of 1. NL4-3 VSVg-pseudotyped strain. Staining performed on day 9 for all conditions.

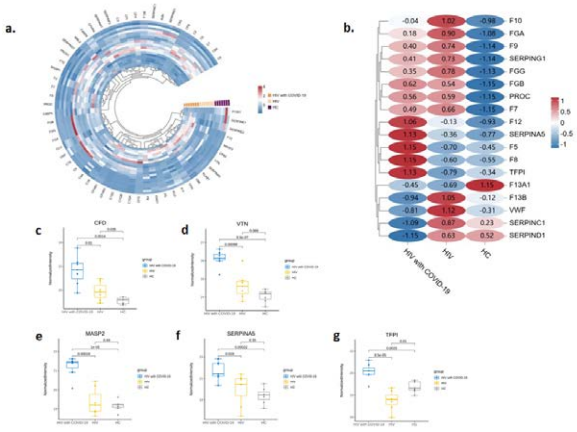
Conclusions: HIV decreases osteoclast number, but favours mature osteoclast morphology, which may contribute to lower bone density in ALWH. IL18 appears to exacerbate rather than mitigate these effects, supporting chronic underlying inflammation as a mechanism for poor bone health.

EP0041

Plasma proteomic profiling of hospitalized HIV patients co-infected with SARS-CoV-2

S. Yinzhong[1], Z. Xinyu[1]
[1]Shanghai Public Health Clinical Center, Shanghai, China

Background: COVID-19 is an infectious disease caused by the SARS-CoV-2, which has resulted in the most devastating pandemic in modern history. HIV destroys immune system cells and weakens the body's ability to resist everyday acquisitions and diseases. Furthermore, HIV-acquired individuals have doubled risk of COVID-19 mortality and experience worse COVID-related outcomes.
The aim of our work was to illustrate plasma proteomic profiling in HIV-positive clients hospitalized with SARS-CoV-2 acquisition.
Methods: Liquid chromatography-tandem mass spectrometry was used to examine plasma protein alterations in seven hospitalized HIV clients co-acquired with SARS-CoV-2, along with seven SARS-CoV-2 PCR-negative HIV clients and seven healthy controls as comparison groups. GO terms and KEGG pathways enrichment analysis were performed on the differentially expressed proteins.
Results: Compared with healthy controls, 477 proteins were significantly upregulated and 783 proteins were significantly downregulated in the plasma of HIV clients with COVID-19. Compared to HIV-only clients, 671 proteins were significantly upregulated and 173 proteins were significantly downregulated in the plasma of HIV clients with COVID-19. The GO terms and KEGG pathways associated with DEPs were highly enriched in processes involved in inflammation, immune cell migration and degranulation, and the most prominent term was complement and coagulation cascades. Several proteins related to complement and coagulation cascades have been shown to be dysregulated in HIV clients with COVID-19, for example, CFD, MASP2, VTN, TFPI and SERPINA5. We also identified several clusters of DEPs associated with SARS-CoV-2 acquisition, including viral receptors and proteases, transcription factors and kinases.



Conclusions: In summary, we have quantified 5,373 proteins in plasma from HIV clients with COVID-19 and identified 1,282 significantly dysregulated proteins compared to non-COVID-19 clients. This proteomic atlas has uncovered potential molecular targets, signaling pathways, small molecular compounds, and promising biomarkers in HIV and SARS-Cov-2 co-acquisition. These findings may contribute to more precise diagnosis and treatment for HIV clients with COVID-19.

EP0042

The impact of HIV and hepatitis B Co-infection on T-cell immune activation, exhaustion biomarkers, and reservoir size among virologically suppressed people living with HIV in Ghana

H. Lamptey[1], A. Pobee[2], J.O. Aboagye[3], J. Klutse[3], A.T. Boateng[3,4,5], D.A. Attoh[3], E. Kanda[3], C.Z-Y. Abana[3,4], K.A. Kusi[1], E.Y. Bonney[3], G.B. Kyei[3,5,6]
[1]Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Immunology Department, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, University of Ghana, Immunology Department, Accra, Ghana, [3]Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Virology Department, Accra, Ghana, [4]West African Centre for Cell Biology of Infectious Pathogens (WACCBIP), University of Ghana, Accra, Ghana, [5]Washington University School of Medicine., Department of Medicine, St Louis, MO, United States, [6]University of Ghana Medical Centre, University of Ghana, Accra, Legon, Ghana

Background: The burden of HBV is higher in HIV-endemic regions, with an estimated prevalence of 7-15% or higher. Due to their similar route of transmission, HBV/HIV co-infection is higher in sub–Saharan Africa. Co-infections complicate disease progression and lead to higher mortality rates in HIV, but their impact on T-cell responses and reservoir size is not well understood.
We hypothesize that compared to persons who acquired HIV-only, persons with HIV/HBV will have T cells that are more exhausted hence impact on the reservoir size. We

assessed the differences in T cell responses in persons with HIV/HBV and HIV or HBV only controls (adults >18 years) and measured their reservoir size.

Methods: We screened 390 archived plasma samples from people living with HIV (PLWH) for HBV, using a one-step multi-HBV test kit and selected HIV/HBV co-infected samples for this study. Archived peripheral blood mononuclear cells from these individuals and their paired HIV only counterparts, were stimulated with PMA and ionomycin, stained for activation and exhaustion markers (CD25, CD38, CD69, HLA-DR, PD-1).

Cytokine levels (IL-2, IFN-ɣ, TNF-α) were measured by flow cytometry and analyzed by FlowJo. The reservoir size was determined by RT-PCR using QuantStudio. Levels of these markers were compared among these groups, and healthy non-HIV/HIV controls using Mann-Whitney test.

Results: The prevalence of HBV/HIV was 7.9% (31/390). Females had higher CD4 counts compared to males P=0.003. We found higher levels of CD25+ and CD69+ expression on both CD4+ and CD8+ T cells in HIV/HBV acquired individuals compared to HIV or HBV only. Low levels of CD4+PD1+ and CD8+PD1+ expression on T cells were observed in HIV/HBV acquired persons, compared to HBV only and healthy controls.

However, Impaired cytokine production of IL-2 and TNF-α were observed in persons who acquired HIV/HBV compared to persons with HIV or HIV only. Reservoir size was different in males compared to females.

Conclusions: Differential expression of Immune activation and exhaustion markers was observed in virologically suppressed PLWH, an indication of ongoing residual viral production. The reservoir size was significantly different in HIVHBV co-infections compared to mono infections, although participants are virologically suppressed.

EP0043

High levels of anti-HHV-8 IgG binding capacity are linked with low HHV-8 viremia in people with and without HIV

S. Isnard[1,2], L. Royston[1,2,3], T. Mabanga[1,2], M. Dvorakova[4], C.A. Berini[1,2], B. Brenner[5], C.T. Costiniuk[1,2], S. Yaphe[2,6], B. Lebouché[1,2], R. Thomas[6], J.-G. Baril[7], M. Steben[8], D. Grace[9], G. Lambert[4], J. Cox[4,10,2], J.-P. Routy[1,11,2], Montreal Engage Study

[1]Research Institute of the McGill University Health Centre, Infectious Diseases and Immunity in Global Health Program, Montreal, Canada, [2]McGill University Health Centre, Chronic Viral Illness Service, Montreal, Canada, [3]Geneva University Hospitals, Geneva, Switzerland, [4]McGill University, Engage Cohort, Montreal, Canada, [5]Lady Davis Institute, McGill University, Montreal, Canada, [6]Clinique L'Actuel, Montreal, Canada, [7]Clinique Médicale du Quartier Latin, Montreal, Canada, [8]Canadian Network for HPV prevention, Montreal, Canada, [9]University of Toronto, Dalla Lana School of Public Health, Social and Behavioural Health Sciences, Toronto, Canada, [10]McGill University, Epidemiology department, Montreal, Canada, [11]McGill University Health Centre, Division of Hematology, Montreal, Canada

Background: The human herpes virus 8 (HHV-8) causes Kaposi Sarcoma (KS) and is linked with some type of B-cell proliferation disorders that develop upon aging and immunosuppression, including in people living with HIV (PLWH).

HHV-8 establishes latency in cellular and anatomical reservoirs in epithelial cells as well as B-cells. Factors controlling latency and replication remain seldomly described. We developed HHV-8 specific serological and virological assays to assess *ex-vivo* whether antibodies targeting HHV-8 could control replication.

Methods: Serum and cell lysate were obtained from cis and transgender men of the *Engage* cohort in Montreal. Participants with active KS (11 PWH on ART [HIV KS] and 11 HIV-negative classic KS [cKS]) were included from the McGill biobank. Circulating levels of IgG binding to BCBL1 HHV-8-infected cells were quantified by flow cytometry. CMV serology was assessed using commercial ELISA assays. Digital-droplet-PCR was used to assess HHV-8 DNA levels in blood extracts and biopsies.

Results: In absence of KS, HHV-8 seropositivity was higher in PWH than HIV-negative participants (67.5% *vs.* 41.8%, p<0.001). Moreover, in 106 HHV-8 seropositive participants, levels of anti-HHV-8 IgG were higher in PLWH than in 260 HIV-negative controls (median 1.5 vs 1.2AU, p=0.03). Levels of anti-HHV-8 IgG were negatively correlated with HHV-8 viremia in whole blood extracts (r=-0.48, p=0.004, n=46). Levels of anti-CMV IgG were not correlated with those of anti-HHV-8 IgG (r=0.09, p=0.42), and there was a similar frequency of CMV seroposivity between HHV-8 seropositive and seronegative participants (5.55 and 11% respectively) in HIV-negative participants.

Patients with KS were all seropositive for HHV-8. HIV KS had higher levels of anti-HHV-8 IgG levels than cKS (3.7 *vs.* 1.8AU, p=0.02). Interestingly, HIV KS had lower circulating HHV-8 viremia than cKS (695 *vs.* 8405 copies/10^6 cells,

p=0.04). However, HHV-8 DNA levels were similar in KS lesion biopsies for the 2 groups (HIV KS: 68.10^3 vs cKS: 323.10^3 copies/10^6 cells, p=0.89).

Conclusions: In both symptom-free carrier and KS patients, high levels of anti-HHV-8 IgG were associated with low circulating viremia, independently of ethnicity and CMV seroposivity. Whether higher anti-HHV-8 IgG levels contribute to prevent KS development should be further studied.

EP0044

Investigating the impact of respiratory viral superinfections on HIV-1 pathogenesis: insights from *in vitro* models of HIV-1/H1N1 and HIV-1/RSV superinfections

C. Vanetti[1,2], O. Yazici[1], L.A. Citterio[3,2], I. Saulle[1], M. Cano Fiestas[2], M. Garziano[4,2], J. Aiello[2], D. Bottan[5], D. Trabattoni[2], M. Clerici[1,6], M. Biasin[2]

[1]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy, [2]University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy, [3]University of Pavia, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy, [4]ASST Fatebene Fratelli Sacco, Milan, Italy, [5]University of Pavia, Pavia, Italy, [6]Fondazione Don Carlo Gnocchi, IRCCS, Milan, Italy

Background: Respiratory viruses are frequent causes of acute respiratory illness in PLWH, particularly in HIV-endemic areas, and may influence HIV pathogenesis through poorly understood mechanisms. Given the limited information on respiratory viral infections in PLWH, *in vitro* models can help uncover the molecular dynamics of HIV and viral superinfections.

Methods: Herein, we developed *in vitro* models of HIV-1/H1N1 (H+H+) and HIV-1/RSV (H+R+) superinfections. Three days post HIV-infection (1 ng/1×10^6 cells of HIV-1_{BaL}) PBMCs from 10 healthy volunteers were co-cultured, in a 24 transwell plate, with a human lung epithelial cell line (CaLu3), infected with H1N1 or RSV (0.015 MOI). HIV-1, H1N1 or RSV replication was monitored by p24 ELISA and Real-Time PCR. Five days post HIV-1 infection, both PBMCs and CaLu3 cells were harvested for mRNA expression of antiviral/inflammatory factors by Real–time PCR. T lymphocyte subpopulations, along with Perforin-and IFNγ-producing CD8+ lymphocytes were investigated by flow cytometry.

Results: In the H+H+ superinfection, replication rate of H1N1 was significantly hindered in the presence of HIV-1 compared to H1N1-single infection (p=0.027). In Calu3 cells, the H+H+ condition exhibited a decline in the expression of several anti-viral factors, mainly RIG-I levels compared to H1N1-single infected cells (p=0.041).

Furthermore, a unique immunophenotype was identified in H+H+ PBMCs, characterized by higher percentages of Th2 lymphocytes (CD4+GATA3+, p=0.022) and lower frequencies of Th1 cells (CD4+Tbet+, p=0.05), compared to HIV-1-infected PBMCs.

Conversely, in the H+R+ superinfection, HIV-1 replication rate exhibited a marked increase in the presence of RSV in comparison to HIV-1-single infection (p=0.048). HIV-1-infected PBMCs exposed to RSV exhibited significant increased expression levels of IFITM1 (p=0.05) and IFITM3 (p<0.001), and higher expression levels of CCR5 compared to the other conditions. Increased frequencies in Th17 (CD4+RORγT+, p=0.05) and in IFNγ-producing CD8+ (p=0.023), along with a diminished expression of HLA-DRII on CD4+ lymphocytes (p=0.03), were observed compared to HIV-1 single-infected PBMCs.

Conclusions: These findings reveal virus-specific interactions: HIV-1 dampens H1N1 replication while RSV enhances HIV-1 replication, each shaping distinct immune responses. This underscores the importance of evaluating respiratory viral superinfections in PLWH and highlights *in vitro* models as valuable tools for understanding HIV-viral interactions and their impact on pathogenesis.

EP0045

Differentiating subclinical TB from clinical TB among people living with HIV on ART using predictive immunologic biomarkers

T. Maseko[1,2], R. Perumal[1,2], L. Nandlal[1], M. Letsaolo[1], N. Yende-Zuma[1], M. Moodley[3], A. Sivro[1,2,3], K. Naidoo[1,2,3]

[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]South African Medical Research Council (SAMRC)-CAPRISA-TB-HIV Pathogenesis and Treatment Research Unit, Durban, South Africa, [3]University of KwaZulu-Natal, Durban, South Africa

Background: Subclinical tuberculosis (TB), defined as bacteriologically confirmed TB without classic clinical symptoms, remains a public health challenge, particularly in high-burden countries where it is often undetected by current TB screening tools. This leads to increased transmission and delayed treatment, complicating TB control efforts.

Methods: Participants were enrolled in the TB Recurrence Upon TB and HIV treatment (TRuTH) CAPRISA 005 study, a prospective longitudinal cohort enrolled at the CAPRISA eThekwini clinic in Durban, KwaZulu-Natal, South Africa.

The following definitions were adopted for this analysis:

1. Subclinical TB disease - a negative TB symptom screen, and identification of *Mycobacterial tuberculosis* (*M.tb)* by sputum smear or culture, and;
2. Clinical TB disease - positive TB symptom screen and identification of TB by sputum smear or culture.

Thirty inflammatory cytokines/chemokines were measured using Luminex-based methods and ELISAs in plasma specimens of 203 participants sampled 3-9 months prior to TB recurrence. Here we explored whether established predictive biomarkers of TB could differentiate subclinical TB from clinical TB.

Results: We evaluated immunological biomarkers in 203 people living with TB and HIV with a maximum follow-up of 4 years after a completed index episode of TB; 28 developed clinical TB, 17 developed subclinical TB, and 158 did not experience recurrence (No TB). Higher median plasma levels of sICAM were observed in participants with clinical TB compared to those with subclinical TB and no TB (p=0.004). We observed a dose-response with the highest sICAM levels observed in clinical TB, followed by

participants with subclinical TB who progressed to clinical TB disease, followed by participants who resolved spontaneously, and those with no TB.
In univariable models, a unit increase in log sICAM expression was associated with a 99% reduction in the odds of subclinical TB [odds ratio (OR): 0.01; 95% confidence interval (CI): 0.00 – 0.81, p=0.0408).
In multivariable models adjusting for HIV viral load and $CD4^+$ count, a unit increase in log IFABP expression was associated with an eight-fold higher likelihood of a subclinical TB diagnosis (OR: 8.26, 95% CI: 1.29 – 53.00, p=0.0261).
Conclusions: sICAM and IFABP levels may serve as useful indicators for distinguishing subclinical from clinical TB.

Emerging, re-emerging and neglected virus: epidemiology, pathogenesis, host immune responses, vaccines, immunotherapies and overlap with HIV acquisition

EP0046

Single-cell RNA sequencing reveals unique profiles in hRSV/SARS-CoV-2 co-infected A549-hACE2 epithelial cells

C. Vanetti[1,2], L. Piacentini[3], L.A. Citterio[4,2], M. Garziano[5,2], I. Saulle[1], J. Aiello[2], M. Broggiato[1], C. Fenizia[1], D. Bottan[6], D. Trabattoni[2], M. Clerici[1,7], M. Biasin[2]
[1]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy, [2]University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy, [3]Centro Cardiologico Monzino-IRCCS, Bioinformatics and Artificial Intelligence Facility, Milan, Italy, [4]University of Pavia, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy, [5]ASST Fatebene Fratelli Sacco, Milan, Italy, [6]University of Pavia, Pavia, Italy, [7]Fondazione Don Carlo Gnocchi, IRCCS, Milan, Italy

Background: Respiratory co-infections caused by hRSV and SARS-CoV-2 may be associated with worse outcomes, but the underlying cellular and molecular mechanisms are poorly understood.
Using an *in vitro* model of hRSV and SARS-CoV-2 co-infection, this study aims to elucidate how individual cells respond to simultaneous or single infections, providing insights into synergistic/antagonistic viral interactions and disease pathogenesis.
Methods: Single-cell RNA sequencing (scRNA-seq) data of the A549-hACE2-expressing cell line, co-infected with hRSV and SARS-CoV-2 (MOI: 0.01) were analyzed 72 hours post infection. The expression of SARS-CoV-2 and hSRV-specific genes was examined simultaneously with cellular genes to determine the presence or co-presence of the viruses in each profiled cell.
Gene expression profiles of single/co-infected cells were used to identify specific cell markers and make functional inferences about the different cell states.
Results: Unsupervised clustering analysis of scRNA-seq data identified four distinct cell clusters:
1. Uninfected,
2. SARS-CoV-2-infected,
3. hRSV-infected, and;
4. SARS-CoV-2/hRSV co-infected cells.

Within Cluster 4, two sub-clusters were distinguished based on hRSV gene expression levels: 4a (low) and 4b (high).
Marker analysis revealed molecular signatures of protein-coding and long non-coding (lnc) RNA characterizing each of the four cell clusters. Specifically, co-infected cells showed altered expression of genes linked to viral defense (n=27; $P=6.2\times10^{-8}$), innate immunity (n=30; $P=2.5\times10^{-5}$) and type I IFN regulation (n=8; $P=3.4\times10^{-4}$). Of these, a total of 41 relevant downregulated genes were found to be associated with specific biological processes (*e.g.* ribosome biogenesis).
Analyzing sub-clusters, JAK-STAT (n=8; $P=5.7\times10^{-5}$) and ERK1/ERK2/MAPK (n=15; $P=9.3\times10^{-5}$) pathways were specifically up-regulated in sub-cluster 4a and 4b, respectively. Co-infected cells also showed higher expression of at least 16 lncRNAs. lncRNAs NEAT1 and MALAT1 were downregulated in 4a compared to 4b ($P=1.1x10^{-9}$ and $P=2.3 \times 10^{-16}$, respectively).
Conclusions: Sc-RNAseq analysis revealed that co-infection drives the formation of a transcriptionally singular subpopulation of A549- hACE2 cells. The different expression of functionally related cell genes is presumably associated to a hRSV and SARS-CoV-2 interference within the same cell.
Further analyses will be mandatory to ascertain the functional role exerted by these factors that may have therapeutic relevance in the context of hRSV/SARS-CoV-2 coinfection.

EP0047

Two-step *in vitro* MEMORY TEST to assess SARS-CoV-2-specific immune response

M. Garziano[1,2], R. Zamarato[1], I. Saulle[3,1], S. Strizzi[1], M.A. Cano Fiestas[3,1], L. Citterio[1,4], P. Ogno[1], J. Aiello[1], L. De Luca[1,3], C. Vanetti[3,1], D. Trabattoni[1], M. Clerici[3,5], M. Biasin[1]
[1]University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy, [2]ASST Fatebenefratelli Sacco, Milan, Italy, [3]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy, [4]University of Pavia, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy, [5]Don Gnocchi Foundation, Milanly, Italy

Background: A booster shot is an additional vaccine dose that prolongs immunity. To determine whether humoral/cellular immune responses against SARS-CoV-2 are sufficient to prevent re-infection and make a booster unnecessary, we developed a two-step in vitro "MEMORY TEST."
Methods:
Step1: Neutralizing activity (NA) to SARS-CoV-2 was assessed in plasma samples (n°=100) from SARS-CoV-2 infected/vaccinated (SI) or uninfected/unvaccinated (SU)

subjects. PBMCs of 37 SI and 10 SU subjects were *in vitro* stimulated with inactivated SARS-CoV-2 for 5 days to assess B and T cell memory induction.

Step2: A549-ACE2 cells were SARS-CoV-2 infected (MOI:0.01). After 1-hour supernatants or PBMCs derived from step1 were added to A549-ACE2 infected cells to test if induced SARS-CoV-2 specific humoral/cellular immunity are sufficiently protective to control viral replication over time (48, 72h).

Results: According to their NA, SI subjects were divided in high responders (SIH; NA≥320) or low responders (SIL; NA≤80). After step1, CD4+, CD8+ T cells and B cells from SU did not significantly change their phenotypic or functional profile. Conversely, in SI re-exposure to SARS-CoV-2 stimulated both T and B cell maturation.

Specifically, in SI compared to SU we observed:

1. A significant reduction in naïve B cells ($p=8.8^{-10}$),
2. An increase in the percentage of plasmablast CD20+/CD27+/CD38+($p<0.001$), and;
3. An augmented percentage of polyfunctional CD4+IFNg+TNFa+IL2+ cells ($p<0.004$) and central memory CD8+ T cells ($p=8.3^{-5}$) .

Notably, viral replication in A549-ACE2 cells was not affected in the presence of either supernatants or PBMCs from SU derived from step1.

Contrarywise, viral infection/replication was significantly reduced in the presence of both PBMCs (48h: $p<2.2^{-5}$; 72h: $p<3.7^{-9}$) and supernatants (48h: $p<2.7^{-9}$; 72h: $p<2.7^{-9}$) from SI. Such protective immunity was independent from initial NA as SIH and SIL displayed the same trend in both step 1 and 2.

Conclusions: These findings suggest that humoral and cellular memory triggered by SARS-CoV-2 re-exposure can control viral replication, regardless of NA. Our two-step in vitro MEMORY TEST reliably predicts immune responses to re-exposure, offering a valuable tool to assess the need for booster doses, particularly in immunocompromised individuals, such as PLWH.

EP0048

Epigenetic regulation of RSV replication during co-infection with SARS-CoV-2: the role of microRNAs

L.A. Citterio[1,2], C. Vanetti[3,2], J. Aiello[2], R. Zamarato[2], L. De Luca[2], M. Broggiato[2], M.A. Cano Fiestas[4], D. Trabattoni[2], M. Clerici[3,5], M. Biasin[2]

[1]University of Pavia, PhD National Programme in One Health Approaches to Infectious Diseases and Life Science Research, Department of Public Health, Experimental and Forensic Medicine, Pavia, Italy, [2]University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy, [3]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy, [4]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy, [5]IRCCS Fondazione Don Carlo Gnocchi ONLUS, Milan, Italy

Background: Co-infections of respiratory viruses with similar tropism, such as RSV and SARS-CoV-2, can significantly impact clinical outcomes by either antagonizing or enhancing each other's pathogenicity. Using A549-hACE2 cells infected individually or concurrently with these viruses, we previously demonstrated enhanced replication of RSV during co-infection.

The present work aims to investigate the molecular and epigenetic mechanisms underlying RSV's replicative advantage in this context, with a specific focus on cellular microRNAs.

Methods: We selected eight microRNAs (let-7a-5p, let-7c-5p, miR-16-5p, miR-24-3p, miR-29c-3p, miR-30a-3p, miR-34a-5p and miR-93-5p) known to regulate antiviral responses, inflammation, and ribosomal biogenesis. Total microRNAs were extracted at 24 and 72 hours post-infection (hpi) from uninfected, single infected (RSV or SARS-CoV-2), and co-infected cells.

Reverse transcription followed by ddPCR was performed to assess expression patterns. In parallel, a transcriptome analysis was conducted on mRNAs to obtain an accurate molecular profile of the infected cells.

Results: Among the analyzed microRNAs, three exhibited significantly altered expression across conditions. Specifically: let-7a-5p was highly expressed at 24 hpi in co-infection ($p < 0.05$), but its expression was significantly downregulated at 72 hpi in the presence of both viruses; at 72 hpi, miR-34a-5p and miR-93-5p were upregulated and downregulated by single RSV and SARS-CoV-2 infection, respectively.

However, both miRNAs showed a marked reduced expression in the co-infection compared to RSV single infection ($p < 0.05$), suggesting their potential involvement in the regulation of the RSV replication cycle.

Moreover, we observed an inverse correlation between the expression of these miRNAs and mRNAs of several targets partaking in ribosomal biogenesis (C1QBP, EIF1AX, FBL, NHP2, NOP10, NPM1, PA2G4, PRKDC, RAN and several RPL/RPS), antiviral (DDX60, HERC5, IFIH1, IFIT1/2/3, IRF1, LYST, OASL, PMAIP1, RIGI, RSAD2, TANK, TRAF3, ZC3HAV1 and ZNFX1) and inflammatory (ACE2, ASH1L, CCL5, CYLD, FOXP1, IL15, IL1R1, KLF4, NFKB1, NFKBIA, NFKBIZ, PLCG2 and TNFAIP3) response.

