Conclusions: The low screening uptake among HIV-negative women impacts efforts to eliminate CC by 2030. Emphasis on universal screening and tackling systemic barriers to healthcare access for all women, irrespective of HIV status is key to CC elimination.

EP0112

Implementation of urine-based HR-HPV testing for cervical cancer prevention in a rural clinic in Eswatini

V. Msibi[1], T. Motsa[1], B.A. Nhleko[1], C. Fappani[2], S. Villa[3], M. Gori[2], S.L. Baldi[4], P. Angelone[4], X. Dlamini[5], G. Maphalala[5], G. Buthelezi[5], E. Valentini[6], N.R. Niemann[6], B. Khumalo[6], A. Amendola[2], F. Tediosi[4], M. Sikhondze[1], E. Tanzi[2], M.C.B. Raviglione[4]

[1]Cabrini Ministries eSwatini, St. Philips Mission, Ngcamphalala, Eswatini, [2]Università degli Studi di Milano, Department of Health Sciences, Milan, Italy, [3]Università degli Studi di Milano, Department of Biomedical Sciences for Health, Milan, Italy, [4]Università degli Studi di Milano, Centre for Multidisciplinary Research in Health Science (MACH), Milan, Italy, [5]Ministry of Health, Eswatini Government, Manzini, Eswatini, [6]Cabrini Ministries, Ngcamphalala, Eswatini

Background: Cervical cancer (CC) is a major public health issue in Eswatini. Socio-cultural, economic, and policy barriers restrict women's access to screening and preventive services, leading to late diagnoses and high mortality rates. This is exacerbated by the high prevalence of HIV (28% among adults), which increases susceptibility to high-risk human papillomavirus (HR-HPV) infections and CC development.

Our project aims to implement a "screen, triage and treat" prevention programme introducing a non-invasive urine-based HR-HPV testing at St. Philip's Clinic, a rural primary care centre in Eswatini.

Methods: During the 12-month pilot phase (January 2023-February 2024), 508 adolescent girls and women (ages 13–49) were offered and consented to screening by providing a urine sample. After concentration through centrifugation, 1mL of urine sample was tested via Xpert® HPV test (Cepheid) for HR-HPV detection.

Sociodemographic data and HIV status were collected via REDCap. HR-HPV-positive women underwent further assessment with visual inspection with acetic acid (VIA) and treatment, if necessary.

Results: 454 out of 508 participants obtained conclusive Xpert® HPV results. Notably, 228 (45%) women were CC screened for the first time in this program. 189 women tested positive for HR-HPV (41.6%) (median age 27). Among HR-HPV-positive women, 51% were women living with HIV (WLHIV), which showed a 1.9 times increased risk of being HR-HPV positive compared to HIV-negative girls and women (95%IC 1.3-2.7).

VIA was performed in 93 women, with pre-cancerous lesions found in 4. Treatment was performed locally through thermocoagulation or at nearby clinics by loop electrosurgical excision procedure. 96 HR-HPV-positive women were considered lost at triage.

Conclusions: Our project revealed a high prevalence of HR-HPV among Swazi women highlighting the urgency for improved access to effective, rapid, and acceptable screening tools, especially for younger and WLHIV, who face heightened risk due to immunosuppression. Urine-based HR-HPV testing in rural settings appears feasible and acceptable, potentially increasing adherence to screening. Challenges such as inconclusive results and loss at triage highlight the importance of strengthening community engagement, enhancing linkage to care, and integrating CC prevention into routine HIV services. Addressing these gaps could significantly reduce CC burden, offering a scalable model for other high-burden, resource-limited settings.

EP0113

Mortality and causes of death among antiretroviral-therapy naïve adults undergoing systematic screening for intensified tuberculosis case-finding and tuberculosis preventive therapy in Uganda

F. Nangobi[1], S. Makumbi[1], L. Chaisson[2], D. Dowdy[3], P. Phillips[2], B. Opiira[1], M. Kamya[1,4], F.C. Semitala[1,4,5], C. Yoon[2]

[1]Infectious Diseases Research Institute, Kampala, Uganda, [2]University of California San Francisco, Division of Pulmonary and Critical Care Medicine, San Francisco, United States, [3]Johns Hopkins University, Departments of Epidemiology, International Health, and Medicine, Baltimore, United States, [4]Makerere University College of Health Sciences, Department of Medicine, Kampala, Uganda, [5]Makerere University Joint AIDs Program, Kampala, Uganda

Background: In Africa, early mortality after ART initiation is high (8-26% at 12-months post-ART initiation), with tuberculosis (TB) accounting for >50% of all deaths. Although intensified case-finding (ICF) and TB preventive treatment (TPT) improves HIV outcomes, implementation has been suboptimal. We evaluated mortality post-ART initiation and causes death among PWH in the context of rigorous TB screening.

Methods: From 11/2020-01/2023, we enrolled consecutive adults initiating ART from four clinics in Uganda in a trial comparing different WHO-recommended TB screening strategies (NCT04557176).

All participants underwent baseline systematic TB screening and ICF (confirmatory testing if screen-positive) or assessment for TPT eligibility (if screen-negative) and followed participants for 2 years.

Decisions to initiate TB treatment or TPT for any participant (regardless of screening result) were made by routine clinicians based on test results and clinical assessment. For participants who died, we describe clinical characteristics and cause(s) of death.

Results: Of 1,719 total participants, 75 (4%) deaths were recorded during 3,318 person-years of follow-up for a 2-year mortality rate of 2.3 per 100-person years (95%CI: 1.80-2.83). Median time-to-death was 83 days (95%CI: 23-316). Of those who died, 64/75 (85%) screened-positive for TB at enrollment, 28 (37%) had prevalent TB, and 10 (13%) received TPT. Active TB was identified as a major cause of death for 29/75 (39%) participants, of whom five deaths (7% of all deaths) were attributed to incident TB, one of whom received TPT. Other common causes of death included non-TB AIDS-related conditions (18/75, 24%) and TB drug-related hepatotoxicity (12/75, 16%), including two deaths (3% of all deaths) attributed to TPT.

A. Demographic and clinical characteristics	Died (n=75)
Female sex	31 (41%)
Age (median years, [IQR])	37 (32-44)
Pre-ART CD4 count (median cells/uL, [IQR])	73 (24-228)
TB screen positive	64 (85%)
Prevalent TB	27 (36%)
Urine LAM- or sputum Xpert Ultra-positive	18/27 (67%)
Received TPT	10 (13%)
B. Causes of mortality[1]	
Active TB	29 (39%)
Prevalent TB	24 (32%)
Incident TB	5 (7%)
TB drug-related hepatotoxicity	12 (16%)
TB treatment-related	10 (13%)
TPT-related	2 (3%)
Non-TB AIDS-related conditions[2]	18 (20%)
Non-AIDS-related infections	8 (11%)
Non-communicable disease	9 (12%)
Unknown	13 (17%)

[1]Other causes of death include trauma (6, 8%) and pregnancy-related deaths (2, 3%). [2]Includes AIDS-related opportunistic infections, malignancies, and IRIS.

Conclusions: Both mortality and the proportion of deaths due to TB among PWH undergoing rigorous screening for ICF and TPT eligibility were lower than prior estimates. Nonetheless, TB remained the leading cause of death; improved TB diagnostics and closer treatment (including TPT) monitoring are needed.

EP0114

The prevalence of oral HPV and oral lesions in people living with HIV in HIV primary care clinics

C. Firnhaber[1,2], B. Crouse[3], O. Abuzaineh[2], B. Thomas[2], D. Taylor[2], H. Kostoff[2], S. Chandler[4], D. Tessmann[3], A. Giuliano[5]

[1]University of Colorado, Division of Infectious Disease, Denver, United States, [2]Vivent Health, Denver, United States, [3]Vivent Health, Milwaukee, United States, [4]Vivent Health, St Louis, United States, [5]Moffitt Cancer Center, Tampa, United States

Background: People living with the Human Immunodeficiency Virus (PLWH) are at increased risk of oropharyngeal cancer. The Human Papillomavirus (HPV) is a risk factor for this cancer and PLWH have a higher prevalence of oral HPV. The presence of oral lesions and associated risk factors needs further evaluation.

Methods: This study was conducted at three HIV clinics in Denver, CO, Milwaukee, WI and St Louis, MO. Eligibility criteria included PWLH who had a CD4 count above 200 cells/mm³, at least two clinical visits, and no history of oral cancer. An oral sample was provided by rinsing using alcohol-based mouthwash and analyzed using the DDL SPF10 LiPA assay for 13 high-risk (hr)HPV types. Head/neck exams were performed by the clinic dentist. Demographics, HIV viral load, CD4 count, smoking, oral hygiene, alcohol use, HPV vaccine status, genital dysplasia and sexual history from medical records were described.

Results: The study enrolled 301 participants (Denver: n=273; Milwaukee: n=27; St. Louis: n=1). Median age was 49 years and 93% of participants were male. HIV viral suppression (<200 copies/ml) was 98.3% and 80% had CD4 > 500 cells/mm³. Participants identified as Caucasian (72%), African American/Black (19%), and as Latino/Hispanic (19%). HPV was detected in 34% of the participants, 9.3% had hrHPV and three had type 16.

Of the 290 participants who underwent head and neck exams, 26 had physical findings or concerning symptoms and six had clinical lesions and/or symptoms requiring follow-up. Three with hrHPV had visible lesions.

Of the 28 participants with oral hrHPV, 15 (53.6%) had a history of anal and/or cervical dysplasia and 25% had history of any type of HPV vaccine. HrHPV types were found in PLWH engaging in oral sex (9%), a >20 pack-year smoking history (10%), and alcohol consumption of three or more drinks a day (7%).

Conclusions: This is one of the few studies done in a primary health care clinic which includes HPV typing, genital health, HPV vaccine information, sexual and substance use with oral exams and oral lesions. Improving access and following comprehensive oral exams should be considered part of the primary care of PLWH.

EP0115

Integrated CECAP and ART services increase access to cervical cancer screening for women living with HIV at health facilities in Malawi

G. Kang'oma[1], F. Tembo[1], B. Kachombo[1], T. Tembo[1], E. Wetzel[1,2], B. Sibale[3], K.R. Simon[1,4], C.M. Cox[1,4]

[1]Baylor College of Medicine Children's Foundation Malawi, Lilongwe, Malawi, [2]Baylor College of Medicine, Houston, United States, [3]Ministry of Health, Reproductive Health Directorate, Lilongwe, Malawi, [4]Baylor College of Medicine, Department of Pediatrics, Houston, United States

Background: Malawi has amongst the world's highest cervical cancer incidence and mortality; cervical cancer accounted for 37% of all new cancer diagnoses in Malawian women in 2020. Women living with HIV (WLHIV) have six times increased risk of developing cervical cancer. Screening and early treatment can prevent cervical cancer, and Malawi National cervical cancer prevention (CECAP) guidelines recommend CECAP screening for women 25-49 years, but CECAP screening services are limited. We scaled up support to CECAP screening and treatment services through intensive programmatic support at health facilities (HF) supported by Baylor College of Medicine Children's Foundation Malawi Tingathe program to increase access to CECAP services in 5 supported districts.

Methods: We describe the expansion of CECAP programming from 25 to 69 HF between 2023 and 2024. HFs with large cohorts of WLHIV and two trained CECAP providers were identified and selected for intensified support. At HF level engagement sessions, barriers to CECAP provision were identified and addressed including procurement of needed supplies; implementation of integrated demand creation, linkage and referral systems; and establishment of reporting and HF screening targets. Ministry of Health

district CECAP coordinators conducted routine supportive supervision and mentorship to all HFs, and Tingathe CECAP nurses provided additional support to new HFs. Routine Tingathe CECAP program reports from April 2023 to March 2024 were analyzed.

Results: From April-September 2023, 15359 women completed CECAP screening. In Oct 2023, the 44 additional HF were engaged. Between October 2023-March 2024, 17510 women were screened, 14% (n=2151) increase. Newly introduced sites (n=44) contributed 3253 (19%) of women screened post-expansion. Rates of identified VIA+ lesions were unchanged pre- and post-intervention at 2.4% and 2.5% respectively. Same day treatment linkage for women with treatment-eligible lesions remained high pre- and post-intervention at 98% (321/327) and 96% (364/379). Throughout, tracing and follow-up for untreated women was ongoing, and women with treatment ineligible lesions were referred for specialist consultation.

Conclusions: Expansion of integrated CECAP and ART services with targeted mentorship, supervision, and engagement can quickly identify and address CECAP service provision gaps to optimize systems, fully engage available human resources and deliver lifesaving CECAP services.

EP0116

High risk human papillomavirus genotypes from anal canal in men who have sex with men living with HIV and associated factors for anal acquisition (GAIA Study)

B.C. Gónzalez-Contreras[1], K.D. Morales-Méndez[1], H. Santillán-Jiménez[1], P.E. Padilla-Noguera[2], J.A. Mata-Marín[3], S. Triana-González[3], A.L. Cano-Díaz[3], G. Barriga-Angulo[3], J.V. Noyola-Gómez[3], A. Chaparro-Sánchez[3], J.E. Gaytán-Martínez[3]

[1]Universidad Autónoma Metropolitana, Mexico City, Mexico, [2]Universidad Nacional Autónoma de México, Mexico City, Mexico, [3]Instituto Mexicano del Seguro Social, Mexico City, Mexico

Background: To determine the prevalence and associated factors for anal high-risk HPV acquisition in men who have sex with men living with HIV (MLH).

Methods: A cross-sectional study was conducted in the Hospital de Infectología, "La Raza" National Medical Center on MLH over 18 years old from January to July 2024. Sociodemographic, clinical and laboratory data was collected, including HPV vaccination history; detection and genotyping were performed from anal swabs using multiplex real-time PCR to identify twenty-eight HPV genotypes.

Results: 200 MLH were included, with a median age of 29 years old (IQR 25-36) and a median age for first sexual contact of 17 years old (IQR 16-19). 127 MLH (63.5%) were on an INSTI-based regimen, 68 (34%) were on a PI-based regimen and 5 (2.5%) were on a NNRTI-based regimen. Regarding HPV vaccination, 67 (33.5%) reported having received at least one dose and only 4.5% had the recommended 3 doses. 180 (90%) MLH tested positive for HPV, of which 155 (77.5%) had at least one high-risk genotype. The most frequent high-risk genotypes were GT16 in 43 (21.5%), GT18 in 34 (17%) and GT53 in 32 (16%). No associations were identified between high-risk genotypes and epidemiological factors, sexual behaviors, or rutinary studies. However, INSTI-based regimens were associated with a protective effect for GT16 OR 0.45 (95%CI 0.23-0.91, P=0.024) and for GT33 OR 0.29 (95%CI 0.094-0.90, P=0.041). On the other hand, PI-based regimen showed an association with HPV acquisition, specifically for GT16 OR 2.6 (95%CI 1.3-5.3, P=0.004) and for GT35 OR 2.5 (95%CI 1.0-6.38, P=0.048).

Genotype	Frequency (%)
GT16	43 (21.5)
GT18	34 (17)
GT51	32 (16)
GT53	32 (16)
GT39	31 (15.5)
GT58	29 (14.5)
GT66	28 (14)
GT56	27 (13.5)
GT59	24 (12)
GT68	21 (10.5)
GT35	20 (10)
GT31	17 (8.5)
GT73	17 (8.5)
GT52	16 (8)
GT33	14 (7)
GT69	14 (7)
GT45	13 (6.5)
GT82	10 (5)
GT26	1 (0.5)

Table 1. High Risk HPV Genotypes.

Conclusions: People living with HIV are at high risk for anal acquisition of malignancy-associated HPV genotypes; INSTI-based regimen had protective effect for GT16 and GT 33, in contrast PI-based regimen was found to be associated with GT16 and GT35.

EP0117

Prevalence and molecular characteristics of chlamydia and gonorrhea infections in a cohort of Kenyan female sex workers

C. Klenke[1,2], V. Schulz[2], P. Adams[2], I. Martin[2], S. Gibbons[2], K. Belindah[1,3], F. Owino[1,3], E. Irungu[3], M. Okumu[3], M. Kungu[3], R. Kabuti[3], J. Kimani[1,3,4], L. McKinnon[1,4], A. Sivro[1,2,5]

[1]University of Manitoba, Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [2]Public Health Agency of Canada, National Microbiology Lab Branch, Winnipeg, Canada, [3]Partners for Health and Development in Africa, Nairobi, Kenya, [4]University of Nairobi, Medical Microbiology, Nairobi, Kenya, [5]University of KwaZulu-Natal, Medical Microbiology, Durban, South Africa

Background: In Kenya, sexually transmitted infection (STI) management is symptom based, and as a result, the current prevalence and incidence of chlamydia and gonorrhea infections are not known. In addition, the distribution of circulating strains and antibiotic resistance remain poorly characterized.

Methods: This project aims to characterize chlamydia and gonorrhea prevalence and characteristics in a cohort of Kenyan female sex workers. Participants were recruited through the Sex Worker Outreach Program (SWOP) based in Nairobi, Kenya as part of an ongoing HPV study. Urine

and cervicovaginal samples were collected bi-monthly over 12 months. STIs were diagnosed by GeneXpert at screening, while confirmatory tests and longitudinal testing were performed using rRNA amplification with the Hologic Aptima Combo 2 assay. Chlamydia-positive samples were genotyped by Sanger sequencing of the ompA gene, which can differentiate between all 19 chlamydia serovars. Gonorrhea-positive samples were typed by *Neisseria gonorrhoeae* Multi-Antigen Sequence Typing (NG-MAST), targeting the porB and tbpB genes, and then tested by RT-PCR to predict resistance to cephalosporins, ciprofloxacin, and azithromycin.

Results: 1868 sex workers were screened for the study, and 701 HPV positive women were enrolled. Participants had a median age of 31 (IQR: 25-37), were 94% cis-women, 13% HIV-positive, and 71% reported condom use during most recent intercourse. Based on sample availability, 376 participants were selected for longitudinal STI testing at enrollment, month-4, 8 and 12.

Results from enrollment and month 4 visit show chlamydia prevalence of 9.8% (95% CI 7.0-13.5) and 15.4% (95% CI 10.0-23.0), and gonorrhea prevalence of 3.7% (95% CI 2.1-6.3) and 4.3% (95% CI 1.8-9.6), respectively. Chlamydia typing revealed serovars D (13.0%), E (16.5%), F (26.1%), G (22.6%), I (11.3%), J (0.9%) and K (9.6%). Gonorrhea testing identified all new NG-MAST sequence types with high ciprofloxacin resistance (92%). Testing and characterization of the follow-up samples are ongoing.

Conclusions: The prevalence of chlamydia and gonorrhea in this population was higher than the overall estimates for the African region. A diverse assortment of chlamydia and gonorrhea types is evident.

Further identification of bacterial types and antimicrobial resistance in this cohort will impact Kenyan STI prevention and treatment policies, contributing to global STI control.

EP0118

Immune subphenotypes associated with 30-day mortality in adults living with advanced HIV and hospitalized with sepsis in Uganda

L. Edwards[1], S.T. Jacob[2], A. Majwala[3], P. Banura[4], J.M. Sturek[5], E. Otoupalova[6], C.C. Moore[7]
[1]Stanford University, Department of Engineering, Stanford, United States, [2]Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom, [3]Lubaga Hospital, Department of Medicine, Kampala, Uganda, [4]Ministry of Health Uganda, Kampala, Uganda, [5]University of Virginia, Division of Pulmonology and Critical Care Medicine, Department of Medicine, Charlottesville, United States, [6]Tulane University School of Medicine, Division of Pulmonology and Critical Care Medicine, Department of Medicine, New Orleans, United States, [7]University of Virginia, Division of Infectious Diseases and International Health, Department of Medicine, Charlottesville, United States

Background: Immune subphenotype data from adults with sepsis and HIV in Africa are limited. While excessive inflammation is detrimental, natural antibodies (NAbs), particularly IgM NAbs, may limit inflammation. We determined associations between cytokines, NAbs, and outcomes in adults hospitalized with sepsis and living with HIV (LWH) in Uganda.

Methods: Among adult participants LWH who were hospitalized with sepsis and enrolled in a fluid resusciation study at two referral hospitals in Uganda, we collected serum samples to characterize immune phenotypes through measurement of 17 cytokines and 6 NAbs plus total IgA, IgM, and IgG. We determined associations between clinical parameters, including the Universal Vital Assessment (UVA) mortality risk score, and 30-day mortality, tuberculosis (TB), and bloodstream infection (BSI) using multivariable logistic regression and principal component analysis (PCA).

Results: Of 175 participants, 101 (58%) were female. Median (IQR) age was 35 (28-40) years and CD4+ T-cell concentration was 37 (11-111) cells/μL. In univariate analysis, IL-6, IL-8, and MIP-1β were associated with increased 30-day mortality ($p<0.05$); anti-ApoB100-IC IgM and anti-P1 IgM were associated with decreased 30-day mortality ($p<0.05$). PCA identified a cluster of IL-6, IL-8, MCP-1, IL-1β, and GM-CSF as most associated with 30-day mortality; and a cluster of anti-ApoB100 IC IgA, total IgM, and total IgA antibodies that was associated with 30-day survival.

Adding IL-8 to the UVA score increased its AUC from 0.58 (95%CI 0.45-0.66) to 0.71 (95%CI 0.62-0.80). A clinical and immune-based logistic regression model that included IL-8, IL-10, MIP-1β, anti-ApoB100 IC IgM, anti-P1 IgM, and blood lactate predicted 30-day mortality with an AUC of 0.79 (95%CI 0.71-0.87).

Logistic regression models that either included IL-8, IL-10, TNF-α, CD4, and blood lactate, or IL-8, TNF-α, IL-6, IL-10, CD4, blood lactate, and UVA score predicted TB and BSI with AUCs of 0.64 (95%CI 0.45-0.75) and 0.66 (95%CI 0.52-0.77), respectively.

Conclusions: In adults LWH and hospitalized with sepsis, we found a positive correlation between mortality, TB, and BSI and a subphenotype comprising pro-inflammatory cytokines; whereas, a subphenotype comprising IgM NAbs was inversely correlated with mortality. Cytokines improved the ability of UVA score to predict sepsis outcomes.

EP0119

Identifying sexually transmitted infections (STIs): the added value of extragenital gonorrhea and chlamydia testing beyond urogenital screening in sexual minority men (SMM) with HIV

H. Jimenez[1,2], S. Mostafa[3], Y. Beche[3], S. Bahnasy[3], J.S. Suh[2,4]
[1]Rutgers University, Pharmacy Practice and Administration, Piscataway, United States, [2]St. Joseph's University Medical Center, Paterson, United States, [3]Rutgers University, Piscataway, United States, [4]Hackensack Meridian School of Medicine, Nutley, United States

Background: The standard of care for diagnosing *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoeae* (NG), urogenital nucleic acid amplification tests (NAATs), has been found to miss infections in extragenital sites. The objective of this study was to evaluate the benefit of the

testing extragenital sites in sexual minority men (SMM) at a clinic for persons with HIV in a marginalized community in the United States.

Methods: This retrospective cohort study examined electronic health records from an HIV clinic within an academic health system from January 1, 2023, to July 1, 2024. Inclusion criteria for this analysis were: at least 18 years of age, cisgender males and transgender women who self-reported sexual contact with male partners that had a rectal, pharyngeal, and rectal CT/NG NAAT performed. The primary endpoint was to compare urogenital and extragenital testing sites in detecting gonorrhea or chlamydia in sexual minority men at our clinic. Variables analyzed will include the impact of age, race/ethnicity, sex assigned at birth, sexual orientation, use of pre- or post-exposure prophylaxis for prevention of Sexually Transmitted Infections (STIs), condom use, and number of partners on test outcome.

Results: We evaluated 672 specimen samples from 112 individual visits where urogenital, rectal, and pharyngeal sites were tested for CT/NG. The mean age of subjects was 34.8 yo. Hispanic individuals made up 79% of the cohort, with those who identify as Black representing 9.5% of cohort. The median number of lifetime partners was 5. Positivity rates were: overall 9.97% (4.17% CT, 5.8% NG); urogenital 3.57% (0.893% CT, 2.68% NG); rectal 16.5% (9.82% CT, 6.70% NG) and pharyngeal 9.82% (1.79% CT and 8.04% NG). In 82% (37/45) of the cases, a positive CT or NG was detected in either a rectal or pharyngeal test with the urogenital site specimen testing negative, 92.6% (25/27) and 66.% (12/18) of CT and NG diagnoses, respectively.

Conclusions: This retrospective study emphasizes the critical role of rectal and pharyngeal testing in detecting sexually transmitted infections (STIs) among sexual minority men (SMM) with HIV. Expanding extragenital testing protocols can improve detection rates, facilitate timely treatment, and ultimately enhance health outcomes for SMM.

EP0120

Hepatitis B surface antigen positivity and associated factors among people living with HIV accessing care at antiretroviral therapy clinics, Andhra Pradesh, India, 2024

M. Thogarucheeti[1], S. Attada[1], N. Surapaneni[2], K. Prasad[1], R. Allam[3], N. Chava[1], R. Agarwal[4], G. Ramesam[5], R. Praveen[5], P. Ajit[5], J. Kurada[5], V. Yeldandi[5], P. Turaka[5], P. Rajendra Prasad[5], S. Chakravarthy[1], P. Nadol[3], C. Das[6]

[1]Andhra Pradesh State AIDS Control Society, Vijayawada, India, [2]Viral Hepatitis Control Program, Vijayawada, India, [3]U.S Centres for Disease Control and Prevention, DGHT, Delhi, India, [4]WHO, Division of HIV, Hepatitis and STI, Delhi, India, [5]Society for Health Allied Research & Education India, Hyderabad, India, [6]National AIDS Control Organization, Delhi, India

Background: People living with HIV (PLHIV) have a higher burden of hepatitis B virus (HBV) due to shared routes and risk factors for transmission. Globally the prevalence of HBV infection among PLHIV is estimated at 7.4%. In India, most (>90%) PLHIV access antiretroviral therapy (ART) care in public sector. We analysed the Hepatitis B Surface Antigen (HBsAg) positivity and associated risk factors among PLHIV accessing HIV care in public sector.

Methods: Data from an observational cohort of a network of 53 ART clinics in Andhra Pradesh (AP) state was analysed. During November 2021-Novemebr 2024, HBsAg screening was integrated as a part of routine care and those negative for HBsAg were offered HBV vaccination. We extracted routine program data from the electronic database containing demographic, laboratory and clinical information. We calculated the HBsAg positivity and included the factors s with biological plausibility and $p<0.1$ in the multivariable model to determine the adjusted odds ratios (AOR) and calculated the 95% confidence interval (CI).

Results: We screened 223,892 PLHIV on ART for HBsAg. The median age was 43 years (IQR: 36-50), 54.5% were females and 14.5% were ART experienced. Overall, 3,804 (1.7%) were HBsAg positive and 90.5% (199,282/220,088) of those testing HBsAg negative received at least one and 66.5% (146,328/220,088) completed three HBV vaccine doses. After adjusting for selected covariates, PLHIV aged 20-49 years (AOR-2.68, CI: 1.92-3.73), & ≥50 years (AOR-2.59, CI: 1.85-3.62), male (AOR-2.06, CI: 1.93-2.21), members of key populations (AOR-1.28, CI: 1.03-1.60) CD4 ≤200 cells/mm3 at HBsAg screening (AOR-1.36, CI: 1.17-1.57), and CD4 200-350 (AOR-1.30, CI: 1.17-1.44) had higher odds of HBsAg positivity compared to persons aged <10 years, women, general population and CD4>500 cells/mm^3.

Conclusions: The analysis highlights the potential opportunity for HBsAg screening among the high-risk groups, males and with older age-bands at ART clinics. Integrated screening for HBsAg at ART clinics may be considered to enhance access for early HBV diagnosis in public sector hospitals.

EP0121

Impact of interventions to prevent mother-to-child transmission of hepatitis B virus in Rwanda: a modelling study

J. Stone[1], A.L. McNaughton[1], H. Fraser[1], D. Kalogiros[1], A.G. Lim[1], A. Azania[2], F.R. Cyiza[3], A. Ngwije[2], G. Rwibasira[3], C.E. Boeke[2], O. Fernandes[2], P. Vickerman[1]

[1]University of Bristol, Bristol, United Kingdom, [2]Clinton Health Access Initiative, Boston, United States, [3]Rwanda Biomedical Center, Kigali, Rwanda

Background: In Rwanda, the prevalence of chronic HBV was 4.0% in 2017, with intervention efforts relying on infant vaccination. In 2024, Rwanda introduced additional interventions to prevent mother-to-child transmission (PMTCT), including screening and treatment of pregnant women (PW) and birth dose (BD) vaccination of newborns of HBsAg-positive mothers (from April 2024). Exisiting HIV program infrastructure provided a strong foundation to set up the HBV PMTCT program. We evaluated the impact of these interventions and their scale-up.

Methods: A dynamic HBV transmission model was developed, including disease progression and vaccination. The model was parameterised and calibrated using Bayesian

methods to national data on HBsAg and HBeAg-prevalence, demographics, and vaccination coverage. PMTCT intervention data from 2024 informed the model: in July-September, 95% of PW were tested for HBsAg, 72% of diagnosed women received viral-load testing and 25% of their newborns received BD vaccination.
Additionally, 10% of PW tested for viral load initiating peripartum antiviral prophylaxis (PAP). We assessed the potential impact of these interventions in 2024 and over 2025-2030 assuming interventions continue at existing levels or are scaled-up such that by end of 2025, 95% of HBsAg-positive PW receive a viral-load test, 95% of PW with high viral-load initate PAP, and 95% of newborns receive BD, assuming universal BD vaccination from mid-2025.
Results: Projections suggest that in 2023, 43.2% (95% credibility interval: 38.0-48.3%) of new chronic HBV infections (CHB) were acquired vertically. The model estimates that PMTCT interventions averted 330 (or 9.2% [8.7-9.7%]) new CHB infections among newborns in 2024, and, if continued, could avert 23.6% (22.3-24.9%) of CHB infections among newborns over 2025-2030. Scaling-up BD vaccination could avert 74.1% (70.2-77.6%) of CHB infections among newborns over 2025-2030, with impact increasing to 78.9% (75.5-81.3%) if PAP is also scaled-up. In this scenario, HBsAg prevalence among children <5 years-old is projected to be 0.24% (0.19-0.30%) by 2030, compared to 1.0% (0.78-1.23%) without PMTCT interventions and 0.77% (0.61-0.97%) if interventions do not scale-up.
Conclusions: Mathematical modelling helps inform Rwanda program's progress towards HBV elimination. Although, the introduction of PMTCT interventions in Rwanda has had limited impact to date, they could have substantial impact if further scale-up is achieved.

EP0122

Cervical cancer screening among women living with HIV accessing ART in Northeastern Nigeria: a descriptive study

E. Esara[1], M. Shallangwa[2], A.U. Umar[2], A. Babatunde[2], J. Shaibu[3], A. Olaitan[3], A. Maaji[2], N. Watsamanda[2], M. Luke[3], Y. Paul[2], B.M. Onimode[4], O.-E. Ughweroghene[4], T. Usha[4], B. Adebobola[5], J. Anenih[6], E. James[4], I. Augustine[4]
[1]Achieving Health Nigeria Initiative, Prevention, Care and Treatment, Yola, Nigeria, [2]Achieving Health Nigeria Initiative, Yola, Nigeria, [3]Family Health International 360, Yola, Nigeria, [4]USAID, Abuja, Nigeria, [5]NASCP, Abuja, Nigeria, [6]NACA, Abuja, Nigeria

Background: Cervical cancer remains a significant global health challenge, particularly for women in LMIC where access to screening and treatment services is limited.
This study assesses the uptake and outcomes of cervical cancer screening using visual inspection with acetic acid (VIA) among women living with HIV accessing Antiretroviral Therapy in Northeastern Nigeria.
Methods: This descriptive study used data from women aged 15 years and above in Northeastern Nigeria: Adamawa, Borno, and Yobe. The data represents a snapshot of all women currently in HIV care as of September 30, 2024, who have ever been screened for cervical cancer. It aims to examine cervical cancer screening uptake, outcomes, and predictors of screening uptake across various variables, including state, facility type, facility size, ART duration, and age.
Results: Of the 37,516 women on ART, 26,933 (72%) were screened for cervical cancer. Screening uptake was highest in Borno (77.4%), followed by Adamawa (73.4%) and Yobe (55.6%). Uptake was higher in primary healthcare facilities (79.8%) compared to secondary (70.7%) and tertiary facilities (75.2%).
Facilities within state capitals had higher screening rates (75%) than those outside (69.4%). The highest uptake was observed in women aged 25-49 (77.1%) and the lowest in those aged 50+ years (51.3%). Screening outcomes revealed that 98.3% of women had negative results, 1.3% tested positive, and 0.4% were suspected of having cancer. Women in Borno had higher odds of being screened than those in Adamawa and Yobe (AOR = 1.24, 95% CI: 1.18-1.31).
Screening was more likely in primary healthcare facilities (AOR = 1.31, 95% CI: 1.13-1.51) and among women aged 25–49 (AOR = 2.0, 95% CI: 1.83-2.18). The likelihood of screening increased with longer ART duration, peaking at 6–10 years (AOR = 2.35, 95% CI: 2.09-2.65), but was lower among facilities located outside state capitals (AOR = 0.76, 95% CI: 0.72-0.79).
Conclusions: Cervical cancer screening uptake among WLHIV in Northeastern Nigeria is suboptimal, with variation across states, facility types, and age groups.
To improve overall screening coverage, efforts should improve access and awareness in Yobe, facilities outside state capitals, among older women, and those accessing care at secondary or tertiary facilities.