Conclusions: These preliminary findings suggest that microRNAs may contribute to RSV's replicative advantage during co-infection with SARS-CoV-2 through the modulation of specific cellular processes. Further studies are warranted to elucidate the epigenetic mechanisms driving this interaction.

EP0049

Elevated MIF plasma levels in people with HTLV-1: exploring a putative role in viral pathogenesis

P. Benencio[1], L.A. Osorio-Ocampo[1], N. Ducasa[1], L. Baquero[1], A. Czernikier[1], A. Osegueda[1], C. Trifone[1], M. Biglione[1], C. Berini[1], G. Turk[1]
[1]*Instituto en Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS, UBA-CONICET), Ciudad Autónoma de Buenos Aires, Argentina*

Background: Human T lymphotropic virus type-1 (HTLV-1) is a globally spread retrovirus that, although mostly asymptomatic, may result in the development of adult T-cell leukaemia/lymphoma (ATLL) or HTLV-1 associated myelopathy (HAM). In Argentina, it is endemic to the Northwestern region. MIF is a proinflammatory cytokine associated with Th17 cell imbalance in pathologic conditions. Previous work from our group demostrated that, in HIV infection, MIF may contribute to viral pathogenesis by generating a microenvironment enriched in activating mediators and Th17-like CD4+ T cells (CD4TC).
Here, we explore the role of MIF in the context of HTLV-1 infection; particularly, its association with phenotype and function of CD4TC subsets among people living with HTLV-1 (PLWHTLV).
Methods: Blood samples were obtained from 12 healthy donors (HD), 10 asymptomatic, 7 ATLL and 9 HAM PLWHTLV. MIF, IL-6, IL-8, IL-10, IL-17A and IFNγ in plasma were evaluated by ELISA. Expression of CD4, CD25, CCR4, IL17A, IFNγ, FoxP3 and CD74 (MIF receptor) was evaluated in lymphocytes by flow cytometry and FlowJo (10.10.0). Statistical analysis was performed using GraphPad Prism (8.4.3).
Results: Plasma MIF was found to be significantly elevated ($p<0.0001$) in asymptomatics (median= 85.8 ng/ml) and ATLL (median=75.2 ng/ml), when compared to HD (median=2.028 ng/ml) and HAM (median=4.7 ng/ml). Percentages of IFNγ-expressing cells were significantly lower in bulk CD4+ ($p=0.0031$), CD4+ CD25+ ($p=0.01$) and CD4+ CD25+ CCR4+ ($p=0.0232$) T cell subsets in ATLL compared to asymptomatics.
No significant differences were found in the percentages of IL17A-expressing cells among CD4TC subsets or study groups. Expression of IL-17A and CD74 were correlated within the CD4+ CD25+ subset in ATLL individuals ($p=0.0002$, $r=0.9531$). No correlation was found between plasma MIF levels and CD4TC subsets.
Conclusions: As in HIV infection, our findings suggest that MIF may play a substantial role in the pathogenesis of HTLV-1, since it was elevated in PLWHTLV plasma. However, no association was found between MIF and CD4TC subsets in this exploratory analysis. Further investigations would be required to establish whether other mechanisms might be involved.

EP0050

Higher T cell activation, exhaustion, and senescence in HIV Controllers compared to ART-treated people living with HIV in Rio de Janeiro, Brazil

A.C. Souza de Lima[1], D. Gama Caetano[1], G. Bello[1], S. Sardinha Dias de Azevedo[1], B. Hoagland[2], L. Melo Villela[2], S. Wagner Cardoso[2], B. Grinsztejn[2], M. Gonçalves Morgado[1], M. Lindenmeyer Guimarães[1], F.H. Cortes[1]
[1]*Instituto Oswaldo Cruz (IOC), FIOCRUZ, Laboratório de AIDS e Imunologia Molecular, Rio de Janeiro, Brazil,* [2]*Instituto Nacional de Infectologia Evandro Chagas (INI), FIOCRUZ, Laboratório de Pesquisa Clínica em IST e AIDS, Rio de Janeiro, Brazil*

Background: HIV controllers (HICs) naturally suppress viral replication but are a heterogeneous group. Some experience disease progression after long-term control linked to immune activation and exhaustion, while others maintain stable CD4 counts without progression.
This study compared immune activation, exhaustion, and senescence between HIC and ART-treated PLWH.
Methods: PBMCs were collected from 19 HICs, including 11 elite controllers (ECs) and 8 viremic controllers (VCs). The ART-treated group (ART) included 8 PLWH with suppressed viral load. All participants were followed at the Instituto Nacional de Infectologia Evandro Chagas, Brazil. PBMCs were stained with FVS450, anti-CD3, CD4, CD8, CD45RA, and CCR7. Activation markers (CD38, HLA-DR), exhaustion markers (PD-1, TIM-3, TIGIT, LAG-3), and senescence markers (CD57, CD28) were analyzed. Samples were acquired using a FACSAria and analyzed in FlowJo. Clinical and sociodemographic characteristics were compared using the Kruskal-Wallis/Dunn's test, and flow cytometry data with Mann-Whitney test.
Results: The frequency of activated CD4+ T cells was higher in VC ($p=0.0205$) and EC ($P=0.0266$) compared to ART-treated PLWH. Similarly, activated CD8+ T cells were more frequent in HIC (EC-$p=0.0041$; VC-$p=0.0006$) than in ART-group.
The frequency of senescent CD8+ T cells was higher in VC ($p=0.0028$) and EC ($p=0.006$) compared to the ART-group, with no difference in CD4+ T cells. CD4+ T cells showed higher frequencies of LAG-3+ cells in total ($p=0.085$) and in TEM cells ($p=0.0134$) compared to the ART-group. VC had higher frequencies of TIGIT+ in TN cells ($p=0.02$) and TIM-3+ in TEM ($p=0.0289$) and TEF ($p=0.0121$) cells compared to the ART-group.
The frequency of PD-1+ cells was higher in EC ($p=0.0018$) and VC ($p=0.0003$) in TEF cells compared to ART-group. In CD8+ cells, VC and EC presented higher frequencies of Lag+(EC-$p=0.04$, VC-$p=0.02$) and TIM-3+ (EC-$p=0.01$, VC-$p=0.0039$) in TEF cells compared to ART-group. EC also showed a higher frequency of PD-1+ TEF cells compared to ART group ($p=0.02$).
Conclusions: Our results suggest that VCs may benefit from ART to reduce immune activation and exhaustion. Additionally, we observed high heterogeneity within the HIC group, particularly ECs, some of whom exhibit very low immune activation and exhaustion.

EP0051

Efficacy of COVID-19 vaccines and immune responses in people living with HIV In Ghana

E.Y.A. Bonney[1], A. Sankofi[2], Y.A. Tay[1], H. Lamptey[3], E.M.K. Kanda[4], P.A. Nartey[1], E.K. Mensah[1], M.E. Hanson[1], J. Klutse[1], A.T. Boateng[1], C.Z.-Y. Abana[1], J.O. Aboagye[1], B. Logonia[5], B. Mensah[5], P. Puplampu[6], M. Adusei-Poku[7], G.B. Kyei[4,8]

[1]University of Ghana, Noguchi Memorial Institute for medical Research, Virology, Accra, Ghana, [2]University of Ghana Medical Centre, Virology, Accra, Ghana, [3]University of Ghana, Noguchi Memorial Institute for medical Research, Immunology, Accra, Ghana, [4]University of Ghana, Noguchi Memorial Institute for Medical Research, Virology, Accra, Ghana, [5]University of Ghana, Noguchi Memorial Institute for medical Research, Epidemiology, Accra, Ghana, [6]University of Ghana medical School, Department of Medicine, Korle Bu, Ghana, [7]University of Ghana Medical School, Department of Microbiology, Korle Bu, Ghana, [8]University of Ghana Medical Centre, Accra, Ghana

Background: Immunocompromised persons, including people living with HIV (PLWH) face increased risk of severe outcomes from COVID-19, and therefore need strategies to manage SARS-CoV infection. The COVID-19 vaccines are known to curb the severity of disease in immunocompetent persons. However, the efficacy of COVID-19 vaccines in immunocompromised people in Ghana remains unknown. Scarcely evaluated and one wonders if HIV infection- induced immunodeficiency will influence the vaccine's efficacy. We evaluated levels of immune response to COVID-19 in both COVID-19 vaccinated versus and unvaccinated PLWH.

Methods: We conducted a cross-sectional study of 60 PLWH aged ≥18 years: 30 COVID-19-vaccinated and 30 unvaccinated. HIV seronegative samples were used as controls. Blood samples were collected and processed into plasma and peripheral blood mononuclear cells (PBMCs). Plasma samples of all 60 PLWH were subjected to ELISA to measure specific IgG response to SARS-CoV-2. The PBMCs of 24 samples (12 COVID-19-vaccinated and 12 unvaccinated) were stimulated with PHA, S, and N-Antigen. LUMINEX multiplex assay was employed to assess the levels of six cytokines (TNF-a, IL-1b, IFN-g, IL-4, IL-10, IL-6) in the stimulated cells.

Results: The PLWH vaccinated group had a 67% higher RBD-OD (OR: 1.67, 95% CI: 1.32–2.11, $p < 0.001$) and a 29% higher N-Ag-OD (OR: 1.29, 95% CI: 1.06–1.57, $p = 0.010$). Receiving booster doses further enhanced antibody levels, particularly against the N-antigen, suggesting a longer-lasting immune response. Cytokine levels were lower in the vaccinated compared to those who were not vaccinated. The differences were statistically significant with TNF-alpha responses approximately 91% lower (OR: 0.09, 95% CI: 0.02–0.49) among vaccinated individuals. Inter - person variability was observed (variance: 5.74, 95% CI: 3.31–9.95). Similarly, IFN-gamma T-cell responses were 85% lower in vaccinated individuals compared to their unvaccinated counterparts (OR: 0.15, 95% CI: 0.03–0.71), with notable variability between participants (variance: 4.02, 95% CI: 2.00–8.07).

Conclusions: These findings demonstrate significant differences in immune response markers between the groups, emphasizing the positive impact of vaccination on immunological outcomes in PLWH, like their HIV seronegative controls.

Course of HIV disease

EP0052

Retention of clients diagnosed through secondary HIV self-testing: a longitudinal analysis over 12 months in Johannesburg, South Africa

M.R. Letsoalo[1], K. Rees[2], J.M. Lethoba[1]

[1]Anova Health Institute, Public Health, Roodepoort, South Africa, [2]Anova Health Institute, Johannesburg, South Africa

Background: Evidence shows that early retention on HIV treatment is a challenge in South Africa. A systematic review estimated an average 6-month retention rate of 85%, and routinely collected data reported 74% of clients engaged 6 months after initiation. HIV self-testing (HIVST) is used to increase access to diagnosis, but linkage to treatment is a concern.

This study aimed to measure the retention rate of Healthcare Users (HCUs) diagnosed through secondary HIVST, as this testing may be reaching a population reluctant to seek healthcare services, and therefore at risk of poor retention.

Methods: This was a retrospective analysis of routine program data. A cohort of clients diagnosed through Secondary HIV-ST from January 2023 to October 2023 were followed for 12 months, and the retention rate was measured at 6 months and 12 months after initiation of treatment. Counselors kept records of every HIVST Kit distributed and followed up with primary clients after 72 hours, or through calling secondary clients directly. Clients with a positive test were recalled to confirm the HIV diagnoses and a retention counselor/case manager was allocated to accompany and link HCUs to services.

This group was identified as potentially high risk and enrolled into case management for enhanced adherence counseling and given appointment reminders 24 hours before each visit.

Results: 1514 test kits were distributed and 189 HCU had their diagnoses of HIV confirmed (12%). After six months 95% (180) of HCUs were still in care and 90% (162) were virally suppressed at less than 50 copies. At 12 months 90% (145) of the HCUs were still in care and 90% (131) were virally suppressed.

Conclusions: In this program setting, despite the population not having sought out HIV testing, we found very high retention and viral suppression rates compared with existing literature. Retention in care and suppression rates can be maintained at the highest level for high-risk populations if intensive psychosocial support is provided, and a conducive, effective, and efficient patient-centred environment is created.

EP0053

Mortality rates and individual characteristics among exposed infants and under-five Children living with HIV at Baylor Foundation Uganda Clinic

V. Ndyanabangi[1], L. Kiyimba[1], R. Ssebunya[1], R. Jjuuko[1], P. Nahirya[1], D. Kiragga[1]

[1]Baylor-Uganda CRS, Kampala, Uganda

Background: A 2021 report by the Centers for Disease Control and Prevention indicated Uganda's under-five mortality rate was 42.1 per 1,000 live births. However, mortality rates among infants exposed to HIV (HEI) or children under five living with HIV (CLHIV<5) years are not well-documented.

This study describes the mortality rate and individual characteristics of HEI and CLHIV<5, attending the Baylor Foundation Uganda (BFU) clinic from January 2022 to December 2023.

Methods: The Data team at Baylor Foundation Uganda conducted a retrospective electronic chart review of children under five who were exposed to HIV or CLHIV<5 and attended the Baylor Foundation Uganda clinic between January 2022 and December 2023. Descriptive statistics were used to analyse mortality rates and the characteristics of children recorded as deceased in the electronic medical records database.

Results: The under-five mortality rate was 5% (99/2118), with 46% (46/99) female and a median age of 12 months (IQR=12). Among the deceased, 32% (32/99) were exposed to HIV, and 58% (57/99) were Living with HIV. Of those LHIV, 66% (38/57) were diagnosed via DNA PCR, and 33% (19/57) via serology.

WHO stage 3 or 4 HIV was observed in 45% (26/57), with 15% (4/26) not receiving antiretroviral therapy at the time of death. HIV stage 3 or 4 was undocumented for 28% (16/57). The BFU clinic received 67% (66/99) of referrals from Mulago wards, with 38% (38/99) from the malnutrition ward. Tuberculosis (TB) accounted for 19% (19/99) of deaths. Other causes included infections, heart disease, and pulmonary diseases, while 56% of deaths had unknown causes.

Conclusions: The under-five mortality rate for infants exposed to HIV and CLHIV<5 was relatively low over two years. Preventable deaths were linked to delayed diagnosis, treatment, and documentation gaps. Leading mortality causes included malnutrition complications and TB. Early diagnosis and treatment are critical for under-fives survival, while mentorship, continuous quality improvement, and better documentation could improve outcomes. Health literacy on malnutrition and TB prevention should be integrated into routine care.

EP0054

Mortality predictors in a brazilian cohort of people with advanced HIV disease

P.M. Fonseca[1], N. Reis[1], A. Pasqualotto[2], F. Perez[3], O. Sued[4], E. Lima[1], A. Noal[1], F. Abbott[1], A.E. Barin[1], T. Vieceli[2], R. de Bastos Ascenço Soares[5], C. Silva de Miranda Godoy[5], D. R. Falci[6], L. R. Silva[7], M. G. Melo[8], N. A. Hatem[2], A. C. G. Castelo[7]

[1]Hospital Vila Nova, Infectious Disease, Porto Alegre, Brazil, [2]Universidade Federal de Ciências da Saúde de Porto Alegre, Infectious Disease, Porto Alegre, Brazil, [3]Pan American Health Organization, Communicable Diseases Prevention, Control and Elimination Department, Washington, United States, [4]Pan American Health Organization, Advisor HIV Care and Treatment, Washington, United States, [5]Hospital Estadual de Doenças Tropicais Dr Anuar Auad/ISG, Goiania, Brazil, [6]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [7]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil, [8]Hospital Nossa Senhora da Conceição, Porto Alegre, Brazil

Background: Despite advancements in antiretroviral therapy (ART), HIV-associated mortality remains a significant global public health concern. In 2023, over 630,000 HIV/AIDS-related deaths were reported worldwide. In Brazil, high mortality rates persist, with Porto Alegre leading among Brazilian capitals. Delays in HIV diagnosis, limited access to healthcare, and non-adherence to treatment, exacerbated by social disparities, contribute to these high mortality rates.

This study aimed to describe the clinical characteristics and risk factors associated with overall mortality and opportunistic infections (OIs)-related mortality, in advanced HIV people in Brazil.

Methods: This prospective cohort study included 419 adults with advanced HIV across five Brazilian hospitals, four located in Porto Alegre and one in Goiânia. Baseline demographic and clinical data were collected. All participants were screened for tuberculosis (TB), cryptococcosis, and histoplasmosis with antigen-based tests and followed for 90 days to assess mortality.

Statistical analysis was conducted to identify variables significantly associated with mortality. Causes of death were classified per the Coding of Death in HIV (CoDe) protocol.

Results: Of the participants, 230 (55%) were cisgender men, 264 (64%) identified as black-brown, and 190 (45%) had not completed elementary school. The cohort had a median CD4 count of 66 cells/mm³, with the majority and most participants (95.4%) having a CD4 count below 200 cells/mm³, and 58% had abandoned treatment.

Opportunistic infections were diagnosed in 46% of clients: TB (34%), cryptococcosis (12%), and histoplasmosis (10%). Among these, 81% were TB-LAM positive, 94% CrAg positive, and 98% Histoplasma antigen positive.

After 90 days follow-up, 76 clients (18%) had died, mostly from AIDS-related causes. Factors significantly associated with mortality included ART-naive status (aHR 1.91; p=0.010), low hemoglobin (aHR 3.89; p<0.001), elevated creatinine (>2x upper limit of normal, aHR 1.52; p<0.001),

and altered mental status (aHR 2.33; p=0.002). Cryptococcal meningitis (p=0.012) and severe histoplasmosis (p=0.013) were also strongly correlated with death.

Conclusions: The study underscores the urgent need for earlier HIV diagnosis and sustained ART to reduce mortality, highlighting clinical and laboratory markers linked to higher death risk. High late-diagnosis rates suggest delayed healthcare access, stressing the need to enhance HIV testing, treatment adherence, and address social disparities.

EP0055

Advanced HIV disease remains common among people with HIV newly enrolled to care in Central Ethiopia in the Test-and-Treat Era

I.J. Abdulahi[1,2], P. Björkman[1,3], S. Sasinovich[1], D. Hailu[2], D.A. Arimide[1], G. Merga[2], F. Bekele[4], B. Nordberg[1,5], A. Mulu[2], A. Mihret[2], A. Abdissa[2], H. Abayneh[2], P. Medstrand[1,6], A. Reepalu[1,3]

[1]Lund University, Department of Translational Medicine, Malmo, Sweden, [2]Armauer Hansen Research Institute (AHRI), Addis Ababa, Ethiopia, [3]Skåne University Hospital, Department of Infectious Diseases, Malmö, Sweden, [4]Oromia Health Bureau, Addis Ababa, Ethiopia, [5]Helsingborg Hospital, Department of Infectious Diseases, Helsingborg, Sweden, [6]University and Regional Laboratories, Department of Clinical Microbiology, Lund,, Sweden

Background: Increased access to HIV testing services allows for early HIV diagnosis and initiation of antiretroviral therapy (ART), which is associated with reduced morbidity and mortality. Yet, identifying people with advanced HIV disease (AHD) at time of diagnosis is important, as they may require additional investigations and interventions. In the Test-and-Treat Era, the availability of CD4 counts has decreased, making identification of AHD difficult. We characterized features of AHD among people with HIV (PWH) aged >15 years newly enrolled in care at public health facilities in Central Ethiopia.

Methods: Participants were included 2022-2024 as part of a prospective cohort study. At inclusion, sociodemographic and clinical data (including routinely obtained CD4 counts) was collected. AHD was defined as WHO stage 3/4 or CD4 count <200 cells/mm^3. Determinants associated with AHD were studied with logistic regression analysis.

Results: Among 622 participants, the median age was 35 years and 364 (58.5%) were female. Based on WHO stage alone, 229 persons had AHD (36.8%). CD4 counts were available in 118 (30.0%) persons with WHO stage 1/2 and led to the identification of an additional 37 persons with AHD (31.4% of persons with WHO stage 1/2 with available CD4 data). Overall, CD4 count results were available for 222 persons, accounting for 35.7% of the overall study participants.

In total (using both CD4 counts and WHO staging), 266(42.8%) participants had AHD. AHD was more common among men (adjusted odds ratio [aOR], 1.47; 95% confidence interval [CI], 1.01-2.16), older people aged >50 years (aOR, 2.64; 95% CI, 1.18-5.90) and rural residents (aOR, 2.98; 95% CI,1.56-5.67). Tuberculosis was the most common opportunistic infection for clinically staging participants as AHD, with 59/186(31.7%) and 15/43(34.9%) of WHO stage III and IV cases, respectively.

Conclusions: A high proportion of PWH enrolling in care in Ethiopia present with AHD. Lack of routine CD4 testing at initiation of ART may have led to missed identification of AHD in nearly one-third of PWH staged as WHO ½ emphasizing the need to improve access to routine CD4 testing. Our findings highlight the need to adapt HIV testing services for men, people 50 years and older, and rural residents.

EP0056

Regional variations in causes of mortality among people living with HIV in Nigeria: insights from a north-south comparative analysis

A. Idemudia[1], M. Ijaiya[2], I. Iyamu[3], C. Obiora-Okafo[1], P. Gado[1], U. Omo-Emmanuel[1], O. Toyo[4], U. Akpan[4], B. Oyawola[1], C. Nwadike[1], B. Onimode[1], B. Pius[1], D. Kimanga[1], D. Ogundehin[1], B. Kagniniwa[5], A. Raji[5], F. Agbo[6], T. Ilori[6], B. Adebobola[7], E. James[1], J. Pius[1], O. Oyelaran[1]

[1]United States Agency for International Development (USAID), Abuja, Nigeria, [2]The Demographic and Health Surveys (DHS) Program, Rockville, Maryland, United States, [3]School of Population and Public Health, University of British Columbia, Vancouver, Canada, [4]Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, [5]United States Agency for International Development (USAID), Washington D.C, United States, [6]National Agency for the Control of AIDS (NACA), Abuja, Nigeria, [7]National AIDS, Sexually Transmitted Infections Control and Hepatitis Programme (NASCP), Federal Ministry of Health, Nigeria, Abuja, Nigeria

Background: Mortality among people living with HIV (PLHIV) in Nigeria varies significantly between northern and southern regions, reflecting differences in disease patterns, healthcare access, and comorbidities. This study investigates these regional variations to inform targeted interventions.

Methods: A retrospective cohort study analyzed data from 8,357 PLHIV (56% female, 44% male) who received care from 2017 to 2024. Mortality causes were classified as AIDS-related, infectious diseases, or non-communicable diseases (NCDs, e.g., diabetes, stroke). Kaplan-Meier survival analysis assessed mortality trends, while logistic regression identified predictors.

Advanced statistical techniques, including Blinder-Oaxaca decomposition, quantified contributions of health determinants to regional disparities.

Results: AIDS was the leading cause of death in the south (52%) and more prevalent than in the north (34%, p < 0.01). Infectious diseases were the primary cause in the north (58%), significantly higher than in the south (29%, p < 0.01). NCDs accounted for 31% of deaths in the south compared to 9% in the north. Logistic regression revealed that late HIV diagnosis (aOR: 4.1, 95% CI: 3.4–5.0), poor ART adher-

ence (aOR: 3.6, 95% CI: 3.0–4.5), and limited healthcare access (aOR: 4.5, 95% CI: 3.8–5.6) were significant predictors of mortality. Decomposition analysis indicated that 65% of regional mortality differences were attributable to variations in healthcare infrastructure and socioeconomic factors.

Conclusions: Mortality in the south is driven by AIDS and NCDs, while infectious diseases dominate in the north. Tailored interventions, including improved infectious disease management in the north and integrated NCD care in the south, are essential to addressing these disparities and improving health outcomes for PLHIV in Nigeria.

EP0057

Characterizing clients interrupting in treatment in the Manzini and Lubombo regions of Eswatini: a setting that has achieved 95-95-95

S. Haumba[1,2], T. Maseko[1], P. Bongomin[1], L. Mamba[1], V. Williams[1,3], F. Khumalo[1], R. Mapaona[1], N. Musarapasi[1], S. Mchunu[1], R. Chekenyere[1], N. Tsabedze-Msibi[1], A. Mafukidze[1], S. Matse[4], S. Ojoo[2], D. Bazira[2], S. Matse[1]
[1]Center for Global Health Practice and Impact, Georgetown University, Clinical Services, Mbabane, Eswatini, [2]Center for Global Health Practice and Impact, Georgetown University Medical Center, Georgetown University Medical Center, Washington, United States, [3]Utrecht University, Julius Global Health, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, the, [4]Ministry of Health, HIV Care and Treatment, Mbabane, Eswatini

Background: Eswatini achieved the second 95 in 2020. The 2021 Population-based HIV Impact Assessment showed that 97.3% of PLHIV in Eswatini are on antiretroviral (ART). This means only 2.7% of PLHIV are not on ART, among which are clients who interrupt treatment (IIT). While IIT predictors have been identified in many studies conducted in non-95-95-95 settings, different factors could be at play in the 95-95-95 setting. PLHIV not on ART threatens sustainment of gains in the 95-95-95 targets in Eswatini. The clients should be characterized and understood so targeted interventions can be designed to reach and keep them in care, hence this study aimed to measure the rate of IIT, characterize the IIT clients, and identify predictors of IIT in a 95-95-95 setting.

Methods: Using programmatic data, a cross-sectional study was conducted among ART clients between January and March 2023 from 84 facilities in Manzini and Lubombo. Descriptive data analysis was conducted to describe IIT rate and characteristics of IIT clients. Lasso regression analysis was conducted to explore client characteristics that predict IIT in a setting that has achieved the 95-95-95 targets.

Results: A total of 93398 clients were included in the analysis. The IIT rate was 1.7% (n=1400). Clients with the highest IIT rates were those aged 10-19 years (3.7%, n=169), WHO stage I&II at ART initiation (30%, n=749), or < 1 year on ART (2.6%, n=367). Manzini had a higher (2.1%, n=1206) IIT rate than Lubombo (0.6%, n=194); urban facilities had a higher IIT rate (2.6%, n=1109) than rural facilities (0.6%, n=291), and virally suppressed clients had higher IIT rates (2.0%) than unsuppressed clients (1.0%). IIT predictors were being from Manzini (AOR:4.5 [95%CI:1.8-11.8], p=0.002), WHO stage III&IV at ART initiation (AOR:2.7 [95%CI:1.2-5.8], p<0.001), and having a treatment supporter who is not a relative (AOR:2.7 [1.1-3.7], p=0.025).