EP0123

Point-of-care ultrasound for the diagnosis of tuberculosis in Mozambican infants hospitalized with severe HIV-associated pneumonia

U. Cassia[1], J. Borrell[2], S. Richardson[2], M. Sidat[1], G. Muvale[3], M. Salgado[4], S. Liasse[4], C. Domingos[5], C. Mavume[1,4], A. Passanduca[1], S. Martins[1], A. Seni[4,6], K. Chhaganlal[6], J. Sacarlal[1], O. Marcy[7], Á. Ballesteros[8], S. Domínguez[8], A. Tagarro[8,9,10], C. Moraleda[8,11], P. Rojo[8,11,12], W.C. Buck[1,2]

[1]Universidade Eduardo Mondlane, Faculdade de Medicina, Maputo, Mozambique, [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, United States, [3]Hospital Geral da Polana Caniço, Maputo, Mozambique, [4]Hospital Central da Beira, Beira, Mozambique, [5]Hospital Central de Maputo, Maputo, Mozambique, [6]Universidade Católica de Moçambique Faculdade de Ciências de Saúde, Beira, Mozambique, [7]University of Bordeaux, Inserm U 1219, IRD EMR 271, Bordeaux, France, [8]Foundation for Biomedical Research of the Hospital Universitario 12 de Octubre-Hospital 12 de Octubre Health Research Institute (i+12), Madrid, Spain, [9]Universidad Europea de Madrid, San Sebastian de los Reyes, Spain, [10]Servicio Madrileño de Salud (SERMAS), Infanta Sofia University Hospital, San Sebastian de los Reyes, Spain, [11]Servicio Madrileño de Salud (SERMAS), 12 de Octubre University Hospital-Paediatric Unit for Research and Clinical Trials (UPIC), Madrid, Spain, [12]Universidad Complutense, Madrid, Spain

Background: Laboratory diagnosis of pulmonary tuberculosis (PTB) in infants remains challenging, contributing to high TB-related mortality. Younger age and advanced HIV disease increase the probability of having concurrent PTB and extrapulmonary TB disease, which could be detected by ultrasound. Focused assessment with sonography for HIV-associated TB (FASH), an exam performed at six thoracic and abdominal positions, has shown promise for pediatric TB diagnosis, but few infants were included in published studies.

Methods: EMPIRICAL (#NCT03915366), an EDCTP-funded (RIA2017MC-2013) randomized controlled trial, recruited infants <12 months of age hospitalized with severe HIV-associated pneumonia to assess the mortality impact of empiric TB and/or cytomegalovirus treatment in addition to the current standard of care. Current or past TB diagnosis and close TB contact were exclusion criteria. In an ancillary study performed at 5 hospitals in Mozambique from 2021-2024, participants had a baseline point-of-care FASH exam performed along with Xpert Ultra on stool and nasopharyngeal aspirates, and urine lipoarabinomannan (LAM). An analysis was done comparing FASH findings in participants with and without laboratory-confirmed TB.

Results: Among 78 participants, median age was 4.3 (IQR:3.2-6.4) months, 41 (52.6%) were female, and median CD4 was 14% (IQR:10%-22%). A total of 17 (21.8%) participants had laboratory-confirmed TB (16 LAM+, 1 stool Xpert+). There was ≥1 positive positional FASH finding in 41.2% and 29.5% of participants with and without laboratory-confirmed TB, respectively (p=0.362). Pericardial effusion was the most common positive finding in both groups (see Table).

	Laboratory-confirmed TB (n=17)	Without laboratory-confirmed TB (n=61)	Total (n=78)	p value
0 positive findings	10 (58.8%)	43 (70.5%)	53 (67.9%)	0.362
≥ 1 positive finding	7 (41.2%)	18 (29.5%)	25 (32.1%)	0.362
≥ 2 positive finding	2 (11.8%)	3 (4.9%)	5 (6.4%)	0.298
Pericardial effusion	4 (23.5%)	13 (21.3%)	17 (21.8%)	0.841
Pleural effusion	1 (5.9%)	1 (1.6%)	2 (2.6%)	0.391
Ascites	2 (11.8%)	4 (6.6%)	6 (7.7%)	0.606
Focal splenic lesions	2 (11.8%)	3 (4.9%)	5 (6.4%)	0.298
Focal liver lesions	0 (0%)	0 (0%)	0 (0%)	-
Abdominal lymphadenopathy	0 (0%)	0 (0%)	0 (0%)	-

Conclusions: Approximately one-third of participants in this ancillary study had at least one positive positional FASH finding, without significant differences between infants with and without laboratory-confirmed TB.
Future analysis will use standardized TB case classifications of confirmed, unconfirmed, and unlikely TB to assess the added diagnostic value of FASH for clinical TB diagnosis in this high-risk population.

EP0124

A low proportion of persons with HIV co-infected with tuberculosis (TB) have lung involvement on CT-scan when TB is diagnosed by urine LAM alone

J. Adong[1], K. Mittal[2], N. Sanyu[3], L. Carlson[4], N. Gnatienko[4], F.S. Khorassani[2], W. Muyindike[5], N. Emenyonu[6], K. Lunze[4,7], S. Bashar[8], S. Rossi[4,9], J. Samet[4,2,7], A. Byamukama[10], K. So-Armah[4,7], K. Jacobson[4,2,7]

[1]Mbarara University of Science and Technology, Paediatrics and Child Health, Mbarara, Uganda, [2]Boston University School of Public Health, Boston, United States, [3]Global Health Collaborative, Mbarara University of Science and Technology, Mbarara, Uganda, [4]Boston Medical Center, Boston, United States, [5]Mbarara University of Science and Technology, Internal Medicine, Mbarara, Uganda, [6]University of California, San Francisco, Department of Medicine, San Francisco, United States, [7]Boston University Chobanian and Avedisian School of Medicine, Boston, United States, [8]Emory University School of Medicine, Atlanta, United States, [9]University of North Carolina at Chapel Hill, Chapel Hill, United States, [10]Kabwohe Clinical Research Centre, Kabwohe, Uganda

Background: In Uganda, urine LAM is the main diagnostic tool for tuberculosis (TB) in persons with HIV (PWH) with CD4 counts <200. It however remains unclear whether a positive urine LAM is detecting pulmonary or extrapulmonary TB. The overlap between urine LAM and sputum GeneXpert-based testing for TB is also unclear. We evaluated the association of both TB diagnostic tests and structural lung/pleural abnormality diagnosed with high-resolution chest CT scans.

Methods: Participants were enrolled within 44 days of TB treatment initiation. Our primary outcome was CT evidence of structural lung/pleural abnormality at enrollment defined as ≥1 of the following: bronchiolar disease, nodules, consolidation, ground glass opacity, or pleural effusion. We compared CT evidence of lung/pleural involvement by grouping participants by type and result

of diagnostic test: Urine LAM only positive, GeneXpert not done (LAM positive); LAM and GeneXpert concordant or GeneXpert only positive (GeneXpert positive); LAM and GeneXpert discordant (discordant). We used logistic regression to evaluate the association between type/result of diagnostic test and abnormal CT findings adjusting for the following confounders: prior TB diagnosis, CD4+ cell count, age, and sex.

Results: Among the 114 participants (mean±SD age 38±11 years, 43% female), 58% were in the LAM only group, 30% were in the GeneXpert positive group, and 12% were in the discordant group. Sixty-three percent had CT evidence of structural lung/pleural abnormality (nodules, 54%; consolidation, 28%; ground glass opacity, 21%; bronchiolar disease, 15%, pleural effusion, 6%), with lowest rates in the LAM positive group (50%), compared to the GeneXpert positive (88%) and discordant (64%) groups. After adjusting for CD4+ count and other confounders, those in the LAM positive group had lower odds of structural lung/pleural abnormality compared to those in the GeneXpert positive group (adjusted odd ratio=0.08; 95% CI 0.02, 0.33; p<0.001). Every 100 cells/ml increase in CD4 count was associated with 24% lower odds of structural lung and chest abnormality (95% CI: 0.61, 0.95).

Conclusions: Urine LAM-based TB diagnosis alone may reflect extrapulmonary TB with minimal lung or pleural involvement. Supplementing urine LAM with other diagnostic tools could be valuable in guiding clinical decisions regarding the selection of TB treatment regimen.

EP0125

Burden and outcomes of multiple etiology meningitis among people living with HIV in rural Northern Uganda

A. Obeny[1], M. Okwir[2,3,4], D. Meya[5,6], P. R.Bohjanen[7,3,8], A. Link[9,10]
[1]Lira Regional Referral Hospital, Medicine, Kampala, Uganda, [2]University of Rochester Medical Center, Internal Medicine, Public Health Sciences, Rochester, Uganda, [3]Lira University, Internal Medicine, Faculty of Medicine, Lira, Uganda, [4]Lira Regional Referral Hospital, Medicine, Lira, Uganda, [5]Makerere University, Medicine, Infectious Diseases Institute, College of Health Sciences, Kampala, Uganda, [6]University of Minnesota, Division of Infectious Diseases and International Medicine,, Minneapolis, Uganda, [7]University of Rochester Medical Center, Public Health Sciences, Rochester, United States, [8]Makerere University, Infectious Diseases Institute, College of Health Sciences, Medicine, Kampala, Uganda, [9]University of Washington, School of Nursing, Nursing, Seattle, United States, [10]University of Rochester, Department of Medicine, Division of Infectious Diseases, Rochester, United States

Background: Globally, HIV remains a significant public health concern, with an estimated 39.9 million people living with HIV (PLWH) by the end of 2023. The burden is disproportionately concentrated in the WHO African Region, accounting for 65% of cases. HIV/AIDS is linked to several opportunistic pathogens, with Cryptococcal meningitis (CM) accounting for over 60% of life-threatening meningitis cases among PLWH. However, multiple etiology meningitis (MEM) and outcomes among PLWH in northern Uganda are poorly understood. MEM is defined as cases where more than one type of meningitis (e.g., cryptococcal (CM), bacterial (BM), tuberculous (TBM), or viral (VM) is present in a single individual.

This study aimed to assess the burden and outcomes of MEM among PLWH in rural northern Uganda, improving outcomes and preventing complication of meningitis in PLWH.

Methods: A retrospective study was conducted using secondary data from clinical record forms and individual files of PLWH diagnosed with meningitis and hospitalized at Lira Regional Referral Hospital (LRRH) from September 2021 to December 2024. Meningitis diagnoses were confirmed through CSF CrAg and culture for CM, TB GeneXpert for TBM, Pastorex and culture for BM, and BioFire for VM, BM, and CM. Descriptive statistics were employed for data analysis using R (version 4.4.1) software.

Results: There were 207 confirmed cases of meningitis among PLWH, the mean age was 26.5 years (IQR: 35.2), with a majority being male 108. MEM was identified in 23/207 individuals predominantly with underlying CM 21/23. CM-BM was the highest MEM combination, comprising 17/23 cases. CM-TBM, CM-VM, and BM-TBM each accounted for 2/23 cases. Overall mortality among all MEM was 65.2%. CM-TBM exhibited the highest mortality at 2/2, while BM-TBM reported no mortality. The mortality for CM-BM was 9/17.

Conclusions: MEM poses an unrecognized health challenge in rural northern Uganda, with high mortality among CM-TBM individuals. This study underpins the necessity for thorough screening and diagnosis of other meningitis etiologies in individuals with CM, given the high MEM burden in this population.

Further research is needed to understand the burden and mortality of MEM in PLWH, to elucidate the mechanisms and pathophysiology contributing to MEM and poor outcomes in this setting.

EP0126

Common HPV high-risk types at the Rustenburg CRS during the INSIGHT TRIAL

M. Senne[1], N. Mnqonqywa[1], M. Thaba[1]
[1]The Aurum Institute, Clinical Trials, Rustenburg, South Africa

Background: Human papillomavirus (HPV) is a sexually transmitted illness (STI) that can cause genital warts and certain types of cancer. It's one the most common STI following the curable STIs. Despite the vaccine program's for girls between 9 to 15 and the recommendation of women who are sexually active and HIV negative should begin HPV screening at age 25-there is a high prevalence of HPV amongst young woman.

Methods: The study involved women between the ages of 16 – 30 years of age, sexually active and interested in taking PrEP. 175 women were enrolled at Rustenburg Research Site between August 2022 until October 2022 with follow-up until July 2023. During the month 6 follow- up

visit HPV DNA testing was conducted on a sample size of n=138 (83%) of retained participants to screen for HPV and for high-risk types using cytobrush vaginal sample collection, once the HPV DNA test was positive an HPV assay 28 genotype test was done.

Results: 78 participants were found to have positive results of the high-risk types with a median age of 24. The following high risk-types were found: 16,18,31,35,39,45,51,52, 56,58,59,66,68 (17%; 6,4%; 9%; 11,5%;14,1%; 12,8%;16,7%;14,1%; 5,1%; 19%; 15,4%; 12,8%;15,4%).

The most prevalent high risk type was 58 ; n=15(19%) and lowest prevalent high-risk type was 56(5,1%); 51% had 2 or more high risk types. 65 (83%) were contacted for referral for PAP smear to their clinics; whilst the remainder were lost to follow-up post month 6.

Follow-up on PAP smear results was then completed through a national laboratory database and only n=5 out of 65 participants completed a PAP smear; of which n=4 had Negative for intraepithelial lesion or malignancy (NILM) – tests were completed in 2023 and 2024; n=1 had Low grade squamous intra-epithelial lesion(LSIL) of which the test was completed in 2023**.** Uptake of the referral letter was generally good (100%) but with only 5 traceable results.

Conclusions: With little data on the common types in Rustenburg; it's clear that HPV still poses a challenge, screening and vaccine programs seem to be have little efficacy with half the number of participants that were enrolled being positive.

EP0127

Exploring the potential for HBsAg loss in individuals with HIV and HBV: is this a reachable goal?

P. Dos Santos[1,2], M. Saud[1], A. Falak[1,2], A. Sisto[1,2], M.J. Rolón[1,2], N. Laufer[1,2,3]

[1]Hospital General de Agudos Dr. Juan A. Fernández, División Infectología, Buenos Aires, Argentina, [2]Universidad de Buenos Aires, Departamento de Medicina - Asignatura Infectología, Buenos Aires, Argentina, [3]CONICET - Universidad de Buenos Aires, Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Buenos Aires, Argentina

Background: Functional cure of hepatitis B (HBV), defined as sustained loss of Hepatitis B surface antigen (HBsAg), is the optimal endpoint for available chronic HBV treatments. However, the incidence of HBsAg loss remains poorly characterized in individuals living with HIV and HBV.

This study aims to estimate the incidence of HBsAg loss in a cohort of individuals living with HIV and HBV in Argentina.

Methods: We conducted a retrospective medical chart review of individuals living with HIV and chronic HBV followed at an HIV/AIDS clinic in Buenos Aires, from 1989 to 2024. The clinic provides care to approximately 3,000 people living with HIV, with an estimated HBV coinfection prevalence of 3%. Descriptive statistics and non-parametric analyses (Wilcoxon t-test) were used.

Results: From the 90 initially estimated subjects with HIV/HBV co-infection, we identified 52 individuals, with data available for 38 (97% male at birth). With a median follow-up of 727 person-years, the median individual follow-up was 19 years (IQR 11-27) since HIV diagnosis and 12 years (IQR 7.5-20.5) since HBV diagnosis. Individuals' laboratory characteristics are described in Table 1.

Tenofovir (disoproxil or alafenamide) treatment was prescribed to all individuals with a median duration of 8.5 years. HCV coinfection was diagnosed in 31% of the individuals (67% received successful treatment with direct antiviral agents). HIV virological suppression was sustained for a median of 10 years (range 0-25). Three individuals (7.8%, 95% CI 2-21%) presented HBsAg loss after 5.3 years (range 1-13) of tenofovir therapy. One of them has received interferon for HCV treatment, losing HBsAg after 2 years of follow-up.

	Baseline	End of follow up	p value
CD4 cells/mL Median (IQR)	272 (164-501)	499 (217-908)	<0.0001
CD4% Median (IQR)	18 (11.5-23)	26 (14.5-35.5)	<0.0001
CD4/CD8 Median (IQR)	0.25 (0.1-0.4)	0.55 (0.2-0.87)	<0.0001
APRI score Median (IQR)	0.81 (0.5-2.3)	0.43 (0.32-0.94)	0.001
ALT Median (IQR)	52 (34-80)	31 (23-50}	0.024

Conclusions: In this cohort of individuals with HIV/HBV on long-term Tenofovir therapy, HBsAg loss occurred in less than 10% of cases, despite significant CD4 cell recovery and improvement in the APRI score.

Given the association of persistent HBsAg with a higher risk of hepatocellular carcinoma and immune dysfunction, exploring new treatment strategies to achieve functional cure in individuals living with HIV and HBV remains critical.

EP0128

Understanding the management of HPV-related skin disease in people living with HIV in Zimbabwe

S. Kelly[1,2], L. Chirimuta[3], T. Shamu[3,4], S. Lowe[3]

[1]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom, [3]Newlands Clinic, Harare, Zimbabwe, [4]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland

Background: Verruca plana and a more severe form, acquired epidermodysplasia, are caused by beta-cutaneous HPV viruses. The condition can be stigmatising and is linked to skin malignancy. The aim of this work was to understand the current management of verruca plana in an urban clinic in Harare, Zimbabwe as part of a quality improvement intervention.

Methods: Clinic records were extracted from 2004 until September 2024. Data including age, sex, age of HIV diagnosis, age of verruca plana diagnosis, CD4 nadir, viral load, HPV vaccination status, HPV related disease and SCC diagnosis was extracted of all patients with a diagnosis of verruca plana. Detailed case notes reviews were carried out for a subset of 50 patients (25 with HIV diagnosis > 30 years and 25 with HIV diagnosis < 30 years) which in-

cluded date of diagnosis, distribution of rash, treatment received, onward referral and presence of co-existent skin disease.

Results: Verruca plana was diagnosed in 395 people. Sixty percent of the population were male (n=237), median age was 28.1 years (IQR 23.6-32.6), median age of HIV diagnosis was 13.0 years (IQR 7.6-23.7) and of verruca plana diagnosis was 17.4 years (IQR 11.5-31.0). Median nadir CD4 count was 165 (IQR 81- 285) and 75.9% had a viral load <50 copies/ml. 20% of the population had received an HPV Vaccination. Four people (1%) with verruca plana were diagnosed with skin malignancy with a median age of skin cancer diagnosis of 24.6years (IQR 23.8-25).

Those with an HIV diagnosis under the age of 30 were more likely to have a generalised rash, 12% of patients were referred to dermatology, 72% of patients received a trial of treatment, most commonly cryotherapy (34%) or salicylic acid (32%) and 88% of patients had an additional skin diagnosis.

Conclusions: In this clinic, verruca plana was most common among those with HIV acquired before age 30. This population is more likely to have a generalised rash consistent with acquired epidermodysplasia verruciformis. The majority are managed outside of dermatology clinics and treatment varies. A small proportion of patients with verruca plana are diagnosed with skin malignancy in their early 20's.

EP0129

Performance of chest X-ray in identifying pulmonary tuberculosis cases among people living with HIV

J. Ndayisenga[1], G. Mutembayire[2], P. Uwizeye[2], Y. Mucyo[2], R. Uwonkunda[2], H. Niyompano[1], F. Hakizayezu[1], T.T. Adegboyega[3], F.K. Rubuga[4], J.C.S. Ngabonziza[1], E. Remera[1], P. Migambi[2]

[1]Rwanda Biomedical Centre, Research, Innovation, and Data Science (RIDS) Division, Kigali, Rwanda, [2]Rwanda Biomedical Centre, TB and Other Respiratory Diseases Division, Kigali, Rwanda, [3]University of Rwanda, College of Medicine and Health Sciences(CMHS), Huye, Rwanda, [4]Centre for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition (CIIC-HIN), Kigali, Rwanda

Background: Tuberculosis (TB) remains the leading cause of death among people living with HIV (PLHIV). TB symptom screening approach is widely used, especially in low- and middle-income countries; however, it fails to identify potential subclinical TB infections, which are more prevalent in PLHIV.

In this study, we assessed the performance of chest X-ray alongside symptom screening followed by GeneXpert *Mycobacterium Tuberculosis*/Resistance to Rifampicin (MTB/RIF) for the early detection of TB among PLHIV.

Methods: A cross-sectional study in 2015 evaluated symptom screening and chest X-ray for TB detection among PLHIV. Participants were screened for five TB symptoms: cough, night sweats, weight loss, fever, and known TB contact. All participants underwent digital chest X-ray screening. Those with abnormal X-rays or ≥1 symptoms were classified as presumptive TB cases. Sputum from presumptive cases was tested using GeneXpert MTB/RIF for confirmation. Sensitivity, specificity, and differences in positivity rates were calculated using McNemar's chi-square test ($p<0.05$).

Results: Among the 11,901 PLHIV screened, GeneXpert confirmed TB in 94 (0.8%) presumptive individuals. Of the 639 (5.4%) participants with typical TB symptoms, 52 (8.1%) tested positive. Chest X-ray identified abnormalities in 1,671 (14.4%) participants, including 42 asymptomatic patients later confirmed by GeneXpert. Comparative analysis revealed that chest X-ray had a higher sensitivity (100%) than symptom screening (55.5%), indicating its ability to identify all true positive TB cases.

Conversely, symptom screening demonstrated higher specificity (95.5%) compared to chest X-ray (88.9%), suggesting it was better at identifying true negative cases. McNemar's chi-square test, showed a significant difference in TB positivity rates between the two methods (Chi-square=40.024, $p<0.001$). This finding highlights the superior detection capability of chest X-ray, particularly for identifying subclinical TB cases.

Conclusions: The study highlights the contribution of chest X-ray to TB screening among PLHIV, by optimizing case detection and improving outcomes for PLHIV. The high sensitivity of chest X-ray in identifying potential TB patients, including those with no reported symptoms, underscores its value as a critical screening tool in high-risk populations. Implementing such a multi-faceted screening strategy can contribute to the global efforts in reducing TB morbidity and mortality among PLHIV.

EP0130

Optimizing linkage and followup to ensure CECAP care completion among women living with HIV at health facilities in Malawi

F. Tembo[1], G. Kang'oma[1], B. Sibale[2], K.R. Simon[1,3], C.M. Cox[1,3]

[1]Baylor College of Medicine Children's Foundation Malawi, Lilongwe, Malawi, [2]Ministry of Health, Reproductive Health Directorate, Lilongwe, Malawi, [3]Baylor College of Medicine, Department of Pediatrics, Houston, United States

Background: Cervical cancer incidence and mortality rates in Malawi are among the highest in the world. Malawi cervical cancer prevention (CECAP) guidelines recommend same day screening and treatment in order to identify and treat precancerous lesions. Completing CECAP care is critical to maximize prevention and minimize morbidity, and tracking women with incomplete screening and/or treatment is difficult. Since 2008, Baylor Foundation Malawi (BFM) has utilized community health workers (CHWs) to help clients navigate longitudinal HIV care cascades and now leverages this platform to establish a continuum of care for integrated CECAP service delivery.

We describe optimization of same-day treatment completion and followup among women living with HIV (WLHIV) in twelve health facilities supported by BFM.

Methods: WLHIV attending ART clinics were referred for CECAP screening with HPV triage and/or visual inspection with acetic acid (VIA) with same day thermocoagulation for eligible precancerous lesions.
To optimize screening and treatment completion:
(1) frequency of CECAP sensitization health talks was increased
(2) Psychosocial support was provided to WLHIV declining care or with abnormal results
(3) Locator details were collected from consenting women who needed followup
(4) files of women needing followup were flagged for ART clinic fast-track and linkage back to CECAP care
(5) CHWs conducted community tracing for women who missed followup
(6) close collaboration was maintained with referral facilities.
We analyzed program data from CECAP screening and treatment registers from January 2022-December 2024.
Results: Among 41,476 screening encounters, 1059 precancerous lesions were identified, a 2.6% positivity rate. Referral for gynaecologic concern or large lesion was made for 104 women.
Of the remaining 955 thermoeligible lesions, 933 were same-day treatment eligible (no menses, cervicitis, etc) with 98% (n=911) completing treatment.
Of 44 women needing followup, 50% (n=22) have been treated. Of 259 women with HPV+ results still needing VIA, 69.4% (n=180) had completed screening by December with only 79 remaining in followup cascade.
Conclusions: Integrated ART and CECAP services with education, followup and collaboration can achieve high completion rates of both screening and treatment at rural facilities in Malawi.
The existing Tingathe program for HIV care can be leveraged for other service delivery including CECAP.

EP0131

Anal cancer screening in men who have sex with men: the relevance of HPV genotyping in people living with HIV after 7 years of screening

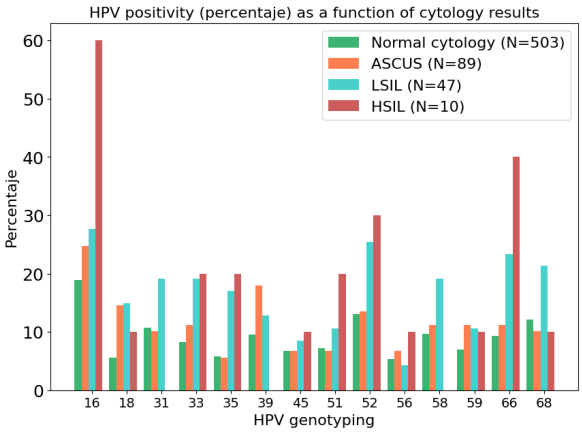
A. Rodriguez[1], A. Villoslada[2], P. Sorni[2], A. Serrano[2], A. Salom[2], A. Morin[2], A. Payeras[2]
[1]IdISBa-Hospital Son Llàtzer, Internal Medicine - Infectious Diseases, Palma, Spain, [2]Hospital Son Llàtzer, Internal Medicine - Infectious Diseases, Palma, Spain

Background: The ANCHOR trial demonstrates the benefit of treating high-grade squamous intraepithelial lesions in the anal mucosa to prevent progression to cancer.
The objective of this study is to evaluate the outcomes of anal cytologies and their relationship with subsequent biopsies, as well as their relationship with different HPV genotypes.
Methods: This is a prospective observational study of a subset of the eVIHa cohort (PLHIV in the Balearic Islands), specifically MSM undergoing HSIL anal screening since June 2017. HPV genotyping detects 14 oncogenic genotypes.
Results: 734 cytologies were performed on 380 MSM. Cytology results: 12% ASCUS, 6.6% LSIL and 14% HSIL. During the screening, 34% of participants had an abnormal cytology at some point.
Comparison of different variables between normal cytology vs LSIL/HSIL is shown in table 1. People with LSIL/HSIL had a higher percentage of nadir CD4<200cel/µL, were more likely to be smokers and had higher rates of previous neoplasia and condyloma.

	Normal Cytology (N=503)	LSIL/HSIL (N=57)	p-value
Age (years)	46 (SD: 11)	46 (SD: 13)	0.844
Years since HIV acquisition	15 (SD: 8)	17 (SD: 9)	0.06
Nadir CD4>200 cel/µL	74 (15%)	17 (30%)	0.006
Smoking	138 (27%)	23 (43%)	0.06
Previous Neoplasia	49 (9.8%)	13 (22.8%)	0.006
Previous condyloma	69 (13.7%)	21 (30%)	<0.001

Table 1. Comparison between normal vs LSIL/HSIL cytology

74 HRA with biopsies were performed, of which 35% were normal, 32% AIN1, and 31% AIN2/AIN3. One carcinoma was also detected. AIN3 cases were predominantly associated with HSIL cytologies.
All 14 HPV studied genotypes were more prevalent in abnormal cytologies, with genotypes 16, 52, and 66 most strongly associated with abnormal findings (Figure 1). Notably, 60% of HSIL cytologies were infected with HPV-16.



Conclusions: In our cohort of MSM-HIV, more than one-third of participants had abnormal anal cytology at some point. Overall, all HPV genotypes were more prevalent in samples with abnormal cytologies, particularly HPV-16, highlighting the importance of HPV genotyping in the screening of anal canal dysplasias.

EP0132

Association between self-reported HIV status at admission and duration of hospital stay among patients isolating with mpox at Mbarara Regional Hospital, Uganda

S. Asiimwe[1,2,3], B. Tweheyo[4], A. Kembabazi[4], N. Wandera[5], R. Muhindo[6]
[1]Mbarara University of Science & Technology (MUST), Community Health, Mbarara, Uganda, [2]Kabwohe Clinical Research Center (KCRC), Research, Kabwohe-Itendero, Uganda, [3]Massachusetts General Brigham, Center for Global Health, Boston, United States, [4]Mbarara University of Science & Technology (MUST), Global Health Collaborative, Mbarara, Uganda, [5]Mbarara Regional Refferal Hospital (MRRH), Special Pathogens Unit, Mbarara, Uganda, [6]Mbarara University of Science & Technology (MUST), Internal Medicine, Mbarara, Uganda

Background: The Mpox case load in Uganda increased since the first case was reported in July 2024. Mpox was declared by the Africa CDC as a public health emergency of continental security in August 2024. People with underlying immunocompromising conditions like HIV are at risk of more severe disease. We evaluate the association between self-reported HIV status at admission and duration of hospital stay at Mbarara Regional Referral Hospital (MRRH), western Uganda
Methods: We conducted a chart review of hospital records of all clients with clinical Mpox admitted at the MRRH special pathogens unit for isolation. More severe or complicated cases stayed on the ward for a longer duration for treatment and support. Descriptive statistics and logistic regression were used to define the relationship between self-reported HIV status and average hospital stay.
Results: 69 cases of Mpox were admitted in the 3 months since October 16, 2024, to January 21, 2025. Majority (59.4%) were male and with a median age of 39 years (range, 19 – 50 yrs). 22, (31.9%) reported being of positive HIV serostatus at time of admission. Older clients (>32 years) had 1.64 odds of having a positive HIV serostatus. Almost all 64 (92.7%) admitted clients had skin and genital lesions. The median inpatient admission length of stay was 8 days (range, 1-30 days). After adjusting for age, sex and type of lesion, HIV was not associated with a longer stay (>8 days) in hospital (OR:1.0, IQR 0.36 – 2.7).
Conclusions: Despite admitting predominantly more older males, HIV co-infected patients with Mpox had a similar duration of stay on the ward for care and support. The risk of severe disease may be similar regardless of HIV serostatus but further studies are needed.

EP0133

High prevalence of Hepatitis B virus infection among people living with advanced HIV disease in Botswana

C. Tsayang[1], E. Schanzer[1], B. Phinius[1], G. Mulenga[1,2], K. Molebatsi[1], K. Lechiile[1], L. Bhebhe[1], T. Ratsoma[1,3], G. Mpebe[1,3], F. Mulenga[1], B. Phakedi[1,4], W. Choga[1], M. Mine[5], S. Lockman[1,6], J.N. Jarvis[1,7], S. Moyo[1,4,6], M. Anderson[1,8,9], S. Gaseitsiwe[1,6]
[1]Botswana Harvard Health Partnership, Research Lab, Gaborone, Botswana, [2]Botswana International University of Science and Technology, Palapye, Botswana, Department of Mathematics and Statistical Sciences, Faculty of Science, Palapye, Botswana, [3]University of Botswana, Deparment of Biological Sciences, Faculty of Science, Gaborone, Botswana, [4]University of Botswana, School of Allied Health Professions, Faculty of Health Sciences, Gaborone, Botswana, [5]Ministry of Health, Gaborone, Botswana, [6]Harvard T. H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston,MA, United States, [7]London School of Hygiene and Tropical Medicine, Department of Clinical Research, Faculty of Infectious and Tropical Diseases, London, United Kingdom, [8]Africa Health Research Institute, Durban, South Africa, [9]The Francis Crick Institute, Londonuu, United Kingdom

Background: Hepatitis B virus (HBV) and human immunodeficiency virus (HIV) remain major global public health challenges. Concomitant HIV/HBV infection results in worse health outcomes with HBV reactivations being observed in profoundly immunocompromised individuals. However, data on concomitant HBV infection in people with advanced HIV disease (AHD) remains sparse.
We aimed to determine the HBV prevalence, risk factors of concomitant HIV/HBV infection and molecularly characterize HBV in a cohort of people living with HIV(PLWH) with CD4 T-cell counts ≤100 cells/μL in Botswana.
Methods: Plasma samples (n=1097) of PLWH with CD4 T-cell count ≤100cells/mm^3 collected between 2014 and 2016 were screened for hepatitis B surface antigen (HBsAg) and HBV core antibodies (anti-HBc). DNA was extracted from all samples that tested HBsAg+. A 415bp region of the HBV surface gene was amplified and sequenced using Sanger sequencing.
Genotypic and mutational analysis was performed using Geno2pheno. Adjusted risk ratios (aRR) were estimated from modified a Poisson regression model to explore risk factors for HBV infection. P-values less than 0.05 indicated statistical significance.
Results: The median age was 37 years (IQR: 32–43), and 565/1097 (51.5%) were female. The prevalence of HBsAg+ was 10.6% (95%CI :8.8% – 12.5%) and anti-HBc prevalence was 50% (95% CI: 46.9% – 52.9%). Risk factors identified were male sex [aRR: 1.6 (p<0.01)], and having a CD4 cell count of 50-100 compared to <50 cells/mm^3 [aRR: 1.45 (p=0.042)]. Eighteen samples were successfully genotyped. The prevalence of genotype A was (12/18 ,66.7%) and D (6/18,33.3%). Sixty-three mutations were identified associated with drug resistance, immune and diagnostic escape. Highly prevalent immune escape mutations in

the surface region were S207N (12/63, 19%) and A194V (9/63, 14.3%). V163I (12/63, 19%) and M129L (12/63, 19%) were highly prevalent in the reverse transcriptase region. Two classical lamivudine-associated drug resistance mutations were observed, each occurring in 1 participant (L180M and V173L). There is no association between mortality and HBsAg status.

Conclusions: The prevalence of HBV in people with AHD is high, highlighting the importance of HBV screening and HIV/HBV co-management in this population.

Co-morbidities and clinical complications of HIV and antiretroviral therapy

EP0134

Prevalence of undernutrition and associated factors among adult HIV patients receiving antiretroviral therapy: a cross-sectional study in Ruhango Provincial Hospital Catchment Area-Rwanda, January -December 2023

M. Niyitegeka[1,2], D. Rinda[3], S. Rwunganira[4], E. Tuyishime[2], A. Ndagijimana[1], T. Nayituriki[5]

[1]University of Rwanda, Biostatics and Epidemiology, Kigali, Rwanda, [2]Ruhango Provincial Hospital, Kigali, Rwanda, [3]University of Rwanda, Biosatistics and Epidemiology, Kigali, Rwanda, [4]AFENET RWANDA, Data management, Kigali, Rwanda, [5]University of Rwanda, Kigali, Rwanda

Background: Undernutrition is a significant public health problem affecting various population groups in developing countries, particularly among people living with HIV(PLHIV). Despite its relevance, limited research has been conducted on undernutrition among PLHIV in Rwanda.

This study aimed to determine the prevalence of undernutrition and associated risk factors among adult HIV patients receiving antiretroviral therapy (ART) in Ruhango Provincial Hospital in Rwanda.

Methods: A cross-sectional study was conducted among PLHIV ≥ 18 years on ART across the Ruhango provincial hospital catchment area from January to December 2023. The sample size was calculated using Dobson formula, 385 study participants were selected through proportional quota sampling. Undernutrition was defined as a participant with a Body Mass Index of less than 18.5 kg/m^2. Data on socio-demographic and clinical characteristics were collected using a standardized questionnaire designed in Kobo Toolbox and analyzed using Stata 15.1; bivariate and multivariate logistic regression analyses with 95% confidence interval were performed to determine factors associated with undernutrition. Variables with p-value of <0.05 were considered statistically significant.

Results: Among the 385 participants, the prevalence of undernutrition was 11.2%. Undernutrition was statistically associated with having chronic diseases (aOR=9.39, 95% CI: 1.95-45.1) and being aged ≥ 50 years (aOR=3.32, 95% CI: 1.41-7.8). In contrast, two marital status sub-groups were found to be significantly associated with lower odds of undernutrition (married, aOR=0.41, 95% CI:0.22-0.78, and widowed, aOR=0.48, 95%CI: 0.23-0.99)

Conclusions: The study revealed that the prevalence of undernutrition among adults with HIV on ART was high. Factors associated with higher odds of undernutrition included the presence of chronic diseases and being aged ≥ 50 years while being married or widowed was associated with lower odds of undernutrition.

These findings highlight the need for comprehensive screening of chronic diseases other than hypertension and diabetes mentioned in routine screening, The establishment of nutritional support programs targeting older adult patients on ART, and enhanced training of healthcare providers in HIV care and nutrition management.

EP0135

Comprehensive metabolomics reveals low BMI, androgen, and dietary changes mediate reduced uric acid in people with HIV

T. Chen[1,2], H. Lin[1,3], X. Chen[1,3], W. Shen[3], S. Wang[3], T. Wang[3], Y. Wang[3], N. He[1,2]

[1]Fudan University, School of Public Health and The Key Laboratory of Public Health Safety of Ministry of Education, Shanghai, China, [2]Fudan University, Shanghai Institute of Infectious Diseases and Biosecurity, Shanghai, China, [3]Taizhou City Center for Disease Control and Prevention, Taizhou, China

Background: Uric acid (UA), an important antioxidant, reduces oxidative stress from immune activation and chronic inflammation. However, differences in UA levels and metabolic mechanisms between people with HIV (PWH) and without HIV (PWoH) remain unclear.

Methods: We conducted an untargeted metabolomics study in 476 PWH and 476 matched PWoH (mean age: 59.9±8.4 vs. 59.6±8.6years; 72.3%male) from the Comparative HIV and Aging Research in Taizhou (CHART) cohort in eastern China. Suspected hyperuricemia (SHUA) was defined as fasting UA≥420μmol/L. Dysregulated metabolites were identified using logistic regression, OPLS-DA and LASSO regression.

Results: PWH had lower UA levels(310.8±96.8 vs. 357.9±99.6μmol/L, *P*<0.001) and lower prevalence of SHUA (12.0% vs. 25.0%, *P*<0.001) compared to PWoH (Fig.A). Multivariable regression indicated that HIV, female sex, non-alcohol consumption, low BMI, lymphocyte count, serum creatinine, and low intake of fish and fried food were associated with lower UA. The association strengths of BMI and alcohol consumption with UA were weaker in PWH than in PWoH (interaction *P*<0.05). Reductions of UA were partially mediated by lower BMI in PWH compared to PWoH (16.6%, *P*<0.001).

In PWH, 20 metabolites were associated with UA(18 positive, 2 negative, Fig.B&C). 1-methylhistidine, 2,6-dihydroxybenzoic acid, 5α-androstan-3β,17β-diol disulfate, histidine, N-acetyl-1-methylhistidine, orotidine were also associated with UA in PWoH. The androgen metabolite 5α-androstan-3β,17β-diol disulfate was positively associated

with UA, with a weaker association strength in PWH than in PWoH (interaction *P*=0.002, Fig.D), and mediated 76.7% of the UA reduction (*P*<0.001). 2,6-dihydroxybenzoic acid and picolinoylglycine (related to fiber and protein intake) also showed mediation effects (57.3% and 43.0%, *P*<0.001, Fig.E).

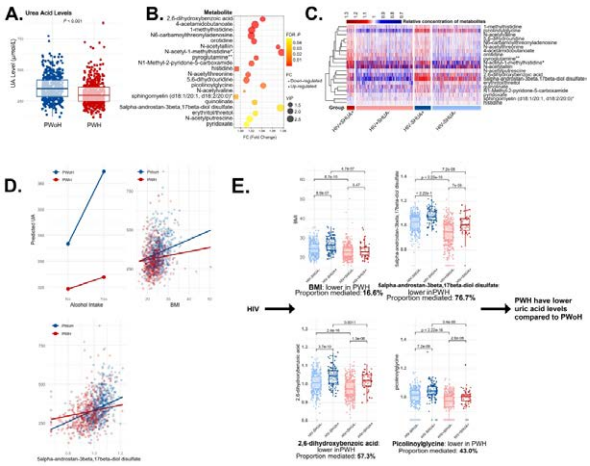


Fig. Uric acid levels and uric acid-associated metabolites in people with HIV
A. Boxplot of uric acid levels in PWH and PWoH
B. Bubble plot of uric acid-associated metabolites in PWH
C. Heatmap of relative metabolite levels between groups
D. The interaction between general characteristics, metabolites and HIV
E. Schematic map of mediation effects of general characteristics and metabolites on HIV and uric acid levels

Conclusions: Lower plasma UA levels in PWH compared to PWoH is mediated by lower BMI and dysregulated metabolites, suggesting that addressing nutritional and hormonal status is essential to counteract the reduced antioxidant capacity due to lower UA level in PWH, which plays a critical role in mitigating chronic inflammation in PWH.

EP0136

Enhancing HIV care through routine non-communicable disease screening: a continuous quality improvement project at Aduku HCIV, Northern Uganda

A. Mutegeki[1], A. Eunice[1], A. Dorcus[1], K. John[2], S. Ezajabo[2]
[1]Aduku Health Centre IV, ART, Kwania, Uganda, [2]Joint Clinical Research Centre, Health, Lira, Uganda

Background: A data review conducted in January 2024 at Aduku HCIV revealed that only 27% of people living with HIV (PLHIV) were screened for Non-communicable diseases (NCDs), falling below the Uganda Ministry of Health's standard of 100%. This low screening rate was attributed to a knowledge gap among staff regarding HIV and NCDs management, inadequate documentation practices where results for screened clients were not recorded in their files and registers, and a lack of essential screening tools.
The objective for CQI was to increase the percentage of PLHIV screened for non-communicable diseases from 27% in January 2024 to 100% by December 2024.
Description: The project, initiated in January 2024, focused on improving NCD screening among PLHIV at Aduku HCIV. The interventions included integrating NCD management into the facility's Continuing Medical Education (CME) schedule for staff to enhance knowledge and skills in managing HIV and NCDs. Additionally, Blood pressure machines, glucometers, and other essential screening tools were provided to the ART clinic to enable staff to perform NCD screenings. An NCD focal person was selected to ensure improved documentation practices by accurately recording results for screened clients in patient files and registers and prompting treatment for NCD-positive clients.
Lessons learned: Integrating NCD management into facility CME sessions significantly improved staff knowledge and confidence in managing both HIV and NCDs. providing essential screening tools addressed a critical barrier to conducting NCD screenings. The appointment of an NCD focal person improved documentation, allowing accurate tracking of screened clients and enabling prompt treatment initiation.
The project demonstrated that continuous training, proper documentation practices, and resource availability are key to successful implementation and sustained improvements in service delivery.
Conclusions/Next steps: The project successfully increased NCD screening rates among PLHIV to 100%, emphasizing the importance of integrating NCD care into HIV services. The focus will be on sustaining these improvements through ongoing staff training and expanding the intervention to other health facilities.
The findings suggest that integrating NCD care into routine HIV care can enhance the overall quality of care for people living with HIV.

EP0137

Cardiac, liver, renal, and other safety profiles in PWH on ainuovirine-based antiretroviral regimen: week 96 results from SPRINT, a randomized phase 3 trial

Q. Zhao[1], H. Wu[2], F. Zhang[3], W. Cai[4], P. Ma[5], H. Wei[6], H. Lu[7], H. Wang[7], S. He[8], Z. Chen[8], Y. Chen[9], M. Wang[10], X. Yun[11], H. Fu[11], H. Qin[11], Y. Li[11]
[1]The Sixth People's Hospital of Zhengzhou, Zhengzhou, China, [2]Beijing Youan Hospital, Capital Medical University, Beijing, China, [3]Beijing Ditan Hospital Capital Medical University, Beijing, China, [4]Guangzhou Eighth People's Hospital, Guangzhou Medical University, Guangzhou, China, [5]Tianjin Second People's Hospital, Tianjin, China, [6]The Second Hospital of Nanjing, Nanjing, China, [7]Shenzhen Third People's Hospital, Shenzhen, China, [8]Public Health Clinical Medical Center of Chengdu, Chengdu, China, [9]Chongqing Public Health Medical Center, Chongqing, China, [10]The First Hospital of Changsha, Changsha, China, [11]Jiangsu Aidea Pharmaceutical Co., Ltd, Yangzhou, China

Background: In the SPRINT study, switch to ainuovirine plus lamivudine and tenofovir DF (ANV/3TC/TDF), resulted in an improving trend in liver and renal function in virologically suppressed (VS) people with HIV-1 (PWH). In the extensional study, PWH continued ANV/3TC/TDF or switched to ANV/3TC/TDF from cobicistat-boosted elvitegravir with emtricitabine and tenofovir alafenamide (E/C/F/TAF) until 96 weeks.

Methods: Out of 762 randomized participants, 376 participants originally assigned to ANV/3TC/TDF (376/381, 98.7%), and 371 participants originally to E/C/F/TAF (371/381, 97.4%) completed the extensional study, respectively.
Changes from baseline (CFBs) in QTcF interval on electrocardiography, and clinical laboratory examinations were primary safety outcomes of interest, including blood biochemistry.
Results: The two arms showed no significant changes in QTcF interval at week 72 or 96; only one participant continuing ANV/3TC/TDF had QTcF prolongation >60 msec at week 96. Liver enzymes remained unchanged in ANV/3TC/TDF arm but increased marginally in E/C/F/TAF→ANV/3TC/TDF arm, including ALT (Figure 1, upper panel), AST, GGT, ALP, and LDH.
Both total and direct bilirubin remained unchanged in both arms. Blood urea nitrogen became constant in both arms, and serum creatinine remained unchanged in ANV/3TC/TDF arm but decreased slightly in E/C/F/TAF→ANV/3TC/TDF arm at week 96 (1.0±7.7 vs. -2.7±8.1 µmol/L) (Figure 1, lower panel).
This accompanied a marginal change in estimated glomerular filtration rate at week 96 (-1.1±7.4vs. 2.5±8.3mL/min/1.73m^2). Serum phosphates remained constant; creatine kinase decreased slightly (-80.4±768.1 vs. -58.3±1232.3 U/L); and amylase remained constant (-0.05±16.5 vs. -0.17±17.0 U/L). Common organ-associated AEs (≥5% in either arm) included elevated AST (5.8% vs. 6.9%), and elevated GGT (4.5% vs. 6.4%).

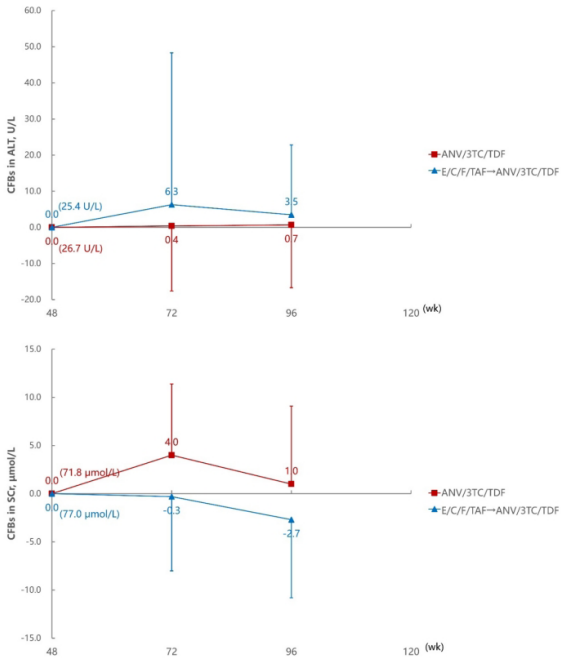

Figure 1. Changes in ALT and SCR at week 72 and 96
ANV/3TC/TDF, ainuovirine/lamivudine/ tenofovir disoproxil fumarate; E/C/F/TAF, elvitegravir/cobicistat/emtricitabine/tenofovir alafenamide; CFB, change from baseline; ALT, Alanine aminotransferase; Scr, Serum creatinine.

Conclusions: Switch to ANV/3TC/TDF is well tolerated in VS PWHs, without clinically significant changes in organ-associated biochemical measures observed. Routine safety laboratory monitoring is generally recommended in PWHs on switching therapy.

EP0138

Prevalence of diastolic dysfunction and associated factors in virologically suppressed PLWH in Salvador, Brazil

S. Amaral[1], L. Fernandes[1], A. Zariffe[1], A. Tolentino[1], D. Zeballos[1], I. Montaño-Castellón[1], M. Arriaga[1], A. Barreto da Silveira[1], K. Page[2], C. Brites[1]
[1]Federal University of Bahia, Salvador, Brazil, [2]University of New Mexico, Department of Internal Medicine, Albuquerque, United States

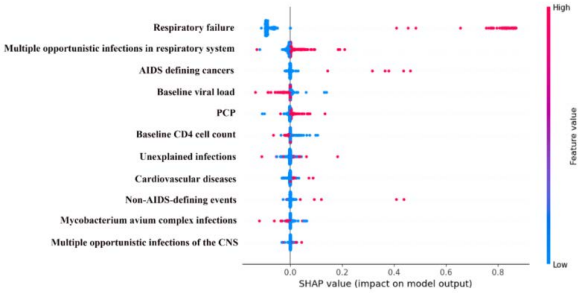
Background: The echocardiographic abnormalities found among PLWH changed since the start of the HIV pandemic. Currently, abnormalities are more associated with pulmonary hypertension, coronary artery disease and left ventricular diastolic dysfunction.
This study aimed to evaluate echocardiographic abnormalities, mainly diastolic dysfunction, and associated risk factors, including inflammatory and immunological factors among PLWH who are virally suppressed.
Methods: We conducted a cross-sectional study, including individuals with undetectable HIV-RNA plasma viral load. The participants were interviewed, and their medical records information was collected. Presence of echocardiographic abnormalities was defined by transthoracic echocardiography and inflammation and immune activation was evaluated by a cytokine panel and flow cytometry. Bivariate analysis and a logistic regression were performed.
Results: 99 individuals living with HIV were included, 57.6% of the participants were male, with an average age of 52.6 years. The racial composition was predominantly mixed (49.5%) or black (39.4%), and the majority was single (56.6%) with more than 8 years of formal education (71.7%). The median current CD4 cell count was 702.0 cells/µL (IQR: 483 - 845 cells/µL), and the median nadir CD4 cell count was 204.5 cells/µL (IQR: 53 - 324.75 cells/µL). 52.6% had a previous history of an AIDS-defining condition. 37.4% had at least one previously diagnosed comorbidity, central obesity was the most prevalent (28%), closely followed by hypertension (25.3%).
The prevalence of echocardiographic abnormalities was 71.7%, diastolic dysfunction occurred in 40.4% of participants. In the logistic regression, participants with diastolic dysfuction were older (OR 1.11, 95% CI 1.03 - 1.20), mostly with less than eight years of education (OR 4.08, 95% CI 1.06 - 15.78), and were more likely to have comorbidities (OR 8.29, 95% CI 2.34 - 29.35) as hypertension (OR 17.90, 95% CI 3.83 - 83.72). Markers of inflammation and immune activation levels were comparable across groups.
Conclusions: Our findings strengthen the hypothesis that PLWH even on stable ART and with virological suppression present higher prevalence of echocardiographic abnormalities, mainly diastolic dysfunction. They also reinforce classic risk factors, like age and comorbidities, involved in the development of cardiac remodeling.

EP0139

Machine learning algorithms to predict the risk of admission to intensive care units in people living with HIV

J. Li[1], Y. Ding[1], H. Zhao[1], J. Xiao[1], L. Xing[1], Y. Guo[1], C. Gao[1], Y. Zhao[1], Q. Li[1]
[1]Beijing Ditan Hospital, Capital Medical University, Beijing, China

Background: The aim of this study was to forecast the risk factors of admission to the Intensive Care Units (ICUs) for people living with HIV(PLWH) using several different machine learning prediction models, to evaluate the risk of admission to the ICU for PLWH, and to assist doctors in making early clinical interventions and preventing healthcare client from developing serious illnesses.
Methods: Classification models were built based on logistic regression (LOG), random forest (RF), k-nearest neighbor (KNN), support vector machine (SVM), artificial neural network (ANN), and extreme gradient boosting (XGB).
The risk of admission to intensive care units (ICUs) was predicted using Brier score,the area under receiver operating characteristic curve (ROC-AUC) and the area under the precision recall curve (PR-AUC), and evaluated by visualization using ROC, PRC of all models for internal validation and ranked by Shapley plot.
Results: In classification models, ANN model performed best in the internal validation (Brier score = 0.034, ROC-AUC = 0.961, PR-AUC = 0.895) to predict the risk of admission to the ICU for PLWH.
Our study also identified eleven important features to predict the risk of ICU admission based on Shapley plot, including respiratory failure, multiple opportunistic infections in the respiratory system, AIDS defining cancers, baseline viral load, PCP, baseline CD4 cell count, unexplained infections, cardiovascular diseases, non-AIDS-defining events, mycobacterium avium complex infections, and multiple opportunistic infections of the CNS.



Conclusions: An intelligent healthcare prediction system could be developed based on the medical records of PLWH, and the ANN model had performed best in effectively predicting the risk of ICU admission, which helped physicians make timely clinical interventions, reduce the likelihood of PLWH developing serious illnesses, alleviate people living with HIV suffering and reduce the expenditure of healthcare resources.

EP0140

Undiagnosed hypertension among people with HIV in Upper Eastern Kenya: perils of vertical silo-programs

M. M'Muriithi[1], B. Gathendu[2], T. Ireri[2], O. Obiero[2]
[1]CHAK, Health Programs, Nairobi, Kenya, [2]CHAK, Nairobi, Kenya

Background: Hypertension is the most important risk factor for cardiovascular diseases. Despite the documented high prevalence in Kenya (20-28%) hypertension is under-diagnosed among people with HIV. We sought to measure the prevalence of undiagnosed hypertension among people on antiretroviral treatment.
Methods: We carried out a before and after study in three County referral hospital clinics. Baseline data on blood pressure and management of hypertension for clients 19 years and above was compared with measures after re-training healthcare workers. Line-listed de-identified data were extracted from electronic medical records (KenyaEMR) and analysed using Stata version 18.5.
We conducted on-site training of healthcare workers on current management of elevated blood pressure and hypertension using the 2024 ESC guidelines. Nurses and clinical officers measured blood pressure in the subsequent clinic visits. We compared proportions of clients classified as hypertensive before and after the intervention using appropriate statistical measures.
Results: At baseline 7,283 records 4,962 (68.1%) females were analysed, with a mean age of 47.2 years (SD 12.5). The median body mass index was 23.9 (IQR 20.8,27.7). Women had a significantly higher average BMI compared to men; 25.7 (SD 5.2) vs 22.4 (SD 4.0) P<0.001. Only 327 (4.5%) of clients had a documented history of hypertension with only 26.2% controlled.
Only 5,207 (71.5%) had a BP recorded during their last visit with 1,363 with BP ≥140/90 mmHg. After the re-training, 4,288 (58.9%) of the clients had a clinic revisit in three months of whom 3,627 (84.6%) had a BP measurement.
All the 755 re-evaluated clients with baseline elevated blood pressure had a confirmatory BP measurement and 432 (57.2%) were diagnosed with hypertension.
After the intervention, there was a significant rise in the proportion of people correctly classified as having hypertension from 4.5%, to 21.8% p<0.001. The proportion with controlled BP below 140/90 mmHg threshold also rose from 16.2% before to slightly over one third; 56(34.2%) of hypertensive clients on treatment.
Conclusions: Hypertension remains dangerously under-diagnosed in HIV clinics with a triple-edged gap; suboptimal measurement of BP, incorrect classification and suboptimal management. These gaps are reversible through deliberate service integration and structured re-education of healthcare workers.

EP0141

Normalization of inflammatory bio-markers post dolutegravir initiation among a cohort of persons living with HIV in Accra, Ghana: a prospective study

V. Ganu[1,2], E. Kenu[1], K. Torpey[1], S. Ayisi Addo[3], K. Agyabeng[1], A. Afriyie[2], R. Sarkodee[2], M. Lartey[4,2]

[1]University of Ghana, School of Public Health, Accra, Ghana, [2]Korle Bu Teaching Hospital, Accra, Ghana, [3]Ghana Health Service, Accra, Ghana, [4]University of Ghana Medical School, Accra, Ghana

Background: Persons living with HIV (PLHIV) are at increased risk of cardiovascular diseases (CVDs) partly attributed to persisting inflammation and oxidative stress which predispose PLHIV to atherosclerosis and CVDs.
We evaluated the effect of Dolutegravir on plasma levels of alanine transaminase (ALT) and C-reactive protein (CRP), which are independent systemic inflammatory biomarkers, in PLHIV initiated on DTG-based regimen in Accra, Ghana.
Methods: A prospective multi-center observational cohort study was conducted in Ghana from September 2020 and August 2022 among adult PLHIV aged at least 18 years initiated on DTG. Each participant was followed up for 18 months.
We compared the ALT and CRP levels at baseline and 18 months among only those with data for both timelines. Normal ALT and CRP levels were defined as £33 IU/L and <5 mg/L respectively. Comparison of baseline and month-18 median ALT and CRP levels were done using the Wilcoxon signed-rank test at 5% significance level.
Results: A total of 3662 PLHIV were screened of which 73% were female. For ALT, 18% (424/2346) had abnormal ALT at baseline with 63% (266/424) reverting to normal levels by month 18. Median ALT for PLHIV with abnormal ALT at baseline, declined from 43.00 (IQR:37.00-54.50) IU/L at baseline to 29.00 (IQR:21.00-39.00) IU/L by month 18. For PLHIV with normal ALT at baseline, 91% (1741/1922) still had normal levels by month 18. Their median normal ALT at baseline was 20.00 (IQR: 16.00-25.00) IU/L and remained same by month 18.
For CRP, 24% (551/2318) had abnormal CRP at baseline with 62% (343/551) reverting to normal levels by month 18. For PLHIV with abnormal CRP at baseline, their median CRP declined from 9.32 (IQR:6.63-16.26) mg/L at baseline to 3.44 (IQR:1.38-7.16) mg/L by month 18. For PLHIV with normal CRP at baseline, 87% (1531/1767) still remained normal by month 18 with median CRP declining from 1.30 (IQR:0.62, 2.54) mg/L at baseline to 1.17 (IQR:0.51, 2.87) mg/L by month 18.
Conclusions: There was significant decline in ALT and CRP levels to normal levels in PLHIV initiated on DTG implying a reduction in inflammation and possible oxidative stress

EP0142

Declining HDL-cholesterol among persons living with HIV post DTG initiation in Ghana: a risk for coronary artery disease

M. Lartey[1,2], V. Ganu[3,2], E. Kenu[3], S. Ayisi Addo[4], K. Agyabeng[3], G. Akuffo[3], P. Tsekpetse[3], K. Torpey[3]

[1]University of Ghana Medical School, Accra, Ghana, [2]Korle Bu Teaching Hospital, Accra, Ghana, [3]University of Ghana, School of Public Health, Accra, Ghana, [4]Ghana Health Service, Accra, Ghana

Background: Low HDL-cholesterol (HDL-C) is an independent risk factor for coronary artery disease (CAD) and a strong predictor of atherosclerosis. With the increasing burden of chronic, non-communicable diseases among Persons living with HIV (PLHIV) due to increase in life expectancy, it is important to monitor such population to identify any modifiable risk factors for early intervention to reduce the burden.
This study assessed the trends in HDL-C among adult PLHIV initiated on DTG in Ghana.
Methods: A prospective multi-center observational cohort study was conducted among PLHIV initiated on DTG in Ghana from September 2020 and August 2022. Inclusion criteria was adults aged 18 years and above, absence of dyslipidemia and normal HDL-C levels at time of DTG initiation. Each participant was followed up for 18 months.
We compared the HDL-C levels that were measured after a 12-hour fast at baseline and 18 months among those with Normal baseline HDL-C level. Abnormal HDL was defined as HDL-C levels <1.68 mmol/l.
Results: A total of 3662 participants were screened at baseline for HDL-C levels. 31% (1125/3662) of participants had normal HDL-C with 845 of them having both baseline and month-18 HDL measurements.
Majority were females (73%), aged 24 – 49years (53.9%), and ART experienced (94.1%). The median HDL-C level decreased from 2.50 (1.9 - 3.4) mmol/l at baseline to 1.4 (1.2 – 1.6) mmol/l at month 18 (p<0.001). The incidence of abnormal HDL was 77.5% (95%CI: 74.6 – 80.2).
Being overweight (IRR=1.12 (95% CI: 1.02 – 1.24)), obese (IRR: 1.19, 95% CI: 1.08 – 1.31), ART naïve (IRR: 1.20, 95%CI: 1.10 – 1.32) and not having a co-morbidity (IRR: 1.10, 95% CI: 1.01 – 1.20) were associated with higher risk of low HDL-C by month 18.
Conclusions: HDL-C levels in PLHIV on DTG based regimen for 18 months decreased significantly. Increasing BMI and being ART naïve predisposed these PLHIV to having low HDL.

EP0143

Depressive symptoms among adolescents and young adults living with HIV on antiretroviral therapy: outcomes from a cross-sectional study in Accra, Ghana

V. Ganu[1,2], K. Torpey[1], M. Lartey[3,2], M. Odikro[1], V. Shabanova[4], E. Paintsil[4,5], E. Kenu[1]
[1]University of Ghana, School of Public Health, Accra, Ghana, [2]Korle Bu Teaching Hospital, Accra, Ghana, [3]University of Ghana Medical School, Accra, Ghana, [4]Yale University, Yale School of Medicine, New Haven, United States, [5]Boston Medical Center and University, Massachusetts, United States

Background: Systematic screening for depression among adolescents and young adults living with HIV (AYALHIV) is limited or non-existing in some settings in sub-Saharan Africa due to lack of integration of mental health care into HIV programmes. This can increase the risk of suicidal thoughts and cause emotional distress which can have an adverse effect on their treatment outcomes. Establishing evidence of the burden of depression among AYALHIV is key for advocacy for systematic screening.
This study examined the burden of depressive symptoms and associated factors among AYALHIV in Ghana.
Methods: A single center facility-based cross-sectional study was conducted among AYALHIV at the Infectious Disease Center of the Korle Bu Teaching Hospital, Accra, Ghana from May 2023 to March 2024. Depressive symptoms were assessed through the administration of Patient Health Questionnaire for Adolescents (PHQ-A). Prevalence of depressive symptoms (PHQ-A score ≥5) and associated factors were examined using logistic regression at a level of significance of 0.05.
Results: A total of 280 AYALHIV were recruited with 50.7% being female. Sixty percent were young adults, and the rest were adolescents. About 75% were virally suppressed. The prevalence of depressive symptoms was 40.7% (95% CI 34.9% - 46.7%).
Being an orphan (adjusted odds ratio [aOR]=2.59, 95% Confidence Interval [95%CI] 1.21-5.56), female (aOR=1.81, 95% CI 1.08-3.04) and having high perceived HIV stigma (aOR= 2.17, 95% CI: 1.28-3.67) were associated with having depressive symptoms. Viral non-suppression was associated with both high perceived HIV stigma and depressive symptoms.
Conclusions: Depressive symptom burden was high among AYALHIV despite viral suppression in majority of them.
There is need for mental health screening integration into youth-centered HIV programmes based on context for early identification, counselling and treatment of mental health challenges to ensure good quality of life and avert other mental health challenges.