Conclusions: To sustain the gains in the second 95, population segments with higher IIT rates should be targeted with innovative strategies by the HIV Program to retain them in care. The predictors can be used to identify clients most likely to interrupt treatment before they interrupt treatment and be provided innovative IIT preventive interventions.

EP0058

Observed Low PrEP Initiation Rates among HIV Negative Clients and Reasons for PrEP refusal in a Mature HIV Program in Manzini and Lubombo

S. Haumba[1], R. Chekenyere[1], P. Bongomin[1], T. Maseko[1], R. Mapaona[1], E. Nyandoro[1], N. Musarapasi[1], A. Mafukidze[1], S. Matse[1], S. Ojoo[1], D. Bazira[1]
[1]Center for Global Health Practice and Impact, Georgetown University Medical Center, Washington, United States

Background: Eswatini achieved the first 95 HIV target in 2020. The HIV incidence is at 0.62% among adults aged 15 years and older, with a disparity between males (0.17%) and females (1.11%). To sustain the gains in the first 95, Eswatini uses HIV prevention measures such as pre-exposure prophylaxis (PrEP).

The aim of this study was to describe the proportion of PrEP eligible clients who are initiated on PrEP initiation, and the reasons for refusing PrEP among HIV negative clients.

Methods: We conducted a cross-sectional study using HIV program data from 84 facilities in Manzini and Lubombo abstracted between January and December 2023 for program monitoring and reporting on clients who tested HIV negative. We used descriptive statistics to describe PrEP initiation and the reasons for refusing PrEP. We tracked if they were initiated on PrEP or had documented reasons for refusing PrEP.

Results: Out of 82,754 HIV-negative clients, 16% (n=13,537) were initiated on PrEP. PrEP initiation was slightly higher among males (18%, n=4323) compared to females (16%, n=9214). Only 8177 clients had documented reasons for refusing PrEP. Most of the clients were females (77.3%, n=6322), from clinics or public health units (67.9%, n=5549), and located in rural areas (76.3%, n=6157).

The top 10 reasons for refusing PrEP were being not ready (24.3%, n=1986), not interested (18.1%, n=1482), trusting their sexual partner- or having one faithful sexual partner (9.7%, n=792), cannot take the PrEP pill daily (7.4%, n=603), adding PrEP pills to other medication client is currently using (7.3%, n=600), fear of side effects (6.3%, n=513), need to get consent from sexual partner (5.9%, n=480), PrEP being packaged like ART (2.8%, n=231), fear that parent/guardian will know client is sexually active (2.7%, n=219), and fear of losing partner's trust (2.3%, n=190).

A higher proportion of females reported each of these reasons compared to males. Clients aged 20-29 had the highest proportion of clients in each reason category.
Conclusions: PrEP initiation is low among eligible HIV-negative clients. Reasons for refusing PrEP were PrEP were not being ready, not interested, trusting their sexual partner or having one faithful sexual partner.

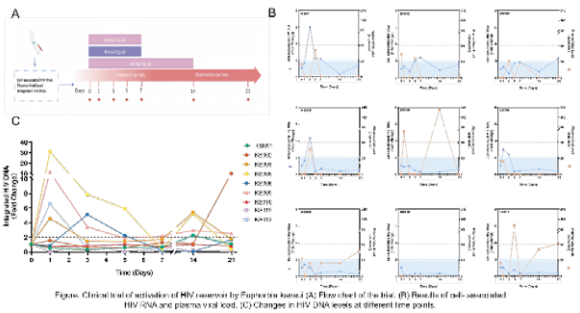
Cure interventions and other strategies and therapies

EP0059

Euphorbia kansui for latent virus reactivation in people living with HIV on suppressive antiretroviral therapy: a phase 2 clinical trial

J. Xun[1], X. Yang[2], J. Chen[1], R. Zhang[1], Y. Shen[1], H. Zhu[2], H. Lu[3]
[1]Fudan University, Department of Infectious Diseases and Immunology, Shanghai Public Health Clinical Center, Shanghai, China, [2]Fudan University, State Key Laboratory of Genetic Engineering and Engineering Research Center of Gene Technology, School of Life Sciences, Shanghai, China, [3]The Third People's Hospital of Shenzhen, Department of Infectious Diseases and Nursing Research Institution, National Clinical Research Center for Infectious Diseases, Shenzhen, China

Background: The ‚Shock and Kill' strategy is pivotal in the quest for an HIV/AIDS cure. Our study explores Euphorbia kansui (Kansui), a traditional Chinese medicine, for its potential to reverse HIV-1 latency while rigorously assessing safety.
Methods: We conducted a phase 2 clinical trial at the Shanghai Public Health Clinical Center (NCT04503928). People living with HIV (PLWH) were randomized into three groups, initially receiving either 1 g qd or 2 g qd of Kansui pills for 7days or 14 days. PBMCs were collected on day 0, 1, 3, 5, 7, 14, and 21.
Primary endpoints included changes from baseline in cell-associated (CA) HIV RNA and plasma HIV viral load, while secondary endpoints involved integrated HIV DNA levels and safety assessments.



Results: Nine male PLWHs (mean age: 38.78±13.85 years old) with a median antiviral treatment duration of 49 months, were enrolled in the clinical study. During the intervention period, four participants experienced >2-fold CA HIV RNA induction, two had viral load reactivation >50 copies/ml during the intervention period. Integrated HIV DNA levels transiently increased during the intervention and then quickly returned to baseline levels without significant decline. Kansui demonstrated a favorable safety profile, with no serious adverse events reported and only mild adverse events observed.
Conclusions: Kansui can reactivate latent HIV viral reservoirs at a low-level in vivo and is well tolerated by PLWHs on antiretroviral therapy which warrant further investigation.

ART resistance

EP0060

Trends of HIV drug resistance and associated factors: an analysis of the Uganda national HIV drug resistance program data, 2021-2024

B. Ainembabazi[1,2], A. Ayitewala[3], J. Nakawesi[4], C. Lwanga[5], R. Migisha[1], M. Luwunzu[6], E. Namusoke Magongo[6], M. Nakawuka[6], A. Ahimbisibwe[6], P. Twesigye[6], C. Katureebe[6]
[1]Uganda National Institute of Public Health, Uganda Public Health Fellowship Program, Kampala, Uganda, [2]Ministry of Health Uganda, STD/AIDS Control Program, Kampalaugug, Uganda, [3]Uganda National Health Laboratory & Diagnostic Services, Kampala, Uganda, [4]Baylor College of Medicine Children's Foundation, Kampala, Uganda, [5]Makerere University, School of Public Health, Kampala, Uganda, [6]Ministry of Health Uganda, STD/AIDS Control Program, Kampala, Uganda

Background: HIV drug resistance (HIVDR) to reverse transcriptase, protease, and integrase strand transfer inhibitors (INSTIs) is associated with increased mortality, program costs, and HIV incidence. We assessed trends of HIVDR during 2021-2024 in Uganda and associated factors.
Methods: We conducted a secondary analysis of program data on HIVDR among people living with HIV with repeat non-suppressed viral loads (≥1000 copies/ml).
All individuals in the national HIVDR database with complete data on the key variables were included in the analysis. Logistic regression was used to identify factors associated with HIVDR, and Mann-Kendall test was used to test significance in the HIVDR trends.
Results: Among 6,311 participants, 3,314 (53%) were female, with a median age of 22 years (IQR: 14-39). Most, 1,795 (43%) had spent 6-10 years on ART, and 3,313 (52%) were on first line ART. 351(5.6%) had HIVDR. HIVDR increased from 3% in July–September 2021 to 9% in July–September 2023, and this had declined to 7% by Jan-March 2024 (p=0.012). Resistance to INSTIs increased from 0% in April–June 2021 to 29% in April-June 2023. This had declined to 23% by Jan–March 2024 (p=0.013).
Participants aged 20-24 (OR=1.6; 95%CI: 1.2–2.2) and those aged ≥50 years (OR=1.9; 95%CI: 1.3–2.8) had higher odds of HIVDR compared to those aged 1–19 years. Males (OR=1.5;

95%CI: 1.2–2.0) and those on ART for ≥11 years compared to those on ART for ≤5 years (OR=1.8; 95%CI: 1.3–2.6) also had higher odds of HIVDR. Participants from HC IVs (OR=0.54; 95%CI: 0.36–0.81) and HIV specialized clinics (OR=0.47; 95%CI: 0.3–0.74) had lower odds of HIVDR compared to those from HC IIIs. Higher odds of HIVDR were observed in the northern (OR=2.5; 95%CI: 1.7–3.5), western (OR=1.8; 95%CI: 1.1–2.9), and eastern (OR=1.8; 95%CI: 1.2–2.5) regions compared to the central region.

Conclusions: HIVDR, particularly to INSTIs, is rising among individuals with repeat non-suppressed viral loads, with higher likelihood observed in males, individuals aged ≥20 years, and those from HC IIIs and non-central regions. There is need to investigate the underlying factors driving resistance and its variation across demographics and geographical locations.

EP0061

Emerging resistance to dolutegravir in Mozambique: patterns and implications from the DREAM Program

F. Ciccacci[1], A.M. Doro Altan[2], N. Majid[3], S. Orlando[1], E. Umuasse[3], M. Rafael[3], Z. Sidumo[3], P. Germano[4], G. Guidotti[5], C.F. Perno[6]

[1]University of Rome Torvergata, Biomedicine and Prevention, Rome, Italy, [2]Link Campus University, Rome, Italy, [3]DREAM Program, Community of Sant'Egidio, Maputo, Mozambique, [4]DREAM Program, Community of Sant'Egidio, Rome, Italy, [5]ASL Roma 1, Rome, Italy, [6]Bambino Gesù Pediatric Hospital IRCCS, Rome, Italy

Background: DTG is widely used in Mozambique as a first-line ART due to its high efficacy and favorable resistance profile. However, increasing reports of DTG resistance in resource-limited settings have raised concerns about its long-term sustainability.

Methods: We characterized resistance mutations in 13 Mozambican patients experiencing virological failure on DTG. Samples were collected from seven DREAM program centers and underwent genotypic resistance testing using Sanger sequencing. Mutations were classified based on their impact on drug susceptibility, and patient characteristics were compared.

Results: This study included 13 patients in virological failure on DTG; 9 (69.2%) exhibited resistance mutations to DTG. The number of resistance mutations per patient ranged from 1 to 5: 3 patients with one mutation, 4 patients with 4, and 1 patient with 5. The most frequent mutations were G118R and E138K, in 5 patients each, followed by R263K, in 3 patients.

Additional mutations included L74M (4 cases) and accessory mutations such as S230SR and E157Q, which were less common. Resistance to RTIs was prevalent among DTG-resistant patients, while no resistance to PIs was observed.

Patients with resistance mutations had a median ART duration of 14.6 years (interquartile range [IQR]: 8.3–17.0), compared to 8.0 years (IQR: 6.4–9.8) in those without resistance. Prior treatment failure was more common among DTG-resistant patients (66.7% vs. 12.5%), while a higher proportion of DTG-susceptible patients had transitioned to DTG during viral suppression (62.5% vs. 22.2%). Sex-stratified analysis showed no significant differences in resistance patterns between males and females, but females represented 60% of those with multiple resistance mutations (≥3 mutations).

Conclusions: This study highlights the emergence of DTG resistance mutations in Mozambique, emphasizing the need for routine resistance monitoring. Tailored strategies are crucial to preserving the efficacy of DTG and mitigating the public health impact of resistance in resource-limited settings.

EP0062

High level HIV drug resistance to second-generation non-nucleoside reverse transcriptase inhibitors: implications for long acting and third-line antiretroviral therapy in Tanzania

J. Rugemalila[1], R. Ndege[2], S. Shabani[3], N. Lisso[4], Y. Mwakabumbe[5], B. Deusderit[6], H. Mimi[7], H. Shimba[8], L. Mapunda[9], E. Aris[10], S. Kalluvya[11]

[1]Muhimbili National Hospital, Internal Medicine, Dar es Salaam, Tanzania, the United Republic of, [2]Ifakara Health Institute, Morogoro, Tanzania, the United Republic of, [3]National AIDS, STIs and Hepatitis Control Program, Dodoma, Tanzania, the United Republic of, [4]Sekou Touré Regional Referral Hospital, Mwanza, Tanzania, the United Republic of, [5]Songea Regional Referral Hospital, Songea, Tanzania, the United Republic of, [6]Bugando Medical Centre, Internal Medicine, Mwanza, Tanzania, the United Republic of, [7]Morogoro Regional Referral Hospital, Pediatrics and Child Health, Morogoro, Tanzania, the United Republic of, [8]Buganndo Medical Centre, Mwanza, Tanzania, the United Republic of, [9]National Public Health Laboratory, Virology Department, Dar es Salaam, Tanzania, the United Republic of, [10]Management and Development for Health, Dar es Salaam, Tanzania, the United Republic of, [11]Catholic University of Health and Allied Health Sciences, Internal Medicine, Mwanza, Tanzania, the United Republic of

Background: Nevirapine and Efavirenz, first-generation non-nucleoside reverse transcriptase inhibitors (NNRTIs served as the default first-line antiretroviral therapy (ART) for people living with HIV (PLHIV) in Tanzania between 2004 and 2018. Currently, second-generation NNRTIs are reserved for third-line regimens.

This study investigated the prevalence of drug resistance, resistance associated mutations (RAMs) patterns, and associated factors for second-generation NNRTIs within the national program.

Methods: We analyzed participant-level data from the National Central Third-Line Committee for 634 adolescents and adults aged 10 years and above with second-line ART virologic failure between March 2020 and December 2023. After confirmed virologic failure, HIV-1 genotyping of the *pol* region was performed using Sanger sequencing at the Temeke Specialized Laboratory (Dar es Salaam) and Mbeya Zonal Referral Hospital. RAMs were

interpreted using the Stanford HIV database (version 9.6). Multivariable logistic regression identified factors associated with NNRTI-RAMs.

Results: Overall NNRTI resistance occurred in 31.9% (432/634) of study participants, with 70.1% having at least one RAM conferring resistance to both etravirine (ETR) and rilpivirine (RPV). The most frequent RAMs included G190A, E138A/Q, Y188L, Y181C, and K101E. Less common mutations (<5% prevalence) were G190S/E, M230L, K101P and Y181I/V. RPV and ETR RAMs conferred high-level resistance in 42.9% and 13.5% of participants respectively and, intermediate-level resistance in 14.2% and 31.4%.

Baseline ART regimens with protease inhibitors (PIs) were significantly associated with a lower likelihood of NNRTI resistance (adjusted prevalence ratio (aPR 0.35, 95% CI: 0.15–0.83, p=0.017).

WHO clinical stage 2 was associated with increased resistance (aPR1.48, 95% CI: 1.04–2.12, p=0.031). Other variables, such as age, sex, and HIV subtype, were not significantly associated with NNRTI resistance.

Conclusions: High-level resistance to second-generation NNRTIs suggest a compromise of their effectiveness in third-line ART regimens. The presence of RPV RAMs highlights careful selection when considering long-acting cabotegravir-rilpivirine therapy for PLHIV particularly those with adherence challenges to daily oral regimens. Notably, HIV disease stage II may be associated with an increased risk for developing RAMs, warranting further investigation.

On the other hand, PI-ART based regimens were associated with a significantly lower likelihood of RAMs, supporting their protective role in managing drug resistance.

EP0063

Transmitted and acquired integrase strand transfer inhibitor (INSTI) resistance mutation in a prospective cohort of Thai people living with acute HIV

P. Promsena[1,2], L. Poonpitak[1], C.P. Sacdalan[1,2], S. Moreland[3,4], S. Pinyakorn[3,4], N. Ratnaratorn[1], N. Sae-Eiaw[1], H. Savadsuk[1], E. Kroon[1], S. Sriplienchan[1], D.J. Colby[3,4], L. Trautmann[3,4], S. Vasan[3,4], N. Phanuphak[5], SEARCH010/RV254 Study Team

[1]SEARCH Research Foundation, Bangkok, Thailand, [2]Research Affair, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [4]Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, MD, United States, [5]Institute of HIV Research and Innovation, Bangkok, Thailand

Background: Data on transmitted and acquired integrase strand transfer inhibitor (INSTI) drug resistance mutations (TDRM and ADRM) in Thailand are limited. This study assessed the prevalence of INSTI TDRM and ADRM in a longitudinal early-treated acute HIV (AHI) cohort in Thailand.

Methods: HIV genotyping was done in RV254/SEARCH010 AHI cohort to identify TDRM at enrolment (before ART initiation) and ADRM in participants experiencing virologic failure (VF). DTG-based regimens and integrase gene sequencing were introduced in SEARCH010/RV254 in 2017, with results analyzed using the Stanford University HIV Drug Resistance Database.

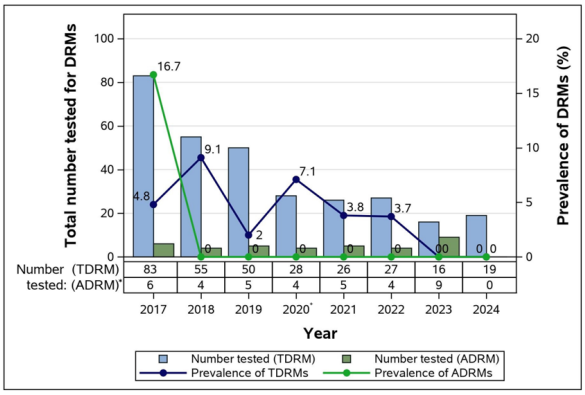
Results: INSTI TDRM data prior to ART initiation were available for 304 participants while sequencing was also available for 32 participants who experienced VF after earlier control on DTG-based ART. HIV-1 subtype AE was predominant (n=191, 62.8%). INSTI TDRM were detected in 15 (4.9%) participants during AHI. TDRM prevalence per year decreased over time, reaching 0% in 2023-2024. TDRM included 1 major mutation in 3 (1.0%) participants and 5 accessory mutations in 12 (4.0%) participants.

Most (96.4%) remained susceptible to all INSTIs; 2 (0.7%) had low level and 6 (2.0%) had potential low-level DTG resistance. Among 32 participants with VF while on DTG-based ART, only 1 had ADRM (1 major and 1 accessory mutation).

Demographic characteristics	Participants with AHI with TDR screening (N=304)	Participants with AHI with ADR testing after VF (N=32)
Age (years), median (IQR)	27.0 (23.0, 32.0)	24.5 (22.5, 28.0)
Male, n (%)	299 (98.4%)	31 (96.9%)
Duration since HIV exposure (days), median (IQR) (N=171)	20.0 (13.0, 27.0)	
Sexual partners in past 30 days, median (IQR) (N=303)	2 (1,3)	
Drug use in past 30 days	59 (19.4%)	
Fiebig staging, n (%)		
1	45 (14.8%)	
2	65 (21.4%)	
3	151 (49.7%)	
4	40 (13.2%)	
5	1 (0.3%)	
6	2 (0.7%)	
HIV RNA (log10 copies/ml), median (IQR)	6.1 (5.0, 6.8)	4.6 (4.0, 5.1)
CD4 cell count (cells/mm3), median (IQR)	342.5 (247.0, 456.0)	584.0 (462.0, 655.0)
HIV subtype, n (%)		
CRF01_AE	191 (62.8%)	25 (78.1%)
CRF01_AE/B	95 (31.3%)	5 (15.6%)
B	3 (1.0%)	1 (3.1%)
CRF01_AE/C		1 (3.1%)
Non-Typable	4 (1.3%)	
Missing	11 (3.6%)	
Exposure of HIV Post-exposure prophylaxis (PEP), n (%)	21 (6.9%)	
Exposure of HIV Pre-exposure prophylaxis (PrEP), n (%)	23 (7.6%)	
Duration between initiate ART until VF (years), median (IQR)		4.6 (2.1, 6.4)
Duration of DTG at genotypic testing (years), median (IQR)		2.8 (1.6, 4.6)

Abbreviations: INSTI, integrase strand transfer inhibitor; ART, antiretroviral therapy; AHI, acute HIV infection; TDR: transmitted drug resistance; ADR, acquired drug resistance; VF, virologic failure

Table 1. Participants with INSTI transmitted drug resistance screening before initiation of ART and participants who experienced virologic failure while on DTG-based regimen.



* Virologic failure occurred in 32 participants at 37 distinct instances
* National rolled out of DTG-based regimen

Abbreviations: INSTI, integrase strand transfer inhibitor; DRM, drug resistance mutation; VF, virologic failure; TDR, transmitted drug resistance;

Figure 1. Prevalence of INSTI DRMs by year.

Conclusions: INSTI TDRM decreased over time in this AHI cohort, reflecting low current community transmission of INSTI resistance. INSTI ADRM was rare after VF, reflecting

high barrier to resistance of DTG-based regimens, which may also be favorable for clinical trials incorporating analytic treatment interruptions and supporting ART switching without drug-resistance testing.

EP0064

Molecular sequence analysis reveals frequent A6 variant associated transmission of rilpivirine resistance and reflects cross-country transmission patterns

Background: Transmitted drug resistance to all key drug classes remains critical from perspective of the clinical care, especially in migrant populations where there is often limited data on viral molecular variability. Since outbreak of full scale war in Ukraine, Poland has not only been involved in care on previously diagnosed PWH but also expanding efforts to diagnose the undiagnosed and investigate molecular epidemiology related to transmissions from Ukraine.
The aim of this study is to report on transmitted drug resistance, clustering and cross-country transmission patterns among Ukrainian migrants newly diagnosed since 2022 in Poland.
Methods: Partial *pol* sequences from 227 newly diagnosed Ukrainian migrant individuals (144 protease/reverse transcriptase (PR/RT) and 78 PR/RT and integrase (IN) and 5 only IN) were analysed for drug resistance mutations (DRMs) using Stanford HIV drug resistance algorithm version 9.8 and subtyping with COMET tool. For phylogenetic clustering analaysis A6 sequences were used and supplemented with 14562 sequences from public database to reconstruct time calibrated maximum likelihood tree reflecting cross-country transmission patters and investigate likely country of transmission event.
We defined a cluster using Shimodaira Hasegawa (SH) local support of at least 0.9 and consist at least for 80% of member taxa isolated in given country.
Results: Dataset included 102 (44.9%) females and 125 (55.1%) males, 71.4% diagnosed late (33.5% with AIDS defining condition); median baseline lymphocyte CD4 count was 192 [interquartile range (IQR):53-376] cells/ul and HIV-1 viral load 5.1 [IQR:4.3-5.7] copies/ml. Subtype A6 was the most common (88.5%) followed by subtype B (9.7%). Nucleoside DRMs were observed in 3.1%, non-nucleoside in 13.5% (of these E138A/K/G in 11.25% with one tranmssison pair), no protease DRMs while in 1.1% major integrase (K263K) mutation was found. 29.6% of sequences were forming transmission clusters repersenting new heterosexual imports of A6 to Poland from Ukraine but some possible within Poland transmissions, representing 5.8% of sequences were found among men who have sex with men.
Conclusions: In late diagnosed Ukrainian migrants the most commonly transmitted DRMs are ripivirine associated E138A/K/G substitutions. Phylogenetic tree analysis confirms the direction of majority of transmissions from Ukraine to Poland but after-migration within Poland transmissions were also revealed.

Recent HIV-1 infection and pre-treatment HIV drug-resistance among adults initiating antiretroviral therapy in rural Tanzania

A. Ntamatungiro[1], J.M. Francis[2], J. Okuma[3], D. Mnzava[4], R.R. Ndege[5], P.S. Njau[6], F. Vanobberghen[7], D. Paris[3], J. Kagura[8], M. Weisser[9], KIULARCO Study Group

[1]Ifakara Health Institute, Biomedical & Clinical Trials, Dar es Salaam, Tanzania, the United Republic of, [2]University of the Witwatersrand, Family Medicine, Johannesburg, South Africa, [3]Swiss Tropical and Public Health Institute, Department of Medicine, Basel, Switzerland, [4]Ifakara Health Institute, Biomedical Research and Clinical Trials, Ifakara, Tanzania, the United Republic of, [5]Ifakara Health Institute, Biomedical Research and Clinical Trials, Dar es Salaam, Tanzania, the United Republic of, [6]National AIDS, STIs & Hepatitis Control Programme (NASHCoP), Dodoma, Tanzania, the United Republic of, [7]Swiss Tropical and Public Health Institute, Department of Medicine,, Basel, Tanzania, the United Republic of, [8]University of the Witwatersrand, Division of Epidemiology and Biostatistics;, Johannesburg, South Africa, [9]University Hospital Basel, Division of Infectious Diseases,, Basel, Switzerland

Background: New HIV-1 infections remain an important threat to ending the HIV epidemic, possibly contributing to spread of viral resistance. We determined the proportion of recent HIV-1 infections (RHI) among newly diagnosed people living with HIV (PLHIV) in rural Tanzania and assessed the prevalence of pre-treatment HIV-1 drug resistance (PDR) in those with RHI.

Methods: Within a cross-sectional analysis we determined RHI using the Asanté™ HIV-1 Rapid Recency® Assay in bio-banked samples from newly diagnosed adult PLHIV enrolled in the Kilombero and Ulanga Antiretroviral cohort from March 2019 to March 2022. Risk factors for RHI were assessed using logistic regression analysis. Genotypic resistance testing (GRT) was conducted for PLHIV identified as having RHI.

Results: Among 599 PLHIV, median age was 39 years (interquartile range (IQR) 30-47), 391 (65%) were female, and 374 (62%) were married or cohabiting (Table). 24 participants (4%) had RHI. We found no factors associated with RHI. GRT was successful in 16/24 (67%) participants, and 5/16 (31%) had HIV-1 drug resistance mutations: 4/16 (25%) for non-nucleoside reverse transcriptase inhibitors, 2/16 (13%) for nucleoside reverse transcriptase inhibitors and 1/16 (6%) for protease inhibitors.

Conclusions: The low prevalence of RHI observed in this hospital-based study indicates a concerning trend of late diagnoses. This underscores the urgent need to strengthen HIV testing strategies to facilitate earlier detection and treatment.

Additionally, routine screening for PDR should be prioritized to enhance treatment outcomes and prevent further resistance development. Although the sample size was limited, the substantial proportion of recently HIV-infected patients with PDR represents a significant public health challenge that demands immediate attention and targeted interventions.

EP0066

Comparison between Sanger and Illumina amplicon-based sequencing to detect integrase strand-transfer inhibitor resistance in people receiving dolutegravir-based antiretroviral therapy

Background: Next-generation sequencing (NGS) has replaced Sanger sequencing for many applications. In the context of the widescale global transition to integrase strand-transfer inhibitor (INSTI)-based ART, we need a better understanding of the frequency and clinical significance of low-frequency drug resistance mutations (lf-DRMs) to inform the potential transition to routine use of NGS for HIV drug resistance testing.

Methods: In DTG RESIST, clinical sites of the International epidemiology Databases to Evaluate AIDS (IeDEA) network enrol adults and adolescents ≥10 years old receiving any DTG-based regimen with at least one routine viral load (VL) ≥1000 copies/mL. In a central laboratory, we perform VL testing on plasma or dried blood spot (DBS) specimens, followed by Sanger sequencing and amplicon-based Illumina sequencing of HIV-1 *pol* for specimens with VL ≥1000 copies/mL. We defined low-frequency DRMs as those detected at 2-20% frequency by NGS. Using the Stanford HIVdb algorithm, we compared predicted DTG resistance based on DRMs detected by Sanger or by NGS at 2% threshold.

Results: We processed 198 specimens with a confirmed VL >1000 copies/mL on the enrolment specimen, and paired Sanger and Illumina integrase sequences were available from 187/198 (94%). The majority (124, 66%) had no major or accessory integrase DRMs detected by Sanger or NGS. Of the 44 with ≥1 major INSTI DRM detected by Sanger sequencing, additional low-frequency major and/or accessory INSTI DRMs were detected by NGS from 15 (34%).

Only one participant had DTG resistance detected by NGS that was not detected by Sanger sequencing: in that case, the major INSTI DRM N155H was detected at ~7% frequency in an individual with confirmed virological failure after 43 months of TLD.

This was the only case where predicted DTG resistance differed for Sanger (susceptible) and NGS (potential low-level resistance). In the 186 other cases, predicted DTG resistance was concordant (39 high-level resistance, 4 intermediate resistance, 1 potential low-level resistance, and 142 susceptible).

Conclusions: In this comparison of Sanger and NGS-based HIV drug resistance testing, low-frequency INSTI DRMs were rare in the absence of majority INSTI DRMs, and predicted DTG resistance was highly concordant.

EP0067

Nucleoside reverse-transcriptase inhibitor resistance patterns in adults and adolescents with virological failure on dolutegravir-based antiretroviral therapy: DTG RESIST study of leDEA

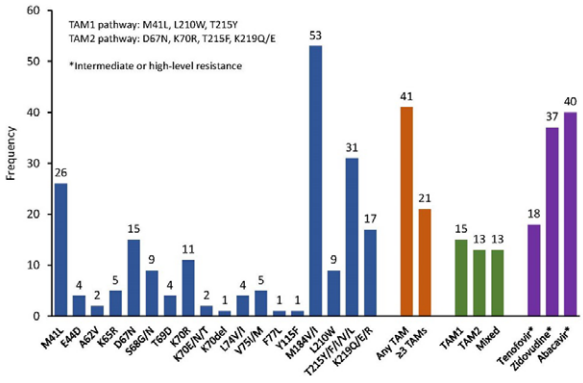
Background: With reports of increasing dolutegravir (DTG) resistance in people receiving DTG-based ART, it is important to understand concomitant NRTI resistance patterns. This is not only to provide insight into risk factors for emergent DTG resistance but also to inform treatment guidelines following failure of DTG-based ART.

Methods: In DTG RESIST, clinical sites of the leDEA network enrol adults and adolescents ≥10 years old receiving any DTG-based regimen with at least one routine viral load (VL) ≥1000 copies/mL, regardless of prior ART history. In a central laboratory, we perform VL testing on plasma or dried blood spot (DBS) specimens, followed by HIV-1 pol Sanger sequencing for specimens with VL ≥1000 copies/mL. We present data on NRTI resistance patterns in specimens processed up to December 2024 from the study sites in Africa.

Results: We processed specimens for 488 participants receiving DTG-based ART enrolled between June 2022 and December 2024 at 16 sites in seven African countries. Most participants (81%) were receiving tenofovir (TDF or TAF), with 12% zidovudine and 7% abacavir. 234/488 (48%) had a VL >1000 copies/mL, and we obtained a reverse tran-

scriptase sequence for 217 (93%); 209 also had an integrase sequence. Overall, 95 (44%) had at least one NRTI drug resistance mutation (DRM): 54/55 (98%) of those with ≥1 major integrase strand-transfer inhibitor (INSTI) DRM, and 37/154 (24%) of those with no major INSTI DRMs. In the subset of 55 participants with ≥1 major INSTI DRM, almost all had M184V/I (n=53, 96%), but K65R was infrequent (n=5, 9%). Thymidine analogue mutations (TAMs) were detected in 41/55 (75%) (Figure). The proportion with TAMs was similar regardless of NRTI backbone (24% tenofovir, 23% zidovudine, and 29% abacavir).



Conclusions: In people with emergent DTG resistance on ART, the predominant NRTI resistance pattern was M184V/I and TAMs, regardless of current NRTI backbone.

Pandemics, conflict and climate

EP0068

Epidemiology, clinical presentation and outcome of human mpox in Rivers State, Nigeria during the 2022-23 outbreak: an observational retrospective study

C.A. Onyeaghala[1], A. Somiari[2], U. Ichechiek[1], J. Ogan[1], B. Otike-Odibi[1], O. Maduka[2], D. Alasia[1]
[1]University of Port Harcourt Teaching Hospital, Internal Medicine, Port Harcourt, Nigeria, [2]University of Port Harcourt Teaching Hospital, Community Medicine, Port Harcourt, Nigeria

Background: There is a paucity of studies describing the epidemiology, clinical manifestation, and outcome of human mpox in Rivers State, Nigeria.
Methods: An observational retrospective study of suspected mpox cases was conducted between October 21, 2021, and April 30, 2023, at the mpox treatment center and outpatient clinic at the University of Port Harcourt Teaching Hospital, Rivers State, Nigeria. Laboratory confirmation of mpox and varicella-zoster virus infection with real-time polymerase chain reaction assay of swabs from the exudate of vesicular or pustular lesions and/or crust skin specimen was done at the National Reference Laboratory of the Nigerian Center for Disease Control and Prevention, Gaduwa-Abuja, Nigeria. A data extraction form was used to obtain sociodemographic information (such as age, gender, occupation, and sexual orientation), potential MPXV transmission routes (such as animal contact, close contact, and sexual exposure), clinical manifestations, presence of comorbidities (e.g., concomitant chickenpox coinfection), HIV status, vital signs, laboratory information, and treatment received.
The primary outcome was the rate of hospitalization and death. Associations between categorical variables were done using Fisher's exact test. We considered a p-value of < 0.05 (two-sided) as statistically significant.
Results: Of 35 participants, 24 (68.6%) were males with a mean age [± standard deviation] of 33.7 (± 9.9 years), and 5 (14.3%) were living with HIV. The majority (n=33, 94.3%) reported being in a heterosexual relationship with a household identified as the probable place of contact (n=13, 72.2%). None of the participants reported having contact with animals or a travel history. The most common symptoms were skin rash (35, 100%), followed by fever (26, 74.3%), and fatigue (26, 74.3%). Concomitant varicella-zoster virus infection (n=6, 17.1%), hospital admission (n=28, 80%), and death (n=3, 8.6%) were also observed. There was a statistically significant association between mortality and people living with HIV (p = 0.002).
Conclusions: The 2022-23 mpox outbreak in Rivers State predominantly affected young adults characterized by human-to-human transmission and typical febrile rash syndrome with an association between mpox mortality and living with HIV. Targeted and strategic public health interventions are needed to control the spread of mpox in Nigeria.

EP0069

Retention in HIV care at a health facility severely impacted by Cyclone Freddy in Phalombe District, Malawi: a look 18 months post-cyclone

K. Simon[1,2], V. Guzani[1], R. Majoni[1], F. Joshua[1], A. Mazenga[1], S. Sibakwe[3], G. Kaunda[1], S. Chu[1,2], C.M. Cox[2,1]
[1]Baylor College of Medicine Children's Foundation Malawi, Lilongwe, Malawi, [2]Baylor College of Medicine, Department of Pediatrics, Houston, United States, [3]Ministry of Health, Phalombe, Malawi

Background: On March 14, 2023, a devastating cyclone struck Southern Malawi, causing extensive flooding and destruction resulting in displacement of many communities and service disruptions at health facilities. Over 65,000 PLHIV receiving care in Phalombe district were at risk of treatment interruption due to inaccessible roads, population displacement, damaged infrastructure and lost commodities. Mudslides completely destroyed Nkhulambe Health Centre.
We describe the number of people receiving antiretroviral therapy (ART) at a severely affected facility prior to, immediately after and 18 months following the cyclone.
Description: In collaboration with Ministry of Health and other stakeholders, integrated emergency health services were provided in temporary structures and mobile clinics.

Community health workers (CHW), clinical staff, and psychosocial counselors conducted health talks and counseling sessions to facilitate emergency ART refill access.
Multi-month antiretroviral therapy (ART) prescribing was prioritized to minimize client visits, and clients were referred to nearby facilities or outreach clinics as needed.
Psychosocial counselors received capacity building on care of disaster survivors; they subsequently provided phone-based and in person psychosocial support to clients and health workers; clients without phones utilized CHW phones for virtual counseling. Health services continued to be provided in temporary structures.
We compared the number of people enrolled in HIV care at the end of the quarter preceding the cyclone (December 2022); following the cyclone (June 2023); and September 2024, 18 months post-cyclone.
Lessons learned: Following the cyclone, the cohort of PLHIV enrolled in care dropped to a low of 1,859 clients (55% of the pre-cyclone cohort). By end September 2024, the Nkhulambe cohort had returned to 3,059 clients (92% of the pre-cyclone cohort).
Conclusions/Next steps: Despite significant disruptions, a rapid, coordinated, multi-stakeholder response resulted in service continuation for the cohort of PLHIV at Nkhulambe HC following Cyclone Freddy. Client-centered approaches to ensure health services met clients' needs were critical to retention following natural disaster.

EP0071

HIV clients' retention in care before and during COVID-19 among clients on anti-retro viral therapy in Hawassa City, Ethiopia

M. Guyassa[1], T. Ayana[2], E. Lejore[2], D. Taye[3]
[1]Africa Centres for Disease Control and Prevention, Emergency Preparedness and Response, Addis Ababa, Ethiopia, [2]Hawassa University, School of Public Health, Hawassa, Ethiopia, [3]Uk Health Security Agency, British Embassy in Ethiopia, IHR Strengthening Project, Addis Ababa, Ethiopia

Background: Maintaining anti-retroviral therapy (ART) throughout any health-system disruptions caused by other outbreak and pandemics is of highest priority for HIV control programs in reducing morbidities and mortality. Clients who are retained in care are more likely to have better clinical results.
The objective of the study was to assess magnitude retention to care before and during the COVID-19 pandemic at Hawassa Comprehensive Specialized Hospital and Adare General Hospital in Hawassa Town.
Methods: A facility based cross-sectional study was conducted among ART clients, who are on follow up and treatment at Hawassa Comprehensive Specialized Hospital and Adare General Hospital from 1st March 2019 to 30th February 2021, the study included 368 clients data who were selected by a systematic simple random sampling.
The data was collected from the electronic medical record review of clients' data enrolled on ART, using checklist. Data were entered, coded and cleaned using Epi.info 7 and analysed using Statistical Package for the Social Sciences, SPSS version 25.
Results: Socio-demographic characteristics and the ART dispensing before and during COVID 19 of HIV Clients on treatment are as follows in tables below.

Variable	Category	Frequency	Percent (%)
	<= 24	37	10.1
Age	25-49	265	72.0
	>=50	66	17.9
Sex	Male	144	39.1
	Female	224	60.9
Address	Urban	323	87.8
	Rural	45	12.2

Variable	Category	Frequency	Percent (%)
ART Dispensing Before COVID 19	Monthly	219	59.5
	6 Monthly	149	40.5
ART Dispensing During COVID 19	Monthly	13	3.5
	3 Monthly	131	35.6
	6 Monthly	224	60.9

The proportion of clients retained on ART care was 302 (78.3%) before COVID 19 period and 305 (82.9 %) clients during COVID 19 period.
Conclusions: Increased retention 78% before COVID -19 to 83% during COVID 19 showed that maintaining essential services strategies devised (i.e., multi-month dispensing, virtual adherence counselling) were effective and critical to maintain the retention in care during COVID 19 period. In addition, service provision of enhanced adherence counselling (in-person or virtual using calls) given to high viral load clients should also be extended to rest of clients to increase magnitude of retention even more.

EP0072

Antiretroviral treatment retention and associated predictors among clients receiving care through mobile brigades in conflict-affected districts in Cabo Delgado, Mozambique, 2019–2024

D. Bila[1], M.G. Lain[1], S.R. Cassy[2], M. Bolacha[3], M. Tovela[1], F. Paulo[4], M. Stefanutto[1], A. Nguimfack[5], P. Vaz[6]
[1]Fundação Ariel Glaser Contra o SIDA Pediátrico, Technical, Maputo, Mozambique, [2]Faculty of Science, Eduardo Mondlane University, Maputo, Mozambique, [3]Provincial Health Directorate, Pemba, Mozambique, [4]Fundação Ariel Glaser Contra o SIDA Pediátrico, Technical, Pemba, Mozambique, [5]US Centers for Disease Control and Prevention, Division of Global HIV & TB, Maputo, Mozambique, [6]Fundação Ariel Glaser Contra o SIDA Pediátrico, Executive Directorate, Maputo, Mozambique

Background: HIV-integrated mobile brigades (MB) are client-centered service delivery models providing HIV care to people in remote or conflict areas with limited access to health facilities. We describe antiretroviral treatment (ART) retention and predictors among clients receiving MB services in seven conflict-affected districts in Cabo Delgado.
Methods: We extracted medical record data from clients receiving MB services January 2019–January 2024. A client had ART retention if they were on ART and did not trans-

fer out or discontinue ART during the follow up period. We used Kaplan-Meier to calculate probability of retention by months on ART (m), by age group (using age at the time of analysis), and by pregnancy status.
We used Cox regression to estimate adjusted hazard ratios (aHR) of retention with 95% confidence interval (CI).
Results: Among 6,111 clients, 5,323 (87%) were 25+ years-old, 276 (5%) <15-year-olds, and 4,086 (67%) were female, among whom 1,249 (31%) had ever been pregnant. The median time on ART was 45 months (interquartile range=28–71m).
Probability of retention was: 96.1% (CI=95.6–96.6%), 93.1% (CI=92.4–93.7%), 84.1% (CI=83.1–85.0%), 69.6% (CI=68.4–70.8%), 56.2% (CI: 54.8–57.5%) and 44.7% (CI=43.3–46.0%) at 6m, 12m, 24m, 36m, 48m, and 60m, respectively. Retention among pregnant women was 97.5% (CI=96.5–98.2%), 95.7% (CI=94.4–96.7%), 88.9% (CI=87.0–90.5%) at 6m, 12m, and 24m.
Among 15–19-year-olds, retention was 87.2% (CI=75.0–93.7%), 85.3% (CI=72.7–92.3%), 68.2% (CI=53.9–78.9%) at 6m, 12m, and 24m. Among 25+ year-olds, retention was 96.7% (CI=96.2–97.2%), 94.0% (CI: 93.3–94.7%), and 85.6% (CI=84.6–86.5) at 6m, 12m, and 24m.
Predictors of retention were: age 0–9 years (aHR 1.35=CI 1.13–1.63), 20–24 years (aHR=1.82, CI=1.63–2.03) vs 25+ years; Balama (aHR=1.60, CI=1.32–1.93); Montepuez (aHR=1.50, CI=1.36–1.65); Namuno (aHR=1.44, CI=1.26–1.65) vs Ancuabe district, and having TB vs not (aHR=0.71, CI=0.61–0.82).
Conclusions: Clients receiving services through MB, including pregnant women, had >90% retention up to 12 months on ART, but retention decreased over time.
Results suggest that MB can be effective in retaining clients on ART in conflict areas, but additional efforts may be needed for retention after 12 months.

EP0073

Mobile brigades and integration of elimination of vertical transmission services in Mozambique: challenges and solutions

M. Matsinhe[1], N. Eliseu[1], M. Da Cunha[1], O. Tiberi[1], A. Wate[2], M. Tomo de Deus[3], K. Tibana[3], I. Gaspar[1], A. Couto[4]
[1]Ministry of Health, National STI, HIV/AIDS Control Program, Maputo, Mozambique, [2]United States Agency for International Development, Mozambique, Maputo, Mozambique, [3]Center for Disease Control, Maputo, Mozambique, [4]Ministry of Health, National Directorate of Public Health, Maputo, Mozambique

Background: Mozambique faces challenges in reaching the global goals for the HIV epidemic, with 80% of the estimated 2.46 million people living with HIV (PLHIV) on ART in june, 2024. In addition, there is a 10% vertical transmission rate among the 125,000 pregnant women Living with HIV (PWLHIV), contributing to an estimated 12,000 pediatric infections annually. Mobile Brigades (MB) were initially designed to improve immunization coverage but have evolved to provide integrated health services, including Elimination of Vertical Transmission (EVT) interventions, in remote and underserved communities. We aimed to report the integration of EVT into MBs from January- December 2023, identify barriers to implementation, and propose solutions to enhance their effectiveness in improving maternal and child health outcomes in Mozambique.
Description: Mobile Brigades deliver a wide range of health services, including immunization, antenatal and postnatal care, family planning, nutrition, TB services, and HIV care. For EVT, MBs provide HIV counseling and testing, antiretroviral (ART) enrolment and follow-up, tuberculosis (TB) screening and treatment, and sample collection for viral load (VL), CD4, and early infant diagnosis (EID).
Eligibility for MB integration as a Differentiated service delivery (DSD) includes remote communities with limited access to health facilities, high HIV positivity rates, and low retention rates, MB scale-up needs availability of funds for human resources and commodities.
Lessons learned: In 2023 MB provided services to 55,299 PLHIV, including 4,607 pregnant women, 862 lactating women, and 118 HIV exposed-infants under 2 months old. Key challenges included: poor road access, limited funding for human resources, Laboratory including EID point of care, and frequent stockouts of essential commodities. Lessons learned emphasize the need for increased financial support, a strengthened health system, and stronger stakeholder coordination, to overcome barriers and improve the reach and quality of EVT services.
Conclusions/Next steps: Integrating EVT services into MBs has proven effective in expanding access to HIV care for remote populations. However, overcoming logistical and financial challenges is essential to sustaining and scaling these efforts.
By implementing the proposed solutions, Mozambique can improve MB performance, improve retention in care, reduce vertical transmission rates, and advance progress toward EVT goals.

HIV and ageing

EP0074

Recurrent falls as a marker for frailty in virologically suppressed PLWH in Salvador, Brazil

S. Amaral[1], A. Tolentino[1], D. Zeballos[1], I. Montaño-Castellón[1], M. Arriaga[1], K. Page[2], C. Brites[1]
[1]Federal University of Bahia, Salvador, Brazil, [2]University of New Mexico, Department of Internal Medicine, Albuquerque, United States

Background: With an increase in the life expectancy of PLWH, problems related to the earlier onset of comorbidities and geriatric syndromes as falls stand out in the care required for this population.
This study aimed to evaluate the prevalence of falls and recurrent falls among PLWH with undetectable viral load and their associated factors.
Methods: We conducted a cross-sectional study including 222 individuals with 18 years old or more, and undetectable HIV viral load. The possible associated factors

for any falls and recurrent falls were assess by an interview and evaluation of medical records. Bivariate analysis and a logistic regression by backward method were performed.

Results: The prevalence of falls in one year was 17.1%, while the prevalence of recurrent falls was 5.4%. Most participants were male (60.4%), with a mean age of 52,7 (±10,7) years, had more than 8 years of schooling (64.4%), and self-identified as Black or mixed race (89.0%). The median current CD4 T lymphocyte count was 672 cells/µL (IQR 473–831), while the median nadir CD4 count was 199 cells/µL (IQR 74–318), additionally, 57.6% of participants had a history of AIDS. In the logistic regression, any falls were associated with female sex (aOR 3.94, 95% CI 1.73 – 8.94), the use of central nervous system medications (aOR 3.90, 95% CI 1.05 – 14.42), and being single (aOR 0.33, 95% CI 0.13 – 0.81). For recurrent falls, female sex (aOR 4.23, 95% CI 1.10 – 16.20), the use of benzodiazepines (aOR 10.22, 95% CI 1.40 – 74.79), and frailty (aOR 6.53, 95% CI 1.28 – 33.36) were associated factors.

Conclusions: Our findings emphasizing recurrent falls as a more specific outcome in the evaluation of frailty in PLWH than any or simple falls. They also reinforce classic risk factors to any falls and recurrent falls, as female sex and central nervous system medications.

EP0075

Outcomes on antiretroviral therapy for adults 50 years and older: a retrospective cohort study from Newlands Clinic, Harare

C. Taderera[1,2], T. Shamu[3,4], R. Lessells[5]
[1]Royal United Hospital, Geriatrics, Bath, United Kingdom, [2]Newlands Clinic, Adult medicine, Harare, Zimbabwe, [3]Newlands Clinic, Laboratory, Harare, Zimbabwe, [4]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [5]University of KwaZulu-Natal, University of KwaZulu-Natal, KwaZulu-Natal Research Innovation & Sequencing Platform, Durban, South Africa

Background: HIV acquisition in older adults can be associated with increased mortality, often due to late diagnosis and presentation with advanced HIV disease (AHD). This single centre study compared treatment outcomes for clients initiated on antiretroviral therapy (ART) from 2014-2022 while aged ≥50-years with those of clients initiated at 30-49 years.

Methods: We performed a retrospective cohort analysis of clients initiated on ART at Newlands Clinic while aged 30-49 and ≥50-years between January 2014 and December 2022. We abstracted data from electronic medical records and analysed data using Stata BE17. We used descriptive statistics to summarize baseline demographic and clinical characteristics, and to describe outcomes up to two years post-ART initiation. We analysed differences in outcomes by age group using survival analysis methods with Kaplan Meier curves and Cox proportional hazards multivariable model.

Results: Data from 2420 clients was analysed of whom 1993 were aged 30-49 and 427 were aged ≥50 years. Majority of clients were female (59%). Median age was 38 (IQR 34-43) in the 30-49-year-olds and 55 (IQR 51-60) in the ≥50-year-olds. The proportion with AHD (CD4 ≤200cells/mm^3) at ART initiation was 47% in 30-49-year-olds and 48% in ≥50-year-olds. While 7% (146/1993) of the younger cohort experienced adverse drug reactions this was 16% (67/427) in the older cohort.

Mortality rate per 1000 person years was 23.6 in 30-49-year-olds and 47.13 in ≥50-year-olds. Over 70% of those who died in both groups had baseline AHD and >70% of deaths occurred within a year of initiating ART.

Strong associations were found between mortality and age ≥50 years with adjusted hazard ratio (HR) 2.01, 95%CI 1.37-2.96), baseline CD4 ≤200cells/mm^3 (HR 3.43, 95%CI 2.36-4.98) and presence of OIs (HR 2.28, 95%CI 1.57-3.31). Proportions with viral load <50copies/ml at 6-months were 78% in 30-49-year-olds and 84% in ≥50-year-olds.

Conclusions: Although the proportions of baseline AHD were similar in both cohorts, older people experienced more adverse drug reactions and had higher mortality post-ART initiation.

They however had better virological response to ART. There is need to target them for earlier testing and treatment to reduce mortality.

EP0076

Long-acting Cabotegravir/Rilpivirine (CAB/RPV LA) in older adults with HIV: high adherence and low complications in a real-world setting

J. Kuretski[1], H. Bolivar[1], M. Ramgopal[1]
[1]Midway Specialty Care Center, West Palm Beach, United States

Background: Long Acting cabotegravir/rilpivirine (CAB/RPV LA) has demonstrated similar efficacy to oral antiretrovirals (ART), but the safety and effectiveness of CAB/RPV LA has been derived from studies overrepresented by young adults, with a median age of 30. There are concerns that this does not apply to older persons with HIV (PWH) due to unique challenges such as the presence of polypharmacy and age-related changes (sarcopenia).

Given the complexity of treating older PWH, we studied the use of CAB/RPV LA to address the lack of data available in the real-world setting.

Methods: We performed a retrospective review to describe adherence to on-time injections, viral suppression and reasons for discontinuation of CAB/RPV LA in PWH ages 50 and older at Midway Specialty Care Center in Florida. 181 PWH, ages 50 years and older, received their first CAB/RPV LA dose between January 2021 and January 2024. Population demographics are described in Table 1. We used descriptive statistics to describe study outcomes.

Results: 99% of 1,988 CAB/RPV LA injections were given on time. 97% were virally suppressed. The incidence of injection site reactions (ISR) leading to treatment discontinuation was low (4%). 3 PWH experienced virologic failure (2 with RPV resistance and 1 with CAB and RPV resistance). 45% discontinued CAB/RPV LA with a median time of 273 days on treatment before discontinuation. Almost 40% of those who discontinued CAB/RPV LA stopped due to mov-

ing to a new geographic area. Only 13% stopped due to injection specific reasons such as ISR, adverse events (AE) or virologic failure.