EP0144

Prioritization of people living with HIV (PLHIV) for mental health screening: Early learnings from implementation of integrated HIV/ Mental health care in rural Zimbabwe between October 2023-September 2024

R. Dhliwayo[1], C. Hera[1], E. Mandere[1], B. Mushangwe[1], W. Mlilo[1], P. Maunganidze[2], G. Gonese[1], T. Maphosa[3], H.J. Cham[3], B. Makunike-Chikwinya[1], K.A. Thomson[4]
[1]Zimbabwe Technical and Training and Education Centre for Health (Zim-TTECH), Public Health, Harare, Zimbabwe, [2]Ministry of Health and Child Care, Mental Health, Harare, Zimbabwe, [3]Division of Global HIV & TB (DGHT), U.S. Centers for Disease Control and Prevention (CDC), Public Health, Harare, Zimbabwe, [4]University of Washington, International Training and Education Centre for Health (I-TECH), Seattle, United States

Background: Mental health care in Zimbabwe has traditionally been centralized within specialty services available in urban areas, creating unmet needs among people living with HIV (PLHIV) and those residing in rural settings.
The Ministry of Health & Child Care prioritized building capacity of primary care health workers to identify and treat mental illnesses including depression, anxiety, and substance use through the Mental Health Gap Action Program (MhGAP), a WHO initiative to facilitate mental health services delivery through non mental health specialists.
Description: Between October 2023 and September 2024, seven public-sector facilities in Hurungwe District integrated screening and treatment for mental illnesses among PLHIV ≥ 10 years self-presenting for clinical consultations.
Eighteen nurses were trained on the MhGAP curriculum to facilitate management of common mental illnesses, and 30 community health workers (CHWs) were trained in peer-to-peer cognitive behavioural intervention, Problem-Solving Therapy (PST), and use of translated screening tools for depression and anxiety including [Shona Symptom Questionnaire (SSQ14), Mental Health Questionnaire (PHQ9), and Generalized Anxiety Disorder (GAD7)].
Screening at facility level mainly included screening using PHQ9 and GAD 7, with SSQ14 sometimes administered. Clients scoring above standard thresholds for moderate symptoms received PST and further assessments through nurses . Some clients with lower scores self-reporting problems also received PST sessions through CHWs.
Lessons learned: Within the 1st year of implementation 41% (4,640/11,311) of facility cohorts were screened for mental health disorders. Based on SSQ14 results, 25% (110/446) had a need for PST and were assisted by CHWs.
Among these, 25% (28/110) were referred to trained nurses for further management, including 19 clients with warning signs such as suicidal thoughts and hallucinations.
According to the GAD 7 assessment, 7% (297/4,194) had moderate -severe anxiety, while the PHQ9 identified 4% (169/4,193) experiencing moderate - severe depression. From these 31 severe cases of anxiety and depression were further referred to a secondary level of care.

Conclusions/Next steps: This mental health screening initiative demonstrated that integration of mental health screening and treatment into HIV care is feasible with appropriate training, task-shifting, and referral planning; without which mental health challenges could go undiagnosed and untreated.

EP0145

Stigma-directed intervention to improve linkage to HIV care for people living with HIV in Rural Tanzania: a pre-post implementation study

E. Luoga[1], R. Magnolini[2,3], E. Senkoro[1], F. Vanobberghen[4,5], A.V. Kalinjuma[1,6], M. Battagay[5,7], A. Eichenberger[1,8], E. Krinke[9], L. Samson[1], O. Kitau[1], G. Mollel[1], J. Okuma[4,5], T. Glass[4,5], J. Brakowski[9], M. Weisser[1,8]

[1]Ifakara health institute, Ifakara, Tanzania, the United Republic of, [2]Arud Centre for Addiction Medicine, Zürich, Switzerland, [3]Institute of Primary Care (IHAMZ), University Hospital Zurich and University Hospital Zurich, Zürich, Switzerland, [4]Swiss Tropical and Public Health Institute, Basel, Switzerland, [5]University of Basel, Basel, Switzerland, [6]School of Public Health, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [7]Division of Infectious Diseases, University Hospital of Basel, Basel, Switzerland, [8]Inselspital, Bern University Hospital, University of Bern, Infectious Diseases, Bern, Switzerland, [9]Psychiatric University Clinic, Zürich, Switzerland

Background: HIV-related stigma remains a significant barrier to achieving timely linkage to care, retention, and optimal treatment outcomes in resource-limited settings. This study assessed the impact of a bundle of stigma-directed services at the time of HIV diagnosis on linkage to HIV care and viral suppression in rural Tanzania.

Methods: We conducted a pre-post analysis of newly implemented stigma-directed services within the Kilombero and Ulanga Antiretroviral Cohort (KIULARCO) at St. Francis Referral Hospital, Ifakara, Tanzania.

The pre-implementation phase (07/2017-01/2019) provided standard of care, while the post-implementation phase (02/2020-08/2021) introduced stigma-directed services for newly diagnosed people living with HIV (PLWH): post-test counseling, educational videos, group support therapy, and mobile health interventions, delivered by trained peer counselors.

Outcomes included linkage to care (ART initiation within two months), retention, viral suppression, self-reported stigma and depression scores, and mortality within one year. Data were analyzed using logistic and linear regression adjusted for baseline characteristics.

Results: A total of 1,334 participants, 848 (64%) female, median age 38 years (IQR 30-46) were enrolled (810 pre-implementation and 524 post-implementation). Linkage to care did not improve statistically in the post-implementation group (71%) compared to the pre-intervention group (69%) (Table).

Retention in care, viral suppression and mortality rates were comparable between the two groups. Self-reported stigma and depression scores declined over time, with greater improvements noted among participants who received all components of the stigma-directed intervention.

Outcomes	Pre-Implementation (n (%))	Post-Implementation (n (%))	Univariable (95% CI)	Multivariable (95% CI)	Adjusted p-value
Linkage to care	560 (69%)	370 (71%)	0.96 (0.76, 1.20)	1.05 (0.76, 1.45)	0.76
Retention in care (6–12 months)	491 (61%)	312 (60%)	0.96 (0.76, 1.20)	1.05 (0.76, 1.45)	0.78
Viral load suppression (6–12 months)	446 (92%)	280 (93%)	1.11 (0.63, 1.93)	1.53 (0.92, 2.31)	0.10
Mortality (6–12 months)	32 (4%)	27 (5%)	1.32 (0.78, 2.23)	1.33 (0.64, 2.77)	0.44
Self-reported stigma (Mean, SD)	26.35 (8.91)	19.24 (10.62)	-7.11 (-9.35, -4.86)	-6.61 (-9.75, -3.56)	<0.001
Self-reported depression symptoms	9 (8%)	8 (5%)	0.51 (0.26, 1.28)	0.43 (0.15, 1.17)	0.12

Table: Association Between Stigma-directed services and outcomes among newly diagnosed PLHIV (n=1334)

Conclusions: Stigma-directed services did not improve linkage to care among newly diagnosed PLWH. Further research is needed to understand the poor linkage during the first year of care.

EP0146

Week 96 Results from Dolutegravir/lamivudine versus bictegravir/ emtricitabine/tenofovir alafenamide fumarate: Real-world Assessment of weight Gain in people with HIV of Asian OrigiN (DRAGON)

C.-Y. Cheng[1], L. Li[2], C.-J. Yang[3], Q. Zhao[4], W.-H. Hsih[5], M.-W. Ho[5], T.-C. Chen[6], M.-S. Tsai[3], S.-Y. Lee[1], Y.-C. Lin[1], C.-P. Chen[1], S.-H. Cheng[1], X. Zhang[4], M. Zou[7], Y.-W. Wu[8], M.-H. Huang[8], T.-C. Hung[9], P. Ma[10], H.-Y. Ku[1]

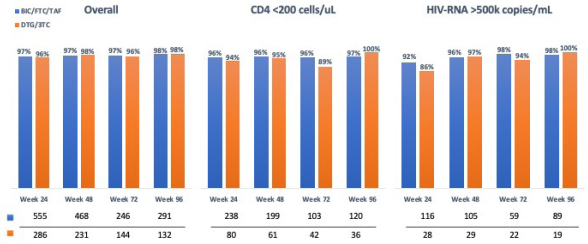
[1]Taoyuan General Hospital, Ministry of Health and Welfare, Department of Infectious Diseases, Taoyuan City, Taiwan, Province of China, [2]Guangzhou Medical University Affiliated Eighth Hospital, Guangzhou, China, [3]Far Eastern Memorial Hospital, New Taipei, Taiwan, Province of China, [4]Henan Infectious Diseases Hospital, Zhengzhou, China, [5]China Medical University Hospital, Taichung City, Taiwan, Province of China, [6]Taichung Hospital, Ministry of Health and Welfare, Taichung City, Taiwan, Province of China, [7]Nantong Third People's Hospital, Jiangsu, China, [8]Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien County, Taiwan, Province of China, [9]Ditmanson Foundation Chiayi Christian Hospital, Chiayi City, Taiwan, Province of China, [10]Tianjin Second People's Hospital, Tianjin, China

Background: Several studies have demonstrated low CD4 counts, high HIV RNA levels, female sex, and Black race have been associated with a higher likelihood of weight gain in some people with HIV (PWH) after initiating antiretroviral therapy. The DRAGON study aimed to compare weight gain among Asian ART-naïve patients initiated on DTG/3TC or BIC/FTC/TAF.

Methods: This was a retrospective, multi-center, observational cohort study conducted at ten hospitals from March 2019 to January 2024 in Taiwan and mainland

China-mainland. The primary endpoint was the risk factors of participants who experienced a ≥10% increase in weight. Secondary endpoint included achieving HIV RNA levels <200 copies/mL after initiating DTG/3TC or BIC/FTC/TAF (per-protocol analysis).

Results: A total of 1,053 patients were included, with 372 in the DTG/3TC group and 681 in the BIC/FTC/TAF group. Figure 1 showed that the effectiveness was not significantly different between DTG/3TC and BIC/FTC/TAF.



The mean weight change at week 48 was 2.9 kg in the DTG/3TC group and 4.2 kg in the BIC/FTC/TAF group (difference:1.3 kg; p=0.01), and it was 3.5 kg and 5.1 kg (difference:1.6 kg; p=0.05) at week 96.

Additionally, 143 (24.3%) and 134 (33.7%) patients exhibited ≥10% weight gain at weeks 48 and 96. A logistic regression model was conducted to identify the risk factors, including CD4 <200 cells/μL and BMI <24 kg/m². (Table 1)

	Adjusted odds ratio (Week 48)	95% CI	p	Adjusted odds ratio (Week 96)	95% CI	p
BIC/FTC/TAF vs DTG/3TC	1.44	0.84 - 2.47	0.19	1.76	0.90 - 3.43	0.10
Age <40 vs ≥40 years	0.87	0.55 - 1.38	0.55	0.95	0.56- 1.63	0.86
Male vs female	1.81	0.69 - 4.75	0.23	0.95	0.48 - 0.90	0.93
Men who have sex with men	1.11	0.50 - 2.45	0.80	0.32	0.09 - 1.16	0.08
Injection drug user	0.97	0.53 - 1.75	0.91	1.001	0.54 - 1.85	0.99
Heterosexual	1.04	0.24 - 4.62	0.96	0.98	0.20 - 4.82	0.98
CD4 <200 vs ≥200 cells/uL	2.32	1.52 - 3.54	<0.01	2.19	1.36 - 3.53	<0.01
HIV RNA ≥100K vs <100k copies/mL	1.27	0.83 - 1.94	0.28	1.16	0.72 - 1.86	0.54
BMI <24 vs ≥24 kg/m²	2.58	1.54 - 4.32	<0.01	2.32	1.31 - 4.10	<0.01

Conclusions: Our study showed that DTG/3TC was comparable to BIC/FTC/TAF in achieving virologic suppression. Furthermore, low CD4 counts and BMI were associated with a higher likelihood of weight gain among treatment-naïve PWH in Asia.

EP0147

Impact of dual therapy on weight gain and metabolic outcomes in naïve people living with HIV (PLHIV) with CD4 counts <200 cells/mm3: findings from the DOLCE study

C., United States

Background: Weight changes can impact health outcomes. While weight loss has been associated with advanced HIV disease, individuals with low CD4 counts may experience weight gain, potentially associated with antiretroviral therapy (ART) initiation.

We report the effects of dolutegravir-based dual and triple therapy on weight, glucose, and lipid profiles after 48 weeks of treatment in PLHIV with low CD4 counts.

Methods: The DOLCE study reported comparable rates of virologic suppression between dual therapy (DT) and triple therapy (TT) in PLHIV with CD4 counts <200 cells/mL.[1] Key outcomes included weight, BMI, glucose, and lipid profiles.

Metabolic changes were analyzed with a mixed-effect linear regression model, controlling for baseline values, sex, and race.

Results: Out of 230 subjects, 153 were in the DT arm and 77 in TT. 75.7% were male, 24.3% female; 42.6% Hispanic/Latino, 38.7% White, and 15.2% Black. Median baseline weight was 64 kg for DT and 63 kg for TT, with 48-week weights of 74 kg (DT) and 71 kg (TT).

Weight increase was 14% (DT) vs 11% (TT) (p=0.017). Median baseline BMI was 22.6 for DT and 22.7 for TT, significantly increasing by W48 in both arms: DT 25.8, TT 25.5.

Metabolic changes were also observed. The median increase in total cholesterol, LDL-C, and HDL-C was less in TT: 22% vs 5% (cholesterol, p<0.001) and 22% vs 4% (LDL-C, p<0.001).

Triglycerides increased more in the TT group (17% vs 0%). Despite the increase, the values remained within the upper normal limit Blood glucose remained unchanged in both arms during the 48 weeks (Table 1).

Table 1. BSL and Week 48 Metabolic Outcomes. Median percentage change from baseline

	DT (n=152)			TT (n=77)		
Median (IQR)	BSL Median*	W48 Median*	Median % change**	BSL Median*	W48 Median*	Median % change**
Weight	64 (57-62)	74 (66-82)	+14 (9;27)	63 (58-73)	71 (65-85)	+11 (4;20)
Total cholesterol	137 (119-169)	172 (149-196)	+22 (4;41)	142 (123-170)	155 (134-170)	+5 (-8;20)
HDL	37 (29-45)	48 (39-57)	+29 (10;52)	36 (29-46)	42 (36-52)	+14 (0;47)
LDL	77 (59-97)	98 (78-115)	+22 (1;52)	82 (63-97)	86 (75-102)	+4 (-14;27)
Triglycerides	116 (82-152)	105 (73-144)	0 (-25;27)	101 (83-158)	87 (63-111)	-17 (-42;10)
Glucose	85 (80-92)	87 (81-95)	+1 (-6;11)	85 (80-90)	88 (83-95)	+5 (-5;14)

* Unit weight kg; unit cholesterol, HDL, LDL, triglycerides, glucose mg/dl

** Median percentage increase between baseline and week 48. Percentage change was calculated at each specific time point for each subject as (concentration [week 48] - concentration [baseline]) / (concentration [baseline]) x 100.

Conclusions: Both DT and TT resulted in significant weight gain and lipid changes in HIV-positive individuals with low CD4 counts, with no effect on glucose levels. The weight gain likely reflects a return to health due to ART initiation in this severely immunosuppressed population.

EP0148

Predictors of liver fibrosis in people living with HIV-HBV co-infection on antiretroviral therapy: a long-term observational cohort study

T. Huang[1], H. Liang[2], L. Huang[2], B. Liang[1]

[1]Guangxi Medical University, Nanning, China, [2]Qinzhou First People's Hospital, Qinzhou, China

Background: Human Immunodeficiency Virus (HIV) and Hepatitis B Virus (HBV) share transmission routes, and co-infection increases the risk of liver fibrosis compared to HBV alone. Liver fibrosis is a potential predictor for severe liver disease. However, the risk factors in HIV-HBV co-infected individuals remain poorly understood.

This study aimed to evaluate the incidence of liver fibrosis and identify the determinants associated with its progression in this population.

Methods: An observational cohort study was conducted among adults with HIV and HBV co-infection receiving ART from 2005 to 2022 in the Southwest of China. Participants without fibrosis before ART therapy underwent blood tests every 3 months, including liver function, white blood cell counts, blood glucose, platelet counts, and hemoglobin. HIV clinical index, including CD4+ T cell counts and HIV viral load, were conducted every six months. Liver fibrosis was defined using the Aspartate Aminotransferase to Platelet Ratio Index (APRI) and Fibrosis-4 Index (FIB-4). Cox proportional hazard models were employed to identify factors associated with liver fibrosis.

Results: 810 participants (49.51% male, median age 41 years) were followed for 1,786.94 person-years, with a median follow-up period of 2.21 person-years. During the follow-up, 30.7% of participants met the primary endpoint of liver fibrosis.

Multivariable Cox regression models indicated that the incidence of liver fibrosis was associated with an increased risk of older age (35-49 years, aHR = 1.76, 95% CI, 1.28-2.43; ≥50 years, aHR = 2.00, 95% CI, 1.33-3.00), male sex (aHR = 1.67, 95% CI, 1.21-2.31), higher baseline FIB-4 score (≥1.45, aHR = 1.59, 95% CI, 1.11-2.29), ALT levels at baseline ≥40 U/L (aHR = 1.44, 95% CI, 1.05-1.97), Hepatitis C Virus (HCV) positivity (aHR = 1.88, 95% CI, 1.34-2.64), and lower CD4+ T cell counts at baseline (0-199 cells/μL, aHR = 1.46, 95% CI, 1.05-2.04) compared to those without liver fibrosis.

Conclusions: This study revealed a high prevalence of fibrosis among individuals with HIV-HBV co-infection after ART. Fibrosis progression was associated with older age, male sex, higher initial FIB-4 scores and initial ALT, HCV co-infection, and lower initial CD4+ T cell counts, emphasizing the need for early monitoring and comprehensive management of hepatitis co-infections.

EP0149

Improving cervical cancer screening among women on antiretroviral therapy in community-based decentralized service delivery model in southern nigeria using a multi-strategy approach

N. Ibah[1], K.-A. Ukpong[1], W. Egome[2], I. Edet[1], U. Jane[2], U. Sampson[1], J. Abua[1], E. Ogar[2], O. Otu[3], I. Udoh[4], A. Amos[2], M. Unimuke[2], E. Ekanem[1], O. Ekele[2], B. Gana[2], U. Akpan[2], O. Onwah[2], E. Nwanja[2], O. Toyo[2], D. Ogundehin[5], E. James[5], J. Pius[5], O. Oyelaran[5], O. Onyedinachi[5], A. Adegboye[2], A. Eyo[2]

[1]Achieving Health Nigeria Initiative, Uyo, Nigeria, [2]Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, [3]State Ministry of Health (SASCP), Cross River, Nigeria, Cross River, Nigeria, [4]State Ministry of Health (SMOH), Akwa Ibom, Nigeria, Uyo, Nigeria, [5]Office of HIV and TB, United States Agency for International Development, Abuja, Nigeria

Background: Differentiated Service Delivery (DSD) models are designed for healthcare services to meet the diverse needs of people living with HIV (PLHIV). However, these models, if out-of-facility, can significantly impact access to facility-based services like cervical cancer screening.

This study describes a multi-strategy approach to integrating cervical cancer screening into community-based DSD models to increase access for women living with HIV (WLHIV).

Methods: This study was conducted using routinely collected program data of WLHIV. In the study area, screening was done using visual inspection with acetic acid (VIA).

Four Strategies were employed to improve Cervical Cancer screening among WLHIV:

1. Task shifting to increase the pool of healthcare workers with skills to conduct the screening, thus reducing missed opportunities due to healthcare workers' unavailability. These providers were trained in screening and identification of precancerous lesions.
2. Identifying health facilities not receiving program support, training the healthcare workers on counselling and screening, and linking them in a hub-and-spoke mechanism to a supported facility. Here, eligible women who missed cervical cancer screening during their clinic appointment were referred to these spoke centers for screening.
3. Referrals to the health facility during annual reassessment visits.

4. Clustering eligible women based on their locations for cervical cancer screening, leveraging clinicians in the mobile community teams to conduct the screening.
This multi-strategy approach was implemented between October 2023 -November 2024 across 31 Local Government Areas in Akwa Ibom State, Nigeria. The outcomes were assessed by extracting cervical cancer screening data from the electronic medical records and analysed using Statistical Package for the Social Sciences (SPSS).
Results: 6417 out of 9457 women of reproductive age eligible for cervical cancer screening received ART in community DSD between October 2023 and November 2024. The median age was 37 [IQR: 32-42] years. In November, 5653(88%) of unscreened WLHIV received CXCA screening, increasing screening access for WLHIV in Community DSD from 32% (3040/9457) at baseline to 54%(5093/9457) at 6months, 85%(8039/9467) at 12months and 92% at end line (8693/9457).
Conclusions: This study provides evidence that integrating cervical cancer screening into community DSD is feasible and can increase screening rates among WLHIV.

EP0150

Impact of different blood pressure control definitions on blood pressure control prevalence among individuals receiving integrated HIV-hypertension care in Lilongwe, Malawi

B.A. Banda[1], V. Kumwenda[1], K. Balakasi[2], E. Gulule[3], K. Nyirenda[2], M. Chimombo[1], J. Njala[4], H. Kanise[4], M. Chivwara[3], A. Moses[5], S. Phiri[4,6], R. Hoffman[7], J.J. van Oosterhout[4,7]
[1]Partners in Hope, Moyo Clinic Center of Excellence, Lilongwe, Malawi, [2]Partners in Hope, Science Department, Lilongwe, Malawi, [3]Partners in Hope, Monitoring and Evaluation Department, Lilongwe, Malawi, [4]Partners in Hope, Programs Department, Lilongwe, Malawi, [5]Partners in Hope, Medical Facility, Lilongwe, Malawi, [6]Kamuzu University of Health Sciences, School of Global and Public Health, Blantyre, Malawi, [7]University of California Los Angeles, Department of Medicine, David Geffen School of Medicine, Los Angeles, United States

Background: The prevalence of blood pressure (BP) control among individuals from sub-Sahara Africa with HIV and hypertension has varied, but is generally low. We explored the impact of different definitions of BP control on its prevalence.
Methods: The Partners in Hope Moyo Centre of Excellence for HIV Care and Treatment, is a PEPFAR-supported HIV clinic in Lilongwe, Malawi. It has a one-stop-shop model for integrated HIV-hypertension management with free-of-charge medication (antihypertensives and antiretroviral therapy) and aligned multi-month dispensing.
We compared 2 commonly used BP control definitions:
A. based on the last BP measurement in a quarter (October-December 2023), and;
B. based on the last 2 or 3 BP measurements over the previous year (January-December 2023), of which at least 2 meet the control threshold (systolic <140 mmHg and diastolic <90 mmHg).
From the clinic database, we identified individuals with hypertension and randomly selected equal numbers with and without BP control according to definition A). On this population, we applied definition B) to estimate the impact on the prevalence of BP control.
Results: 220 individuals on ART and with hypertension were included, 64% female, median age 54 years (IQR 47–62), median duration ART 13 years (IQR 9.7–15.3), 31% obese (BMI≥30kg/m^2), 81% on >1 antihypertensive drug, 11% with diabetes mellitus. Using definition A), 50% (110/220) of clients were controlled. Using definition B), 47% (104/220) were controlled.
Of 110 individuals with controlled BP according to definition A), 83 (76%) also had controlled BP according to definition B). Of 110 with uncontrolled BP according to definition A), 89 (81%) also had uncontrolled BP according to definition B). 48 (22%) individuals changed from controlled to uncontrolled BP or vice versa using a different BP control definition.
Conclusions: There were moderate differences between the two definitions of BP control with limited impact on BP control prevalence. These definitions should be further explored in larger studies in diverse settings. Reports of blood pressure control can vary widely and standardizing the definitions would help comparing data within and across programs with high prevalence of HIV and hypertension co-morbidity.

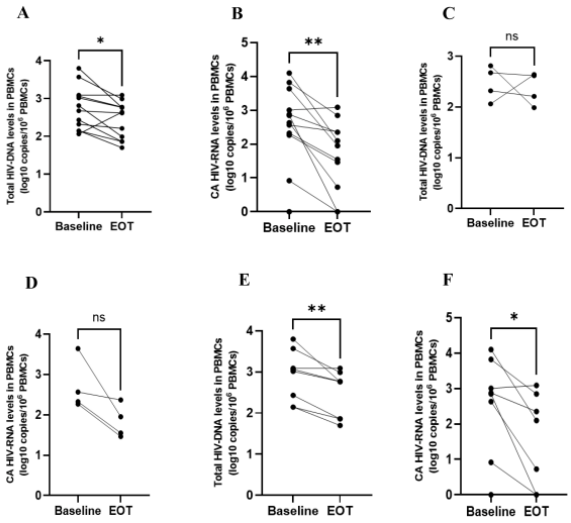
EP0151

Viral tropism and quasispecies dynamics in AIDS-related non-Hodgkin's lymphoma under immunochemotherapy

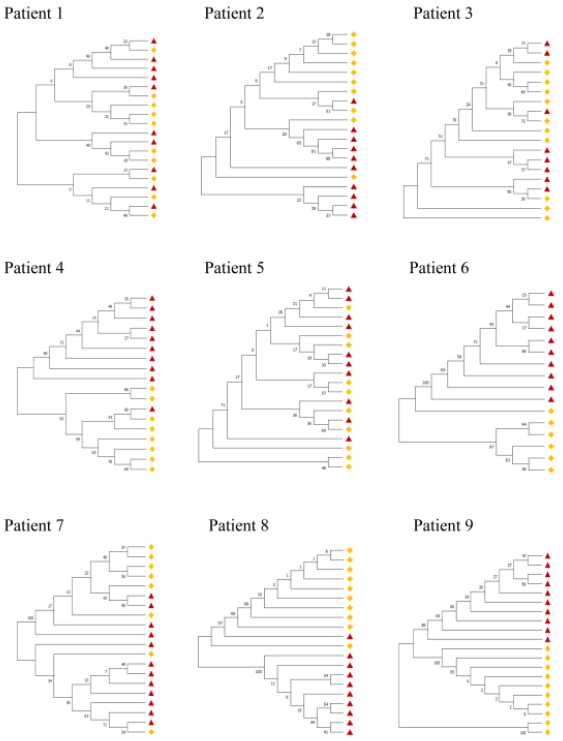
Y. Xiong[1], L. He[1], Z. Wan[1], B. Dai[1], Y. Guo[1], Y. Huang[1], B. Zhu[1]
[1]The First Affiliated Hospital, School of Medicine, Zhejiang University, The Department of Infectious Diseases,State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, Hangzhou, China

Background: Combination antiretroviral therapy (ART) effectively suppresses HIV replication and significantly prolongs survival in people with HIV (PWH). However, the virus persists in latent reservoirs, making complete eradication elusive. This article aims to explore the effects of ART combined with immunochemotherapy on HIV.
Methods: Baseline blood samples from 39 PWH with newly diagnosed non-Hodgkin's lymphoma (NHL) were analysed for HIV-1 tropism. For PWH who provided complete blood samples before and after immunochemotherapy, additional analyses were performed, including assessing HIV reservoir changes, quasispecies diversity and complexity, phylogenetic relationships, and evolutionary dynamics.
Results: Among the 39 PWH with newly diagnosed NHL, 25.64% exhibited X4 tropism as determined by V3 region sequence analysis. Twelve PWH provided paired blood samples for further analyses. ART combined with immunochemotherapy led to a significant reduction in intracellular HIV DNA and cell-associated HIV RNA levels post-treatment (p = 0.022 and 0.0019, respectively). Phy-

logenetic tree analysis of the *env* nucleotide sequences from nine of 12 PWH, for whom amplification was successful, revealed intersections or distinct clusters corresponding to treatment time points. Quasispecies distributions shifted, with some quasispecies disappearing post-treatment and novel quasispecies emerging that were absent at baseline.



Conclusions: In PWH with NHL, immunochemotherapy combined with ART effectively reduced viral reservoirs. However, dynamic changes in viral genetic variation and quasispecies following treatment highlight the need for further research to optimize individualized treatment strategies.



EP0152

Knowledge and attitudes about solid organ transplant for people with HIV among Australian healthcare providers and consumers

D. Griffin[1,2], K. Vaz[3], B. Gopal[4], W. Mulley[5,6], S. Kotecha[7], K. Levin[7], A. Leet[8], G. Snell[7], J. Trevillyan[9], A. Cogle[10], J. Rule[10], C. Burnett[11], J. Lau[1,2], S. Lee[1,2], J. McMahon[1,2], J. Hoy[1,2]

[1]Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia, [2]Monash University, School of Translational Medicine, Melbourne, Australia, [3]Victorian Liver Transplant Unit, Austin Health, Heidelberg, Australia, [4]Alfred Hospital, Department of Renal Medicine, Melbourne, Australia, [5]Monash Health, Department of Nephrology, Clayton, Australia, [6]Monash University, Department of Medicine, Clayton, Australia, [7]Alfred Hospital, Lung Transplant Service, Melbourne, Australia, [8]Alfred Hospital, Alfred Heart Transplant Service, Melbourne, Australia, [9]Austin Health, Department of Infectious Diseases, Melbourne, Australia, [10]National Association of People with HIV Australia, Newtown, Australia, [11]Living Positive Victoria, Melbourne, Australia

Background: Demand for solid organ transplantation (SOT) in people with HIV (PWH) is increasing. However, PWH experience disparate access to SOT, with multiple barriers reported. There is no legislative barrier to SOT for PWH in Australia.

This study aimed to explore knowledge about and barriers to organ receipt and donation for PWH among Australian healthcare providers (HCP) and consumers.

Methods: We conducted two surveys:

1) HCPs involved in HIV and SOT-related care, and;

2) consumers with chronic comorbidities and/or HIV.

Surveys were developed with HIV community organisations and hosted in Qualtrics. Survey responses were multiple choice or five-point Likert scale and shared via clinics, mailing lists, community and professional networks in Australia.

Results: 132 HCP and 175 consumers responded. 51% of HCP were HIV-specialists, and 49% were organ-specialists. 110/128 (86%) HCP thought PWH could be organ recipients, but 36/118 (30%) thought PWH could donate. 61/107 (57%) HCP indicated that comorbidities were the greatest barrier to SOT receipt, while 53/107 (49%) reported HIV and 34/107 (31%) felt legislation was the main barrier to donation.

Consumers included 122 PWH, and 53 controls. Fewer PWH than controls believed they would be eligible to receive an organ to prolong their life (51% vs 87%, p<0.001), that they were eligible to donate (40% vs 68%, p=0.002) or were registered as donors (22% vs 44%, p=0.01).

PWH were more willing to be deceased donors (96% vs 82%, p=0.002), but not living donors (71 vs 76%, p=0.53) than controls. PWH reported HIV superinfection (n=45, 40%) as the main concern about organ receipt from a donor with HIV.

Controls were most concerned about HIV infection (n=18, 40%) and safety (n=16, 35%). Age <55 [OR 0.48, (95% CI 0.23- 0.99)] and HIV care outside a hospital [OR 0.47 (95% CI 0.23-0.98)] predicted lower known eligibility to receive organs in PWH.

Conclusions: Most providers were aware that PWH could receive organ transplants, few were cognisant of the eligibility to donate. Consumers' awareness of the ability of PWH to both receive and donate organs is limited. Opportunities exist to improve knowledge and overcome misconceptions about SOT for PWH in Australia.