	N = 181
Age, **mean** (*range*)	**60**(50 – *91*)
• Age 65 years and older, **n** (%)	**42** (23%)
Gender Identity, **n** (%)	
• Cisgender Female	**41** (23%)
• Cisgender Male	**139**(76%)
• Transgender Female	**1** (1%)
Baseline BMI, **mean** (range)	**28.7** (16.89 – 52.91)
• BMI > 30, **n** (%)	**44** (24%)
Baseline Absolute CD4, **mean** (range)	**788** (97 – 2435)
Baseline HIV-1 RNA level	
• ≤ 200 copies/ml, **n** (%)	**174** (96%)
Race, **n** (%)	
• American Indian	**1**(0.5%)
• Asian	**2**(0.5%)
• Black	**39**(22%)
• White	**114**(63%)
• Other/Unknown	**25**(14%)
Ethnicity, **n** (%)	
• Not Hispanic/Latinx	**148** (82%)
Years Since Diagnosis, **mean** (range)	**20** (2 - 39)
Presence of Polypharmacy, **n** (%)	
• Yes, 5 or more medications	**123**(68%)
• No	**58**(32%)
Presence of Multimorbidity, **n** (%)	
• Yes, 2 or more conditions	**123**(68%)
• No	**58**(32%)
CAB/RPV LA Discontinuations*	**81** (45%)

* Reasons for Discontinuation: Moved (35), Unknown (1), Death (Not HIV Related) (5), ISR (7), Scheule Change by Patient (2), No Longer Want Injection (4), AE (not ISR) 6, Viremia (No Genotype < 200 copies/mL) (7), Virologic Failure (RPV or CAB resistance confirmed on genotype) (3), Insurance no longer covered (3), Lost to Follow Up (8)

Table 1.

Conclusions: Adherence rates of on time injections were high in this older population with HIV. There were minimal complications as ISR, AE and virologic failure rates were low. CAB/RPV LA demonstrated comparable clinical outcomes to younger individuals and can be considered a viable ART option for aging populations with HIV.

EP0077

Survival outcomes of older people living with HIV from 2001 to 2021 in Hunan, China: a retrospective cohort study

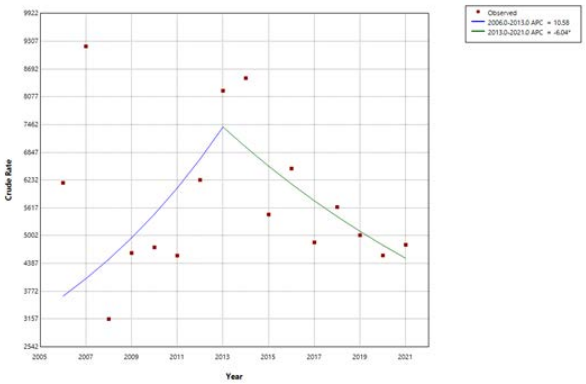
H. Zuo[1], Z. Yaqin[1,2], X. Zhang[3], Y. Gao[4], J. Meng[5], X. Zou[6], J. He[6], W. Wang[2], X. Chen[6], H. Wang[1]

[1]Central South University, Changsha, China, [2]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, [3]University of Memphis, Memphis, United States, [4]Shenzhen Institute of Advanced Technology, Shenzhen, China, [5]Anhui Medical University, Anhui, China, [6]Hunan Provincial Center for Disease Control and Prevention, Changsha, China

Background: The prevalence of HIV is on the rise among older adults, necessitating insights into their distinct characteristics and survival outcomes. This study aims to investigate the survival status and relevant factors among older people living with HIV (OPLHIV).

Methods: This retrospective cohort study extracted data of OPLHIV aged 50 and older between 2001 and 2021 from the Hunan provincial HIV/AIDS Comprehensive Response Information Management System. Joinpoint regression, Kaplan-Meier, and multivariate Cox proportional hazards regression analytic methods were used for the analysis.

Results: All-cause mortality among 21,597 participants were 4,553. The median survival time was 172.60 months (95% confidence interval [CI]: 163.08-186.92). Survival rates at months 12, 36, 60, and 120 were 92%, 81%, 74%, and 59%, respectively. From 2001 to 2021, the crude mortality rate among OPLHIV showed an increasing and then decreasing trend, with a turnaround in 2013. Several demographic and clinical factors were associated with a higher risk of all-cause mortality. These include males (HR=1.640, 95% CI: 1.520-1.770), 70 years and older at the HIV diagnosis (HR=2.656, 95% CI: 2.449-2.880), farmers (HR=1.397, 95% CI: 1.233-1.582), unmarried (HR=1.226, 95% CI: 1.156-1.301), primary school or illiterate (HR=1.518, 95% CI: 1.345-1.712), heterosexual transmission (HR=2.129, 95% CI: 1.635-2.774). In addition, clinical characteristics such as baseline CD4 cell counts less than 200 cells/μL (HR=2.151, 95% CI: 1.907-2.427), not initiating antiretroviral therapy within 30 days of diagnosis (HR=2.151, 95% CI: 1.907-2.427) were also associated with a higher risk of all-cause mortality.



Conclusions: The overall survival rate of OPLHIV is concerning. Enhancing early HIV diagnosis and ensuring rapid initiation of antiretroviral therapy following diagnosis are crucial for improving survival outcomes.

Diagnostic and monitoring tools

EP0078

ART adherence; viral load and CD4 monitoring among transgender community in Nairobi, Kisumu and Mombasa cities

E.P. Mwore[1], J. Walimbwa[1], J. Zech[2], S. Wambua[3]

[1]Ishtar, Research, Nairobi, Kenya, [2]ICAP University of Columbia, Research, New York, United States, [3]Key Populations Consortium, Research, Nairobi, Kenya

Background: The transgender community in Kenya faces distinct challenges in HIV prevention, treatment, and care, often resulting in suboptimal ART adherence and viral load suppression. Understanding the unique barriers and facilitators to ART adherence, as well as the role of viral load and CD4 monitoring, is critical for improving health outcomes for transgender individuals living with HIV in Kenya.

This study examines ART adherence, viral load, and CD4 monitoring among transgender individuals in Nairobi, Kisumu, and Mombasa cities, with a focus on contextual factors affecting their engagement with HIV care.

Methods: A mixed-methods study was conducted between 2023 and 2024, involving 300 transgender individuals living with HIV who were accessing care at the Ishtar

MSM Health and Wellness Center in Nairobi, alongside health facilities in Kisumu and Mombasa. Quantitative data on ART adherence, viral load suppression, and CD4 count monitoring were collected through patient records and self-reported questionnaires.

Qualitative interviews were conducted with 30 transgender individuals, 15 healthcare providers, and 10 community stakeholders to explore experiences with HIV care, challenges in adherence, and perspectives on viral load and CD4 monitoring.

Results: Preliminary findings indicate that adherence to ART among transgender individuals is influenced by several factors, including social stigma, discrimination, and inadequate healthcare provider knowledge of transgender-specific health needs.

Of the participants, 60% demonstrated good ART adherence, but only 45% achieved consistent viral load suppression, and 50% had regular CD4 count monitoring. Barriers to adherence included the lack of transgender-friendly healthcare settings, economic constraints, and limited education on ART and HIV management.

However, supportive relationships with healthcare providers and peer networks were key facilitators to better adherence and retention in care.

Conclusions: This study highlights the critical need for targeted interventions to improve ART adherence, viral load suppression, and CD4 monitoring in the transgender community.

Enhancing the capacity of healthcare providers to offer transgender-inclusive services, addressing financial and social barriers, and fostering community-based support networks are essential to improving HIV outcomes.

These findings have implications for developing inclusive HIV care policies and interventions to meet the needs of the transgender population in Kenya and beyond.

EP0079

A randomized cross-over study comparing usability of two self-sampling blood devices for HIV viral load monitoring in resource-limited setting

M. Limbada[1], C.R. Phiri[1], A. Schaap[1,2], M. Simuyamba[1], B. Hensen[3], I. De Baetselier[3], D. Van den Bossche[3], B. Kawambwa[1], B. Chiyanta[1], M.R. Larrea[2], T. Platteau[3], B. Kosloff[1], J.D. Whaley[4], E. Berthier[4], M. Simwinga[1], C. Fraser[5], D. Bonsall[5], H.M. Ayles[1,2]

[1]Zambart, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [3]Institute of Tropical Medicine, Antwerpen, Belgium, [4]Tasso, Inc, Seattle, United States, [5]University of Oxford, Oxford, United Kingdom

Background: HIV viral load (VL) monitoring is essential for evaluating antiretroviral treatment effectiveness. In high-burden settings, venepuncture at clinics delays timely VL results, often postponing awareness of treatment failure.

Previous studies demonstrated that 500 µL of blood suffices for VL and drug resistance testing using NGS methods. Self-sampling devices, offering minimally invasive alternatives, allow pre-appointment sample submission, reducing clinic visits and expediting results. Tasso+ is a microneedle device attaching to the upper arm, while Collect2Know V1.0 (C2K) attaches to the finger with a lancet and costs one-tenth as much. We evaluated the usability of these devices among PLHIV in Zambia.

Methods: An individually randomized crossover trial was conducted with 70 stable PLHIV attending routine ART visits (October–December 2024). Participants used each device in random order, with supervision for the first use and a second, unsupervised home sampling one week later. Success was defined as self-collection of ≥ 0.5 mL of blood during unsupervised use. A questionnaire captured perceptions of device usability, compared to standard venepuncture options.

Results: Of 62 participants completing the study (35.5% male, 64.5% female, aged 18–50+), 87.1% (54/62) successfully collected ≥ 0.5 mL with Tasso+, compared to 37.1% (23/62) with C2K (McNemar test, p <0.001; OR 11.45, 95% CI: 4.83–27.10). Among Tasso+ users, 61.1% (33/54) failed to achieve success with C2K (Table 1).

Healthcare workers highlighted reduced clinic congestion as a key benefit of self-sampling, while participants cited less pain, reduced fear, and improved privacy as significant advantages.

	Failure C2K (n, %)	Success C2K (n, %)	Total
Failure Tasso+	6 (9.7%)	2 (3.2%)	8 (12.9%)
Success Tasso+	33 (53.2%)	21 (33.9%)	54 (87.1%)
Total	39 (62.9%)	23 (37.1%)	62 (100%)

Table 1: Success and Failure to collect 5ml of blood by Device.

Conclusions: This crossover RCT demonstrated that device-assisted, minimally invasive sampling offers higher usability for self-collection among PLHIV compared to traditional methods. The adoption of such client-led technologies could streamline HIV monitoring, enhance client experience, and enable timely detection of treatment failure.

Further exploration of minimally invasive sampling devices, including advancements to improve existing methods, is warranted in broader, resource-limited contexts.

EP0080

Ensuring quality in early infant diagnosis of HIV through local proficiency testing panels production for GeneXpert point-of-care testing

U.K. Omo-Emmanuel[1], T. Yakubu[2], T. Usha[1], B. Oyawola[1], O. Anika[3], U. Onwuzuruigbo[4], B. Airiagbonbu[5], F. Abbah[3], I. Suleiman[3], G.-J. Ayodele[6], D. Bulus[7], O. Emmanuel[8], E. Ndali[9]

[1]United States Agency for International Development, HIV/AIDS and TB, Abuja, Nigeria, [2]DauLab BioGenomics, Kaduna, Kaduna, Nigeria, [3]Family Health International, Abuja, Nigeria, [4]Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, [5]Heartland Alliance LTGE, Lagos, Nigeria, [6]Health Initiatives for Safety and Stability in Africa (HIFASS), Abuja, Nigeria, [7]Achieving Health Nigeria Initiative (AHNi), Maiduguri, Nigeria, [8]National AIDS, Sexually Transmitted Infections Control and Hepatitis Programme (NASCP), Abuja, Nigeria, [9]Heartland Alliance LTGE, Yenagoa, Nigeria

Background: Point-of-care testing(POCT) early infant diagnosis(EID) significantly reduces turnaround times from sample collection to caregiver result receipt and antiretroviral therapy initiation for HIV-exposed infants. To ensure accurate and reliable EID testing, sites are required by ISO15189 to participate in quality assurance. However, the high cost of procuring proficiency testing (PT) panels has been a barrier. To address this, USAID collaborated with FMOH to pilot local production and validation of GeneXpert EID PT panels(EPP).

This study reports on the performances of sites using the locally produced EPPs between 2023 and 2024.

Methods: The EPPs consists of 7-blinded DBS specimens: four HIV-negative and three HIV-positive. Positive EPPs were prepared by spiking HIV-negative EDTA-anticoagulated packed cells with pooled HIV-positive plasma containing HIV-1 RNA (11,000, 5,500, and 2,200) copies/ml to whole blood. EPPs were labeled with coded identifiers prior to spotting with 100ul of HIV-negative whole blood or HIV-spiked whole blood to DBS cards in separate processing rooms and dried overnight at room temperature in a biosafety cabinet.

Mini EPPs were prepared and tested on GeneXpert and Cobas 4800 platform to verify the characteristics of each. EPPs were packed in glassine paper, and stored in liquid-tight plastic sealable storage bags with desiccant sachets and humidity indicator card. Validation was carried out by testing 10 EPPs randomly selected from the beginning, middle and end of each batch produced prior to packaging and shipment

Results: Two cycles of EPPs were prepared and administered, Cycle0123/June2023 and Cycle0124/March2024. For Cycle 0123, 82 Laboratories were enrolled but 72 submitted results (87.8% participation), 34.7% (25/72) passed with a score of ≥90%. 65.3% (47/72) failed due to wrong identification/interpretation of panels (83.9%) and incomplete documentation(16.1%). Cycle0124 enrolled 98 laboratories with 94%(92/98) submitted results; 88% (81/92) passed. 12% (11/92) failed due to wrong identification/interpretation (80%), incomplete documentation(10%), and stockout of cartridges (10%).

A comparison of performance of both Cycles showed a significant improvement in complete documentation ($p<0.01$), correct interpretation/identification of panels ($p<0.01$), and performance score ($p<0.01$).

Conclusions: Our data showed an improvement in enrolment, participation and performance of the laboratories in the PT program.The PT program has contributed in improving the competence of the testing laboratories, documentation, and interpretation of EID test results at participating POCT laboratories in Nigeria.

EP0081

Biomarkers associated with risk of negative clinical outcomes in people living with HIV on opioid replacement therapy

L. Azzoni[1], L. Zhang[2], K. Zhu[2], M. Fair[1], E. Hiserodt[3], K. Mounzer[3], J.J. Wallin[2], L.J. Montaner[1], Y. Cai[2]

[1]The Wistar Institute, Philadelphia, United States, [2]Gilead Sciences, Inc., Foster City, United States, [3]Philadelphia FIGHT, Philadelphia, United States

Background: Opioid use impairs immune response, but the mechanism of action remains unknown. In people with HIV (PWH), opioid use may exacerbate chronic inflammation and possibly limit antiretroviral therapy (ART)-mediated immune reconstitution.

To address the knowledge gap, we sought to identify inflammatory and immune biomarkers in PWH on opioid replacement therapy, including full (methadone, MET) or partial agonists (suboxone, SUB) of the μ-opioid receptor (MOR), and to assess a possible association with clinical outcomes.

Methods: The study enrolled 3 virally suppressed PWH groups that included control (ART alone, n=14), SUB (ART+-SUB, n=15), and MET (ART+MET, n=14) groups. Circulating proteome was analyzed with the SomaScan platform using anticoagulated citrate dextrose plasma specimens. Analyte selection and SomaSignal signature determinations were gated with a signal-to-noise ratio of >3. Statistical methods included Wilcoxon rank-sum test and beta regression; *P* values were adjusted for false discovery rate.

Results: The mean age of participants (48.6 years) and mean length of ART (10.4 years) were similar across all cohorts, but the percent of female participants was lower in the control group (14.3%) compared with the SUB (40.0%) and MET groups (42.9%).

SomaSignal analysis indicated that PWH receiving MET had a higher risk for kidney disease, heart failure, and dementia, and a trend for lower visceral fat and alcohol impact, compared with other groups.

The increased risks for kidney disease and dementia were confirmed using beta regression analysis. The levels of 12 unique proteins identified by 13 SOMAmers were differentially expressed between the control and MOR agonist groups. HSP70, KERA, NTRI, FLRT2, sCD14, SDF-1, IGLL1, AT1B2, and ROR1 levels were higher in PWH exposed to MOR agonists, but MMAC, IGFALS, and ELA2A were higher in the control group (*P*<.001). Standard ELISA analysis confirmed that readouts of HSP70, IGLL1, and sCD14 were concordant

with the SomaScan results. The levels of HSP70, IGLL1, and sCD14 measured by ELISA were significantly different between PWH exposed to MOR agonists and controls.
Conclusions: These data suggest that PWH chronically exposed to MOR agonists have higher levels of specific circulating protein biomarkers that may be linked to increased risk of negative clinical outcomes.

EP0082

Comparative analysis of viral load testing trends in a molecular laboratory in Akwa Ibom State, Southern Nigeria

Background: Access to HIV viral load (VL) testing is affected by long turnaround times (TATs) and laboratory throughput. To optimize VL testing, PEPFAR, through the USAID-funded Accelerating Control of HIV Epidemic projects, supported the University of Uyo Teaching Hospital (UUTH) in Akwa Ibom State to upgrade its laboratory equipment. Three Abbott Alinity M instruments replaced the Abbott m2000, along with the installation of a solar backup power supply and timely commodity deliveries. The Abbott Alinity (tests 960 samples in 24 hours) has a testing capacity approximately twice that of the Abbott m2000 (465 samples/24 hours). This study assessed the TAT pre- and post-intervention and the error rate pre-and post-intervention.
Methods: Using routinely collected data on the number of samples received and tested and results dispatched from the National Laboratory Information System, we compared the testing output rates and TATs in the year prior to the intervention (October 2022–September 2023) with those in the post-intervention period (October 2023–September 2024). An unpaired t-test was used to compare the average monthly TATs; p-values <0.05 were considered significant.
Results: A total of 525,517 samples were received over the 24 months, with 57% (299,818/525,517) in the pre-intervention period (Table 1).
Average number of tests per month decreased from 23,905 pre-intervention to 18,804 post-intervention. The average monthly VL TAT for sample processing decreased significantly from 8.4±5.9 to 2.3±0.6 days (p=0.002). There was a reduction in the mean error rate from 23.11% pre-intervention to 5.62% post-intervention.

Indicator	Fiscal year 2023	Fiscal year 2024	Difference
Total number of VL samples received	299,818	225,699	-74,119
Total number of patients tested	286,860	225,644	-61,216
Total number of VL results dispatched	286,860	225,644	-61,216
Samples tested	95.70%	99.98%	
Results dispatched	100%	99.98%	
Mean error rate	23.11%	5.62%	17.49
Standard deviation of the error rate	25.16%	3.32%	
Standard error of the mean	7.26%	0.96%	

Table 1. Number of samples received, tested, and dispatched

Conclusions: The expansion of molecular platforms to improve VL diagnostic service coverage in the UUTH PCR laboratory demonstrated an increased capacity to handle a similar workload, with sustained sample quality, shorter TATs, and a reduced error rate.

EP0083

An assessment of advanced HIV disease: clinical and epidemiological insights from Burundi

P.C. Habonimana[1], N. Ntakaburimvo[1], S. Jovanovski[2], B. Nijirazana[1], A. Ndayizeye[3], H. Nzomwita[3], J.B. Nsengiyumva[1], E. Ndayiragije[4], C. Kaze[5], J.-J.K. M'Bea[1], R. Fayorsey[2], M. Tesema[2], G. Vandebriel[1], E. Poirot[2]
[1]ICAP at Columbia University, Mailman School of Public Health, Bujumbura, Burundi, [2]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [3]Programme National de Lutte Contre le SIDA et les Infections Sexuellement Transmissibles, Bujumbura, Burundi, [4]Centre Nouvelle Esperance, Bujumbura, Burundi, [5]USAID, Bujumbura, Burundi

Background: Burundi has made significant progress towards HIV epidemic control, with 91% of people living with HIV (PLHIV) on treatment. However, 1,200 deaths occur annually due to AIDS.
We aimed to quantify and describe advanced HIV disease (AHD) among PLHIV using point-of-care VISITECT CD4 to inform AHD management in Burundi.
Methods: We conducted a cross-sectional analysis among PLHIV at 22 health facilities supported by the Reaching Impact Saturation and Epidemic Control and USAID Baho Mbeho projects, in 8 provinces from June–September 2024. Eligible PLHIV ≥15 years new on ART, returning to treatment (RTT) after >6-month interruption, or with detectable viral load (dVL) underwent CD4 testing. Individuals with AHD received GeneXpert testing, and clin-

ical information was abstracted from client records. AHD was defined as a CD4 count <200 cells/μL. Descriptive and comparative statistics were used to estimate and characterize those with AHD.

Results: During this period, we enrolled 492 PLHIV: 238 (48%) PLHIV new on ART, 67 (14%) PLHIV RTT, and 187 (38%) PLHIV with dVL. Of these, 49% (243/492) had AHD (52%, 123/238 among new on ART; 64%, 43/67 among those RTT; and 41%, 77/187 among dVL). Among PLHIV new on ART, 85% (62/73) in WHO stage 3 or 4 compared to, 37% (61/165) in WHO stage I or 2 had AHD. The median age of PLHIV with AHD was 36 years, 38% (92/243) male and 15% (37/243) part of a key population group.

Of those with AHD with GeneXpert results, 9% (21/241) were diagnosed with TB. AHD was more common among PLHIV RTT vs PLHIV new on ART (64% vs 52%, p =0.07), aged ≥45 years vs 15-24 years (57% vs 41%, p =0.01); male vs female (60% vs 45%, p = 0.002), and body mass index <18.5 vs ≥18.5 (59% vs 46% p = 0.02).

Conclusions: Nearly half of participating PLHIV had AHD suggesting that burden is high in Burundi, and especially among those RTT. There is an urgent need to scale up services for PLHIV with AHD, increase access to HIV testing to improve early identification of PLHIV and minimize AIDS-related deaths due to interruption in treatment.

EP0084

Reliability of the AIDS clinical trials group ART adherence questionnaire across administration modes and languages among Ugandan women living with HIV

M. Nabwana[1], P. Atuhaire[1], J. Etima[1], K. Jim Aizire[2], T. Taha[2], M. Nolan[1], L. M. Atuyambe[3], M.G. Fowler[4], A. Owora[5]

[1]Makerere University - Johns Hopkins University Research Collaboration, Kampala, Uganda, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [3]Makerere University School of Public Health, Department of Community Health and Behavioral Sciences, Kampala, Uganda, [4]Johns Hopkins University, Department of Pathology, Baltimore, United States, [5]Indiana University School of Medicine, Department of Pediatrics, Bloomington, United States

Background: The AIDS Clinical Trials Group (ACTG) antiretroviral therapy (ART) adherence questionnaire is widely used although the psychometric properties across different administration modes and languages remain underexplored. This study investigates the reliability of the ACTG ART adherence questionnaire across four administration modes.

Methods: Women living with HIV (WHIV) on ART were enrolled in Kampala, Uganda (2020-2021). We administered the ACTG ART adherence questionnaire at baseline, 6- and 12-month visits, divided into four participant groups: Audio Computerized self-Assisted interviews in English (A+E), in Luganda (A+L), Interviewer guided in English (I+E), and in Luganda (I+L). Internal consistency of the ACTG questionnaire was assessed using Cronbach's alpha (≥0.7 = reliable).

Test-retest reliability was evaluated using intraclass correlation (ICC), with values >0.6 deemed good. A mixed effects model was used to examine whether internal consistency changes over time with visit month, group and their interaction as fixed effects, and participant ID and visit month as random effects. Statistical significance was set at p<0.05.

Results: We enrolled 276 WHIV, median age at study-entry was 34 years (inter-quartile range (IQR) 31–38), and ART duration 1.7 years (IQR: 1.2–4.1). Majority (75.4%) self-reported reading ability as "quite very well" in English or Luganda. Reliability was high overall (Cronbach's α = 0.878); as well as subgroups; A+E (α = 0.910), A+L (α =0.8699), I+E (α =0.752), and I+L (α = 0.881). Reliability across visits was consistently high, baseline (α=0.888), month 6 (α=0.868), and month 12 (α=0.880).

Among domains, depression exhibited the highest internal consistency (α = 0.884), followed by self-efficacy (α = 0.863), anxiety (α = 0.810), and social support (α = 0.801). Internal consistency remained stable over time for the tool and its domains. The ACASI administration modes exhibited superior test-retest reliability compared to interviewer-guided methods (ICC = 0.63 vs 0.22, p<0.001).

Conclusions: The ACTG adherence questionnaire demonstrates high reliability across different modes of administration and languages, with ACASI outperforming interviewer-guided methods in reliability.

These findings highlight the suitability of the ACTG questionnaire for assessing self-reported ART adherence in diverse contexts including African settings, and reassuringly, underscores the utility of ACASI in ensuring consistent, reliable data collection.

EP0085

Variability in HIV viral load quantification in real-world service delivery settings: Findings from a prospective cohort study in Rwanda

G. Murenzi[1], S. Munyentwari[1], R. Barthel[2], J.P. Mivumbi[1], M.G. Bahire Rutwaza[1], F. Kanyabwisha[1], D. Nash[2,3], E. Brazier[2]

[1]Research for Development (RD Rwanda), Einstein-Rwanda Research and Capacity Building Program, Kigali, Rwanda, [2]City University New York Institute for Implementation Science in Population Health (ISPH), New York, United States, [3]City University of New York, Graduate School of Public Health and Health Policy, New York, United States

Background: While developments in HIV viral load testing (VLT) technologies have improved detection of low-level viremia, there is substantial variation in the quantitative results of available polymerase chain reaction tests, particularly around assay lower limits of quantification.

We aimed to describe the VLT results reported by three labs in Rwanda, characterize discordancy in viral load (VL) detectability and identify factors associated with discordant VL detectability.

Methods: In prospective study of people living with HIV, aged ≥40 years conducted by the Rwanda cohort of the International epidemiology Databases to Evaluate AIDS (IeDEA), we used a private lab and public hospital lab to

process paired specimens, and compared results from each lab with VLT results within 12 months (+/-) from Rwanda's national reference lab recorded in medical records. We used Cohen's Kappa to assess agreement of results at assay detectability cut-offs (20-39.8 copies/mL) and at <200, and <1,000 copies/mL, and we examined patient characteristics (age, sex, CD4 count, treatment regimen, time on regimen and prior detectable VL reported by the reference lab) independently associated with discordant VL detectability reported by the private and public labs via multivariable logistic regression.

Results: For 504 sets of VLT results reported by the three labs, mean patient age was 54.4 years (standard deviation: 7.1), and over 55% were females. Participants' median time on ART was 16.4 years, 95.4% were on DTG-based regimens, and 96.6% had CD4 cell counts of >200 cells/mm^3. VL detectability rates were 28.8%, 5.4% and 10.1%, respectively, for the private, public, and reference labs, with low agreement in VL detectability for the paired private-public lab results (Kappa 0.21) and private-reference lab results (Kappa: 0.11). Between-lab agreement increased at higher cut-offs of <200 copies/mL (Kappa 0.48 and 0.15, respectively) and <1,000 copies/mL (0.63 and 0.37, respectively). No participant characteristics were associated with discordant VL detectability between the private and public labs.

Conclusions: While VL detectability differed substantially across the three labs, there was high agreement at higher cut-offs generally used in clinical decision-making.

Our findings underscore the need for caution in relying solely on VL detectability, as results may differ across labs, irrespective of participant characteristics.

EP0086

Updates on the clinical epidemiology of HIV-1 group O strains in Cameroon and potential implications on diagnosis and treatment strategies

J. Fokam[1,2,3], C. Chenwi[1,4,5], D.A. Takou Komego[1,6], O.E.G. Beloumou Angong[5,1], S.C. Djupsa Njdeyep[1], E. Ngoufack Jagni Semengue[4,1], A.D. Nka[1], A.C. Ka'e[1], V. Mekel[5,1], N.-K. Background: Cameroon is an epicentre of diverse HIV-1 viral strains, posing diagnostic and therapeutic challenges in clinical management. Groups N, P and O have been reported, with a declining trend (1.1% to 0.6%) of group O

from 2006 to 2013. In the era of dolutegravir-based therapies and transition from a 2-test to 3-test diagnostic algorithm in Cameroon (2.7% HIV national prevalence), we sought to update the prevalence of HIV-1 non-M and compare the diagnostic-performance of the 2-test vs. 3-test algorithms.

Methods: A facility-based study was conducted in February 2024 on 2 207 HIV-1 clinical-samples of individuals from all 10 regions of the country, monitored for HIV drug resistance at the Chantal BIYA International Reference Centre, Yaoundé-Cameroon. Socio-demographics, duration since diagnosis and recent viral-load were collected. Molecular-phylogeny and rapid-subtyping were performed for identifying HIV-1 non-M; Inno-Lia was performed for characterising reactive biomarkers on any HIV-1 non-M.

Performances of rapid diagnostic tests (RDTs) used in the 2-test (determine and KHB) vs. 3-test (First Response, One Step and KHB) algorithm were evaluated on HIV-1 non-M, including ACRO Rapid Test (HIV1/2 &p24) as an independent RDT.

Results: Overall, no HIV-1 group N (0%) nor P (0%) were found while 09 HIV-1 group O strains were identified (0.4%; 95%CI: 0.2%-0.8%). Of the individuals harbouring HIV-1 group O, mean-age was 43±12 years, 50% female, median [IQR] duration since HIV-diagnosis, 627 [423-775] weeks, median [IQR] viremia, 12,385 [5,340-72,682] copies/ml and median [IQR] CD4 count, 52 [39-228] cells/mm^3.

Following RDT, One Step, KHB and ACRO Rapid Test (HIV1/2&p24) detected 8/8 HIV-1 group O (100%-performance), First Response HIV1-2.0 detected 7/8 (87.5%-performance) versus 6/8 (75%-performance) with Determine HIV1/2, p=1.000. The two non-reactive samples on Determine HIV1/2 had indeterminate results on Inno-Lia.

Conclusions: In this Cameroonian setting, HIV-1 group N and P are scarce while group O remains low (<1%), with a potential declining trend over the years.

On eight HIV-1 group O strains, the 2-tests algorithm detected 75% against 87.5% for the 3-tests algorithm. Thus, transitioning to the 3-tests algorithm could lead to improved diagnostic performance on currently circulating HIV-1 group O, calling for updates in RDTs to adapt to viral dynamics.

EP0087

Employing a team-based process flow chart to sustain high viral load monitoring rates among paediatric HIV clients at Rundu State Hospital, Namibia from 2020-2024

W. Bakari[1], M. Said[1], T. Danda[1], G. Barnabee[1], E.-L. Kafidi[1], M. Shepard[1], M. Laurens[2], S. Ashikoto[2], K. Battey[3], P. Kalimugogo[3], N. Forster[1]

[1]International Training and Education Centre for Health (I-TECH), Department of Global Health, University of Washington, Seattle, Windhoek, Namibia, [2]Ministry of Health and Social Services, Windhoek, Namibia, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Windhoek, Namibia

Background: Timely viral load monitoring (VLM) has been recognized as crucial for managing people living with HIV (PLHIV) on antiretroviral therapy (ART). In Namibia, the proportion of paediatric HIV clients receiving timely VLM per national guidance (every 6-months for clients aged 19 years and below) remains below the national target of 95%.

We used a team-based quality improvement (QI) approach to develop a process flowchart to standardize and streamline paediatric VLM at Rundu Hospital, Namibia to improve and sustain VLM above 95%.

Methods: In November 2020, a QI team identified low VLM among paediatric clients. To address issues related to VLM processes and improve VLM to above 95%, the team brainstormed an improved VLM flowchart including:

1. Appointment reminders via phone/SMS a week before appointments;
2. VLM eligibility verification and recording upon arrival;
3. Blood samples drawn and barcodes affixed to client records;
4. Result tracking within 1–2 weeks;
5. Missed appointment follow-up calls/SMS;
6. Results entered into records and electronic systems before filing;
7. Bi-weekly data quality assessments (DQAs);
8. Enhanced care for high viral load (>40 copies/mL) clients, followed by repeat tests after three months of good adherence, and;
9. Monitoring suppressed viral load (<40 copies/mL) clients at six-months.

The number and proportion of paediatric HIV clients receiving VLM per national guidance were calculated monthly using routine programmatic data from the electronic client management system and analyzed descriptively from November 2020 through May 2024 to assess achievement and sustainment of the 95% target.

Results: Paediatric VLM at Rundu Hospital increased from 41% (180/440) in November 2020 to 99% (315/317) in May 2024. From January 2022 through May 2024, achievement above 95% was sustained with performance peaking at 100% (304/305) in September 2023.

Conclusions: The standardized and streamlined VLM process ensured that paediatric clients eligible for VLM were not overlooked, all VLM results were accurately documented, and missed opportunities for VLM were swiftly identified and addressed. Rundu Hospital's success

demonstrates how a QI-driven approach can achieve and sustain high VLM rates among paediatric clients, providing a replicable model for similar settings.

EP0088

Levels of red blood cell indices alter HbA1c diagnostic cut-off for diabetes mellitus among persons living with and without HIV in Nigeria

J. Jumare[1], F. Anumah[2], T. Ngondomb[3], G. Odonye[4], M. Ibrahim[4], K. Yunusa[3], A. Nwachukwu[4], M. Nwegbu[5], S. Lai[1], A. Abimiku[1], M. Charurat[1]
[1]Institute of Human Virology, University of Maryland Baltimore, Division of Epidemiology, Baltimore, United States, [2]University of Abuja Teaching Hospital, Medicine, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, Laboratory Services, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, Research Center, Abuja, Nigeria, [5]University of Abuja Teaching Hospital, Chemical Pathology, Abuja, Nigeria

Background: Glycosylated hemoglobin (HbA1c) test has been widely adopted for the diagnosis and monitoring of diabetes mellitus (DM). However, multiple factors related to biological variability in glycosylation are believed to affect HbA1c levels. We examined DM diagnostic cut-offs by HIV status and strata of red blood cell (RBC) indices.
Methods: Persons aged 35 years or older, living with and without HIV (PLHIV and PWoH), were recruited in a cross-sectional study underway at the University of Abuja Teaching Hospital, Nigeria.
Participants underwent standard 75g oral glucose tolerance test (OGTT). Complete blood count was performed using 'Sysmex KX21N' while glucose and HbA1c were measured with 'Selectra ProS'. Levels of hemoglobin [Hb] and RBC indices (mean corpuscular hemoglobin [MCH], mean corpuscular volume [MCV], RBC distribution width [[RDW]) were categorized into low, normal and high according to WHO criteria.
Two-hour glucose results from the OGTT, as gold standard, and HbA1c levels were used to generate receiver operating characteristic curves with cut-offs determined based on optimal estimates of Youden's index, Euclidean distance, sensitivity/specificity (Sen/Sp) and area under the curve (AUC).
Results: Of the 285 PLHIV and 288 PWoH, women constituted 49.8% and 50.2% respectively. The median age of the PLHIV was 49 years while that of the PWoH was 44 years. The prevalence of DM based on the two-hour glucose were 2.46% (95% CI:0.99, 4.99) and 2.43% (95% CI:0.98, 4.94) among the PLHIV and PWoH respectively. HbA1c diagnostic cut-off for DM was 7.19% (Sen:0.86; Sp:0.94; AUC:0.88) and 7.23% (Sen:0.71; Sp:0.96; AUC:0.87) among PLHIV and PWoH respectively.
The HbA1c cut-off was lower among those with low hemoglobin (7.19% [Sen:0.8; Sp:0.94; AUC:0.88]) compared to normal Hb (8.93% [Sen:0.78; Sp:0.99; AUC:0.86).
Similar cut-offs for low and normal levels (7.19% vs 8.93%) were found for MCH, MCHC, and MCV. Those with elevated as compared to normal RDW had 7.19% and 7.23% cut-offs respectively.
Conclusions: DM diagnostic cut-offs in this study were higher than the 6.5% adopted from high-income settings. Larger studies are required to determine appropriate cut-off for the Nigerian population. Meanwhile, clinicians should consider alternative tests to confirm abnormal HbA1c results especially among persons with hematological abnormalities.

EP0089

The performance of low HIV viral load values for the diagnosis of acute HIV infection in the Beijing PRIMO cohort

F. Zhao[1], L. Li[1], D. Yuan[2], X. An[1], X. Tian[1], B. Wang[2], H. Wu[1], T. Zhang[1], L. Liu[1], B. Su[1]
[1]Beijing Youan Hospital, Capital Medical University, Beijing, China, [2]Southeast University, Nanjing, China

Background: Early diagnosis is critical for rapid antiretroviral therapy (ART) initiation and the prevention of subsequent viral transmission. The proposed viral load threshold for diagnosing human immunodeficiency virus (HIV) infection has been updated from 5,000 copies/mL to 1,000 copies/mL in China, and the impact of low viral load values on the diagnosis of HIV needs to be investigated.
Methods: A prospective study cohort, the Beijing PRIMO cohort, was established from 2006 to 2013, the enrolled subjects were from HIV high-risk population, and their HIV RNA levels were tested every 2 months to detect acute HIV-1 infection.
The distributions of the confirmatory western blotting antibody results and viral load values in 347 individuals in the Beijing PRIMO cohort were analyzed to investigate the performance of low HIV viral load values for the diagnosis of acute HIV infection. In addition, the CD4/8 T-cell ratios were also characterized.
Results: Among the 347 individuals in the Beijing PRIMO cohort, the viral loads of 4 (1.15%) patients ranged from 20 copies/mL to 999 copies/mL before positive confirmatory antibody results were obtained, and in 3 of the above four patients, the western blot results transitioned from indeterminate to positive.
The longest time interval between the detection of a viral load of fewer than 1000 copies/mL and the positive western blot result was 42 days. Twelve participants had at least one viral load value ranging from 1000 copies/mL to 5000 copies/mL before the positive western blot results were obtained.
In addition, of the 112 participants who had CD4/8 T-cell ratio results available that were obtained no later than the positive western blot results, 109 participants (97.3%) had a CD4/8 T-cell ratio <1.0.
Conclusions: The threshold of 1000 copies/mL being used for the diagnosis of HIV-1 infection in China still carries a risk of a missed diagnosis.
Our findings provide valuable information for the diagnosis of acute HIV infection and the development of an HIV laboratory testing algorithm.

EP0090

Innovative strategies for combating advanced HIV disease and tuberculosis: lessons learned from a data-driven approach across healthcare facilities in Nigeria

E. Mbaba[1], N. Kelvin-Kanayo[2], E. Clement[3], S. Okoro[3], U. Malah[4], F. Yinka[4]

[1]Excellence Community Education Welfare Scheme (ECEWS), Technical Officer, Abuja, Nigeria, [2]Watford General Hospital, Acute Medicine Department, West Hertfordshire NHS Trust, United Kingdom, [3]National Agency for the Control of AIDS, Community Prevention, Care and Services, Abuja, Nigeria, [4]National Agency for the Control of AIDS, Performance Management & Resource Mobilisation, Abuja, Nigeria

Background: In Nigeria, 32% of PLHIV who received CD4 tests in 2018 had AHD, this population had the highest morbidity & mortality rates. AHD-related comorbidities like TB, contribute to increased morbidity and mortality. This study evaluates the implementation of AHD screening, treatment, and TB/HIV collaborative interventions in primary and tertiary healthcare facilities.

Methods: Data was collected across Fiscal-Year (FY) 2024, focusing on clients newly initiated on antiretroviral therapy (ART) and returning-to-treatment (RTT). Screening for AHD utilized clinical assessments, CD4 testing, Lateral flow urine lipoarabinomannan-assay (LF-LAM), and Cryptococcal Antigen (CrAg). TB diagnosis was conducted using GeneXpert and chest X-rays (CXR).

Descriptive analyses of service coverage, testing yields, and treatment linkage rates were performed. Programmatic activities, including stakeholder collaboration, healthcare worker training, and service innovations, were reviewed.

Results: Out of 3794 newly diagnosed HIV cases, 96% underwent CD4 testing, with 32% presenting CD4 <200. Clinical stage 3 or 4 cases accounted for 8%, and 1.7% were children under five. Among AHD clients, 74% were evaluated with LF-LAM, yielding a 20% TB positivity rate, while CrAg testing reached 62%.

For returning clients, 91% received CD4 tests, with 9% showing CD4 <200, and 64% were screened using LF-LAM. GeneXpert testing identified 1 TB-positive case, with an overall positivity yield of 2.7%. TB/HIV integration achieved a 99.8% screening rate for new and existing ART clients.

Among new clients, 10% were presumptive for TB; GeneXpert and CXR confirmed 154 TB cases, and 220 clients were started on treatment. For clients already on ART, 2.3% were presumptive, with a positivity-yield of 8.4%. Free CXR services in Q4 enhanced pediatric TB detection, especially for sputum-negative children.

Conclusions: While screening rates for AHD and TB among PLHIV were high, significant gaps in testing and linkage persist, attributed to stockouts and infrastructure limitations. To optimize AHD and TB/HIV outcomes, there's a need to scale up point-of-care CD4 testing and LF-LAM availability through public-private partnerships.

Expanding free CXR services and enhancing pediatric TB case identification through community and facility-based interventions are critical.

Continuous training for healthcare workers and leveraging technology for real-time data tracking will strengthen program implementation and sustainability.

Co-infections (including opportunistic infections)

EP0091

Yield from integrated HIV & TB testing service sites in Ekiti State, Nigeria

O. Emmanuel[1], O. Adebayo[2], E. Ubochioma[3], O. Fadare[1], O. Chijioke-Akaniro[3], O. Omosebi[3], T. Adetiba[4], A. Agbaje[4], M. Sheshi[5]

[1]World Health Organization, UCN, Abuja, Nigeria, [2]Ekiti State TB, Leprosy and Buruli Ulcer Control Programme, SMoH, Ado-Ekiti, Nigeria, [3]National TB, Leprosy and Buruli Ulcer Control Programme, FMoH, Abuja, Nigeria, [4]Institute of Human Virology, Nigeria, Public Health, Abuja, Nigeria, [5]KNCV Tuberculosis Foundation, Public Health, Abuja, Nigeria

Background: Nigeria bears a three-way burden for TB, MDR-TB, and HIV. At a prevalence of 1.4% for HIV and incidence of 219 per 100,000 population for TB, the country bears a huge burden for both diseases in Africa. Key population (KP) are key driver of the HIV epidemic in Nigeria. Although KP account for 3.4% of the population, they account for 11% of new HIV infection. Ekiti state has an HIV prevalence of 0.6% and an annual TB case notification of 10/100,000. Finding HIV and TB in these subpopulations is key to ending the HIV & TB epidemic in the country.

This research is tailored therefore to measure the yield from an integrated HIV and TB service provision across Ekiti State, Nigeria.

Methods: All 414 HIV & TB services sites were identified and mapped, small-volume facilities (spokes) were group, to feed into closest high-volume facilities (hub) for viral load testing and Xpert MTB/RIF assay and LF LAM. Healthcare providers were identified and had their capacity built on provision of integrated HIV & TB services. HIV test kits were provided across all facilities by the HIV programme. Clients with a viral load of ≤200 copies/mL had LF LAM testing done.

Results: Between July and September 2024, total of 22,636 people was screened, out of which 3,640 (16%) Presumptives TB case persons were identified, 99.8% (3,632) of Presumptives TB case were offered HIV testing services, out of these, 147 persons had HIV (104 previously known status and 43 persons with newly acquired HIV), 205 (6%) confirmed TB cases were notified, 196 (96%) started on treatment. 49 (24%) clients were TB/HIV co-acquired, and all dually acquired clients are started on ART. Finding children with TB and/or HIV was a missed opportunity.

Conclusions: TB and HIV continue to plague the country. Intentional efforts to addressing both diseases should be integrated leveraging on existing systems and structure of both programmes for a more impactful result.

EP0092

AI-enabled mobile X-ray for integrated screening of tuberculosis, cardiovascular disease and chronic respiratory diseases in HIV clinics in Nigeria: a cross sectional Study

C. Okoye[1,2], J. Creswell[2], J. Ilozumba[1], R. Fukunaga[3]
[1]Catholic Caritas Foundation of Nigeria, TB/HIV, Abuja, Nigeria, [2]STOP TB Partnership Geneva, TB, Geneva, Switzerland, [3]US CDC, TB/HIV, Atlanta, United States

Background: Studies have shown that PLHIVs are most at risk of developing Tuberculosis (TB) and other cardio pulmonary conditions, yet early detection is usually hampered due to atypical clinical presentation and lack of active screening at the HIV clinics. AI mobile X-ray technology have shown the potential of improving diagnostic access and early detection TB and other cardiopulmonary conditions. We conducted an integrated screening of TB, Cardiovascular disease (CVDs), and Chronic respiratory disease (CRDs) using AI-enabled X-ray for PLHIVs at HIV clinics.

Methods: A cross sectional study was done between January to December 2024 in 10 high burden PEPFAR supported HIV clinics in Enugu state Nigeria, PLHIVs aged 18 years and above currently on ART and who visited the clinic for their appointments were screened using the WHO parallel screening algorithm which offers both TB symptomatic screening and AI Enabled X-ray screening simultaneously. Samples were collected for Gene Xpert testing from presumptive TB cases identified from either the WHO symptomatic Screening or from the AI report (we used a cut off or AI 0.3 and Above). for those who had abnormal X-ray suggesting CVDs or CRDs they were referred to see a specialist. the client's demographics clinical histories, AI reports and diagnostics results were analyzed using excel.

Results: A total of 3,063 PLHIVs were screened using the AI-enabled X-ray machine, 922 (30%) had an abnormal chest X-rays report, of the abnormalities identified from the AI report 25% (229) were presumptive TB cases, 40% (371) were presumptive CVD cases, and 35% (325) were presumptive CRD cases. A total of 325 samples were collected for Gene Xpert testing (from both symptomatic individuals and those with an AI score above 0.30), resulting in the identification of 48 TB cases which were initiated on TB treatment. the CVDs and CRDs presumptive conditions were reviewed by the clinicians.

Conclusions: From the results this study highlights the urgent need to expand the focus on CRDs and CVDs for PLHIVs in care. the use of AI technology for routine screening at the HIV clinics is important to promote early detection and the provision of a comprehensive health care for PLHIVs

EP0093

High completion rate and low side effects of the National Short-Course Tuberculosis Preventive Treatment implementation among people living with HIV in Thailand, 2023-2024

S. Noknoy[1], R. Lolekha[2], L. Santashinkul[1], A. Avihingsanon[3], P. Thaisiam[4], S. Watcharasuwansaree[5], T. Palakawong Na Ayuthaya[6], S. Jirajariyavech[7], S. Kusuwan[8], N. Punsuwan[1], S. Northbrook[2], N. Haetanurak[1]
[1]Division of AIDS and STIs, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, [2]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Nonthaburi, Thailand, [3]The HIV Netherlands Australia Thailand Research Collaboration, Thai Red Cross AIDS Research Center, Bangkok, Thailand, [4]Nakornsrithammarat Hospital, Nakornsrithammarat, Thailand, [5]Udonthani Hospital, Udonthani, Thailand, [6]Public Health Center 28, Health Department, Bangkok Metropolitan Administration, Bangkok, Thailand, [7]Taksin Hospital, Medical Service Department, Bangkok Metropolitan Administration, Bangkok, Thailand, [8]Chiangrai Prachanukroh Hospital, Chiangrai, Thailand

Background: Thailand faces a significant burden of tuberculosis (TB) and HIV, with <1% of newly diagnosed people living with HIV (PLHIV) receiving Tuberculosis Preventive Treatment (TPT). The 2023 national guidelines recommend short-course TPT (3HP (Isoniazid/rifapentine) or 1HP) for newly diagnosed PLHIV, those on antiretroviral therapy (ART) with a CD4 count <200 cells/mm³, patients lost to follow-up with a viral load >1,000 copies/mL, individuals with positive IGRA tests, and those recently exposed to pulmonary TB. In FY23, the Thai Ministry of Public Health distributed TPT job aids and trained healthcare providers to increase TPT uptake nationally.

Methods: We analyzed the national TPT uptake (number of PLHIV initiating TPT), completion rates (number of PLHIV completing TPT divided by number of PLHIV who initiated TPT in the same time period), and side effects (abdominal pain, nausea, vomiting, numbness, flu-like symptoms, fever >39°C, rash, other) using the national HIV/TPT dataset from October 2022 to September 2024. We used the annual average of 25,000 newly diagnosed PLHIV reported in the National AIDS Program as a denominator to calculate TPT coverage among newly diagnosed PLHIV.

Results: A total of 4,147 PLHIV received TPT (1,655 in FY23 and 2,492 in FY24) across 195 hospitals in 59 out of 77 provinces. Of these, 70% were male, 94% were Thai, and the median age was 39 (IQR 29–48) years. The most common TPT regimen was 3HP (77%). Overall, completion rate was 85% in FY23, with a higher completion rate reported for 1HP than 3HP (93% and 85%, respectively). TPT was initiated in 1,805 newly diagnosed PLHIV (682/25,000 [2.7% coverage] in FY23 and 1,123/25,000 [4.5% coverage] in FY24), 930 PLHIV interrupting treatment, 380 PLHIV with CD4 count <200 cells/mm³, and 343 PLHIV with positive IGRA or TST tests. Reported side effects were <1%, mainly flu-like symptoms and gastrointestinal issues.

Conclusions: Although our findings revealed few side effects and high completion rates for short-course TPT, coverage among newly diagnosed PLHIV remained low

against the global target of 90%. Additional efforts to communicate the benefits of short-course TPT, address gaps in initiation, and ensure adherence may increase uptake among PLHIV and reduce TB incidence.

EP0094

Implementation of cryptococcal infection screening and treatment for clients with advanced HIV disease using a hub-and-spoke model in Ethiopia, 2024

I. Ahmed[1], F. Tefera[1], M. Kemal[2], M. Getachew[3], D. Adugna[2], A. Mulugeta[2], A. Asmamaw[2], S. Berhanu[2], A. Mekonnen[1], T. Assefa[2], Z. Melaku[2]

[1]U.S. Centers for Disease Control and Prevention (CDC), Addis Ababa, Ethiopia, Addis Ababa, Ethiopia, [2]ICAP at Columbia University's Mailman School of Public Health, Addis Ababa, Ethiopia, [3]Ministry of Health of Ethiopia, Addis Ababa, Ethiopia

Background: Despite improvements in access to antiretroviral therapy, there has been high burden of advanced HIV disease (AHD) in Ethiopia due to late presentation. Over 40% of newly diagnosed adult HIV clients presented with CD4 count <200 cells/mm^3.

Nevertheless, access to package of AHD management services, especially diagnostics and treatment of cryptococcal meningitis (CM), have been a challenge.

Description: As part of improving access to AHD management, we developed a hub-and-spoke model that linked hospitals (HPs) to health centers (HCs) to extend AHD management to lower-level health facilities. Spokes are HCs with a capacity to test for cryptococcal infection (CI) and refer clients with sign and symptoms (S&S) of CM to the hubs (HPs). CDC supported the development of AHD management guidelines, training manuals, revision of electronic medical record to integrate CM into the existing HIV service database, and provision of training and mentorship to healthcare workers (HCW).

The Ministry of Health secured necessary commodities including CD4 and cryptococcal antigen (CrAg) tests, amphotericin B, flucytosine, and fluconazole through Global Fund. The initiative was implemented in February 2024 at 209 sites. We analyzed reports from 163 sites from February-August 2024.

Lessons learned: AHD screening was done using CD4 testing prioritized for newly diagnosed with HIV, return to treatment after interruption, and those with treatment failure. Of 2,189 clients with CD4 count <100 cells/mm^3, 95% (2,090) had access to CrAg test, and CI was found in 177 (8%). Of these, 58% (102) clients had S&S of CM, but only 58% (59) had access to cerebrospinal fluid CrAg test, with 56% (33) positivity. Overall, of 177 serum CrAg positives, 95% (169) had received either treatment (52) or prophylaxis (117) for CM. Gaps in supplies for lumbar puncture, HCW's capacity to assess CM, documentation, and missed opportunities for CrAg test were some of the challenges observed during implementation.