EP0153

A client-centered approach for the integration of hypertension screening in HIV services: a comparison between newly initiated and those already on antiretroviral therapy

J.H. Songoro[1], R. Van de Ven[1], F. Haraka[1], R. Shigi[2], S. Kimambo[1], C. Genge[3]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Technical, Dar Es Salaam, Tanzania, the United Republic of, [2]Elizabeth Glaser Pediatric AIDS Foundation, Technical, Arusha, Tanzania, the United Republic of, [3]Elizabeth Glaser Pediatric AIDS Foundation, Technical, Dar es salaam, Tanzania, the United Republic of

Background: People living with HIV (PLHIV) have an increased risk of developing non-communicable diseases (NCDs), including hypertension. We explored trends and outcomes in integrated screening for hypertension in antiretroviral therapy (ART) clinics across five regions supported by USAID Afya Yangu (My Health) Northern project in Tanzania.
This abstract outlines the experience of screening PLHIV for early hypertension detection, focusing on comparing clients identified with hypertension at ART initiation with those who developed it during long-term ART use.
Description: Healthcare providers at ART clinics were trained on screening PLHIV for NCDs using standard treatment guidelines, to ensure regular hypertension screening for PLHIV attending ART clinics.
Essential supplies, including blood pressure machines and weighing scales, were procured to facilitate this process. Non-identifiable client-level data were extracted from the national electronic HIV database. Providers at facilities completed client records on hypertension screening.
PLHIV who had at least one record of blood pressure measurement between October 2023 and September 2024 were included. We did a descriptive analysis of hypertension screening and results, disaggregated by sex, age, and HIV treatment status (new or already on ART).
Lessons learned: Overall, 82,997 PLHIV on ART were screened for hypertension. Out of those, 92% (76,318) were already on ART by 30 September 2023, and 8% (6,679) were newly initiated during the review period.
Among all participants, 59,248 (71%) were female. Among PLHIV already on ART, 4.2% (3,170/76,318) had high blood pressure, compared to 2.2% (144/6,679) for those newly initiated on ART.
The prevalence of hypertension among females on ART above the age of 50 years was 8.6%, compared to 7.0% in males of the same age group. The table below shows outcomes by age and sex.

Sex	Age group	No. of New ART clients	No of New clients with HTN	Proportion of new clients with HTN	No. of Current ART clients	No. of current clients with HTN	Porportion of current clients with HTN
Male	<25	251	1	0.4%	2,308	17	0.7%
	25-50	1,310	26	2.0%	10,759	246	2.3%
	50+	504	18	3.6%	8,617	604	7.0%
Female	<25	1,268	8	0.6%	7,866	49	0.6%
	25-50	2,519	45	1.8%	30,754	876	2.8%
	50+	827	46	5.6%	16,014	1,378	8.6%
Total		**6,679**	**144**	**2.2%**	**76,318**	**3,170**	**4.2%**

Conclusions/Next steps: PLHIV already on ART had higher prevalence of hypertension than those newly initiated on ART, with those aged fifty years and above having higher rates.

EP0154

Managing TB/HIV co-morbidities among children and adolescents co-infected with TB & HIV through targeted structural interventions in Northern Nigeria: a pathway to improved health outcomes

C. Odima[1], J. Ashivor[1], H. Mohammed[1], J. Anyanti[1], K. Eruchalu[1], K. Ukueku[1], O. Farinu[1], S. Makka[1], Q. Akewusola[1], J. Ojo[1], B. Yerima[1], O. Omede[1], M. Yalwe[1], R. Obilor[1], O. Adebayo[2], B. Pillatar[2], H. Raji[2], U. Ugwoke[2], E. Vincent[2], O. Opeyemi[2], O. Isaac[1], S. Okeh[1], A. Saleem[3], D. Mohammed[4], M. Zamsu[5], N. Workneh[5], O. Idogho[1]
[1]Society for Family Health, Global Fund N-THRIP, Abuja, Nigeria, [2]Insitute of Human Virology, Nigeria, Global Fund N-THRIP, Abuja, Nigeria, [3]Kwara State Agency for the Control of AIDS (KWASACA), HIV, Ilorin, Nigeria, [4]Gombe State Agency for the COntrol of AIDS (GOMSACA), HIV, Gombe, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, HIV, Geneva, Switzerland

Background: Tuberculosis (TB) is the leading cause of death among people living with HIV (PLHIV) with the risk of developing active TB 20 times higher compared to those without HIV. TB remains a significant public health challenge in Nigeria. Children and adolescents under 15 years represents 11% of global TB cases. Structural interventions aim to reduce HIV transmission and morbidities by changing social norms, policies, and other social barriers to treatment. We reviewed TB cascade monitoring and treatment outcomes for children and adolescents living with HIV and enrolled in care in 54 Health facilities providing HIV/TB comprehensive services in both states for the past 3 years.
Description: SFH implemented targeted interventions to optimize care for children and adolescents with TB/HIV co-morbidities. These included establishing virologic clinics for specialized care, enhanced case management, same-day CD4+ testing with results, CrAg screening, and laboratory investigations, enrolling orphans and vulnerable children into programs promoting health, safety, and education, Operation Triple Zero (OTZ) clubs to ensure zero missed appointments, avoid treatment interruption and ensure suppressed viral loads, scaling up early infant diagnosis (EID) and integrated testing using GeneXpert machines and PIMA point-of-care technology.
Program data from the Electronic medical records was reviewed for outcome of TB screening, diagnosis and treatment.

Lessons learned: 1,031 children and adolescents were screened for TB from December 2021 to October 2024. 13 (6 Males, 7 Females) children were diagnosed and treated successfully using standard medications. GeneXpert was leveraged to diagnose 85% of cases with the clients provided close monitoring to ensure all treated clients achieved viral load suppression.
Also, all the clients were successfully treated for TB with zero deaths and no signs of TB recurrence post-treatment. Among those treated, 23% were on ABC-3TC-DTG, while 77% were on TDF-3TC-DTG and all 13 children and adolescent attained 100% VL suppression.
Conclusions/Next steps: Improved monitoring and surveillance for TB among HIV/TB co-infected clients through active targeted screening can ensure early diagnosis and management of TB among children and adolescents. This is in addition with improved case management and targeted differentiated care towards optimizing treatment outcomes.

EP0155

Exploration of common molecular mechanisms and hub genes in diffuse large B cell lymphoma shared with AIDS using bioinformatics and machine learning strategies

C. Gao[1], J. Li[1], J. Xiao[1], H. Zhao[1], L. Sun[2]
[1]Clinical and Research Center of AIDS, Beijing Ditan Hospital, Capital Medical University, China, Beijing, China, [2]Division of Pathology, Beijing Ditan Hospital, Capital Medical University, China, Beijing, China

Background: The study aimed to explore the common molecular mechanisms, hub genes and screen small molecular drugs of hub genes in DLBCL shared with HIV/AIDS.
Methods: DEGs were screened separately in HIV and DLBCL datasets with "limma" R package, which was intersected with Venn analysis to identify the common DEGs. GO and KEGG signaling pathway analysis were further performed, PPI network was constructed and node genes were identified. ML algorithms were used to screen potential hub genes, which were evaluated with ROC curve and IHC staining.
Hub genes-associated signaling pathways were enriched, while immune cell infiltration and relationship with hub genes was derived based on CIBERSORT package. Potential small molecular drugs were screened and molecular docking was conducted with hub genes.
Results: MCM3 was identified as hub gene based on ML algorithms, which was demonstrated high expression in samples of DLBCL in HIV/AIDS patients with IHC staining.
GSVA analysis indicated that high expression of MCM3 protein was enriched in IL-2 STAT5 signaling pathway, angiogenesis, EMT, Kras signaling, Notch signaling and Wnt-β Catenin signaling pathway, while infiltration of activated CD8+ T cells, CD4+T cells and NK cells increased more significantly in DLBCL and HIV infection,separately, and presented positive relationship with MCM3.
Potential small molecular drugs were screened and identified that Belinostat has good molecular docking stability and may be the most potential compound.
Conclusions: MCM3 genes played a key role in tumorigenesis, and Belinostat was identified as a valuable small molecule drugs for precise treatment in DLBCL shared with HIV/AIDS.

EP0156

Exploring the relationship between dolutegravir and diabetes using programmatic data in a cohort of ART clients in Lubombo and Manzini

S. Haumba[1,2], T. Maseko[1], F. Khumalo[1], S. Ojoo[2]
[1]Center for Global Health Practice and Impact, Georgetown University, Clinical Services, Mbabane, Eswatini, [2]Center for Global Health Practice and Impact, Georgetown University Medical Center, Georgetown University Medical Center, Washington, United States

Background: Studies have documented the pathways and predictors of type 2 diabetes (T2DM) among people living with HIV (PLHIV). Recent studies reported that health providers perceive dolutegravir (DTG), an antiretroviral therapy drug of choice in Eswatini since October 2018, as a driver of T2DM among PLHIV. This is due that in many ART clients who developed T2DM after switching to DTG, were diagnosed within 12 months of transitioning to DTG. Some studies have noted that PLHIV are transitioned to DTG-based regimen without T2DM screening, making it difficult to adequately establish a causal relationship between DTG and T2DM, yet other studies have reported a rather protective relationship between DTG and T2DM.
This study aimed used programmatic data to document the association between DTG and T2DM among PLHIV on ART in Eswatini using programmatic data.
Methods: We conducted a retrospective cohort analysis on clients active on ART by 31 December 2022 in Manzini and Lubombo using programmatic data.
Descriptive statistics were used to compare diabetes prevalence between clients on DTG-based regimen and those not on DTG-based regimen. Predictive statistics were used to determine if DTG is a predictor of T2DM, and its covariates.
Results: A total of 67,417 participants were included in the analysis, and 1.1% (n=785) of clients were diabetic. Of the 785 clients, 4.2% (n=33) developed T2DM before ART initiation, and 95.8% (n=752) developed after ART initiation, of which 22.3% (n=168) were never exposed to DTG, and 77.7% (n=584) developed T2DM after exposure to DTG. The highest prevalence was on clients who were never on DTG (2.0%, n=33) or transitioned from DTG (2.0%, n=77).
Clients initiated and remained on DTG had the least rate (0.4%, n=48). Predictors of T2DM were age (AOR:1.1(95%-CI:1.0-1.1), p<0.001), body mass index (BMI) (AOR:1.1(95%-CI:1.05-1.09), p<0.001), and duration on ART (AOR: 1.2 (1.1-1.3), p<0.001). DTG was protective from T2DM (AOR:0.5(95%-CI:0.4-0.6), p<0.001).
Conclusions: Most diabetes cases developed after ART initiation, with a lower prevalence among those consistently on DTG. Key factors associated with T2DM development included age, BMI, and duration on ART.

EP0157

Can dolutegravir-associated weight gain be reversed? Experiences from Harare, Zimbabwe

T. Shamu[1,2], C. Chimbetete[1], T. Mudzviti[1,3], N. Anderegg[2]
[1]Newlands Clinic, Harare, Zimbabwe, [2]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [3]University of Zimbabwe, School of Pharmacy, Harare, Zimbabwe

Background: Many people living with HIV transitioned from efavirenz-based (ART_{EFV}) to dolutegravir-based antiretroviral therapy (ART_{DTG}), but some experience excess weight gain, raising the risk of non-communicable diseases. We investigated whether discontinuing dolutegravir (DTG) reverses this weight gain.

Methods: We used data from Newlands Clinic in Zimbabwe, including longitudinal weight measurements from adults (≥18 years) who switched from ART_{EFV} to ART_{DTG} excluding those underweight.

We compared proportional weight change while on ART_{DTG} between those who later discontinued DTG and those who remained on it. For those who stopped DTG, we used Bayesian linear mixed models to estimate monthly weight change trends from 1.5 years before to 3 years after discontinuation.

Separate models were fitted for pre- and post-discontinuation periods, including sex, time, and their interaction as fixed effects, with participant as a random intercept.

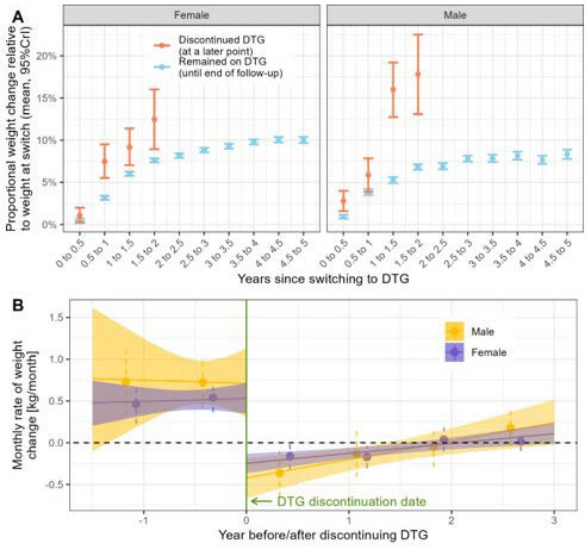


Figure 1. A) Proportional weight gain (relative to weight at switch) while on DTG in all adults who have switched to DTG at Newlands Clinic. Points show 6-monthly means, while error bars show 95% credible intervals. B) Estimated monthly rates of weight change before and after discontinuing DTG. Lines correspond to posterior medians; shaded areas to 95% credible intervals. Regression models were fitted to individual-level data, the dots in B) represent 9-monthly averages to illustrate model fit.

Results: We analysed 52,870 weight measurements from 2,969 adults (72% female, n=2,141), including 1,713 measurements from 108 individuals who discontinued DTG. After switching to ART_{DTG}, those who later stopped DTG had greater weight gains compared to those who remained on it.

For example, at 6-12 months post-switch, mean gains were 5.9% vs. 3.9% in males and 7.5% vs. 3.2% in females *(Figure 1A)*. In those who remained on DTG, weight stabilised 3-4 years post-switch.

Among those who discontinued DTG , estimated monthly weight gain rates were constant before stopping (0.75 kg/month in males, 0.5 kg/month in females; *Figure 1B)*. Immediately post-discontinuation, estimated weight loss rates were 0.42 kg/month in males and 0.25 kg/month in females, progressively diminishing without evidence of weight change after two years.

Conclusions: Stopping DTG in people with excess weight gain resulted in weight loss. Weight reductions were partial, indicating incomplete weight-gain reversal. Regular weight monitoring and counselling around weight reduction strategies remains important for individuals on ART_{DTG}.

EP0158

Effect of Dolutegravir compared to Darunavir/Cobicistat, both with TDF/FTC, in neuropsychiatric effects at 12 weeks of treatment in PLH with baseline neuropsychiatric disorders and no antiretroviral therapy experience

M. Rodriguez Evaristo[1], J.A. Mata Marin[2], S. Triana Gonzalez[2], O.C. Martinez Carrizalez[3], J.E. Gaytan Martinez[2]
[1]Instituto Mexicano del Seguro Social, Hospital de Especialidades CMN La Raza, Ciudad de Mexico, Mexico, [2]Instituto Mexicano del Seguro Social, Hospital de Infectologia La Raza, Department of Infectious Diseases, Ciudad de Mexico, Mexico, [3]Instituto Mexicano del Seguro Social, Hospital de Infectologia La Raza, Psychiatric Department, Ciudad de Mexico, Mexico

Background: Integrase strand transfer inhibitors (INSTI) are associated with neuropsychiatric adverse events (NPS). The aim was to assess the change in NPS in people living with HIV (PLWH) who had baseline NPS symptoms without prior experience of antiretroviral therapy (ART) and who started a regimen with Dolutegravir (DTG) compared to Darunavir/Cobicistat (DRV/c), both with Tenofovir Disoproxil Fumarate/Emtricitabine (TDF/FTC).

Methods: A randomized open-label clinical trial conducted at the Hospital de Infectología, Centro Médico Nacional "La Raza" from June 2023 to December 2024 (ClinicalTrials.gov Identifier: NCT06787976), to evaluate changes in NPS scales for depression, anxiety, insomnia, and sleep quality in PLWH initiating ART with either a DTG or DRV/c regimen, both combined with TDF/FTC. All patients were assessed by psychiatry before starting ART.

Discontinuation was considered if patients experienced exacerbation of NPS scales associated with adverse events of grade ≥2. Scores were compared at weeks 4 and 12.

Results: A total of 54 male patients were included, with 27 (50%) receiving DRV/c and 27 (50%) receiving DTG. The median age was 26 years (IQR 23-30), baseline CD4+ count was 248 (IQR 162-365), and baseline HIV-1 RNA was 4.4 log^{10} (IQR 3.9-4.9) (Table 1).

Prior to ART initiation, 10 patients (17.8%) reported suicidal thoughts. In the DTG group, 7 individuals (28%) discontinued ART due to the new onset of suicidality and exacerbation of NPS symptoms. Scores were compared at baseline and at 12 weeks, showing significant reductions in both

groups. A significant difference was found in the HADS-A and PHQ-9 scales, with a lower score in DRV/c group. No difference was found in the other scales (Table 2).

Table 1. Baseline characteristics of the studied population.

Characteristic	DTG + TDF/FTC N=27	DRV + TDF/FTC N=27	p
Age, median,(IQR) years	26 (21-39)	28 (23-36)	0.937
CD4+, median (IQR) cells/mm3	346 (162-480)	299 (154-326)	0.739
VIH-1 Viral load, median (IQR), log_{10}	4.4 (3.9-4.9)	4.4 (3.7-4.7)	0.848
ART discontinuation, n (%)	7 (28%)	2 (7%)	0.135
Basal PHQ-9, median (IQR), score	16 (10-19)	14 (9-20)	0.224
Basal ISI, median, (IQR), score	12 (8-16)	10 (9-17)	0.067
Basal HADS-A, median (IQR), score	11 (9-12)	12 (9-13)	0.105
Basal HADS-D, median (IQR), score	8 (5-10)	10 (8-11)	0.079
Basal PSQI, median (IQR), score	10 (8-13)	9 (6-10)	0.297

Table 2. Comparison of scores at 12 weeks

Parameter	DTG + TDF/FTC N=13	DRV + TDF/FTC N=13	p
PHQ-9 12 weeks, median (IQR), score	9 (5-13)	7 (3-14)	**0.038**
ISI 12 weeks, median, (IQR), puntos	8 (4-12)	6 (2-14)	0.406
HADS-A 12 weeks, median (IQR), score	9 (5-12)	7 (4-11)	**0.005**
HADS-D 12 weeks, median (IQR), score	8 (2-9)	6 (2-10)	0.388
PSQI 12 weeks, median (IQR), score	8 (4-11)	6 (3-9)	0.946

Conclusions: Preliminary data from this study, with 12 weeks of follow-up, suggests difference in HADS-A and PHQ-9 scores between the two groups. Patients in the DTG + TDF/FTC group reported a higher risk of suicidality.

EP0159

CD4-driven advanced HIV disease diagnosis, cryptococcosis, and TB-LAM testing in Kenya

D. Achwoka[1], L. Odero[2], N. Maina[3], S. Siamba[1], G. Omora[4], M. Gikura[5], S. Okutoyi[1], D. Kimanga[6], K. Muthoka[5], L. Momanyi[7], R. Bhattacharje[8], D. Goldstein[3]

[1]USAID/Kenya, HPN-Treatment, Nairobi, Kenya, [2]HJFMRI, Nairobi, Kenya, [3]United States Agency for International Development (USAID), Washington, United States, [4]U.S. Department of Defense, Nairobi, Kenya, Nairobi, Kenya, [5]Palladium, Nairobi, Kenya, [6]U.S. Centers for Disease Control (CDC), Nairobi, Kenya, [7]Kenya Ministry of Health, National AIDS & STI Control Program (NASCOP), Nairobi, Kenya, [8]GHTASC, Credence Management Solutions LLC, Washington DC, United States

Background: Despite significant progress toward achieving the UNAIDS 95-95-95 goals, in 2022 Kenya was estimated to have the eighth-highest number of AIDS-related deaths globally. Advanced HIV disease (AHD), defined as CD4 count of <200 cells/mm³ or WHO stage 3 or 4 conditions, remains a significant contributor to HIV-related morbidity and mortality in Kenya.

This study examines the burden of AHD across Kenya and assesses key gaps in CD4, CrAg, and TB-LAM testing

Methods: We analyzed de-identified records from Kenya's National Data Warehouse (NDW) for individuals aged >5 from October 1, 2022, to September 30, 2023, focusing on three high-risk groups for advanced HIV disease (AHD): those newly initiating ART (TX_NEW), those returning to treatment after ≥3 months of interruption (RTT-IIT), and those with virologic failure (VL ≥1,000 copies/ml for two consecutive tests within six months after adherence support).

We collected demographic data and dates of HIV diagnosis, ART initiation, re-engagement, and viral load, as well as CD4, cryptococcal antigen (CrAg), and TB-LAM testing to assess AHD care. These data were then overlaid on 2024 UNAIDS subnational PLHIV estimates to describe county-level burden.

Results: As of September 30, 2023, Kenya had 1,227,223 active clients on ART reported to the NDW. From the NDW, we identified 150,009 AHD high-risk clients derived from TX_NEW, 76,477 (51.0%), RTT-IIT, 69,650 (46.4%) and virologic failure, 3,882 (2.6%) categories. Two thirds, 99,575 (66.4%) were female. Ages 25-49 constituted 100,711 (67.1%) of clients, 50+ years were 27,067 (18.0%), 15-24 year olds were 17,481 (11.7%), and 05-14 year olds were 4,750(3.2%). CD4 tests were conducted on 38,790 (25.9%) clients, with 13,093 (33.8%) having a count <200 cells/mm³. A follow-on CrAg test was conducted among 5,076(38.8%) of clients with 358 (7.1%) positivity. TB-LAM was done among 472 (3.6%) with 144 (30.5%) positive tests (Table 1).

County AHD prevalence ranged from 1.4-13.8% with Nairobi AHD burden and prevalence at 2,864 and 8.22% respectively.

Conclusions: Kenya faces a significant burden of advanced HIV disease. Improving coverage of CD4 testing that serves as a gateway to AHD care and targeted interventions to address gaps along the care cascade are required. Additionally, expanded access is needed for AHD commodities and screening including CD4 testing, CrAg, and TB-LAM.

EP0160

Time to event analysis for CD4 and CrAg testing among AHD high-risk clients in Kenya

N. Maina[1], L. Momanyi[2], D. Achwoka[3], L. Odero[4], S. Siamba[3], G. Omoro[5], M. Gikura[6], S. Okutoyi[3], D. Kimanga[7], K. Muthoka[6], D. Goldstein[1], R. Bhattacharje[8]

[1]United States Agency for International Development, Office of HIV/AIDS, Washington DC, United States, [2]Kenya Ministry of Health, National AIDS & STI Control Program (NASCOP), Nairobi, Kenya, [3]USAID/Kenya, HPN-Treatment, Nairobi, Kenya, [4]HJFMRI, Nairobi, Kenya, [5]U.S. Department of Defense, Nairobi, Kenya, [6]Palladium, Nairobi, Kenya, [7]U.S. Centers for Disease Control (CDC), Nairobi, Kenya, [8]GHTASC, Credence Management Solutions LLC, Washington DC, United States

Background: Kenya faces a disproportionate burden of advanced HIV disease (AHD). Delays in CD4 and CrAg testing, crucial for diagnosis and care, correlate with higher HIV-related morbidity and mortality.

This study assesses time from AHD high-risk categorization to CD4 testing and from CD4-driven AHD diagnosis to cryptococcosis screening via CrAg test.

Methods: We analyzed de-identified records from Kenya's National Data Warehouse of AHD high-risk clients aged >5 years from Oct 1, 2022, to Sept 30, 2023. High-risk criteria included: newly initiating ART (TX_NEW); returning to treatment ≥ 3 months after interruption (RTT-IIT); and confirmed viremia of ≥1,000 copies/ml for two consecutive tests within six months. Data included demographic characteristics, dates and results for HIV diagnosis, ART initiation and re-engagement, viral load, and CD4 and CrAg data. Time to CD4 testing was defined as the pe-

riod from HIV diagnosis, re-engagement, or second viral load testing to CD4 testing date. Time to CrAg testing was defined as the period from CD4 <200 cells/mm³ to CrAg testing date. Kaplan-Meier curves estimated times to CD4 and CrAg testing by AHD high-risk categories. Log-rank test assessed differences between categories.

Results: Among 150,009 AHD high-risk clients, CD4 testing was conducted on 38,790 (25.9%) clients: 1,012 (2.6%) ages 5-14, 4,920 (12.7%) ages 15-24, 26,893 (69.3%) ages 25-49, and 5,965 (15.4%) ages ≥ 50 years. CD4 tests among females were 26,380 (64.6%). TX_NEW clients received CD4 testing earlier than other categories. Median time to CD4 testing was not assessed as no categories reached 50% testing rate. Log-rank test detected differences in CD4 testing by risk category ($p < 0.0001$). Among 13,093 clients eligible for CrAg testing, 5,076 (38.7%) received a test. Median time to CrAg testing for virologic failure clients was 240 days. TX_NEW and RTT-ITT categories did not reach the 50% testing threshold. Differences in CrAg testing by AHD-risk categories was significant (log-rank $p = 0.0044$).

Conclusions: The analysis reveals significant disparities in time to CD4 and CrAg testing across risk categories. Targeted interventions, especially for RTT and virologic failure clients, and increased access to early testing at facilities are essential to improve AHD detection and outcomes.

EP0161

Comparative analysis of estimated glomerular filtration rate in people living with HIV on ART in AFRICOS study

J. Njegite[1,2], N. Burns[3,4], S. Frndak[3,4], A. Parikh[3,4], H. Kibuuka[5], J. Owuoth[6,7], V. Sing'oei[6,7], J. Maswai[8,9], E. Bahemana[1,2], R. Gervas[1,2], A. Tiamiyu[10,11], Z. Parker[12,4], T. Crowell[3,4], J. Ake[3], N. Shah[3]

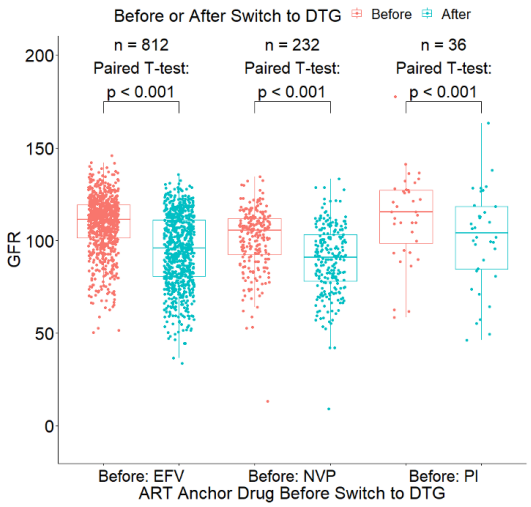
Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, United States, [5]Makerere University Walter Reed Project, Kampala, Uganda, [6]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Kisumu, Kenya, [7]HJF Medical Research International, Kisumu, Kenya, [8]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Kericho, Kenya, [9]HJF Medical Research International, Kericho, Kenya, [10]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Abuja, Nigeria, [11]HJF Medical Research International, Abuja, Nigeria, [12]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Lagos, Nigeria

Background: Renal dysfunction is a significant issue in people living with HIV (PLWH). A sustained estimated glomerular filtration rate (eGFR) reduction (<60 ml/min/1.73 m²) indicates chronic kidney disease. This study aims to assess the association between ART regimen and eGFR among PLWH.

Methods: AFRICOS is an observational cohort study which has been enrolling people living with and without HIV in Kenya, Nigeria, Tanzania, and Uganda since 2013. Creatinine levels were assessed at six-monthly visits until 2020 and then assessed annually. This analysis included PLWH with at least two visits on ART regimens which included anchor drugs DTG, efavirenz (EFV), nevirapine (NVP), or a protease inhibitor (PI). Participants were excluded if they had prevalent persistently reduced eGFR, defined as eGFR <60 at their first two visits. Paired t-tests compared eGFR before and after switching to DTG. The association between ART regimen and incident persistently reduced eGFR (<60 at two consecutive visits) was also evaluated using Cox proportional hazards models.

Results: As of 1 March 2024, 3,275 PLWH on ART were enrolled; 2,630 met inclusion criteria for this analysis. Of these, 99 (3.8%) had incident persistently reduced eGFR. Among the 1,080 participants who switched to DTG during follow-up and had a visit 90-270 days after the switch, eGFR decreased significantly for all prior ART regimens (Figure). However, ART regimen was not associated with incidence of persistently reduced eGFR, possibly due to more subtle changes in eGFR following the switch to DTG.

Figure. eGFR before and after switch to DTG stratified by anchor drug before switch, with paired t-test comparing eGFR before and after switch.



Conclusions: While ART regimen was not significantly linked to persistently reduced eGFR, switching to DTG was associated with a decrease in eGFR, regardless of prior ART regimen. This could highlight changes in kidney function that may not be detected with a focus only on binary normal vs reduced eGFR. Further research is needed to understand the long-term renal effects of DTG.

EP0162

Integrating lay health worker-supported blood pressure screening into routine HIV care identifies people with hypertension and links them to care at health facilities in Malawi

C.M. Cox[1,2], V. Guzani[1], A. Mazenga[1], G. Kaunda[1], S. Chu[1,3], K.R. Simon[1,3]

[1]Baylor College of Medicine Children's Foundation Malawi, Lilongwe, Malawi, [2]Baylor College of Medicine, Department of Pediatrics, Houston, United States, [3]Baylor College of Medicine, Houston, United States

Background: People living with HIV (PLHIV) are at risk of poor outcomes from cardiovascular disease. Integration of blood pressure (BP) screening into routine HIV care facilitates early detection of hypertension and linkage to treatment.

Since 2022, Malawi HIV ART guidelines have recommended integrated BP screening for PLHIV 30+ years. Baylor Foundation Malawi (BFM) has utilized community health workers (CHWs) since 2008 to help clients navigate longitudinal HIV care cascades in Malawi.

We describe integration and scale-up of BP screening and referral into this continuum of HIV care.

Methods: Baylor Foundation Malawi supports delivery of HIV prevention, care and treatment services in 96 health facilities. Lay health workers (CHWs) were trained to deliver hypertension health education, to identify those eligible for BP measurement; to measure BP using automated cuffs; and to refer people with elevated BP (>140/90) or taking anti-hypertensive medication for clinical evaluation at ART. Automated BP cuffs were provided for use during ART clinic triage.

Cluster-based CHW trainings included video demonstrations of BP measurement followed by practicals, modeled health talks on BP lifestyle modification, and use of a tally for tracking and reporting. Trained CHWs integrated screening into ART triage and tracked eligibility, BP results, and referrals. Routine program data was analyzed.

Results: BP screening integration began in February 2024 with 11% (n=10) sites reporting week 1, 49% (n=47) week 2, and 91% (n=86) by week 5 with 96% sites (range: 88-100%) consistently reporting from July.

From February - 30 Nov 2024,106,837 blood pressures were measured, with 6.6% (n=7072) high BP (>140/90). Reported completed counseling sessions for people with high BP increased consistently from July 2024 (Figure 1).

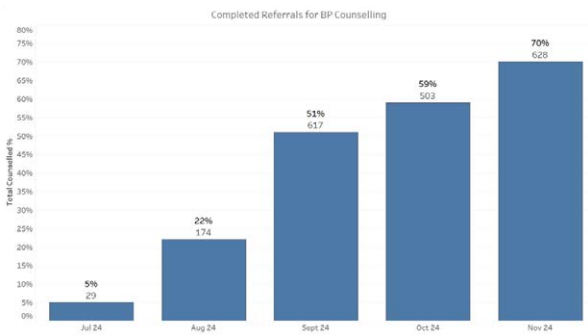


Table 1.

Conclusions: Leveraging a CHW-supported longitudinal care cascade for PLHIV to integrate BP screening in routine ART care is feasible and facilitates identification and linkage to care. Quantification of medical treatment linkage is underway.

EP0163

Prevalence of dyslipidemia and associated factors among people living with HIV in Rwanda

S. Tuyishime[1], V. Dushimiyimana[2,3,4], Y.M. Ishimwe Kirunga[2], C. Nsanzabaganwa[2], F. Nasibu[5], M. Twagirumukiza[3], N. A. B. Ntusi[4], S. Callens[3], Brenda Asiimwe Kateera, Eric Remera, Albert Tuyishime, Gallican Nshogoza Rwibasira, Pacifique Mukashema, Gregorie Muhorakeye, Francois Uwinkindi, Clarisse Musabanaganwa,Leopold Bitunguhari, Tugirimana Jean Berchmans, Deo Mutambuka

[1]Université de Montréal, Ecole de Santé Publique, Montréal, Canada, [2]Rwanda Biomedical Centre (RBC), Kigali, Rwanda, [3]Ghent University Hospital, Département of Internal Medicine, Ghent, Belgium, [4]University Cape Town, (Medicine) and South Africa Medical Research Council, Cape Town, South Africa, [5]Rwanda NCDs Alliance, Kigali, Rwanda

Background: HIV infection and antiretroviral therapy are linked with metabolic disorders, which increase the risk of cardiovascular diseases among people living with HIV (PLHIV). This study aimed to determine the prevalence of dyslipidemia and its associated factors among PLHIV in Rwanda.