Conclusions/Next steps: A hub-and-spoke model of care was a feasible approach to provide CM prevention and treatment services. Close monitoring, mentorship and uninterrupted supply of commodities are important for the success of the program. The findings were used to inform expansion of the service to 388 additional sites in the country.

EP0095

Serology change-based clinical interpretation of indeterminate serostatus post-hepatitis B virus infection in people living with HIV

E. Kinai[1], M. Ishikura[1], T. Muramatsu[1], R. Miyashita[1], T. Yamaguchi[1], Y. Chikasawa[1], A. Ichiki[1], R. Sekiya[1], M. Bingo[1], M. Yotsumoto[1], T. Hagiwara[1], K. Amano[1]

[1]Tokyo Medical University, Department of Laboratory Medicine, Tokyo, Japan

Background: After hepatitis B virus (HBV) infection in people living with HIV (PLWH), various forms of indeterminate serostatuses, including "isolated anti-HBc (IAHBc)", are observed, but their clinical interpretation remains controversial despite the recent trend of sparing anti-HBV agents from antiretroviral therapy.

Methods: We conducted a single-center and retrospective cohort study of PLWH with past HBV infection and no history of vaccination. For PLWH with indeterminate serostatus, defined as neither seroconversion [HBsAg(-)/anti-HBs(+)/anti-HBc(+)] nor chronic infection [HBsAg(+)/anti-HBs(-)/anti-HBc(+)], chronological sub-serostatus and clinical interpretations were determined based on long-term changes in serology.

Results: Of 878 PLWH with past-HBV infection and no vaccination, 640 (73%) showed seroconversion, 60 (7%) had chronic infection, and 178 (20%) were considered the indeterminate group. Based on analysis of repeated serologic tests over a median period of 12.2 years (12.4 repeats of tests), the indeterminate group was classified as IAHBc (n=118, 66%), "anti-HBs alone" (n=35, 20%), and "lost anti-HBs/anti-HBc" (n=25, 14.0%). Serostatus changed during the study in 132 (74%). In IAHBc and lost anti-HBs/anti-HBc, chronic infection, viral rebound and non/weak-seroconversion were observed in 2/143 (1%), 5 (4%) and 27 (19%), respectively, while none showed gradual decline/loss of anti-HBs after seroconversion (resolved infection pattern). In contrast, sustained seroconversion and post-exposure protection were found in 23 (66%) and 5 (14%) in anti-HBsAb alone.

Conclusions: In PLWH, indeterminate HBV serostatus is highly unstable and can change with time, raising risk of misdiagnosis. IAHBc and lost anti-HBs/anti-HBc in PLWH do not indicate resolved but weak/unstable immunity against HBV, whereas anti-HBsAb alone infers robust immunity.

EP0096

Prevalence and incidence of high-risk penile HPV genotypes in transgender women and men who have sex with men

D. Salusso[1], A. Gun[1], A. Nava[1], J.R. Garcia[1], M. Abba[2], M.E. Salas[2], P. Delgado[1], A. Grinpelc[1], J. Naipauer[3], C.F. Perez[1], C. Cesar[1], P. Cahn[1], M.I. Figueroa[1], V. Fink[1]

[1]Fundacion Huesped, Research Department, Buenos Aires, Argentina, [2]Facultad de Ciencias Médicas, Universidad de La Plata, Centro de Investigaciones Inmunológicas Básicas y Aplicadas,, La Plata, Argentina, [3]UBA-CONICET, Instituto de Fisiología, Biología Molecular y Neurociencias, Buenos Aires, Argentina

Background: Persistent anogenital high-risk human papillomavirus (hrHPV) infections can lead to malignant lesions. People with HIV (PWH) have an increased risk of persistent infections.

This study evaluated the prevalence and incidence of penile hrHPV infections in men who have sex with men (MSM) and transgender women (TGW), including people with and without HIV.

Methods: We collected demographic and clinical data. To study HPV infection, we obtained samples at baseline and follow-up visits (FUV) using a 600-grit emery paper and a Dacron swab. Fifteen hrHPV genotypes were analyzed with ATILA AmpFire HPV High-Risk Genotyping. Samples with amplification failure were excluded.

Logistic regression assessed the prevalence and incidence of any hrHPV, genotypes included in the nonavalent vaccine (n-hrHPV), and HPV-16, considering gender, HIV status, condom use, and lifetime sex work.

Results: From June-2022/February-2024, 201 participants performed both visits and had available results. At baseline, median age: 33 years (IQR 29–40), 99%(199) identified as Hispanic-Latino, 13.5%(27) were circumcised, and 27.9%(56) PWH (median CD4 count: 712 cells/mL, IQR 529–942); 41.3%(83) reported prior anogenital warts, 12.4%(25) had completed quadrivalent HPV vaccination (Table 1). Median time between visits: 174 days [IQR:168–209].

	MSM	TGW	p	PWH	HIV negative	p
Tertiary education level	144/167 (86.2%)	10/34 (29.4%)	<0.001	30/56 (53.6%	124/145 (85.5%)	<0.001
STIs:						
-History of STIs (i.e, syphilis, gonorrhea, chlamydia, hepatitis B-C)	125/167 (74.9%)	30/34 (88.2%)	0.090	49/56 (87.5%)	106/145 (73.1%)	0.029
-HIV diagnosis	36/167 (21.6%)	20/34 (58.8%)	<0.001	-	-	-
Sexual variables:						
-Lifetime sexual work	32/167 (19.2%)	28/34 (82.4%)	<0.001	26/56 (46.4%)	34/145 (23.4%)	0.001
-Lifetime insertive vaginal sex	88/167 (52.7%)	13/34 (38.2%)	0.12	29/56 (51.8%)	72/145 (49.7%)	0.8
-Condom use in anal/ vaginal insertive sex (more than 50% of sexual encounters)	96/149 (64.4%)	26/29 (89.7%)	0.007	34/46 (73.9%)	88/132 (66.7%)	0.4

Table 1. Baseline characteristics stratified by gender and HIV status.

Prevalence of any hrHPV and n-hrHPV was higher in PWH and those reporting sexual work, with no differences regarding gender. HPV-16 prevalence was 4.5% with no associations found in the logistic regression model.

Condom use during at least half of insertive intercourses reduced the odds of hrHPV detection at FUV by 54%. Additionally, being a TGW was significantly associated with hrHPV incidence after adjustment (Table 2)

hrHPV HR 95% CI	Crude OR (95%CI)	p	Adjusted OR (95%CI)	p
Prevalence				
PWH vs HIV negative	2.62 (1.37, 5.03)	0.003	2.79 (1.25, 6.29)	0.012
TGW vs MSM	1.49 (0.68, 3.18)	0.308	NS	NS
Condom use	1.27 (0.67, 2.47)	0.469	NS	NS
Sexual work	3.41 (1.80, 6.52)	<0.001	5.02 (2.18, 12.1)	<0.001
Incidence				
PWH vs HIV negative	1.16 (0.44, 2.84)	0.751	NS	NS
TGW vs MSM	1.69 (0.59, 4.50)	0.308	NS	NS
Condom use	0.46 (0.20, 1.07)	0.073	0.33 (0.12, 0.84)	0.024
Sexual work	1.16 (0.44, 2.84)	0.751	NS	NS
n-hrHPV HR 95% CI	Crude OR (95%CI)	p	Adjusted OR (95%CI)	p
Prevalence				
PWH vs HIV negative	4.29 (2.09, 8.92)	<0.001	5.00 (2.15, 12.0)	<0.001
TGW vs MSM	1.52 (0.62, 3.48)	0.337	NS	NS
Condom use	2.03 (0.95, 4.57)	0.074	NS	NS
Sexual work	2.86 (1.40, 5.84)	0.004	2.78 (1.11, 6.96)	0.028
Incidence				
PWH vs HIV negative	1.73 (0.45, 5.73)	0.386	NS	NS
TGW vs MSM	2.67 (0.67, 9.03)	0.129	15.9 (2.03, 167)	0.011
Condom use	0.78 (0.23, 2.62)	0.681	NS	NS
Sexual work	0.52 (0.08, 2.06)	0.411	NS	NS

Table 2. Logistic regression model.

Conclusions: PWH had a higher n-hrHPV prevalence. Those using condoms showed a lower incidence of any hrHPV. Prevention strategies including condom use and gender-neutral vaccination with nonavalent HPV vaccine may benefit this population.

EP0097

Progress and challenges in achieving the WHO 90-70-90 target for cervical cancer prevention among women living with HIV in low-and middle-income countries: a systematic review

C. Nwachuya[1,2], A. Isah[1,2], G. Ezenri[1,2], E. Ugochukwu[1,2], U. Okafor[2,3], J.C. Onyehalu[1,2], C. Chukwudi[2], A.P. Ngige[1,2], M.A. Gbuchie[4,2], C. Idabor[1,2], A. Ugwu[2,5], M.M. Abubakar[2,6,7], B.O. Ukoha-Kalu[2,8]

[1]University of Nigeria, Department of Clinical Pharmacy and Pharmacy Management, Nsukka, Nigeria, [2]University of Nigeria, Person-Centered HIV Research Team, Nsukka, Nigeria, [3]West African Postgraduate College of Pharmacists, Nigeria Chapter, Yaba, Nigeria, [4]Act4Her Health Initiative, Department of Sexual and Reproductive Health Research, Yenagoa, Nigeria, [5]Alex Ekwueme Federal University Teaching Hospital, Abakiliki, Nigeria, [6]Directorate of Therapeutic Services, Medical Services Branch, Nigerian Air Force., Abuja, Nigeria, [7]Directorate of Public Health and Humanitarian Services Research Pillar Lab, Nigerian Air Force, Abuja, Nigeria, [8]University of Nottingham, School of Medicine, Nottingham, United Kingdom

Background: Cervical cancer ranks as the fourth cause of death in low- and middle-income countries (LMICs). Women Living with HIV (WLHIV) are six times more likely to develop cervical cancer. The WHO's 90-70-90 target aims to eliminate cervical cancer by 2030 through 90% HPV vaccination, 70% screening between ages 35 and 45, and 90% treatment coverage. This review evaluates progress and challenges achieving these goals in LMICs among WLHIV.

Methods: We searched PubMed, EMBASE, Scopus, and Google Scholar for primary studies published between 2010 and August 2024 from LMICs reporting on cervical cancer prevention and HIV care, focusing on vaccination, screening, treatment, and challenges.

We applied a stepwise title, abstract and full-text review process to select final articles. Included studies encompassed cohort studies, cross-sectional studies, and randomized controlled trials. PROSPERO (CRD42024525160).

Results: We identified 4,023 unique studies (n), of which 73 were included in the final synthesis from 19 LMICs with a total sample size of 553,441 WLHIV. The median age range was 35-45 years. Screening coverage for cervical cancer varied from 29.4% in Kenya to 85% in Zimbabwe. Screening methods included Visual inspection with acetic acid (n=53), Pap smears (n=31), and HPV-DNA testing (n=9). WLHIV on antiretroviral therapy demonstrated improved screening uptake (n=45), reduced prevalence of precancerous lesions (n=9), and lower HPV persistence decreasing the progression to CIN2+ lesions (n=17). Treatment outcomes include same-day treatment (n=23) ranging from 68% in Namibia to 93% in Malawi.

Screen-and-treat approaches were employed in Malawi, Uganda, and Kenya, including thermal ablation and cryotherapy (n=32). Limited advanced screening technologies (n=13), poor follow-up (n=45), and weak integration of cervical cancer screening into HIV-care (n=17) have hindered progress in LIMCs. HPV vaccination for WLHIV remained low in LMICs, with no major data reported in the included studies

Conclusions: Evidence-based progress has been made in LMICs, but substantial challenges remain in achieving the ambitious WHO 90-70-90 target. Expanding HPV vaccination coverage, integrating HIV care and cervical cancer services, and adopting cost-effective interventions like self-sampling and digital tools are essential to closing gaps. Strengthening health systems and ensuring sustainable funding are critical to mitigating the dual burden of HIV and cervical cancer.

EP0098

Performance of baseline hemoglobin in predicting incident tuberculosis among people with HIV: a longitudinal study

H. Zhang[1], Y. He[1], Y. Ning[1], L. Li[1], X. Tang[1], Y. Dai[1]

[1]Guangzhou Eighth People's Hospital, Infectious Disease Center, Guangzhou, China

Background: Anemia and low hemoglobin (Hb) are associated with the incidence and progression of tuberculosis (TB) in people with HIV (PWH). To what extent the utility and threshold of Hb in predicting incident TB among PWH during antiretroviral therapy (ART) remain insufficiently explored.

Methods: Baseline and time-updated data were analyzed from a large longitudinal cohort of PWH in China. All participants were tested for *Mycobacterium tuberculosis* infection, underwent chest radiography, had blood and serum results at baseline, and actively surveilled for incident TB over a three-year period.

The TB cases confirmed at baseline were excluded. Poisson analyses, Kaplan-Meier curves, receiver' s operation curve (ROC), and logistic regression were used to delineate the association and predictive accuracy of baseline Hb for incident TB.

Results: Between September 2005 and November 2021, 12474 PWH were included in the predictive accuracy analysis. During a follow-up of three years, 220 (1.76%) cases of incident TB occurred. Age (≥65 years), Hb, CD4 counts, CD8 counts and CD4/CD8 ratio were identified as independent predictors.

Incident TB occurrence increased according to the severity of anaemia. Time-dependent ROC analyses revealed that baseline Hb performed well in predicting incident TB over three years.

In the first year, when nearly 80% of incident TB cases occurred, Hb thresholds of 132.5 g/L for male and 105 g/L for females yielded strong predictive performance, with an AUC of 0.81 (95% CI 0.78-0.84) in males and 0.74 (95% CI 0.63-0.86) in females.

However, incorporating CD4 counts, CD8 counts, and CD4/CD8 ratio did not significantly improve the utility of baseline Hb. Interferon-γ released assay (IGRA)-positive PWH with moderate and severe anemia at baseline were four times more susceptible to TB progression compared to those without anemia.

Conclusions: Baseline Hb alone can effectively predict incident TB in PWH during long-term ART. Monitoring Hb may serve as a simple and feasible strategy to support TB case finding and preventive therapy among PWH.

EP0099

Causes of death in people diagnosed with HIV-associated cryptococcal meningitis: a sub-study of the AMBITION trial

C. Mutata[1], J. Gakuru[2], D. Lawrence[3], J.N. Jarvis[3], C. Ndhlovu[4], T. Leeme[5], M. Mosepele[5], N. Youssouf[5], C. Muzoora[6], C. Chawinga[7], K. Murphy[8], G. Meintjes[8], E. Nyirenda-Dziwani[9], E. Nuwagira[2], C. Kanyama[7], D.B. Meya[2], H. Mwandumba[9], S.F. Molloy[10], T.S. Harrison[10], AMBITION Group

[1]University of Zimbabwe, Clinical Research Center, Harare, Zimbabwe, [2]Infectious Diseases Institute, Makerere University, Kampala, Uganda, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]University of Zimbabwe, Department of Medicine, Harare, Zimbabwe, [5]Botswana–Harvard AIDS Institute Partnership, Gaborone, Botswana, [6]Makerere University, Kampala, Uganda, [7]UNC Project, Lilongwe, Malawi, [8]University of Cape Town, Cape Town, South Africa, [9]Malawi Liverpool Wellcome Program, Blantyre, Malawi, [10]City St George's, University of London, London, United Kingdom

Background: Mortality from HIV-associated cryptococcal meningitis remains high despite available therapy. The AMBITION trial was conducted in Botswana, Malawi, South Africa, Uganda, and Zimbabwe comparing a single, high-dose liposomal amphotericin B based regimen with the previous WHO recommended regimen based on seven daily doses of amphotericin B deoxycholate. We analysed causes of death in AMBITION.

Methods: We analysed data from participants who died during ten-weeks of follow up. Study doctors documented case narratives and reported causes of death which were reviewed by a blinded clinician to agree a cause, consulting a third individual if necessary.

After the trial, each report was reviewed by two additional blinded clinicians, with a third consulted if necessary. Using case definitions, we allocated diagnoses reported at time of death, their certainty, and whether they were considered to contribute to death. We allocated primary and secondary (if applicable) causes and whether the death was cryptococcal-related. We described data and compared across treatment arms.

Results: There were 218/814 deaths: 89 (40.8%) females; median age 39 years (IQR 33-45); median time to death 17 days (IQR 4-33); 104 (47.7%) deaths in the first two-weeks. Incident cryptococcal meningitis was primary cause of death in 145 (66.5%), subsequent immune reconstitution inflammatory syndrome in 11 (5.1%) and relapse in 4 (1.8%) (Table 1).

Overall, including primary and secondary causes, 171(78.4%) deaths were cryptococcal-related, at a median 9 days (IQR 2-25) versus 35 (IQR 25-47) for non-cryptococcal-related (p<0.001).

A slightly lower proportion of deaths in the AMBITION arm were cryptococcal-related than in the control arm, although this was not statistically significant (81.2% vs 75.2%, p=0.3).

Primary cause of death (%)	Overall (n=218)	AMBITION (n=101)	Control (n=117)	
Cryptococcal meningitis	145 (66.5	64 (63.7	81 (69.2)	
Cryptococcal IRIS	11 (5.1)	4 (4.0)	7 (6.0	
Cryptococcal relapse	4 (1.8	2 (2.0	2 (1.7)	
Septicaemia	17 (7.8)	7 (6.9)	10 (8.5)	p=0.481
TB	14 (6.7	8 (7.9)	6 (5.1)	
Pneumonia	9 (4.1)	5 (5.0)	4 (3.4)	
Other	18 (8.3)	11 (10.9)	7 (6.0)	
Was the death cryptococcal-related?				
Yes (%)	171 (78.4)	76 (75.3)	95 (81.2)	p=0.287

Table 1: Causes of death overall and by trial arm.

Conclusions: Cryptococcal disease was the leading cause of death in both study arms. Most cryptococcal-related deaths occurred early during treatment, with non-cryptococcal related deaths occurring several weeks after meningitis treatment was initiated. New therapies are required to further reduce mortality from cryptococcal meningitis.

EP0100

Baseline CSF HIV viral escape is associated with improved neurocognitive outcomes at 3-months amongst Ugandan adults diagnosed with HIV-associated cryptococcal or tuberculous meningitis: a prospective cohort study

L. Nsangi[1], B. Dai[2], K. Hullsiek[2], A. Namudde[1], G. Menya[1], G. Hale[1], M. Kabahubya[1], D. Williams[2], A. Musubire[1], N. Bahr[2], D. Boulware[2], D. Meya[1], M. Abassi[2], F. Cresswell[3], J. Ellis[3]

[1]Infectious Diseases Institute, Makerere University, Research, Kampala, Uganda, [2]University of Minnesota, Minneapolis, United States, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Cryptococcal (CM) and Tuberculous meningitis (TBM) are leading causes of neurocognitive impairment among people living with HIV. Cerebrospinal fluid (CSF) HIV viral escape is common in HIV-associated meningitis and is associated with improved survival. We investigated whether escape is associated with neurocognitive outcomes.

Methods: We recruited adults with HIV-associated CM or TBM from Uganda. We tested paired baseline plasma and CSF HIV viral load (Xpert; Cepheid). We defined escape as any quantifiable level of HIV in CSF above that in plasma. Participants underwent neurophysiological assessment evaluating eight cognitive domains at 3- months post-meningitis. The composite quantitative neurocognitive performance score was a mean of 8 independent z-scores (QNPZ-8). We classified the QNPZ-8 score as mild (0 to -1), moderate (-1 to -2), or severe (£ -2) impairment. We compared baseline characteristics and QNPZ-8 score by escape status.

Results: We recruited 93 participants; 54% were male, median age 35 (IQR 30-42) years, median CD4 count 42 (12-97) cells/mm^3, 35% were on ART. Majority (69%) of participants had CM, 31% had TBM. Overall, 70 (75%) had HIV viraemia, and 40 (43%) had escape. **E**scape was strongly associated with CSF pleocytosis (p<0.001), and being ART

naïve (p=0.002). Participants with escape had a higher median QNPZ-8 score at 3- months (-1.18 vs -2.05, p = 0.135), and a lower proportion of severe neurocognitive impairment (28% vs 51%, p = 0.057) vs. those without escape. After adjusting for ART status, meningitis diagnosis, and CSF pleocytosis, the mean QNPZ-8 score among participants with escape was 0.53 higher (95%CI 0.09- 0.97, p = 0.02) than those without escape.

	Total cohort (N=93 N(%) or median (IQR)	Viral Escape (N=40) N(%) or median (IQR)	No Viral Escape (N=53) N(%) or median (IQR)	p-value[1]
Diagnosis				
Cryptococcal meningitis	64 (69%)	27 (68%)	37 (70%)	0.812
Definite/Probable TBM	29 (31%)	13 (33%)	16 (30%)	
ART naïve	43 (47%)	26 (68%)	17 (32%)	0.002
Currently on ART	32 (35%)	9 (24%)	23 (43%)	
Not ART naïve, currently not on ART	16 (18%)	3 (7.9%)	13 (25%)	
CD4 cell count (cells/μL)	42 [12, 97]	38 [17, 83]	49 [10, 132]	0.773
CSF white cell count (cells/μL)	48 [<5, 169]	113 [43, 268]	<5 [<5, 76]	< 0.001
QNPZ-8 score at 3-months		-1.18 [-2.10, -0.83]	-2.05 [-2.71, 0.75]	0.135[2]
QNPZ-8 score group				0.057[2]
>-1	31(33%)	15(38%)	16(30%)	
(-2, -1)	24(26%)	14(35%)	10(19%)	
<-2	38(41%)	11(28%)	27(51%)	

[1]Pearson's Chi-squared test; Wilcoxon rank sum test; Fisher's exact test
[2] Wilcoxon rank sum test; Pearson's Chi-squared test

Table 1. Baseline characteristics and neuro-cognitive outcomes of 93 adults with HIV-associated cryptococcal or tuberculous meningitis, stratified by CSF HIV viral escape status.

Conclusions: Amongst adults diagnosed with HIV-associated CM or TBM, baseline escape was associated with better neurocognitive outcomes at 3-months, suggesting that baseline escape is indicative of an effective immune response with the trafficking of HIV-containing CD4 lymphocytes and macrophages into the CSF.

EP0101

Genomic insights and treatment outcomes of Rifampicin-Resistant Tuberculosis in People Living with HIV in Botswana

T. Mogashoa[1,2], O.T. Choga[2,3], J. Loubser[1], J.T. Ngom[1], T. Makhondo[4], W.T. Choga[2,3], T. Molefi[4], R. Musonda[2], J.M. Makhema[2], S. Gaseitsiwe[2,5], R.M. Warren[1], S. Moyo[2,5,6], A. Dippenaar[7], E.M. Streicher[1]
[1]Stellenbosch University, Division of Molecular Biology & Human Genetics, Cape Town, South Africa, [2]Botswana Harvard Health Partnership, Research Laboratory, Gaborone, Botswana, [3]University of Botswana, Department of Medical Sciences, Gaborone, Botswana, [4]Botswana National Tuberculosis Program, Ministry of Health, Gaborone, Botswana, [5]Harvard T.H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [6]Stellenbosch University, Division of Medical Virology, Cape Town, South Africa, [7]University of Antwerp, Family Medicine and Population Health, Antwerp, Belgium

Background: Rifampicin-resistant tuberculosis (RR-TB) and HIV acquisition pose a significant public health challenge, particularly in high-burden settings like Botswana. This study aimed to evaluate treatment outcomes, characterize drug resistance profiles and associated drug-resistance mutations (DRM) among people living with HIV (PLWH) clinically diagnosed with RR-TB in Botswana.

Methods: The retrospective study analyzed 103 *Mycobacterium tuberculosis* (*M.tb*) isolates from PLWH clinically diagnosed with RR-TB between 2017 and 2023. *M.tb* genomic DNA was extracted using the Hexadecyltrimethylammonium bromide method, followed by library preparation with the Illumina DNA Prep kit and sequenced on the Illumina NextSeq 2000. *M.tb* lineages and drug resistance profiles were determined using TB-profiler pipeline.
Treatment outcomes, lineage proportions, drug resistance profiles and DRMs were analyzed with 95% confidence intervals (CI). Logistic regression models were used to identify predictive factors associated with unfavourable treatment outcomes.
Results: Among 103, 62% were male, and the median age was 41years (Q1,Q3: 32, 48). Among them, 78.6% (95% CI: 69.5–86.1) were new TB cases. Treatment outcomes were available for 98 individuals: 71.8% (95% CI: 62.1–80.3) were cured, 10.7% (95% CI: 5.5–18.3) died, and 1.9% (95% CI: 0.2–6.8) defaulted.
Whole genome sequencing revealed the following drug resistance profiles: Multi-drug resistant-TB (50.5%, 95% CI: 40.4–60.5), Pre-extensively drug-resistant (22.3%, 95% CI: 14.7–31.6), and Rifampicin mono-resistant (26.2%, 95% CI: 18.0–35.8). The most prevalent *M.tb* lineages were Lineage 4 (49.5%, 95% CI: 39.5–59.5) and Lineage 1 (32%, 95% CI: 23.2–42). Predominant DRMs for rifampicin, isoniazid and fluoroquinolones were *rpoB* S450L (19.4%), *katG* S315T (49.5%), and *gyrA* A90V (19.4%), respectively.
No mutations associated with bedaquiline or delamanid resistance were detected. Being a male (odds ratio (OR): 1.05, 95% CI:1.01-1.09, *p*-value=0.03), older (OR: 0.8, 95% CI:0.34-1.96, *p*-values=0.65) and having had previous TB treatment (OR: 0.50, 95% CI: 0.15-1.62, *p*-value=0.25) were not significantly associated with unfavourable treatment outcomes.
Conclusions: Although the study revealed high treatment success outcomes among PLWH in Botswana, a significant number of new cases. These findings underscore the need for strategies targeting the interruption of TB transmission. Further research with larger sample sizes is warranted to evaluate treatment outcomes and associated factors among PLWH.