Methods: A cross-sectional study was conducted among PLHIV aged 18 years and above, recruited from 12 health facilities offering HIV and non-communicable disease (NCD) services. Participants had been on antiretroviral therapy for at least 12 months. Data were collected using the WHO STEPwise approach to NCD risk factor surveillance (STEPS). Descriptive statistics and chi-square tests were used for categorical variables, and binary logistic regression was employed to identify factors associated with dyslipidemia.

Results: The study included 785 participants, with 63.6% being female and a median age of 44 years. The overall prevalence of dyslipidemia was 60.2%. Specific lipid abnormalities included total cholesterol (TC) ≥ 200 mg/dl (13.3%), high-density lipoprotein (HDL) cholesterol < 40 mg/dl in men and < 50 mg/dl in women (46.7%), low-density lipoprotein (LDL) ≥ 130 mg/dl (9.7%), and triglycerides (TG) ≥ 150 mg/dl (16.6%).

Significant associations were found between dyslipidemia and age, gender, body mass index (BMI), smoking, and alcohol consumption. Older age groups (45-54 years: OR=2.10, 95% CI=1.46-3.03; above 55 years: OR=1.71, 95% CI=1.17-2.50) and higher BMI (obese: OR=2.40, 95% CI=1.54-3.74; overweight: OR=1.85, 95% CI=1.36-2.51) were strongly associated with dyslipidemia. Women were more likely to be diagnosed with dyslipidemia compared to men (OR=0.43, 95% CI=0.34-0.54). Smoking was not found to be agravating the risk of dyslipidemia in this study (OR=0.57, 95% CI=0.44-0.76).

Conclusions: The study highlights a high prevalence of dyslipidemia among PLHIV in Rwanda, particularly among women, older adults, and those with higher BMI. These findings underscore the need for integrating metabolic monitoring and interventions into the care of PLHIV to mitigate the risk of cardiovascular diseases.

EP0164

Evaluating body mass index as a predictor of hypertension among people living with HIV: evidence from a Tanzanian cohort to enhance public health and policy interventions

A. Charles[1,2], J. Kimaro[1,2], J. Magoma[1], H. Msangi[1]
[1]Temeke Regional Referral Hospital, Dar es salaam, Tanzania, the United Republic of, [2]Management and Development for Health, Dar es salaam, Tanzania, the United Republic of

Background: Hypertension and obesity are emerging public health challenges, particularly among PLWHIV in low- and middle-income countries. Hypertension affects 15–46% of PLWHIV. In sub-Saharan Africa, where HIV prevalence is highest, 20–45% of PLWHIV are hypertensive, and obesity rates are rising. In Tanzania, 27% of adults are hypertensive, and 29% are obese, with PLWHIV disproportionately affected.
This study explores BMI as a predictor of hypertension among recipients of care at Temeke Regional Referral Hospital, aiming to inform targeted public health and policy interventions to address the dual burden of HIV and NCDs.
Methods: A retrospective data collection was conducted using clinical records at Temeke Regional Referral Hospital Care and Treatment Clinic from year 2023 March to 2023 September. Data on BMI, blood pressure, age, marital status, ART regimen, duration on regimen, were extracted from patient records.
Hypertension was defined as systolic blood pressure ≥140 mmHg and/or diastolic blood pressure ≥90 mmHg or a documented diagnosis. Statistical analysis included descriptive statistics and multivariate logistic regression to identify predictors of hypertension.
Results: From study population of 949 hypertensive clients, 305(32.2%) were male and 644(67.8%) were female. 102 (10.7%) were underweight, 260 (27.4%) were overweight, 329 (34.7%) had a normal BMI, and 258 (27.2%) were obese. Females accounted for 76.7% (198/258) obese. Chi-square analysis showed a significant association between BMI and hypertension ($\chi2=90.74$, $p<0.001\chi^2 = 90.74$, $p < 0.001\chi2=90.74$, $p<0.001$).
Logistic regression revealed that being overweight (Adjusted Odds Ratio [AOR]: 2.45; 95% Confidence Interval [CI]: 1.89–3.18) or obese (AOR: 3.12; 95% CI: 2.21–4.39) significantly increased the odds of hypertension. Advanced WHO clinical stages (Stage 3: 81.1%, 770/949; Stage 4: 16.2%, 154/949) were also significantly associated with hypertension.
Conclusions: The study confirms that elevated BMI is a key predictor of hypertension among PLWHIV. The associations between sociodemographic factors and hypertension further highlight the importance of health interventions. hypertension screening programs into HIV care services should be adopted to strengthening integrated HIV-NCD care for PLWHIV.

EP0165

Determinants of good physical activity among urban adults with and without HIV in Zambia and Zimbabwe

K. Hamusonde[1], A. Mandiriri[2], J. Daka[1], G. Muula[1], C. Bolton-Moore[1], S. Bosomprah[1], M. Vinikoor[1], C. Chimbetete[2], G. Wandeler[3], B. Chihota[1], for leDEA Southern Africa
[1]Center for Infectious Diseases and Research in Zambia, Lusaka, Zambia, [2]Newlands Clinic, Harare, Zimbabwe, [3]Bern University Hospital, Bern, Switzerland

Background: The growing burden of Noncommunicable diseases (NCDs) in sub-Saharan Africa (SSA) is primarily driven by rapid urbanization and the adoption of sedentary lifestyles. We aimed to assess factors associated with good physical activity (PA), based on WHO recommended levels, among a cohort of adults living with and without HIV in Zambia and Zimbabwe.
Methods: Data were collected from adults aged 30+ from ongoing NCD clinic-based cohorts in Zambia, and Zimbabwe. Self-reported PA and dietary habits were collected using WHO questionnaires. Objective PA was measured in a sub-set of participants using ActiGraph wGT3X-BT accelerometers. Good-PA was defined using the WHO threshold of ≥600 metabolic-equivalent minutes (MET-minutes)/week. We determined factors associated with good-PA measured by accelerometry using logistic regression.
Results: Between 2019 and 2023 we enrolled 969 adults, 409 (42%) PWH and 560 (58%) females. Accelerometry data was available for 87 individuals including 65 (75%) women and 26 (30%) PWH. Median age was 38 years (IQR: 32–47), 32 (37%) participants were employed and 41 (47%) had self-reported alcohol use. Mean fruit and vegetable intake was 2.4 servings per day which is less than recommend ≥5 servings per day. Participants self-reported an average of 9,024 (SD 4,674) MET-mins/week, whereas accelerometery measured an average of 1,039 MET minutes/week (SD: 623.4), with 71% (n = 62) meeting recommended good-PA. In the logistic model, PWH had lower odds of meeting good-PA (aOR 0.27, 95% CI: 0.09–0.77), and there were trends towards better PA in men (aOR = 1.17, 95% CI: 0.38–3.90) and unemployed participants (aOR = 2.87, 95% CI: 0.90–10.09) (Figure 1).

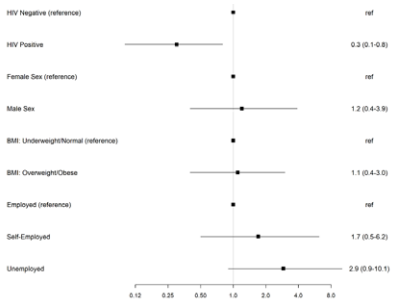

Figure 1. Factors associated with good physical activity defined as ≥600 MET-minutes/week on accelerometry.

Conclusions: Urban adults in Africa may over-report PA levels. While the majority of the sample had good PA, PWH were less-likely to meet recommended PA. These findings underscore the need to incorporate objective PA measures and interventions in routine healthcare for NCD prevention.

EP0166

Knowledge and associated factors of diabetes among people living with HIV in Rwanda: a cross-sectional study

P. Mukashema[1], V. Dushimiyimana[2,3], R. Rutayisire[4,5], P. Karame[6], D. N. Uwera[7], G. N. Rwibasira[8], F. Uwinkindi[8], B. A. Kateera[9], N. Nduwamungu[9], L. Bitunguhari[5,10], V. Vincent[10], N. A. B. Ntusi[11], M. Twagirumukiza[3], S. Callens[3], L. Nshimiyimana[12]

[1]Rwanda Network of People Living with HIV, Kigali, Rwanda, [2]Rwanda Biomedical Center, RIDS, Kigali, Rwanda, [3]Ghent University Hospital, Département of Internal Medicine, Ghent, Belgium, [4]Rwanda Biomedical Center, Kigali, Rwanda, [5]University of Rwanda, College of Medicine and Health Sciences, Kigali, Rwanda, [6]South Eastern Finland University of Applied Sciences, Department of Research and Development, Active Life, Mikkeli, Finland, [7]Univeristy of Rwanda,5. University of Rwanda, College of Medicine and Health Sciences, Kigali, Rwanda, [8]Rwanda Biomedical Centre, Kigali, Rwanda, [9]Clinton Health Access Initiative, Kigali, Rwanda, [10]Kigali Teaching University Hospital, Internal medicine department, Kigali, Rwanda, [11]University Cape Town, (Medicine) and South Africa Medical Research Council, Cape Town, South Africa, [12]Rwanda Biomedical Centre, Research Innovation and Data Science, Kigali, Rwanda

Background: The dual burden of communicable and non-communicable diseases remains a big public health challenge, particularly in sub-Saharan Africa. People living with HIV (PLHIV) are at a higher risk of developing diabetes due to chronic inflammation, antiretroviral therapy, and lifestyle factors. Despite the high burden of diabetes among PLHIV, in our setting there limited research on diabetes knowledge and associated factors among PLHIV which could affect early detection, treatment adherence, and the health outcomes.
This study aimed to assess the level of knowledge of diabetes among PLHIV in Rwanda and identify demographic, healthcare, and lifestyle factors associated with awareness to inform targeted interventions in HIV care programs.
Methods: A cross-sectional study was conducted nested within an ongoing cohort on health determinants for major NCDs among PLHIV in Rwanda between March and September 2021. Using random sampling 1,175 adults aged 18+ without a prior diabetes diagnosis were selected from 12 health facilities across five Rwandan provinces. Data were collected by trained research assistants under supervision of principal investigator using a structured and validated questionnaire; and descriptive statistics and multivariate logistic regression were used to identify determinants of diabetes awareness.
Results: Of participants, 36.56% reported no knowledge of diabetes, while 63.44% had some awareness. Women (55.72%) showed higher knowledge compared to men (53.52%). Awareness was significantly lower among older individual (40.94%) compared to younger (18–35 years) participants (59.6%). Educational attainment emerged as a critical factor, 84.78% with tertiary education showing awareness compared to 49.25% with no formal education. Lifestyle factors such as physical activity for at least 10 minutes was associated with better diabetes knowledge (OR=1.70, p=0.009), however, low-frequency stress at work has a modest (OR=1.31, p=0.212) and fruit and vegetable intake (AOR = 0.81, 95% CI: 0.51–1.21, p = 0.297) were not significant of diabetes knowledge.
Conclusions: The study highlights the urgent need to integrate diabetes education into HIV care programs, focusing on vulnerable groups such as older people and those with lower education levels. Gender-sensitive and age-specific interventions are essential to bridge identified knowledge gaps and enhance health outcomes for PLHIV.

EP0167

Visual inspection with acetic acid (VIA) in the community; reaching wider coverage for cervical cancer screening among key population women living with HIV (KP-WLHIV): Adamawa experience

G. Dauda[1], H. Bwari[2], M. Kigbu[3], R. Zitta[2], N. Udofia[2], W. Anosike[4]

[1]KNCV, Program, Bauchi, Nigeria, [2]Society for Family Health, Program, Yola, Nigeria, [3]NASCP, Program, Jalingo, Nigeria, [4]Society for Family Health, Program, Sokoto, Nigeria

Background: Cervical Cancer is a leading cause of cancer in women second to breast cancer in Nigeria. The incidence of cervical cancer is more among women living with HIV due to their low immune status.
The Visual Inspection with Acetic acid (VIA) technique was recommended by the WHO for screening of cervical cancer especially in low resource settings (WHO, 2012).
Society for Family Health (SFH) is currently implementing a USAID funded project, Key Population Community HIV Services for Action and Response (KP CARE 2) which adopted this technique to screen all KP-WLHIV in Adamawa state.
Description: In the initial kick-off of the VIA campaign, the OSS Clinicians were trained on the VIA technique and use of Cryotherapy for treatment of VIA positive pre-cancerous lesions. These procedures were done mainly in the OSS which yielded small coverage.
A review necessitated the setup of community level structure, recruiting and training Community Health care workers (nurses and midwives) across the state.
Overall, all the LGAs in the state were clustered into 6 zones based on locations where the Program sited its Community Clinical Services Assistant Point (CCSAP) with each cluster having a trained community worker carrying out VIA screenings in the CCSAPs and conducting outreaches in hard-to-reach locations.

Lessons learned: In 2021 when screening was only done at the facility, 194 clients were screened. Following the use of community structure in 2022, 714(368%) clients were reached and screened. This was accompanied by consistent increased coverage in the following years.
Though there was an initial fall in the number VIA positive clients in 2022 and 2023 as compared to the initial 6 in 2021. But a significant result of 25 positives (417% compared to 2021) was achieved which was as a result of the continuous capacity building of the community workers. All the VIA positive clients had cryotherapy done at the OSS.

YEAR	2021	2022	2023	2024
No of women screened	194	714	1062	1242
NO VIA POSITIVES	6	5	2	25

Conclusions/Next steps: The use of trained community health workers for cervical cancer screening using the VIA technique has a significant impact in reaching a wider coverage of KP-WLHIV.

Antiretroviral therapies and clinical issues in adults

EP0168

First-line treatment failure in HIV care: insights from a 10-year multicenter observational study of over 6,500 people living with HIV in Senegal

B.S. Wembulua[1], D. Ka[1], V.M.P. Cisse[1], N.F. Ngom[2], A. Mboup[2], I. Diao[2], A. Massaly[3], K. Diallo[4], M.B. Diallo[1], J.L. Diouf[5], J. Kombila[6], M. Diop[7], P.S. Ba[7], N.M. Manga[4], S.O. Wembonyama[8], Z.K. Tsongo[8], M. Seydi[1]
[1]Department of Infectious and tropical diseases of Fann University Hospital, Dakar, Senegal, [2]Centre de Traitement Ambulatoire (CTA),), Fann university hospital, Dakar, Senegal, [3]Pavillon de traitement ambulatoire (PTA), Regional hospital of Kaolack, Kaolack, Senegal, [4]Unit of Infectious and tropical diseases, Hôpital de la Paix, Ziguinchor, Senegal, [5]Heath District of Ziguinchor, Ziguinchor, Senegal, [6]Unit of Infectious and tropical diseases, Regional hospital of Kolda, Kolda, Senegal, [7]Department of Infectious and tropical diseases of Hôpital Principal de Dakar (HPD), Dakar, Senegal, [8]University of Goma, Goma, Congo, the Democratic Republic of the

Background: Antiretroviral resistance is a major challenge, especially in low-income countries where access to advanced diagnostic tools remains limited. In Senegal, 20% of people living with HIV (pwHIV) on tenofovir-based regimens develop drug resistance mutations within 12 months, highlighting the need for better access to genotypic testing and improved evaluation
Methods: This multicenter, cross-sectional study was conducted among people living with HIV (pwHIV) followed-up at seven HIV clinics, including three university hospitals in Dakar and three regional hospitals in Ziguinchor, Kaolack, and Kolda, from 2013 to 2023. We included pwHIV aged 18 years or older who had been on antiretroviral treatment for at least six months. Therapeutic failure, as defined by WHO criteria, included clinical, immunological, and virological failure. The prevalence of therapeutic failure was reported as a proportion with a 95% confidence interval (95% CI), and associated factors were analysed using multivariable logistic regression.
Results: A total of 6,878 PLHIV were included in the study, of whom 4,316 (62.8%) were female, 3,294 (47.9%) were married, and 2,456 (35.7%) were from Dakar. The median age was 40 years (interquartile range [IQR]: 30–50). At enrollment, 731 participants (10.6%) were classified as WHO clinical stage IV, with a median CD4 count of 223 cells/mm³ (IQR: 69–447). Hepatitis B surface antigen (HBsAg) was detected in 10.5% of the participants. The median follow-up period was 69.1 months (IQR: 39.8–98.9). The prevalence of first-line treatment failure was 3.6% (95% CI: 3.1–4.1). Multivariable analysis identified significant associations between treatment failure and age <20 years (adjusted odds ratio [aOR] 4.4; 95% CI: 1.1–14.4; p=0.02), being part of Dakar cohorts (aOR 2.1; 95% CI: 1.1–4.1; p=0.03), the presence of opportunistic diseases (aOR 13.2; 95% CI: 6.8–26.0; p<0.001), and initiating antiretroviral therapy before 2016 (aOR 4.6; 95% CI: 1.9–13.8; p=0.002).
Conclusions: The prevalence of first-line treatment failure is low but is associated with younger age (<20 years), enrollment in Dakar cohorts, opportunistic diseases, and treatment initiation before 2016. Active failure monitoring, strengthening the "test and treat" strategy, and improving access to genotypic testing are essential to optimize HIV care in Senegal.

EP0169

Patient-reported outcomes among virally suppressed people living with HIV switching to dolutegravir/lamivudine vs. continuing bictegravir/emtricitabine/tenofovir alafenamide from the randomized DYAD study

C.-P. Rolle[1,2], J. Castano[1], V. Nguyen[1], F. Hinestrosa[1,3], E. DeJesus[1,3]
[1]Orlando Immunology Center, Orlando, United States, [2]Emory University Rollins School of Public Health, Global Health, Atlanta, United States, [3]University of Central Florida College of Medicine, Orlando, United States

Background: We previously demonstrated noninferior efficacy of switching to dolutegravir/lamivudine (DTG/3TC) vs. continuing bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) among stably suppressed adults through Week (W) 48 in the DYAD study. Here, we present changes in patient-reported outcomes (PROs) through W48 among those switching to DTG/3TC vs. continuing B/F/TAF.
Methods: DYAD utilized PRO measures to evaluate HIV and antiretroviral-related symptom burden (HIV-SI), treatment satisfaction (HIVTSQ/c) and willingness to switch at baseline, W24 and W48 (willingness to switch only assessed at baseline among those on DTG/3TC). HIV-SI responses were dichotomized into bothersome vs. not bothersome and compared across time by treatment group using Chi-squared testing. Changes from base-

line in HIV-SI and HIVTSQ/c scores were compared between treatment groups with ANCOVA models adjusted for baseline score, gender, age, race/ethnicity, duration of HIV infection, duration of antiretroviral use and prior duration of B/F/TAF.

Results: Overall, 199 completed W48 and were included, 134 on DTG/3TC and 65 on B/F/TAF. At W24, 16% on DTG/3TC reported headache as bothersome compared to 6% on B/F/TAF (p=0.04), however, at W48 there was no significant difference in headache. At W48, 10% on DTG/3TC reported diarrhea as bothersome compared to 0% on B/F/TAF (p=0.01), however, there was no significant difference in diarrhea at W24. There were no other significant differences in bothersome symptoms through W48. At W48, both DTG/3TC and B/F/TAF participants demonstrated small reductions in the total HIV-SI symptom score (-5.9 vs. -4.3 respectively, adjusted treatment difference -1.6, 95% confidence interval (CI): -4.8; 1.5) and treatment satisfaction score (-3.7 vs. -3.2 respectively, adjusted treatment difference -0.5, 95% CI: -6.5; 5.5) with no significant differences by treatment arm. At baseline, top reasons for willingness to switch among those on DTG/3TC were interest in HIV research (85%) and physician request for study participation (61%).

Conclusions: In DYAD, both switching to DTG/3TC and continuing B/F/TAF were associated with similar and small reductions in overall symptom and treatment satisfaction score at W48. These data are the first describing PRO outcomes from a randomized clinical trial of DTG/3TC and B/F/TAF and support DTG/3TC as a switch option with comparable symptom burden and treatment satisfaction to modern 3-drug integrase inhibitor-based regimens.

EP0170

The power of choice: strong preference for CAB+RPV LA following rapid suppression with DTG/3TC in newly diagnosed people living with HIV

F. Felizarta[1], C. Gutner[2], C. Jonsson-Oldenbüttel[3], I. Kolobova[2], J.-M. Molina[4], K. Hove[5], S. Lupo[6], R. Trehan[5], J.C.L.B. de Quiros[7], J. Priest[2], P. de los Rios[2], S. Somvanshi[8], M. Bui[9], L. Garside[9], R. Grove[9], H.P. Garges[2], K. Brown[2], J. van Wyk[5]

[1]Private Practice, Bakersfield, United States, [2]ViiV Healthcare, Durham, United States, [3]MVZ München am Goetheplatz, Munich, Germany, [4]Paris Cité University, Paris, France, [5]ViiV Healthcare, London, United Kingdom, [6]Instituto Centralizado de Asistencia e Investigación Clínica Integral, Rosario, Argentina, [7]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [8]Development Statistics, GCC, GSK, Bengaluru, India, [9]GSK, London, United Kingdom

Background: Dolutegravir/lamivudine (DTG/3TC) and long-acting cabotegravir plus rilpivirine (CAB+RPV LA) have demonstrated high efficacy and favorable tolerability, providing people living with HIV (PLWH) a greater number of options for two-drug regimens with different modalities and dosing frequencies to meet their individual needs. Understanding individuals' unique treatment choices is critical for ensuring person-centered care for PLWH.

Methods: VOLITION is a Phase 3b, multicenter, non-randomized, parallel-group, open-label study. ART-naive adults receiving initial treatment with daily DTG/3TC (~16-week Suppression Phase) were offered the choice to switch to CAB+RPV LA dosed every two months at the immediate next study visit (Day of Choice [DoC]) after attaining viral suppression (HIV-1 RNA <50 copies/mL). Participant experience was assessed at baseline/DoC using questionnaires that evaluated preference, advantages of having the option to choose, as well as reasons for, and feasibility of, switching.

Results: Overall, 171 participants initiated DTG/3TC, including 26% women, 30% Black or African American, and 51% Hispanic/Latinx. Baseline questionnaires demonstrated interest in LA therapy, with 85% (n=101/119) of participants expressing an interest in switching to CAB+RPV LA. At DoC, 129 (89%) of 145 eligible participants chose to switch to CAB+RPV LA and 16 (11%) chose to continue DTG/3TC. Treatment-naive participants valued being empowered with the option to switch after achieving rapid suppression and its associated advantages (**Table**). Participants reported switching as highly feasible (Feasibility of Intervention Measure [n=155]: mean, 4.3/5.0). The most common reasons why participants chose to switch to CAB+RPV LA were not having to worry about missing a dose each day (80%) and not having to carry medication (68%).

Question*	n=155
"How does it feel to be given a choice about your future HIV treatment?" n (%)	
I am happy to know there are options for future treatment to match my lifestyle	111 (72)
It provides me with an option to suit my needs and daily life	86 (55)
It gives me hope for the future	82 (53)
"What are the advantages of having the option of switching from a daily pill for HIV treatment to a long-acting HIV injection treatment to keep your HIV undetectable (virally suppressed)?" n (%)	
The option to switch fits my life better	108 (70)
Freedom to travel without concern about keeping my HIV undetectable	104 (67)
I get more of a say/more autonomy in my treatment	90 (58)

*Includes all participants who were offered the option to switch from DTG/3TC to CAB+RPV LA (10 participants answered surveys at DoC but were later deemed ineligible to switch). Responses are not mutually exclusive. The three most commonly reported answers are provided.
3TC, lamivudine; CAB, cabotegravir; DoC, Day of Choice; DTG, dolutegravir; LA, long-acting; RPV, rilpivirine.

Table. Participant perceptions of being given the option to switch to LA therapy and associated advantages (DoC).

Conclusions: Empowering newly diagnosed people with HIV with the opportunity to switch to CAB+RPV LA immediately after achieving rapid virologic suppression with DTG/3TC allowed participants to choose a treatment option that best met their individualized needs, which is essential for treatment success and quality of life.

EP0171

High virologic suppression and few virologic failures with Long-Acting Cabotegravir + Rilpivirine in Treatment Experienced Virologically Suppressed Individuals from COMBINE-2 cohort in Europe

A. Pozniak[1], G. Sridhar[2], L. Assoumou[1,3], A. Gonzalez-Cordon[4], E. Negredo[5], N. De Castro[6], C. Fletcher[7], L. Ragone[2], A. Shah[8], J. van Wyk[9], V. Vannappagari[2]

[1]The European Treatment Network for HIV, Hepatitis and Global Infectious Diseases (NEAT-ID), London, United Kingdom, [2]ViiV Healthcare, Durham, United States, [3]Sorbonne Université, INSERM, Institut Pierre Louis d'Épidémiologie et de Santé Publique, Paris, France, [4]Hospital Clinic Barcelona, Barcelona, Spain, [5]Hospital Germans Trias I Pujol, Fundació Lluita contra les Infeccions, Barcelona, Spain, [6]Hospital Saint Louis, Paris, France, [7]Research Organization (KC) Ltd., London, United Kingdom, [8]GlaxoSmithKline, London, United Kingdom, [9]ViiV Healthcare, London, United Kingdom

Background: Cabotegravir (CAB) + rilpivirine (RPV) is the first complete long-acting (LA) regimen indicated for virologically suppressed (viral load (VL) <50 copies /mL) people with HIV (PWH) on stable antiretroviral regimen without viral resistance to, and no prior virological failure with NNRTI and INI class. We assessed clinical outcomes among individuals initiating CAB+RPV LA regimen in real-world settings in Europe.

Methods: Treatment experienced, virologically suppressed PWH initiating CAB+RPV between December 2020 and May 2024 enrolled at NEAT-ID Network sites across seven European countries were included. VLs were assessed from first injection until discontinuation or time of analysis. Confirmed virologic failure (CVF; 2 VL ≥200 copies/mL or 1 VL ≥200 copies/mL+discontinuation) was assessed among those with follow-up VL.

Results: All 956 individuals initiating CAB+RPV were treatment experienced, had VL <50 copies/mL at initiation, no previous virologic failure or history of NNRTI or INSTI mutations among those with history available (62%). Median age was 45 years (IQR: 37-53), 85% males and 10% with BMI ≥30 kg/m^2 at initiation. 919 individuals (96%) had on-time injections with 3% having delayed doses and 1% missed injections. At time of analysis, 92% of individuals remained on CAB+RPV LA regimen with median follow-up of 10.2 months (IQR: 7.1, 16.6). Among 937 individuals with follow-up VLs, 925 (99%) had last measured VL <50 copies/mL. Of those with 6, 12, and 24-month VLs, 97%, 96% and 94%, respectively had follow-up VLs <50 copies/mL. Virologic control was similar regardless of BMI at initiation (last VL <50 copies/mL 99% vs. 99% among BMI <30 kg/m^2 and ≥30 kg/m^2 respectively). Five individuals (0.5%) had CVF after initiation of CAB+RPV with history of resistance data unavailable. Of them, 3 had resistance mutations to NNRTI and/or INSTI class at failure and 4 individuals suppressed after switching to PI and INI-based regimen with data unavailable on one individual.

Conclusions: This real-world data on PWH virologically suppressed at initiation on CAB+RPV LA in Europe demonstrated high levels of virologic control with low CVF. These data demonstrate high levels of adherence and persistence to the regimen. Among few with CVF, suppression was achieved after switching to PI or INI-based regimen.

EP0172

Efficacy of dolutegravir plus lamivudine in treatment-naïve people with HIV with baseline transmitted drug-resistance mutations: a subanalysis of the D2ARLING study

E. Cordova[1], J. Hernandez Rendon[1], G. Arevalo Calderon[1], S. Seleme[1], V. Mingrone[1], N. Porteiro[1]

[1]Fundacion IDEAA, Research Department, Buenos Aires, Argentina

Background: The two-drug regimen DTG+3TC is a recommended treatment option for antiretroviral-naïve people with HIV (PWH). In the pivotal GEMINI 1-2 trials, participants with any detectable transmitted resistance-associated mutations (tRAMs), regardless of their impact on the regimen, were excluded.

Consequently, the potential effect of tRAMs that do not compromise the activity of DTG+3TC regimen on virological response has not been assessed in randomized clinical trials.

This subanalysis of the D2ARLING study aimed to evaluate the efficacy of DTG+3TC compared to DTG+TDF/XTC in the context of such tRAMs.

Methods: This is a preplanned subanalysis of the D2ARLING trial, a randomized, open-label, phase IV study evaluating DTG+3TC versus DTG+TDF/XTC in treatment-naïve PWH without baseline resistance testing information. Per protocol, baseline genotypic resistance testing (RT and PI genes) was performed but remained blinded until study completion) (INSTI-tRAMs not tested).

This analysis included participants with baseline resistance results (n=211; 3 excluded due to amplification failure).

Efficacy was assessed as the proportion achieving HIV-1 RNA <50 copies/mL at week 48 in the presence of major NRTI, NNRTI, or PI tRAMs (IAS-USA mutation list, 2023) using an ITT-exposed snapshot algorithm and an observed analysis (participants with available HIV-1 RNA data or those who discontinued due to lack of efficacy).

Results: Of 211 participants, 104 received DTG+3TC, and 107 DTG+TDF/XTC. Major tRAMs were detected in 25% of the participants (NNRTIs: 21%, PIs: 3%, NRTIs: <1%) with no differences between arms. None of the identified NRTI-tRAMs compromised susceptibility to 3TC/FTC or TDF. Overall, participants with tRAMs had lower baseline HIV-1 RNA (27,520 vs. 49,600 copies/mL, p=0.014).

At week 48, among participants with tRAMs, 86% (24/28) (DTG+3TC) and 92% (22/24) (DTG+TDF/XTC) achieved HIV-1 RNA <50 copies/mL (p=0.67; ITT-exposed).

Observed analysis showed 96% suppression in both groups. Within the DTG+3TC group, suppression rates were comparable regardless of the presence or absence of tRAMs (96% vs. 99%, *p*=0.45). No protocol-defined virological failures occurred with DTG+3TC; and one with DTG+TDF/XTC.

Conclusions: DTG/3TC showed high efficacy at week 48, comparable to DTG+TDF/XTC in participants with tRAMs not affecting this regimen. The presence of such tRAMs did not compromise treatment outcomes in treatment-naïve individuals in this setting.

EP0173

Long-term persistence, effectiveness, safety, and metabolic impact of bictegravir/emtricitabine/tenofovir alafenamide fixed-dose combination in treatment-naïve and experienced people living with HIV in a large Latin American cohort

D.M. Cecchini[1], M. Brizuela[1], G. Copertari[1], B. Bacelar[1], C. Lamaizon[1], J. Ianiro[1], E. Bottaro[1], I. Cassetti[1]
[1]Helios Salud, Medical Department, Buenos Aires, Argentina

Background: Real-world data for bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) fixed-dose combination (FDC) emerges mainly from cohorts from high-income settings, with scarce data on long-term effectiveness and safety for Latin American population.
We describe 48-month outcomes of people living with HIV (PLWH) prescribed B/F/TAF in clinical practice in Argentina.
Methods: Observational, retrospective open cohort study of treatment-naïve (TN) and experienced (TE) PLWH initiating B/F/TAF between 10/2019-12/2022. We evaluated persistence and virologic suppression (VS, <50 copies/mL), occurrence of adverse events (AE) and metabolic parameters (fasting glucose, cholesterol and triglycerides) at 24, 36 and 48-month time points.
Results: We included 3057 PLWH: 425 TN (14%) and 2632 TE (86%). Baseline characteristics: median age (IQR) was 45 (36-52) years; 73% were male; 99.6% were of latin/hispanic ethnicity. TN were younger than TE PLWH (median 36 vs. 46 years), had less frequency of comorbidities (21% vs. 49%) and lower CD4 T-cell counts (median 318 vs. 624/uL). In the TE group, 89% had VS when switched to B/F/TAF, while in the TN group, the median baseline viral load was 47,300 c/mL. TE subjects were switched mainly for simplification (54%) from boosted-PI (36%) and first-generation NNRTI (34%) regimens. In TN, at 24, 36, and 48 months, persistence and VS rates were 99%, 97%, and 95%; and 95%, 93%, and 90%, respectively. AE rate was zero. For TE, persistence and VS rates were 98%, 96%, and 88%; and 96%, 98%, and 98%, respectively. AE rates were 0.4%, 0.1%, and 0%. No virological failure occurred.
In both groups, no changes in fasting glucose were observed. TN PLWH showed increases in LDL, HDL and total cholesterol values (p <0.001) from baseline to 24, 36 and 48 months without changes in triglycerides values. In TE, all cholesterol values remain stable while triglycerides decreased over time (p <0.001).
Conclusions: In TN and TE PLWH from Argentina, B/F/TAF demonstrated high persistence and sustained VS, with low AE rates over 48 months. To our knowledge, these findings represent the first long-term real-world evidence from Latin America, supporting B/F/TAF in guidelines as an effective and well-tolerated treatment option.