EP0102

Prevalence and determinants of post-acute sequelae of SARS-CoV-2 (PASC) among people living with HIV in Rwanda: a cross-sectional study

F. Rwamwejo[1], G. Rukundo[2], V.U. Niyonkuru[1], C. Ruranga[3], E. Krebs[3], E. Remera[2]
[1]Rwanda Ministry of Health, Kigali, Rwanda, [2]Rwanda Biomedical Centre, Kigali, Rwanda, [3]University of Rwanda, Kigali, Rwanda

Background: People living with HIV (PLHIV) may have an increased risk of Post-Acute Sequelae of SARS-CoV-2 (PASC) due to immune dysfunction and chronic inflammation. This study investigated the prevalence and risk factors for PASC among individuals who had COVID-19 in Rwanda, with a specific focus on PLHIV, highlighting the role of comorbidities.

Methods: A cross-sectional study was conducted from August to October 2024, sampling 3,143 individuals from national COVID-19 registries. Eligible participants included those with a confirmed COVID-19 diagnosis and care-seeking behavior for COVID-19-related symptoms. Randomly screened individuals, such as those tested during mass screening campaigns without symptoms, were excluded. Data analysis involved descriptive statistics and multivariable logistic regression, with covariates adjusted and statistical significance set at $p < 0.05$.

Results: The study included 3,143 participants, comprising 1,265 males (40.2%) and 1,878 females (59.8%). Age distribution revealed that 30.4% were aged 18–34 years, 41.8% were aged 35–49 years, and 27.8% were aged 50 years or older. The prevalence of post-acute sequelae of COVID-19 (PASC) was 34.2% (1,076 participants) overall, with a higher prevalence of 36.8% (343 participants) among HIV-positive individuals. Predictors of PASC among PLHIV included hospitalization during their COVID-19 episode (AOR: 2.8, 95% CI: 1.5–5.9) and older age, particularly 35–49 years (AOR: 2.131, 95% CI: 1.428–3.21) and 50+ years (AOR: 1.748, 95% CI: 1.114–2.762). Education level was inversely associated with PASC, with lower odds observed among those completing secondary school (AOR: 0.392, 95% CI: 0.213–0.714, p=0.002) and university (AOR: 0.288, 95% CI: 0.152–0.539). In addition, the presence of hypertension as a comorbidity significantly increased the risk of PASC.

Conclusions: This study highlights the substantial burden of PASC in Rwanda, particularly among PLHIV, who accounted for 29.6% of our sample—significantly higher than the 3% prevalence in the general population.

This overrepresentation underscores the disproportionate impact of COVID-19 on PLHIV and emphasizes the urgent need for targeted interventions to address PASC in this population.

EP0103

The Incidence of anal pre-cancerous lesions is high in attendees of an anal cancer screening clinic in Vancouver, Canada: 2003-2021

R. Azmin[1], W. Zhang[2], M. Hedgcock[3,4], J. Li[2], V. Lima[2,5], P. Sereda[2], J. Toy[4,2], J. Trigg[2], T. Wasserfall[3,4], J. Montaner[2,5,4], T. Grennan[1,5,4]

[1]British Columbia Centre for Disease Control, HIV/STI Program - Clinical Prevention Services, Vancouver, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Spectrum Health, Vancouver, Canada, [4]St. Paul's Hospital, Vancouver, Canada, [5]University of British Columbia, Medicine, Vancouver, Canada

Background: In 2024, the first anal cancer screening guidelines were published, recommending yearly, age-based screening in key populations using cytology, HPV testing and high-resolution anoscopy (HRA), heavily focused on men who have sex with men (MSM) living with HIV. Despite this, there are no organized, public anal cancer screening programs in existence. In this study, we describe findings from Canada's largest anal cancer screening clinic over its nearly two decades of operation.

Methods: This is a retrospective cohort study of all individuals attending one of Canada's anal cancer screening clinics in Vancouver, Canada. Demographic and clinical data was analyzed using descriptive statistics, and logistic regression was used to examine predictors of histologic high-grade squamous intraepithelial lesion (HSIL), the precursor lesion to cancer.

Results: There were 1752 individuals seen between 02/2003-06/2021 included in the analysis. Median age at first visit was 48 years, and 83.4% were male; 59.0% of participants were living with HIV. The period prevalence of HSIL was 38.6%, yielding an incidence rate of 15.6 per 100-person years.

Of the 656 individuals ever diagnosed with HSIL, 443 (67.5%) were living with HIV. Being a male living with HIV was significantly associated with HSIL (odds ratio [OR] 2.2; 95% confidence interval [CI] 1.7-2.8).

A history of warts was predictive of HSIL and carcinoma *in situ* development (OR 1.7; 95%CI 1.4-2.1). A prior history of anal malignancy was highly associated with the development of both carcinoma *in situ* (OR 16.5; 95%CI 6.8-40.2) and invasive carcinoma (OR 9.9; 95%CI 2.3-42.8).

Conclusions: In this large cohort of anal cancer screening clients, over one third developed incident anal HSIL, with male sex and living with HIV being major risk factors. This is consistent with recently-published screening guidelines highlighting MSM with HIV as the highest risk group for anal cancer.

This study emphasizes the need for targeted anal cancer screening, particularly for higher-risk key populations including MSM living with HIV. It also highlights the importance of addressing the lack of widespread screening programs for early detection and management of anal HSIL, and the importance of close monitoring with HRA in those with previous anal cancer.

EP0104

Understanding the influence of Pre-Exposure Prophylaxis (PrEP) on the behavior changes and the escalation of Sexually Transmitted Infections (STIs): a survey analysis

R. Monton[1], H.R. Kihom[1], K.G. Garcia[1], V.G. Salvadora[1]

[1]Tropical Disease Foundation, Inc., HIV Program, City of Makati, Philippines, the

Background: The introduction of pre-exposure prophylaxis (PrEP) in the Philippines has effectively reduced HIV transmission, but its behavioral effects remain unclear. Research indicates that PrEP use may lead to risk compensation behaviors, such as reduced condom use and more sexual partners, potentially increasing sexually transmitted infection (STI) rates (Marcus et al., 2020; Traeger et al., 2019). The Department of Health's Epidemiology Bureau reports a 34% rise in syphilis cases and a 47% increase in Neisseria gonorrhoeae infections from 2021 to 2022.

This study examines behavioral shifts among PrEP users in Metro Manila and their correlation with STI trends, hypothesizing that PrEP use may contribute to higher STI incidence due to altered risk perceptions, thus requiring informed public health strategies.

Methods: This three-month study in Metro Manila used a qualitative online survey to ensure anonymity and accessibility. The target population included males who have sex with males (MSM) and transgender women, at higher risk for HIV and STIs.
Stratified random sampling ensured diverse age and socioeconomic representation. Data collected focused on sexual behaviors, PrEP usage, and STI history. Power analysis determined the sample size for statistically significant results.
Results: Among 278 respondents, 67% (n=187) acquired syphilis, 23% (n=65) Neisseria gonorrhoeae, and 9% (n=25) herpes simplex virus (HSV). Syphilis was most prevalent in those aged 18–25 (40%, n=75), followed by 26–35 (27%, n=50), and 36+ (15%, n=28). HSV was highest in the 18–25 group (5%, n=14). Transgender women represented 34% (n=94) of STI cases.
Additionally, 66% of respondents reported a reduced HIV risk perception after PrEP enrollment, leading to more unprotected sex. 34% believed contracting other STIs was acceptable, as they are treatable.
Conclusions: This study highlights a significant association between PrEP use and increased STI diagnoses, potentially linked to the rising syphilis and gonorrhea cases reported by the Department of Health.
Incorporating Behavior Change Communication (BCC) into PrEP programs is essential to promote safer practices, alongside STI education and routine screening. Targeted interventions for younger individuals and transgender women are crucial to balancing HIV prevention with sexual health education, informing public health policy to reduce STI risks within these vulnerable groups.

EP0105

Cytomegalovirus viraemia is strongly associated with 6-month mortality amongst adults living with advanced HIV disease: a prospective cohort study in South Africa

J. Ellis[1,2], N.P. Govender[3,4,5], M. Hsiao[4], T. Omar[3], C. Nel[3], A.H. Mazanderani[6,3], A.S. Karat[1], C.T. Tiemessen[6,3], T.S. Harrison[5,7,8], J.N. Jarvis[1], R.M. Wake[3,5]
[1]LSHTM, London, United Kingdom, [2]Infectious Diseases Institute, Kampala, Uganda, [3]University of the Witwatersrand, Johannesburg, South Africa, [4]University of Cape Town, Cape Townsouth, South Africa, [5]City St George's University of London, London, United Kingdom, [6]National Institute for Communicable Diseases, Johannesburg, South Africa, [7]University of Exeter, Exeter, United Kingdom, [8]St George's Hospital NHS Trust, London, United Kingdom

Background: Despite antiretroviral treatment (ART) adult outpatients living with advanced HIV disease have a high risk of death. We hypothesised that cytomegalovirus (CMV) viraemia may contribute to mortality.
Methods: A cohort study of adults with CD4 count <100 cells/mm^3 to ascertain 6-month survival and cause of death (minimally invasive autopsies). We measured baseline plasma CMV viral load (qPCR). We report on the prevalence of CMV viraemia, associations between co-variates and CMV viraemia status, and the relationship with 6-month mortality.
Results: Amongst 146 participants, 50% were male, median age 39 (IQR 33-48) years, median baseline CD4 count 31 (IQR 10-60) cells/ mm^3. At baseline, 20% (29/146) were receiving ART, 33% (48/146) were CrAg positive in blood; and 40% (59/146) had a past/current history of TB. Baseline CMV viraemia was detected in 59% (86/146), with a median viral load of 366 (IQR 171-1,187) IU/mL.
Participants with CMV viraemia had lower CD4 counts vs. those without CMV viraemia (26 vs. 38 cells/μL, p=0.03). There was no evidence that CMV viraemia was associated with cryptococcal antigenemia, cryptococcal meningitis, or TB disease.
Overall, 6-month mortality was 18% (26/146); mortality was significantly higher in those with CMV viraemia (26%), compared to those without (7%), p=0.01. Participants with CMV viraemia had greater than 4 times the odds of 6-month mortality (OR 4.81, 95%CI 1.56-14.8, p=0.006) compared to those without CMV viraemia.
After adjustment for age, sex, CD4 count, baseline ART status and CrAg status, CMV viraemia remained strongly associated with increased 6-month mortality (aOR 4.39, 95%CI 1.36-14.2, p=0.01). Minimally invasive autopsies were performed for six participants with CMV viraemia, showing confirmed CMV end-organ disease in two participants *(Table 1)*.

Baseline clinical details	CD4 cell count in cells/μL	Baseline CrAg status	ART status	Baseline CMV qPCR VL (IU/ml)	Time to death (days)	Histological evidence of CMV end organ disease at MIA	MIA evidence of co-prevalent AIDS defining illness
42M	19	Negative	ART naïve	311	24	CMV pneumonitis: Enlarged cell with CMV confirmed by immunohistochemistry (arrow). 	Pneumocystis pneumonia
25F	12	Positive	ART naïve	285,980	6	CMV pneumonitis: CMV inclusion body (arrow), CMV confirmed by immunohistochemistry (not shown). 	Kaposi's sarcoma
Abbreviations: CrAg = Cryptococcal antigen, ART = Anti-retroviral treatment, CMV = cytomegalovirus, qPCR = quantitative polymerase chain reaction, VL = viral load, MIA = minimally invasive autopsy.							

Table 1. Baseline demographics. clinical details and CMV testing results from two study participants who underwent minimally invasive autopsy (MIA) with confirmed CMV end organ disease.

Conclusions: CMV viremia represents a potentially modifiable risk factor amongst adult outpatients living with advanced HIV disease. A randomised trial of anti-CMV treatment to improve survival in this high-risk population is needed.

EP0106

Genetic insights into HIV-1 and risks of COVID-19 susceptibility, hospitalization and severity: a Mendelian randomisation study

X. Wu[1], Q. Liu[2], R. Sun[2], Y. Chen[2], Y. Zhan[2], H. Zou[1]
[1]Fudan University, Shanghai, China, [2]Sun Yat-sen University, Shenzhen, China

Background: Observational studies have suggested a potential association between HIV infection and the susceptibility and progress of COVID-19. However, the causal relationship remains unknown.
Our study aimed to explore the possible causal relationship between HIV-1 infection and risks of COVID-19 susceptibility, hospitalization, and severity, using the two-sample Mendelian randomization (MR) method.
Methods: Summary statistics from the genome-wide association studies (GWAS) of a meta-analysis of HIV-1 infection (7,303 cases and 587,343 controls) and the COVID-19 Host Genetics Initiative of European ancestry were used for analysis.
The primary approach employed was the random-effects inverse-variance weighted (IVW) estimation method, accompanied by several alternative estimators serving as supplementary methods.
Results: We selected 16 SNPs associated with HIV-1 infection as instrumental variables (IVs). IVW analysis indicated that genetically predicted HIV-1 infection was not significantly associated with COVID-19 susceptibility (OR 1.00, 95% CI 0.96-1.05; P value 0.865), hospitalization (0.98, 0.90-1.07; 0.687), and severity (1.00, 0.88-1.14; 0.994). Similarly, no significant association was observed in other models.
Conclusions: This study demonstrated that HIV-1 infection may not be causally associated with risks of COVID-19 susceptibility, hospitalization, or severity. Nevertheless, further research and interventions targeting this vulnerable population are still warranted to ensure positive health outcomes for PLHIV in the post-pandemic era.

EP0107

Syndromic vs etiologic management of vaginal discharge among sexually active young adult women in Kigali, Rwanda

M.A. Unyuzimana[1], G. Mpawenayo[1], D. Rusa Umutesi[1], P. Mukamusoni[1], C. Umuhoza[1], R. Ingabire[1], R. Parker[2], K. Wall[2], S. Allen[2], L. Rangira[3], L. E. Buzaalirwa[4], D. Nduduzo[5], C. Balibwira[6], E. Karita[1], J. Mutagisha Nyombayire[1]
[1]Center for Family Health Research, Kigali, Rwanda, [2]Rwanda Zambia Health Research Group/Emory University, Department of Pathology and Laboratory Medicine, Atlanta, United States, [3]AIDS Healthcare Foundation, Kigali, Rwanda, [4]AIDS Healthcare Foundation, Kampala, Uganda, [5]AIDS Healthcare Foundation, Manzani, Eswatini, [6]Georgetown University, Independent Contractor, Kigali, Rwanda

Background: Syndromic management of sexually transmitted infections (STIs) is widely recommended in resource-limited settings but often results in misdiagnosis and inappropriate therapy. The most recent guidelines introduced in July 2024 in Rwanda recommend empirical treatment for Neisseria Gonorrhoeae (NG), Chlamydia Trachomatis (CT), Trichomonas Vaginalis (TV) and Candida (CA) when women present with symptomatic vaginal discharge and presence of muco-purulent discharge from the cervix (cervicitis) on physical exam, and treatment for bacterial vaginosis (BV), TV and CA if there is no discharge from the cervix (vaginitis).
The present study was conducted to assess the accuracy of the syndromic management of vaginal discharge.
Methods: From 19 November 2024 to 31 December 2024, we enrolled 497 women with symptomatic vaginal discharge. An endocervical swab was sampled on women who were not menstruating. Microscopy was used to detect BV, TV and CA; point-of-care nucleic acid testing was used to detect NG and CT.
Results: Of the 497 women enrolled, 469 (94.4%) provided an endocervical swab, and 38 of these (8.1%) had cervicitis, while 431 (91.9%) had vaginitis. Overall, 388 women (82.7%) were diagnosed with at least one infection, including BV (65.0%); CA (29.6%); NG (25.4%); CT (18.6%); and TV (11.7%). Among the 38 women with cervicitis, 21.1% were co-infected with both NG and CT, 42.1% had not neither NG nor CT, and none had concomitant infection with NG, CT, TV and CA. Among the 431 women with vaginitis, 33.6% were diagnosed with either NG or CT, but only 1.2% were co-infected with BV, TV, and CA; 24.8% had none of these infections.
Conclusions: This study demonstrates a significant disconnect between syndromic and etiologic STI management. In 42.1% of cases of cervicitis, the syndromic approach may result in needless therapy for NG and CT. Likewise, in women with vaginitis, syndromic treatment overtreats about a quarter of women, and it fails to treat NG or CT in a third of them.
These results highlight the necessity of shifting to etiologic STI treatment under the guidance of diagnostic instruments such as point-of-care nucleic acid testing and microscopy.

EP0108

Prevalence of tuberculosis and rifampicin-resistant tuberculosis among clients with advanced HIV disease in Akwa Ibom State, Nigeria: a retrospective analysis

Background: Tuberculosis (TB) is the leading cause of morbidity and mortality among people living with HIV (PLHIV), accounting for one-third of all deaths. Advanced HIV disease (AHD) presents a heightened risk for opportunistic infections, including TB.

This PEPFAR-and USAID-funded Excellence Community Education Welfare Scheme (ECEWS)-led study aimed to analyze the prevalence of TB and rifampicin-resistant TB (RR-TB) among clients with AHD.

Methods: A retrospective analysis was conducted using program data from the electronic medical record in Akwa Ibom State, Nigeria, focusing on all newly diagnosed HIV-positive clients (TX_NEW) with AHD from January 2023 to August 2024. AHD was defined as HIV clients <5 years and HIV clients ≥5 years with World Health Organization (WHO) clinical stage 3 or 4 or a CD4 count of <200 cells/mm³. Client-level data included demographic information (age and sex), geographic data (rural and urban), WHO clinical staging, CD4 counts, and lateral flow lipoarabinomannan (LF-LAM) and GeneXpert test results. The prevalence of TB and RR-TB and their association with CD4 counts were analyzed using chi-square tests to assess statistical significance.

Results: In total, 3,287 individuals were diagnosed with AHD out of 14,762 TX_NEW clients, with a mean age of 32 years (±15.9 years); 64.8% (2,129/3,287) were female. Of these individuals, 11.7% (383/3,287) were children <5 years, 12.5% (412/3,287) were diagnosed with AHD based on WHO clinical staging, and 85.2% (2,802/3,287) were diagnosed using CD4 counts, of which 306/2,802 (10.9%) were children <15 years.

TB diagnostic tests were conducted on 77.9% (2,561/3,287) of individuals, and 30.4% (778/2,561) were diagnosed with TB. Urine LF-LAM identified 85.5% (665/778) of TB cases, while GeneXpert detected 14.5% (113/778), including 4.4% (34/778) with RR-TB. RR-TB was evenly distributed between males and females (50%, 17/34 each), predominantly found in individuals ages 35–49 (44.1%, 15/34, p <0.001), and rural facilities accounted for 94.1% (32/34, p <0.001) of cases. Among RR-TB cases, 91.2% (31/34) had CD4 counts <200 cells/mm³.

Conclusions: These findings highlight the burden of TB infection and RR-TB among clients with CD4 counts <200 cells/mm³ and emphasize the importance of integrating AHD screening and TB diagnostics for PLHIV.

Uni, United States

Background: The timely diagnosis and treatment of opportunistic infections (OIs) is crucial for the survival of people with advanced HIV disease (AHD) and is an essential aspect of the recommended care package. We implemented an intervention with an AHD care package in five health districts of Côte d'Ivoire.

This abstract reports on the most common OIs diagnosed among clients with AHD.

Description: From September 2023 to August 2024, an AHD care package (i.e., CD4 staging, screening, diagnosis and treatment of opportunistic infections, prophylaxis and preventive treatment) was provided in 30 healthcare centers based on a hub and spoke model. Eligible clients were newly admitted to care, returning to care, and in therapeutic failure. The quasi-experimental study compared data from the pre- and post-intervention periods (socio-demographic, clinical, and biological). Data were extracted from clients' files and captured in a database. A descriptive analysis was completed with frequencies and proportions using post-intervention period data (September 2023 to February 2024).

Lessons learned: Overall, 789 (35.3%) of the 2,235 eligible clients were diagnosed with AHD, the majority of whom were newly admitted (n=595; 74.7%) and female (n=490; 62.1%). There were 375 (45.7%) clients diagnosed with at least one opportunistic infection (OI). A total of 729 (92.3%) AHD clients were screened for tuberculosis and 283 (35.9.%) were diagnosed, including 169 females (59.7%); 39 (10.4%) AHD clients had oral candidiasis. Screening for neurological symptoms was systematically completed among 724 (91.8%) clients, with 17 neuro-abnormal results (2.3%) (mental deficiencies, focal neurological deficits, convulsions, and cranial neuropathies). Sixteen clients (2.0%) were positive for cryptococcal antigen test, with 1 (0.1%) diagnosis confirmed and treated for cryptococcal meningitis. Fourteen clients (1.8%) who had neurological symptoms and no evidence of cryptococcal disease or tuberculosis meningitis were empirically initiated on toxoplasmosis treatment and responded well, leading to a diagnosis of cerebral toxoplasmosis.

Conclusions/Next steps: Tuberculosis remains the most prevalent opportunistic infection among AHD clients. Toxoplasmosis was surprisingly more frequent than cryptococcosis, and had the potential for under-diagnosis. Our findings highlight the importance of screening and diagnosis of OIs among AHD clients. There is a need to strengthen laboratory services to optimize the care of this population.

HPV prevalence among HIV cohorts in Nairobi and Kajiado Counties of Kenya: a retrospective data review from October 2023 to November 2024

E.M. Okapesi[1], J. Juma[1], A. Morwabe[1], A. Anami[1], B. Muge[1], K. Otieno[1], P. Shikuku[1], J. Mecha[1], E. Kubo[2], C. Odhiambo[2], G. Ruttoh[2], S. Arodi[2], R. Marima[2], F. Otieno[1]
[1]University of Nairobi, Clinical Medicine & Therapeutics, Nairobi, Kenya, [2]University of Nairobi-Fahari ya Jamii, Nairobi, Kenya

Background: Sub-Saharan Africa is increasingly bearing the brunt of Human Papilloma Virus/ Human Immunodeficiency virus (HPV/HIV) co-infection. In Kenya, Cancer is the third leading cause of death after infectious and cardiovascular diseases. Cervical cancer which is caused by HPV infection and breast cancer are the two leading causes of cancer related deaths.
We aimed to investigate the prevalence and distribution of HPV among HIV positive female population in Nairobi and Kajiado Counties of Kenya from October 2023 to November 2024.
Methods: A cross-sectional study that included HIV- Positive females aged 18-73 years. The study involved analyzing HPV and HIV viral load data from the National AIDS Control Program's (NASCOP) Early Infant Diagnosis/Viral Load testing database. Excel was used for data retrieval and Python program for performing analysis of variance using (95%CI, p=0.05). Results were visualized using bar graphs and box plots.
Results: A total of 3816 records were sampled. The overall HPV prevalence was 39.84%; other high risk HPV variants most prevalent in the two counties (31.78%), HPV16 (8.93%) and HPV18 (7.50%). The HPV positivity rate was about 0.68% aged (in years) (18-20), 0.41% aged (21-30), 0.40% aged (31-40), 0.39% aged (41-50), 0.395% aged (51-60), 0.397 aged (61-70) and 0.68 aged 71 and above.
Kajiado County registered a higher prevalence of HPV16 (12.57%) & HPV18 (8.68%) than Nairobi; HPV16 (8.62%) and HPV18 (7.55%). The positivity rates within 18-20 years and 70+ age brackets were higher compared to age groups from 21-70.
There was a persistent HPV prevalence above the age of 70. This may have resulted from inadequate clearance of the HPV from the body even as these clients advance in age. HPV prevalence in Kajiado County was higher compared to Nairobi, though the number of samples screened was lower than those in Nairobi.
Conclusions: There is a need to scale up screening among HIV positive and negative female populations and to have follow-up of clients that turn positive for HPV 16/18/ and other high-risk strains. We propose additional studies to determine the time period and factors that lead to viral clearance and complete recovery.

HIV serostatus and uptake of cervical cancer screening among women in Uganda. A cross-sectional survey

I. Muwonge[1], A. Ssetaala[1], A. Nanvubya[1], N. Kyakuwa[1], M. Wambuzi[1], G. Nanyonjo[1], B. Oketch[1], E. De Paepe[2], H. Vermandere[2], O. Degomme[2]
[1]Uganda Virus Research Institute-International Aids Vaccine Initiative Program, Community Studies Department, Kampala, Uganda, [2]Ghent University, Department of Public Health, Ghent, Belgium

Background: Cervical cancer (CC) is the most prevalent cancer among women in Uganda. Early screening is key for prompt management. Screening is often through visual inspection with acetic acid for HIV-negative women and Human Papillomavirus (HPV) DNA testing for HIV-positive women, through the President's Emergency Plan for AIDS Relief (PEPFAR) program.
We explored the relationship between HIV serostatus and the uptake of CC screening among women in Mukono and Wakiso districts, Uganda.
Methods: This cross-sectional survey involved 600 women aged 25-65 years, randomly selected during 08th January and 15th December 2024. An interviewer-administered questionnaire was used to collect data on demographics, HIV status, knowledge, and history of CC screening after informed consent. Multivariable logistic regression was done to establish significant factors.
Results: The mean age was 40 years, with the majority being self-employed (68.8%,413) and living in rural areas (58%, 348). Over half were married (57.8%,347) and of low economic status (61%,366).
Almost all had heard of CC screening (94.7%,568), and nearly one in four had been screened (22.3%,134). One in ten were HIV infected (9.5%,57). Seven in ten HIV-positive women had ever been screened, while only nearly two in ten HIV-negative women had ever been screened.
Uptake of CC screening was associated with increasing age [AOR 1.0, 95% CI (1.0-1.1)], secondary education [AOR 3.1, 95%CI (1.5-6.4], tertiary education [AOR 6.0, 95%CI (2.3-15.4)], knowing someone who has gone for screening [AOR 2.0, 95%CI (1.2-3.3)] and awareness of where to go for screening [AOR 2.7, 95%CI (1.0-7.3)] and being HIV infected ([AOR 13.5, 95%CI (6.5-27.7)].