EP0174

Efficacy, and safety of ainuovirine-based antiretroviral regimen in women with HIV-1: the pooled analysis of the RACER, and SPRINT studies, two multicenter, randomized, active controlled phase 3 trials

H. Wang[1], H. Wu[2], W. Cai[3], P. Ma[4], Q. Zhao[5], H. Wei[6], H. Lu[7], F. Zhang[8], S. He[9], Z. Chen[10], Y. Chen[11], M. Wang[12], H. Fu[13], H. Qin[14], X. Yun[13], Y. Li[13]
[1]Shenzhen Third People's Hospital, Infectious Diseases, Shenzhen, China, [2]Capital Medical University, Clinical and Research Center for Infectious Diseases, Beijing Youan Hospital, Beijing, China, [3]Guangzhou Eighth People's Hospital, Guangzhou Medical University, Infectious Disease Center, Guangzhou, China, [4]Tianjin Second People's Hospital, Infectious Diseases, Tianjin, China, [5]The Sixth People's Hospital of Zhengzhou, Infectious Diseases, Zhengzhou, China, [6]The Second Hospital of Nanjing, Infectious Diseases, Najing, China, [7]National Clinical Research Centre for Infectious Diseases, The Third People' s Hospital of Shenzhen, The Second Affiliated Hospital of Southern University of Science and Technology, Shenzhen, China, [8]Clinical and Research Center for Infectious Diseases, Beijing Ditan Hospital Capital Medical University, Beijing, China, [9]Public Health Clinical Medical Center of Chengdu, Infectious Diseases, Chengdu, China, [10]Drug Clinical Trial Institution, Public Health Clinical Medical Center of Chengdu, Chengdu, China, [11]Chongqing Public Health Medical Center, Division of Infectious Diseases, Chongqing, China, [12]Institute of HIV/AIDS, The First Hospital of Changsha, Changsha, China, [13]Clinical Research & Development, Jiangsu Aidea Pharmaceutical Co., Ltd, Yangzhou, China, [14]Clinical Research & Development, Jiangsu Aidea Pharmaceutical Co., Ltd, China, China

Background: In the RACER, and SPRINT studies, ainuovirine plus lamivudine and tenofovir DF (ANV/3TC/TDF) demonstrated durable virological suppression non-inferior to currently approved antiretroviral regimens in people with HIV-1.
This integrated analysis aimed to evaluate the virological outcomes, and safety profile of ANV/3TC/TDF in women with HIV-1 (WWH) at week 48.
Methods: In the RACER study (N=34), 18, and 16 treatment-naïve WWH were randomized, and medicated with ANV/3TC/TDF, and EFV/3TC/TDF, respectively. In the SPRINT study (N=22), 11, and 11 virologically suppressed WWH were randomized, and medicated with ANV/3TC/TDF, and E/C/F/TAF, respectively. Viral suppression was defined as HIV-1 RNA titer below 50 copies/mL as per the US FDA snapshot algorithm.
Results: High proportion of viral suppression was achieved in either arm at 48 wk, and in both studies. Change from baseline in CD4 cell absolute count was comparable between the two arms in the treatment-naïve women at 48 wk; that was numerically higher with the ANV/3TC/TDF arm compared to that with the E/C/F/TAF arm (28.5±96.3 vs. -42.6±83.0 cells/mm^3).
Frequencies of treatment-emergent adverse events, and adverse drug reactions (ADRs) were also comparable between the two arms in both studies, excepting for

a numerically lower frequency of ADRs with the ANV/3TC/TDF arm compared to that with the E/C/F/TAF arm (45.5% vs. 81.8%). Common AEs consisted mainly of neurological symptoms, and laboratory abnormalities. These AEs were generally similar between the two arms in both studies; however, the difference in frequency of dizziness was statistically significant for the treatment-naïve women (16.7% vs. 68.8%, *P* = 0.006), and those in frequencies of abnormal serum cholesterol, LDL-C, and T-wave on ECG were also statistically significant for the virologically suppressed women (all P-values <0.05). Serum LDL-C, and/or total cholesterol showed a marked divergence in change from baseline (CFB) between the two arms for either study, with a decreasing trend in the ANV/3TC/TDF arm in contrast to an increasing trend in the comparator arm, even at a statistical significance for total cholesterol in the virologically suppressed women.

Conclusions: Although at a small sample size, ANV/3TC/TDF regimen showed high viral suppression comparable to the comparators in both treatment-naïve, and virologically suppressed women.

EP0175

An open-label Phase 1 study to evaluate drug interactions between multiple weekly doses of ulonivirine (MK-8507) and single doses of islatravir in adults without HIV

J. Nussbaum[1], M. Pham[1], R. Vargo[1], Y. Liu[1], I. Triantafyllou[1], N. Boyette[1], R.P. Matthews[1], S.A. Stoch[1], M. Iwamoto[1], G. Gillespie[1]
[1]Merck & Co., Inc., Rahway, United States

Background: Ulonivirine (ULO, MK-8507), an oral NNRTI, is being investigated in combination with islatravir (ISL) as a once-weekly (QW) treatment for HIV-1. Initial clinical development of ULO with ISL 20 mg QW was paused in 2021 due to dose-dependent decreases in total lymphocyte and CD4+ T-cell counts seen across the ISL program; development was recently resumed with ULO 200 mg and ISL 2 mg.

This study aimed to evaluate any drug-drug interactions (DDIs) between ULO 200 mg and ISL 2 mg.

Methods: Two-way DDI was assessed in an open-label, 3-period, fixed-sequence, Phase 1 study in adults without HIV (MK-8507-016).

In Period 1, participants received a single dose of oral ISL 2 mg alone on Day 1. In Period 2, participants received doses of ULO 200 mg alone on Days 1 and 8. In Period 3, a single dose of ISL 2 mg was co-administered with ULO 200 mg 7 days after the Day 8 dose of ULO in Period 2, followed by weekly dosing of ULO until Day 29.

Blood samples were collected for pharmacokinetic (PK) analysis; ULO, ISL, and ISL-triphosphate (TP) PK under each condition were compared. Safety was monitored by clinical and laboratory assessments.

Results: Thirty-six participants (58% female; 67% White) were enrolled; mean age was 42.1 years (range, 19-62 years). Plasma ULO PK were similar with and without ISL, and plasma ISL PK were similar with and without ULO. Although not pre-specified, the 90% CIs for the geometric mean ratios for AUC, C_{168}, and C_{max} were confined within standard bioequivalence bounds [0.8, 1.25] (Table). There were modest decreases in ISL-TP exposure following co-administration with ULO relative to ISL administered alone, but these were not clinically meaningful. The safety profiles for multiple doses of ULO 200 mg QW and single doses of ISL 2 mg, alone or in combination, were similar.

Conclusions: No clinically meaningful DDI was observed when ULO and ISL were co-administered.

Parameter	Plasma ULO [n, ULO+ISL/n, ULO alone]	Plasma ISL [n, ULO+ISL/n, ISL alone]	PBMC ISL-TP [n, ULO+ISL/n, ISL alone]
$AUC_{0\text{-}168}$	1.07 (1.05-1.09) [35/35]	1.06 (1.02-1.09) [35/36]	0.79 (0.74-0.85) [35/36]
$AUC_{0\text{-}inf}$	NA	1.07 (1.03-1.11) [35/36]	0.85 (0.80-0.91) [33/32]
C_{168}	1.08 (1.04-1.12) [35/35]	1.10 (1.02-1.19) [35/36]	0.84 (0.77-0.91) [35/36]
C_{max}	1.03 (0.98-1.07) [35/35]	1.05 (0.98-1.12) [35/36]	0.90 (0.80-1.01) [35/36]

$AUC_{0\text{-}168}$, area under the concentration versus time curve from 0 to 168 hours after dosing; $AUC_{0\text{-}inf}$, area under the concentration versus time curve from 0 to infinity; C_{168}, drug concentration at hour 168; C_{max}, maximum observed concentration; ISL, islatravir; NA, not applicable; PBMC, peripheral blood mononuclear cell; TP, triphosphate; ULO, ulonivirine.

Table. Geometric Mean Ratio With 90% CI Following Co-administration Relative to Single-agent Administration.

EP0176

A double-blind, placebo-controlled, Phase 1 study to evaluate extended multiple dosing of ulonivirine (MK-8507) in adults without HIV

[1]Merck & Co., Inc., Rahway, United States, [2]InoKura, Liege, Belgium

Background: Ulonivirine (ULO, MK-8507), an NNRTI with a favorable safety profile and pharmacokinetic properties that support once-weekly (QW) dosing, is in development in combination with islatravir (ISL) for the treatment of HIV-1. Initial clinical development of ULO with ISL 20 mg QW was paused in 2021 due to dose-dependent decreases in total lymphocyte and CD4+ T-cell counts seen across the ISL development program; development was recently resumed with ULO 200 mg and ISL 2 mg.

This study evaluated the safety and tolerability of extended multiple QW dosing of ULO alone.

Methods: A randomized, placebo-controlled, double-blind, Phase 1 trial (MK-8507-015) was conducted in adults without HIV receiving ULO 200 mg or placebo QW (3:1) for 12 weeks. Safety was assessed by adverse event (AE) reporting and laboratory evaluations. Mean percent change from baseline in total lymphocyte and CD4+ T-cell counts were analyzed; a >10% decrease from baseline in lymphocyte counts would indicate a clinically significant change. Participants had a post-study visit at Week 14.

Results: A total of 80 participants were enrolled; 77 completed study intervention. No pausing or stopping rules were met during the study. AEs of mild or moderate severity were reported by 86.7% and 90.0% of participants in the ULO and placebo groups, respectively. No deaths or serious AEs were reported. One participant in the ULO group met the protocol-specified discontinuation criterion for decreased CD4+ T-cell counts (~35% decrease from

baseline) after a single dose of ULO, the counts returned to baseline after 4 weeks. At the post-study visit, the lower bound of the 95% CI for the mean percent changes in total lymphocyte and CD4+ T-cell counts were greater than −10% (ie, less negative) after administration of ULO (Table).

Conclusions: ULO 200 mg QW demonstrated an AE profile similar to that of placebo and did not decrease total lymphocyte or CD4+ T-cell counts to a clinically significant degree in adults without HIV.

	Baseline[a]		Post-study[a]		Change From Baseline[a]		Percent Change From Baseline LSM[b]
Treatment	n	Mean (SD)	n	Mean (SD)	n	Mean (SD)	(90% CI)
Total lymphocytes							
ULO	60	1.88 (0.430)	58	1.83 (0.425)	58	−0.072 (0.308)	−3.30 (−6.33 to −0.275)
Placebo	20	2.01 (0.455)	19	1.83 (0.468)	19	−0.140 (0.293)	−6.66 (−12.0 to −1.37)
CD4+ T cells							
ULO	60	0.931 (0.290)	58	0.894 (0.251)	58	−0.048 (0.197)	−3.03 (−7.55 to 1.50)
Placebo	20	0.943 (0.267)	19	0.876 (0.267)	19	−0.041 (0.265)	−1.59 (−9.49 to 6.31)

LSM, least squares mean; SD, standard deviation; ULO, ulonivirine.
[a]Arithmetic mean and SD were provided for baseline, post-study, and change from baseline.
[b]The LSM and their 90% CIs on percent change from baseline were estimated from a linear mixed effects model containing fixed effects terms for treatment, timepoint, and treatment by timepoint interaction, with a compound symmetry covariance matrix to model the correlation between different timepoints for the same participant.
Baseline is the average of all available screening and Day 1 pre-dose measurements. Post-study is Day 92 ± 3 days.

Table. Percent Change From Baseline for Total Lymphocyte Counts (10^9 cells/L) and CD4+ T-cell Counts (10^9 cells/L) Following Administration of Multiple Doses of ULO 200 mg or Placebo in Adults Without HIV.

EP0177

Navigating the dynamics of low-level viremia: the role of enhanced adherence counseling in viral suppression

F. Umeozulu[1], O. Oni[2], O. Maduakolam[3], O. Abodunde[2], O. Faleye[4]
[1]Equitable Health Access Initiative, Clinical Laboratory and Quality Improvement Services., Abuja, Nigeria, [2]Equitable Health Access Initiative, Prevention, Care, and Quality Improvement Services, Abuja, Nigeria, [3]Equitable Health Access Initiative, Strategic Knowledge Management & Training, Abuja, Nigeria, [4]Equitable Health Access Initiative, Digitilization, Information Management Unit, Abuja, Nigeria

Background: Antiretroviral therapy (ART) enables viral suppression to below 50 copies/mL in most persons living with HIV (PLWH). However, persistent low-level viremia (pLLV) between 50 and 1000 copies/mL poses a challenge, being associated with virological failure (VF), viral genotype resistance, and residual immune activation leading to adverse clinical outcomes. Enhanced Adherence Counseling (EAC) is a critical intervention for addressing pLLV.

This study evaluated the effectiveness of EAC in achieving viral suppression and explored demographic associations with EAC completion and suppression outcomes.

Methods: The study was conducted in two secondary health facilities in Nasarawa State over a one-year period using a cross-sectional design. The study population included PLHIV with low-level viremia who underwent EAC. Data on EAC completion and viral suppression were analyzed using statistical methods, including ANOVA and t-tests, to evaluate associations with age and sex.

Results: Among 5723 clients tested, 490 (8.6%) had pLLV, and 157 of these completed EAC with repeat viral load testing. Of those, 97 (61.8%) achieved viral suppression below 50 copies/mL. Age was significantly associated with EAC completion ($F(2,3) = 18.322$, $p = 0.021$) and viral suppression ($F(2,3) = 10.743$, $p = 0.043$), with clients aged 20 and above demonstrating higher rates in both outcomes. There was no significant association between sex and either EAC completion ($t(4) = -0.338$, $p = 0.752$) or viral suppression ($t(4) = -0.412$, $p = 0.701$).

Conclusions: This study highlights the critical role of age in adherence and viral suppression, with older clients achieving better outcomes. The lack of gender disparity in outcomes suggests equitable effectiveness of EAC across sexes. Targeted interventions are needed to improve adherence and viral suppression among younger age groups.

EP0178

Clinical outcomes at month 24 after initiation of cabotegravir and rilpivirine long acting (CAB+RPV LA) in an observational real-world study (BEYOND)

G. Blick[1], L. Santiago-Colon[2], D. Richardson[3], B. Sherif[3], L. Zografos[3], C. Schubert[4], D. Merrill[4], P. Teichner[4], C. Garris[4]
[1]Health Care Advocates International, Stratford, United States, [2]HOPE Clinical Research, San Juan, Puerto Rico, [3]RTI Health Solutions, Research Triangle Park, United States, [4]ViiV Healthcare, Durham, United States

Background: CAB+RPV LA is the first complete long-acting regimen for virologically suppressed people with HIV (PWH). The BEYOND real-world study describes the clinical outcomes of PWH initiating CAB+RPV LA in the US.

Methods: BEYOND is a 2-year observational study of utilization, outcomes, and experience of PWH initiating CAB+RPV LA (monthly or every 2 months) across 30 US sites. Healthcare providers completed an electronic case report form (eCRF) at baseline and Months (M) 6, 12, and 24 to capture demographics, medical and treatment history, and clinical outcomes. Final study results at M24 are reported herein.

Results: 308 PWH were enrolled and initiated CAB+RPV LA between Sep 2021-Jul 2022. Mean age was 46 years, 39% were ≥50 years, 13% were assigned female at birth, with 44% White, 33% Black, and 23% other races. This M24 analysis includes 257 PWH of whom 211 completed the study and were continuing CAB+RPV LA following M24, 24 discontinued CAB+RPV LA since M12, and 22 had unknown treatment status at M24.

An additional 43 participants had discontinued and 8 had unknown status as of the M12 analysis and did not contribute data at M24. The most common primary reasons for treatment discontinuation (all timepoints; n=65, missing 2 responses) were 'other' reason (29%), medication cost/access issues (20%), PWH preference (20%) and injection reactions/pain (9%). At M24, 98% were receiving CAB+RPV LA every 2 months and 2% were on monthly dosing. Of

PWH with viral load <50 c/mL at baseline, 97% had a most recent viral load of <50 c/mL at M24 (Table). There were no new confirmed virologic failures (CVF) after Month 6.

	Month 6 (N=308)	Month 12 (N=273)	Month 24 (N=257)
Participants with viral load data available at both baseline and respective timepoint, n*	265	210	204
Participants with baseline viral load <50 c/mL, n	247	196	193
Viral load <50 c/mL, n (%)	235 (95.1%)	190 (96.9%)	188 (97.4%)
Viral load ≥50 c/mL, n (%)	12 (4.9%)	6 (3.1%)	5 (2.6%)
Participants with baseline viral load >50 c/mL, n	18	14	11
Viral load <50 c/mL, n (%)	17 (94.4%)	13 (92.9%)	10 (90.9%)
Viral load ≥50 c/mL, n (%)	1 (5.6%)	1 (7.1%)	1 (9.1%)
Confirmed virologic failure n (%)†	6 (1.9%)	0	0

*Based on most recent viral load on or prior to timepoint
†Confirmed virologic failure was defined as 2 consecutive HIV-1 RNA viral loads ≥200 c/mL or 1 HIV-1 RNA viral load ≥200 c/mL followed by regimen discontinuation within 3 months of viral load ≥200 c/mL. A cumulative total of 6/308 CVFs occurred during the study. The one CVF previously reported at Month 12 was later determined to be reported in error due to the confirmatory viral load being collected after the participant had discontinued CAB+RPV LA.

Table: Virologic Outcomes Observed.

Conclusions: The final results from this 2-year real-world US study of CAB+RPV LA are consistent with the phase 3/3b clinical trials, with few discontinuations due to injection reactions/pain, high rates of virologic suppression, and low rates of virologic failures.

EP0179

Improvement in drug concentrations after an adherence intervention: data from the RETAIN study

C. Orrell[1], C. McDuling[2], T. Mosina[1], L. Jennings[1], L. Sabin[3]
[1]University of Cape Town, Desmond Tutu HIV Centre, Institute of Infectious Disease and Molecular Medicine & Department of Medicine, Cape Town, South Africa, [2]University of Cape Town, Department of Statistical Sciences, Cape Town, South Africa, [3]Boston University, Department of Global Health, Boston, United States

Background: We present data from "Improving RETention and viral load outcomes for people taking antiretroviral therapy (ART) through early IdentificatioN of missed doses (RETAIN)", a cohort study exploring paired drug concentration metrics in people on ART with documented poor adherence, before and after adherence intervention.
Methods: ART-naïve people commencing dolutegravir-based ART from three Cape Town clinics had adherence monitored by missed doses (<80%), missed clinic visit (>30 days late), or by raised VL (>50 copies/ml).
At the first indication of poor adherence by any measure, participants were invited for blood draw (visit 1) for HIV-1 VL, tenofovir plasma concentration (describes adherence over the past 3-5 days), and TFV-DP concentration (describes TVF-DP concentrations over the past 4-8 weeks); and urine collection for tenofovir rapid assay. The same metrics were repeated 12-16 weeks later (visit 2), after completing a counselling-based adherence intervention. McNemar's test was used to assess changes in binary paired observations; Wilcoxon signed-rank test were used for continuous paired observations.
Results: Between July 2022 and September 2024, 180 people identified as being non-adherent were invited to attend visit 1: 129 (72%) were women, mean(±SD) age of 30(±9) years. Poor adherence was objectively confirmed: 48 (27%) had suboptimal plasma tenofovir concentrations (<40ng/ml); 35 (19%) had no tenofovir in their urine; and 45 (25%) were viraemic (>50 copies/ml). Median (IQR) TFV-DP concentrations were suboptimal: 632 (400-864) fmol/punch (normal range >800fmol/punch).
A total of 108(60%) people attended visit 2. In those with paired samples there was no significant improvement in the short-term adherence metrics (urine and plasma tenofovir). However, a significant improvement was observed in median (IQR) TFV-DP: 887 (542-1125) fmol/punch (p<0.00); and fewer, 16(15%), remained viraemic (Fig1).
Conclusions: Poor ART adherence among newly-initiated individuals was confirmed by drug measures. A counselling-based adherence intervention resulted in a significant increase in TFV-DP, indicating an objective improvement in longer term adherence.
Despite this increase, there was no change in short-term adherence metrics, i.e. no change in dosing in the 3-5 days before study visits (likely white-coat dosing). Adherence interventions can result in significant improvement in drug concentrations, but retention in care remains a significant challenge.

EP0180

Effectiveness of long-acting injectable antiretroviral therapy among persons with HIV and adherence barriers

E. Hastie[1], L. Hill[1], L. Bamford[1], A. Karim[1], T. Martin[1]
[1]University of California San Diego, San Diego, United States

Background: Long-acting injectable cabotegravir and rilpivirine (LAI-CAB/RPV) may improve outcomes for persons with HIV (PWH) experiencing adherence difficulties. However, real-world outcome data without conditional economic incentives are limited. This study evaluated LAI-CAB/RPV among PWH with adherence difficulties.
Methods: We conducted a retrospective observational study of PWH with adherence challenges who initiated LAI-CAB/RPV between November 2021 and December 2023 at a single HIV center in Southern California, USA. Adherence challenges were defined as ≥1 HIV viral load (VL) >200 copies/mL in the prior 12 months and either poor response to oral ART or loss-to-follow-up (LTFU) in the prior 18 months. Primary outcomes were virologic failure (VF) requiring therapy change or LTFU within 48 weeks. Secondary outcomes included descriptive outcomes, resistance mutations, and salvage regimens.
Results: Sixty-four PWH initiated LAI-CAB/RPV: 71.9% male, 26.6% female, and 1.6% non-binary; 45.3% White, 17.2% Black, and 34.4% Hispanic. Active substance use and mental health diagnoses were present in 40.6% and 54.7%, re-

spectively. At LAI-CAB/RPV initiation, 45.3% had VL ≥50 copies/mL and 14.1% had VL >10,000 copies/mL. Over 48 weeks, 6 (9.4%) had VL >200 copies/mL, including 3 (4.7%) with VF requiring regimen changes. All VF cases had NNRTI and/or INSTI RAMs but achieved suppression on oral ART (*Table 1*). Eight discontinued LAI-CAB/RPV for other reasons. Three were LTFU, later reengaging in care (*Table 2*).

Logistic regression identified an association between substance use and the primary outcome (OR 8.81, p=0.05). Methamphetamine specifically increased odds (OR 12.06, p=0.03). Multiple logistic regression confirmed active substance use as a predictor (OR 10.55, p=0.04). Other variables (baseline CD4, race, etc.) were not significantly associated.

Participant	NNRTI Mutations	INSTI Mutations	Suppressive Regimen
1	E138A, M230L	G140S, Q148H	TAF/FTC/DRV/c
2	A98G, V108I, E138K	G140C, Q148R	TAF/FTC/DRV/c
3	M230I, E138Q, V179L	-	TAF/FTC/BIC

Table 1. Mutations and Suppressive Oral ART in Clients with VF.

Participant	LTFU Details	Outcome
1	Returned 5 months after last LAI-CAB/RPV injection with suppressed VL while taking TAF/FTC/DRV/c	Continued on TAF/FTC/DRV/c with suppression of VL
2	Returned 6 months after last LAI-CAB/RPV injection (sporadically took TAF/FTC/BIC during this time), VL 146 copies/mL on representation	Continued on TAF/FTC/BIC with suppression of VL
3	Returned 10 months later, admitted for Cryptococcal meningitis	LTFU again after hospitalization

Table 2. Outcomes of Clients LTFU.

Conclusions: In a real-world setting, LAI-CAB/RPV among PWH with adherence difficulties demonstrated low rates of VF or LTFU (combined 9.4%) within 48 weeks of initiation. LAI-CAB/RPV should be considered in individuals with adherence difficulties.

EP0181

Adherence to antiretroviral therapy and its association with quality of life among people living with HIV/AIDS in Nigeria

A. Abba[1], M. Ogochukwu[1], I. Abdulmumin[1], D. Aluh[1], B.G. Abubakar[2], M.K. Musa[3], A.Y. Faragai[4], K.A. Gulma[5], A. Salihu[5], J. Anyanti[6], O. Idogho[7], Y. Hassan Wada[7]

[1]University of Nigeria, Department of Clinical Pharmacy, Nsukka, Nigeria, [2]Usmanu Danfodiyo University Teaching Hospital, Sokoto, Nigeria, [3]University of Michigan, College of Pharmacy, Ann Arbor, United States, [4]Aminu Kano Teaching Hospital, Kano, Nigeria, [5]Euclid University, School of Global Health and Bioethics, Banjul, Gambia, the, [6]Society for Family Health, Strategy, Technical and Growth, Abuja, Nigeria, [7]Society for Family Health, Policy, Advocacy and Systems Strenthening, Abuja, Nigeria

Background: Antiretroviral therapies have remained the cornerstone to improving the quality of life among people living with HIV. Although advances in ART have improved treatment success rates, adherence remains important to achieving the best outcomes. Thus, this study was conducted to assess the effect of adherence to ART and, on the health-related quality of life of People Living with HIV/ AIDS in Northwestern Nigeria.

Methods: This was a cross-sectional descriptive study involving PLWHA accessing care in three tertiary hospitals in Nigeria. Respondents were selected and administered a sociodemographic questionnaire, the Simplified Medication Adherence Questionnaire, and the 15D QoL Questionnaire. Appropriate descriptive and inferential statistical analyses were conducted using SPSS version 21.

Results: The study involved 877 people living with HIV/AIDS, who were predominantly females (64.5%), 66% were between the ages of 31-50 years and were mostly married (63.5%). More than half (63.8%) of the participants had secondary-level education and earned less than 30 USD/month. Non-adherence was observed in 456 (52.5%) participants, with a mean 15D score of 0.97 ± 0.42. The mean QoL score was significantly lower ($p < 0.001$) among non-adherent respondents (0.96, S.D. ± 0.33), compared to those who adhered to their medication (0.98, S.D. ± 0.04). A linear regression model showed that age over 60 years old (β = -0.020, $p = 0.032$), being divorced (β =-0.021, $p = 0.04$), and having a comorbid condition (β = -0.013, $p = 0.002$) were negative predictors of QoL. In contrast, adherence (β = 0.09, $p = 0.017$) was a positive predictor of QoL.

Conclusions: Adherence to ART was suboptimal in this study. This calls for the need to review and optimize the existing strategies for improving adherence in HIV clinics. Age, comorbid conditions, and adherence were significant predictors of QoL. Elderly PLWHA, especially those with comorbid conditions or any of the negative predictors of QoL, are at increased risk of poor QoL and, thus, should be prioritized for QoL optimization strategies in HIV clinics.

EP0182

Comparative effectiveness of modern antiretroviral therapy regimens among people living with HIV in China: a multicenter cohort study

X. Wu[1], Y. Chen[2], W. Zhang[2], L. Fu[2], H. Zou[1]

[1]Fudan University, Shanghai, China, [2]Sun Yat-sen University, Shenzhen, China

Background: Given the slow introduction of new antiretroviral therapy (ART) drugs, poor adherence resulting from high costs, and slow updates in treatment policies in low- and middle-income countries (LMICs), there is an urgent need for new evidence to reinforce the prioritization of integrase strand transfer inhibitor (INSTI) as the primary treatment option for people living with HIV (PLHIV) in these countries.

We aimed to explore the effects of modern ART regimens on CD4 counts among PLHIV in China, using larger multicenter cohorts and robust approaches, thereby providing real-world evidence on this topic from LMICs.

Methods: Anonymised clinical data for PLHIV treated at major infectious disease hospitals from 12 provinces and municipalities in China who initiated ART between January 1, 2017 and September 30, 2020, were included and

followed-up until December 31, 2020. Most frequently used third ART drugs included nevirapine, efavirenz, dolutegravir, lopinavir, and others (including darunavir, raltegravie, elvitegravir and rilpivirine).
We used linear mixed-effects models with a first-order autoregressive covariance structure and interaction terms (time-versus-treatment group) to assess whether CD4 count changes of PLHIV differed significantly over time between the treatment groups.
To evaluate whether there were differences in the time of immune recovery among different ART regimen groups, we used negative binomial models to fit the time of immune recovery (CD4 >500 cells/μL) of PLHIV.
Results: 54,919 individuals contributed 96,260 person-years of follow-up. Results from the mixed-effects model supported significant advantages in CD4 count gains of PLHIV who initiated dolutegravir-, lopinavir-, and others in China compared to initiating efavirenz-based ART. Results from negative binomial model suggested that dolutegravir- and others-based ART demonstrated a positive impact on the time of immune recovery of PLHIV, leading to reductions of 0.21 years and 0.47 years, respectively.
Conclusions: Our findings further reinforce the positioning of dolutegravir-based regimens as preferred options in LMICs.

EP0183

Leveraging 340B funding to implement long-acting ART at a hospital-based clinic

H. Safa[1], A. Joffe[1], S. Wilson[1], A. Dalal[1]
[1]Jefferson Einstein, Family Medicine, Philadelphia, United States

Background: Long-acting injectable cabotegravir-rilpivirine (LAI CAB/RPV) was approved in 2021 for treatment in people living with HIV (PLWH). Administered every 2 months, it is an alternative to daily oral medication. The Immunodeficiency Clinic (IDC), a hospital-based clinic at Albert Einstein Medical Center, developed a protocol for the implementation of LAI CAB/RPV.
Description: The medical director and program director developed a detailed protocol and workflow for implementing LAI CAB/RPV, which included a prescribing and monitoring protocol for clinical staff, and a workflow for ordering medications through the 340B pharmacy, obtaining insurance prior authorization, medication delivery and refrigerated storage, medication administration and tracking of patient injection appointments. Per initial treatment data and guidelines, patients were virologically suppressed at initiation.
A cross-sectional analysis was performed to compare virologic suppression in patients on LAI CAB/RPV vs oral medication.
Lessons learned: As of September 30, 2024, 130 PLWH in our clinic are on ongoing LAI CAB-RPV. A total of 137 initiated LAI CAB-RPV since 2021; 5 are now discharged from the practice and 2 are deceased from non-HIV related illnesses. Of the 130 patients on LAI CAB-RPV, 90% (117/130) have a viral load of <50 viral copies/ml, compared to 76% (632/832) of patients on oral antiretroviral medication, X^2 (1, N=962) = 12.9 p<.01. To date, 100% of patients on LAI CAB-RPV (130/130) have a viral load of < 200 viral copies/ml, compared to 92% (767/832) of patients on oral ART.
Conclusions/Next steps: A protocol and workflow for LAI CAB/RPV was successfully implemented at our hospital-based clinic with a high rate of virologic suppression.
As a result of robust demand and use of the 340B pharmacy to obtain medication, the incremental revenue allowed for salary coverage of a dedicated medical assistant (MA) *and* a nurse (RN) to obtain authorization, administer medication and track appointments help with supervision and additional clinical services.

EP0184

Real-world efficacy and tolerability of long-acting cabotegravir/rilpivirine in woman with HIV and polypharmacy plus comorbidities

M. Rosas-Cancio[1,2], A. Moreno[1,2], S. Del Campo Terrón[1,2], M.J. Vivancos[1,2], A. Garcia García-Ruiz de Morales[1,2], J. Martínez-Sanz[1,2], J. Díaz-Álvarez[1,2], R. Ron[1,2], M.J. Cárdenas-Isasi[1,2], M. Vélez-Díaz-Pallarés[3], S. Moreno[1,2], M.J. Perez Elías[1,2]
[1]Hospital Ramón y Cajal, Madrid, Spain, [2]Ciberinfec, Madrid, Spain, [3]Hospital Ramón y Cajal, Pharmacy Department, Madrid, Spain

Background: Women, particularly older adults with comorbidities and polypharmacy, are underrepresented in clinical trials of long-acting (LA) antiretroviral therapy (ART).
This real-world study aimed to evaluate, from gender perspective, the efficacy and safety of LA cabotegravir/rilpivirine (CAB/RPV) in a cohort of adults with extensive prior ART, multiple comorbidities, and polypharmacy.
Methods: From the overall CAB/RPV cohort, using propensity score matching by age, Spanish origin, ART duration, baseline BMI, and CD4 counts, women were paired 1:3 with men. The study focuses on comparing gender differences on virologic failure (including viral blips), adverse events (including injection site reactions), treatment discontinuations, preference to continue LA ART and whether initiation of LA ART was driven by person with HIV suggestion or physician request
Results: From January 2023 to July 2024, we included a total of 169 participants, forty-one women and 128 men, with a median follow-up of 11 months. Despite a higher rate of comorbidities 35 (85.37%) vs.72 (56.25%) p=0.004 in women vs. men, virologic failure was comparable, only one woman experienced virologic failure 1 (2,44%) vs. 0 (0.0%) p=NS, few viral blips were observed (4.88% vs. 2.34% in men, p=0.405), none of them led to virological failure. In women, it was observed a tendency to more adverse events (12.2% vs.3.91% p=0.050) and similarly for treatment discontinuations (12.2% vs. 3.91%, p=0.050).
We observed few adverse events leading to discontinuation in both sexes 3 (7.32%) vs. 4 (3.12%) p=0.241. Physician-driven initiation of CAB/RPV was more common among women (70.73% vs. 50.81% in men, p=0.026), while men more often initiated therapy at their request.

Conclusions: Women starting CAB/RPV presented a higher rate of comorbidities and were advice by their physicians more frequently to do so. Virologic failure rates were similar between men and women, but women had non-significant higher rates of adverse events, treatment discontinuation, suggesting potential sex-based differences in tolerability to LA ART.

EP0185

Double-dose dolutegravir and lamivudine versus efavirenz-based antiretroviral therapy for individuals with HIV and tuberculosis: a multicenter, open-label, randomized trial

Y. Shen[1], X. Le[1], W. Song[1], L. Gu[1], L. Liu[1], Y. Dou[2], K. Lan[2], Z. Meng[2], Y. Zhou[3], Y. Lu[3], Y. Chen[3], M. Jiao[4], X. Yang[4], Y. Sun[4], C. Wu[5], Z. Huang[5], M. Zou[5], B. Shao[1], J. Wang[1], J. Chen[1], R. Zhang[1]

[1]Shanghai Public Health Clinical Center, Fudan University, Department of Infection and Immunity, Shanghai, China, [2]Chest Hospital of Guangxi Zhuang Autonomous Region, Department of Infectious Diseases, Liuzhou, China, [3]Chongqing Public Health Medical Center, Chongqing, China, [4]Henan Provincial Hospital of Infectious Diseases, Zhengzhou, China, [5]Nantong Third People's Hospital, Nantong, China, [6]the Third People's Hospital of Kunming, Kunming, China, [7]the Fourth People's Hospital of Nanning, Nanning, China, [8]Guiyang Public Health Clinical Center, Guiyang, China, [9]Jiangxi Chest Hospital, Nanchang, China

Background: This study evaluated the efficacy and safety of a dual therapy regimen comprising double-dose dolutegravir plus lamivudine in treating HIV-positive people with tuberculosis.

Methods: This was a randomized, open label, parallel-controlled trail conducted at sixteen centers in China (ChiCTR2300075493). It included HIV-positive adults who were antiretroviral therapy-naïve and had initiated rifampicin-based anti-tuberculosis therapy ≤2 weeks prior. Participants were randomized (1:1) to receive either dolutegravir (50 mg twice daily) plus lamivudine (2DR arm) or efavirenz (600 mg daily) with tenofovir and lamivudine (3DR arm), beginning at 2-4 weeks after anti-tuberculosis treatment.

The primary outcome was virological suppression (HIV-1 RNA <50 copies/mL) at week 24 in the modified intention-to-treat exposed group.

Results: Between July 2023 and July 2024, 32 participants were randomly assigned to either the 2DR (N=21) or 3DR (N=11) arm. In the 2DR group: 38.1% (8/21) had baseline HIV RNA >500,000 copies/mL. Mean baseline HIV-1 RNA: 5.49 ± 0.66 $\log_{10}$ copies/mL. Median CD4+ count: 48 cells/μL (IQR 28.2-107.1).

For the 3DR group: 9.1% (1/11) had HIV RNA >500,000 copies/mL. Mean baseline HIV RNA: 5.36 ± 0.62 $\log_{10}$ copies/mL. Median CD4+ count: 78.8 cells/μL (IQR 37-294). At week 24, virological suppression rates were 76.2% (16/21) in the 2DR group and 90.9% (10/11) in the 3DR group (For more details, see Figure 1).

There was no statistically significant difference in viral suppression (P = 0.637). No virological failures occurred. Three IRIS events were reported: two in the 2DR group and one in the 3DR group, with no discontinuations due to IRIS.

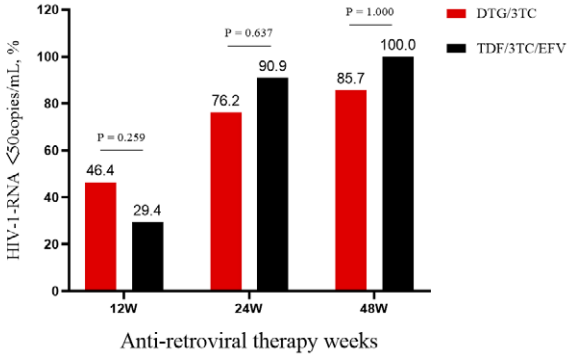

Figure 1. Comparison of HIV-1 RNA <50 copies/mL between the 2DR (DTG/3TC) and 3DR (TDF/3TC/EFV) groups at 12, 24, and 48 weeks of antiretroviral therapy. The numbers of cases in the 2DR vs. 3DR groups were 28 vs. 17 at 12 weeks, 21 vs. 11 at 24 weeks, and 7 vs. 6 at 48 weeks.

Conclusions: Double-dose dolutegravir with lamivudine was equally effective for HIV-positive adults on rifampicin-based anti-tuberculosis treatment compared to a three-drug regimen of efavirenz, tenofovir, and lamivudine. This dual therapy may provide a new option for people with HIV-associated tuberculosis.

EP0186

The prevalence and associated factors of potential drug-drug interactions in people living with HIV/AIDS: a retrospective study at a Nigerian tertiary hospital

M. Umoh[1], A. Ekpema[1], E. Anwana[1], M. Umoren[1], M. Nwofia[2], B. Andong[3]

[1]University of Uyo Teaching Hospital, Pharmacy, Uyo, Nigeria, [2]Nnamdi Azikiwe University Teaching Hospital, Pharmacy, Nnewi, Nigeria, [3]University of Uyo, Pharmacy, Uyo, Nigeria

Background: The challenge of HIV treatment regimens, often involving multiple medications, raises concerns about drug-drug interactions (DDIs) that can adversely affect the safety and treatment efficacy. This study aimed to assess potential DDIs and contributing factors among adults diagnosed with HIV/AIDS.

Methods: The study was performed at the University of Uyo Teaching Hospital, Uyo, Nigeria. A retrospective cross-sectional design was employed, analyzing medical records from September 2023 to August 2024. A systematic random sampling method was used to select 385 records from a total of 3,726. Data extraction included demographics, HIV stages, comorbidities, and prescribed medications. DDIs were identified using the Medscape Drug Interaction Checker. Statistical analysis was performed using R programming, incorporating descriptive statistics, Chi-Square test, and logistic regression to explore associations between DDIs and various risk factors.

Results: Among the 385 individuals, 242 (62.9%) were <50 years old, and 143 (37.1%) were ³50 years old. The HIV stage distribution included 116 (30.1%) in stage 1, 167 (43.4%) in

stage 2, 54 (14.0%) in stage 3, and 48 (12.5%) in stage 4. A total of 149 (38.7% of the sample) had comorbidities, with hypertension (31.5%), tuberculosis (28.2%), urinary tract diseases (15.4%), and malaria (14.9%) being the most common. Of the 4,042 prescriptions analyzed, 3,937 (97.4%) showed interactions, with 74.8% classified as minor, 13.9% as requiring close monitoring, 11.0% as serious, and 0.3% as contraindicated.

The primary contributors to serious drug-drug interactions (DDIs) were Erythromycin+Loratadine (56.8%), Rifampin+Pyrazinamide (20.0%), and Rifampin+Isoniazid (17.5%). The only contributors to contraindicated DDIs included Erythromycin+Artemether/Lumefantrine (58.3%) and Erythromycin+Fluconazole (41.7%). Individuals aged ≥50 were more likely to experience serious DDIs (OR = 2.50, 95% CI: 1.80–3.50, $p < 0.001$), and there was a significant association between HIV stage and DDI severity ($\chi^2(9) = 145.32$, $p < 0.001$) with those in advanced HIV stages (stages 3 and 4) more likely to experience serious and contraindicated DDIs.

Conclusions: This study underscores the high prevalence of drug-drug interactions among individuals living with HIV/AIDS, particularly in older ones and those with advanced disease stages. These findings highlight the need for enhanced medication management strategies to improve safety and treatment outcomes.

EP0187

Early programmatic outcomes of 512 self-reported ART naïve people in the era of dolutegravir-based regimens

L. Jennings[1], C. Schreuder[1], T. Mosina[1], L. Sabin[2], C. Orrell[1]
[1]University of Cape Town, Desmond Tutu HIV Centre, Institute for Infectious Disease and Molecular Medicine, Cape Town, South Africa, [2]Boston University School of Public Health, Department of Global Health, Boston, United States

Background: The test-and-treat era has shifted the focus of antiretroviral therapy (ART) programmes from access to care to increasing retention and achieving viral suppression. Despite this, few interventions focus on early treatment, a period when retention has been shown to predict future treatment success. We assessed early programmatic outcomes of participants in a longer adherence study.

Methods: We enrolled ART-naïve individuals >16 years, initiating dolutegravir-based ART at three Cape Town clinics, into a randomised adherence study assessing outcomes at 24 months. Per South African National ART Guidelines, viral load (VL) testing should be performed 3-6 months after initiation. We assessed early virological outcomes, retention, and adherence for all study participants, using routine clinic data. We included any VL performed within the first 8 months of treatment to allow for variance in timing. We calculated adherence up to 8 months as a medication possession ratio (MPR). We determined retention status as per clinic designation at 8 months with lost to follow-up (LTFU) defined as >12 weeks late for a visit and unconfirmed LTFU defined as 7 days to 12 weeks late.

Results: We enrolled 512 individuals with a median (IQR) age of 28 (23-34); 70.7% (N=362) were female. Sixty-four percent (N=328) of participants were retained in care at 8 months with 20.3% (N=104) LTFU, 6.3% (N=32) unconfirmed LTFU, and 4.5% (N=35) with no retention data. Twenty-five participants transferred to another clinic (N=24) or died (N=1) prior to the 6-month time point and were excluded from analyses.

Of the remaining 487 participants, 380 (78%) had a VL performed; 67.6% (N=329) were virally suppressed (<50 copies/mL), 5.7% (N=28) had low-level viraemia (LLV), and 4.7% (N=23) had a VL >1000 c/mL. Median MPR at 8 months was 87.5% for all participants and was inversely correlated with VL (96.1% for virally suppressed, 87.5% for LLV, 73.7% for VL>1000 c/mL, and 37.5% for those without a VL).

Conclusions: Early disengagement from care remains a concern even in the era of dolutegravir-based single tablet regimens, leading to viral suppression rates well below the 95-95-95 targets. ART programmes should focus retention efforts on the early stages of treatment.

EP0188

Safety and efficacy of four-weekly Albuvirtide plus Dolutegravir in virologically suppressed adults living with HIV-1: a pooled analysis based on two prospective studies

H. Long[1], X. Xie[1], Y. Fu[1], L. Gan[1], X. Yang[1], Y. Song[1], C. Song[1], F. Sun[1], L. Guo[1]
[1]Guiyang Public Health Clinical Center, Guiyang, China

Background: Two completed prospective single-arm studies have shown that four-weekly ABT combined with oral DTG in virologically suppressed adults living with HIV-1 has good safety and efficacy. In order to further verify its efficacy and safety, we combine the data of the participants from these two clinical trials for analysis.

Methods: Two studies were completed at the Guiyang Public Health Clinical Center in 2023 and 2024 respectively. Participants with HIV-1 RNA less than 50 copies/mL were switched to a treatment regimen of 640mg of four-weekly ABT plus DTG . The inclusion and exclusion criteria for both studies were the same, and the follow-up time was 24 weeks.

However, the study completed in 2023 used ABT administered by intravenous drip, while the study completed in 2024 used ABT administered by intravenous bolus. Both of the two studies evaluated the safety, pharmacokinetic profile of ABT in plasma, HIV-1 viral load and CD4+ T cell counts during treatment.

Results: A total of 19 participants were included in this pooled analysis, among which 10 participants received ABT by intravenous drip and 9 participants received ABT by intravenous bolus. All participants maintained virological suppression (HIV-1 RNA < 50 copies/mL) after 24 weeks of treatment.

After 24 weeks of treatment, the CD4 + T cell count increased by 91.74 ± 160.49 cells/μL from the baseline ($P = 0.023$). The ratio of CD4 to CD8 increased by 0.04 ± 0.07 from the baseline, and this result was statistically significant ($P = 0.031$). The steady-state trough concentrations

of ABT measured at the 12th week of administration in the two studies were 2.33 ± 0.87 µg/mL and 1.95 ± 0.93 µg/mL respectively, both of which were higher than the protein-adjusted concentration required for 90% viral inhibition (PA - IC90). All treatment-emergent adverse events (TEAEs) were mild and moderate, and no serious adverse events (SAE) were reported.

Conclusions: Whether ABT is administered by intravenous infusion or bolus injection, the drug concentration within the body remains above the effective concentration. Additionally, good safety and efficacy have been initially observed, warranting further validation of the clinical efficacy of this regimen.

EP0189

Early ART response in a Brazilian acute phase cohort: T cell subsets, activation, exhaustion, and reservoirs

S. Santana de Moura[1], D. Gama Caetano[2], M. Lindenmeyer Guimarães[2], R. Mendes da Silva[2], M. Ribeiro-Alves[1], I. Georg[3], D. Vieira Gomes dos Santos[1], F. Sabec Folgueral[1], S. da Costa Cruz Silva[4], S. Nazer[1], R. Teixeira Fraga[1], B. Hoagland[1], L. Villela[1], B. Grinsztejn[1], V. G. Veloso[1], F. Heloise Côrtes[2], S. Wagner Cardoso[1]

[1]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas - Laboratório de Pesquisa Clínica em IST e AIDS, Rio de Janeiro, Brazil, [2]Fundação Oswaldo Cruz, Instituto Oswaldo Cruz - Laboratório de Aids e Imunologia Molecular., Rio de Janeiro, Brazil, [3]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas. Laboratório de Imunologia., Rio de Janeiro, Brazil, [4]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas. Plataforma de Laboratório Multiusuário, Rio de Janeiro, Brazil

Background: Investigating immunological and viral reservoir dynamics in PBMC and GALT during acute HIV phase advances understanding of HIV persistence. Here we investigated the dynamics of T cells and HIV reservoirs after start ART in acute phase.

Methods: We evaluated the ART impact at 12 (M12) and 24 months (M24) on immunological, virological, and reservoir markers of 24 participants starting ART at Fiebig ≤ V (Baseline = D0) in a Brazilian cohort. We measured the frequency of T cell activation, exhaustion, memory subsets, Th17 and pTfh cells by flow cytometry and quantified total HIV DNA by qPCR in PBMC (n=24) and GALT (n=11).

Results: Most participants were cisgender MSM (95.9%), with median age of 27 years (IQR 25–36). At enrollment (D0), four participants used triple ART as PEP, and two were on oral PrEP and they exhibited higher CD4/CD8 ratios.

Higher CD4/CD8 ratios were also observed in participants classified as Fiebig I-III. 92% achieved viral suppression at M12 and 96% at M24. CD4 counts rose from 646 to 861 cells/mm³, and the CD4/CD8 ratio improved from 0.76 to 1.24 ($p<0.01$). HIV DNA in PBMCs decreased 4-fold by M12 and 61-fold by M24, with 50% undetectable by M24 ($p<0.01$). In GALT, undetectable HIV DNA increased from 27% at D0 to 75% at M12. HIV DNA in PBMCs and GALT correlated with plasma VL, while the CD4/CD8 ratio was inversely linked to PBMC reservoirs (rho= -0.66; $p<0.05$). Early ART reduced activated CD8+ T cells ($p<0.05$) but had minimal effects on CD4+ T cells or exhaustion markers. By M24, CD8+ TCM increased, and CD8+ TEF decreased ($p<0.01$), while Th17 and pTfh levels remained stable.

Conclusions: Early ART led to viral suppression, immune restoration and influence reservoir dynamics. The CD4/CD8 ratio was shown as key marker of early treatment success. A quarter of participants identified while starting PEP/PrEP draw attention to considering the window of acute phase according to vulnerability.

Recent PEP/PrEP use often excludes participants from clinical trials on bNAbs and therapeutic vaccines targeting viral reservoirs during acute phase of HIV - populations that may benefit from these strategies. Larger studies of including these populations are needed.

EP0190

Lenacapavir plus Cabotegravir real-world use cases from the National Clinician Consultation Center

P. Saberi[1], C. McAnaney[2], C. Bositis[2], M. Gandhi[2], C. Chu[2]

[1]University of California, San Francisco, Medicine, San Francisco, United States, [2]University of California, San Francisco, San Francisco, United States

Background: The combination of long-acting injectables (LAIs) lenacapavir (LEN) + cabotegravir (CAB) +/- rilpivirine (RPV) could improve viral suppression in people with HIV (PWH) with adherence challenges to oral antiretroviral therapy (ART) or resistant virus. These combinations have not been studied in clinical trials and data are limited on their effectiveness and tolerability.

We report observations on the real-world use of these combinations from the National Clinician Consultation Center (NCCC), a tele-consultation resource for US-based clinicians that provides access to HIV experts.

Methods: Providers contacting NCCC from 12/1/2022–8/30/2024, whose consultations included consideration of ART modification were surveyed. Cases involving a combination of LEN subcutaneously twice-yearly +CAB (+/-RPV) intramuscularly every 4 or 8 weeks were identified and data were extracted from NCCC's secure database. Descriptive statistics and viral load outcomes were summarized.

Results: Among 76 eligible cases, 50 (66%) surveys were completed. From these 49, 14 (28%) had modified ART to any combination of LEN+CAB+/-RPV; this included 9 (64%) who changed to LEN+CAB/RPV, 1 (7%) to LEN+CAB, and 4 (29%) who did not indicate the LAI-ART regimen.

Reasons for changing to LEN+CAB+/-RPV included detectable viral load on oral ART (n=6, 43%), nonnucleoside reverse transcriptase inhibitor mutation(s) (3, 21%), inability/refusal to take oral ART (3, 21%), integrase strand transferase inhibitor mutation(s) (2, 14%), or continued viremia on CAB/RPV alone (2, 14%).

Among 10 cases with available follow-up information, all viral loads decreased to <500 copies/mL corresponding to a 3.88$\log_{10}$ copies/mL reduction in viral load within a mean of 80 days (SD=53). Half of these individuals experienced

injection-site reactions that were rated by the provider to be "not at all" to "slightly" problematic. There were no delayed/missed injections. All but one case noted a desire to continue this combination of LAI-ART.

Conclusions: In this case series of 10 PWH with virologic failure on oral ART, LEN+CAB+/-RPV was highly effective in achieving viral suppression. The most common reason for modification was detectable viral load on oral ART. These data and other case series of LEN+CAB support further research on LEN+CAB+/-RPV among PWH who are unable to adhere to oral ART or have a drug-resistant virus.

EP0191

Characteristics of non-suppressed recipients of care post implementation of Viremic Clinic as a differentiated service delivery model in Lusaka, Zambia (2020-2022)

M. Wa Mwanza[1], D. Ngosa[2], K. Moomba[3], K. Mwila Kazimbaya[4], S. Bosomprah[2,5], C. Bolton[6], I. Sikazwe[7], M.E. Herce[8], N. Vlahakis[1], L. Mulenga[9], S. Sivile[9], F. Mwape[10], W. Mumba[10], N. Simkonde[10], S. Msiska[10], C. Simulyamana[10], T. Savory[3]

[1]Center for Infectious Disease Research in Zambia, Clinical Care, Lusaka, Zambia, [2]Center for Infectious Disease Research in Zambia, Data Analysis, Lusaka, Zambia, [3]Center for Infectious Disease Research in Zambia, Strategic Information, Lusaka, Zambia, [4]Center for Infectious Disease Research in Zambia, Research Department, Lusaka, Zambia, [5]University of Ghana, Department of Biostatistics, School of Public Health, Accra, Ghana, [6]Center for Infectious Disease Research in Zambia, Chief Medical Officer, Lusaka, Zambia, [7]Center for Infectious Disease Research in Zambia, Chief Executive Officer, Lusaka, Zambia, [8]Center for Infectious Disease Research in Zambia, Implementation Science, Lusaka, Zambia, [9]Ministry of Health, Infectious Disease, Lusaka, Zambia, [10]Ministry of Health, Provincial Health Office, Lusaka, Zambia

Background: For over a decade, Zambia has implemented differentiated service delivery models (DSD) to improve HIV clinical outcomes for recipients of care (ROCs). The Zambian Ministry of Health, supported by the Center for Infectious Disease Research in Zambia (CIDRZ), effectively implemented HIV viremic clinics as a DSD for non-suppressed (≥ 1000 copies/ml) ROCs. The DSD improved viral re-suppression (< 1000 copies/ml) from 55% (95% CI 50.0%, 59.8%) to 82% (74.4%, 88.1%). While the viremic DSD was successful, a better understanding of those who did not reach viral re-suppression despite DSD participation, is important to continue closing the gap toward achieving epidemic control in Zambia.

Description: We conducted a cohort analysis across 20 HIV clinics providing the DSD for non-suppressed ROCs in Lusaka, Zambia from October 2020 to September 2022. Our eligibility criteria included a non-suppressed viral load measure and completion of the enhanced adherence counseling (EAC) package. We evaluated association between non-suppression at six months of follow-up across sex, age, time on antiretroviral therapy (ART), and ART- regimen. We estimated adjusted risk of non-suppression using generalized linear model regression family (binomial) link (log).

Lessons learned: Of the 133 eligible ROCs, 62.4% (83/133) were female, the median age was 37 years old (interquartile range [IQR] 32, 46), 88.7% (118/133) were on a dolutegravir-based ART regimen, and the median time on ART was 5.2 years (IQR 2.4, 9.8 years). The proportion of ROCs with non-suppression at six months was 18% (24/133).

The median age for non-suppression was 35.5 years (IQR 27.5, 37.5) while for suppression it was 38 years (IQR 33, 47). Among ROCs aged ≤ 24 years, 38% (3/8) had non-suppression, followed by 22% (8/36) among those aged 25 – 34 years, while no ROCs aged ≥55 years had non-suppression. Increased age reduced risk of viral non-suppression while adjusting for sex, ART duration and ART-regimen (aRR 0.93; 95% CI 0.89, 0.97; p<0.001).

Males were at increased risk of viral non-suppression while adjusting for age, ART duration and ART-regimen (aRR 2.31; 95% CI 1.03, 5.17; p=0.042).

Conclusions/Next steps: To improve viral re-suppression, HIV viremic clinics should implement age-appropriate interventions, in consideration of ROC sex.

EP0192

Improving management of recipients of care with HIV viremia to optimize viral suppression in Zambia (2018 – 2022): a mixed methods evaluation

M. Wa Mwanza[1], K. Mwila Kazimbaya[2], D. Ngosa[3], C. Mwamba[2], K. Moomba[4], A. Sharma[2], C. Bolton[5], M. Ilunga[1], C. Chambwe[1], M.E. Herce[6], N. Vlahakis[1,1], S. Bosomprah[3,7], P.L. Mulenga[8], S. Sevile[8], C. Mwale[9], J. Simpungwe[10], K. Mweebo[10], M. Tenforde[10], N. Kancheya[11], T. Savory[4]

[1]Center for Infectious Disease Research in Zambia, Clinical Care, Lusaka, Zambia, [2]Center for Infectious Disease Research in Zambia, Research department, Lusaka, Zambia, [3]Center for Infectious Disease Research in Zambia, Data Analysis, Lusaka, Zambia, [4]Center for Infectious Disease Research in Zambia, Strategic Information, Lusaka, Zambia, [5]Center for Infectious Disease Research in Zambia, Chief Medical Officer, Lusaka, Zambia, [6]Center for Infectious Disease Research in Zambia, Implementation Science, Lusaka, Zambia, [7]University of Ghana, Department of Biostatistics, School of Public Health, Accra, Ghana, [8]Ministry of Health, Infectious Disease, Lusaka, Zambia, [9]Ministry of Health, Provincial Health Office, Lusaka, Zambia, [10]Division of Global HIV and TB, Global Health Center, U.S. Centers for Disease Control and Prevention, Care and Treatment, Lusaka, Zambia, [11]Division of Global HIV and TB, Global Health Center, U.S. Centers for Disease Control and Prevention, CDC, Lusaka, Zambia

Background: Enhanced adherence counselling (EAC) is conducted to assist non-suppressed recipients of care (ROCs) (viral load [VL] ≥1,000 copies/ml) six months of ART initiation to identify issues contributing to treatment failure. Zambia national guidelines highlight the importance of EAC and encourage differentiated service delivery (DSD) models to

optimize viral suppression. HIV viremic clinics (VCs) were introduced in October 2020 as a novel DSD model to provide EAC. We report early outcomes here.

Methods: We used a pre/post quasi-experimental design employing mixed methods to explore VC acceptability and evaluate viral suppression among ROCs. We included implementation data from ROCs with non-suppressed VLs in 20 health facilities offering EAC across 3 districts in Lusaka. during pre VC (October 2018-September 2020) and post VC (October 2020-September 2022) periods. We estimated risk ratios (RR) and 95% confidence intervals using generalized linear regression models.

We conducted in-depth interviews with ROCs, focus group discussions with health workers, and structured observations at 4 clinics after VC implementation. We used thematic analysis to understand facilitators and barriers at individual, service delivery, and health system levels.

Results: Data from 548 ROCs were analyzed. At 6 months, 81.9% (109/133) of ROCs who completed EAC post VC implementation were suppressed compared to 54.9% (228/415) ROCs who completed EAC pre VC implementation .There was a 31% and 39% increased likelihood of viral suppression for ROCs who completed EAC post VCs compared to those who completed EAC pre VCs at 6months (adjusted RR (aRR)=1.31 (95%CI:1.13, 1.52) and 12 months (aRR=1.39 (95%CI:1.21, 1.60), respectively.

Innovative ideas from ROCs to improve suppression included injectable/simplified ART formulations, longer duration drug refills, rapid and point-of-care VL testing, mental health services, community DSD models, and improved access to support groups.

Table1: Effect of delivering enhanced adherence counselling on viral suppression in Viremic Clinics in Lusaka, Zambia, (2018 – 2022).

Evaluation group	VL results (% of total)	Viral suppression n (% of row total)	Unadjusted risk ratio[1] (95% CI)	Adjusted risk ratio[2] (95% CI)
At 6 months	**N =548**	**N=337**		
EAC Pre-VC	415 (75.7)	228 (54.9)	**ref**	**ref**
EAC Post-VC	133 (24.3)	109 (81.9)	1.49 (1.32, 1.67)	1.31 (1.13, 1.52)
At 12 months	**N= 322**	**N= 241**		
EAC Pre-VC	221 (68.6)	147 (66.52)	**ref**	**ref**
EAC Post-VC	101 (31.4)	94 (93.1)	1.40 (1.26, 1.56)	1.39 (1.21, 1.60)

EAC Pre-VC – EAC before implementation of VCs; EAC Post-VC – EAC after implementation of VCs

[1] Risk Ratios and 95%CIs were estimated using a generalized linear model, [2] Estimates were adjusted for sex, age, ART duration in ROC with high viral load *and Drug regimen, EAC Enhanced Adherence Counselling, CI Confidence Interval, VL Viral load, * Statistically significant at α=5% significance level*

Conclusions: A viremic clinic model improved VL re-suppression for ROCs at risk of treatment failure in Zambia.

EP0193

Phase 2 once-weekly dose optimization for ulonivirine in combination with Islatravir 2 mg

M. Pham[1], G. Gillespie[1], T. Diamond[1], S. Klopfer[1], R.P. Matthews[1], M. Johnson[1], R. Vargo[1]
[1]Merck & Co., Inc., Rahway, United States

Background: Ulonivirine (ULO) is a non-nucleoside reverse transcriptase inhibitor (NNRTI) being investigated for once-weekly (QW) treatment of HIV-1 in combination with islatravir (ISL). Doses of 100, 200, and 400 mg ULO with 20 mg ISL QW were being investigated in Phase 2 before dosing was stopped due to ISL dose-dependent lymphocyte decreases observed across the ISL clinical development program. ULO data from Phase 1 and the previous Phase 2 studies were used to predict a safe and efficacious Phase 2 ULO dose to be combined with ISL 2 mg QW, which is the lower ISL dose used in ongoing clinical trials in combination with oral lenacapavir [NCT06630286; NCT06630299] and is expected to be safe and efficacious.

Methods: Reduction in viral load (measured as log10 plasma HIV-1 RNA copies/mL]) and ULO pharmacokinetics (PK) from a Phase 1b study where treatment-naïve participants living with HIV-1 received single oral doses of ULO (40, 80, or 600 mg) were used to establish a wild-type (WT) efficacy PK threshold.

Simulations using a ULO PopPK model developed with Phase 1 and 2 data were used to select doses providing exposures above the PK thresholds for WT and common NNRTI variants. Viral efficacy was explored through viral dynamics modeling (VDM). ULO and ISL QW regimens were simulated to predict the proportion of participants maintaining <50 copies/mL through 48 weeks.

Results: A ULO trough concentration target of 70 nM was determined based on PKPD analysis. Updated popPK simulations (n=1000) support 200 mg ULO QW achieves efficacious exposure to cover both WT and common NNRTI variants. VDM simulations (n=1000) with low doses of ISL (2 mg QW) demonstrated highly efficacious regimens for weekly ULO doses >100 mg ULO.

Conclusions: Dose selection factors weighed PK coverage and virological efficacy. Weekly 200 mg ULO in combination with ISL 2 mg was selected for Phase 2 for continued clinical development.

EP0194

Enhanced viral load coverage for optimal EMTCT outcomes, a retrospective cohort study at Aids Information Center - Kampala, Uganda

S. Mubiru[1], D. Mayambala[1]
[1]Aids Information Center Uganda, Medical, Kampala, Uganda

Background: Effective Prevention of Mother-To-Child Transmission (PMTCT) of HIV is vital for achieving the global UNAIDS 95-95-95 targets by 2030, particularly the third 95, which aims for 95% of people on antiretroviral therapy (ART) to have a suppressed viral load. The Ministry of Health (MOH) recommends viral load (VL) testing every three months to monitor ART response.

At Aids Information Center (AIC)- Kampala center of excellence, we implemented a comprehensive strategy to ensure timely VL monitoring for pregnant and breastfeeding mothers living with HIV.

The purpose of this study was to evaluate the impact of timely VL coverage in PMTCT.

Methods: To fast-track VL coverage, we employed a multifaceted approach. Central to this were weekly appointment follow-ups and viral load line lists of mothers due for VL testing, ensuring regular monitoring and timely interventions.

Complementing appointments, a PMTCT audit tool identified and addressed necessary services, focusing on VL monitoring. Engagement of peer mothers provided continuous follow-ups and education, fostering support and

adherence. A retrospective cohort study analyzed the impact of these strategies on mothers who were active in EMTCT during Jan-March 2024.

Results: 115 PLHIV women active in PMTCT and all underwent timely VL testing, achieving comprehensive coverage of 100%. Remarkably, only three mothers had unsuppressed VL, yielding a suppression rate of 97%, surpassing the 95% threshold for both coverage and suppression. Such outcomes underscored strategy efficacy.

Conclusions: Our comprehensive approach significantly improved viral load monitoring frequency and consistency, ensuring mothers achieved viral suppression. Weekly follow-ups, audit tool use, line list reviews, and peer support were critical. These results affirm our commitment to UNAIDS targets and contribute to eliminating mother-to-child transmission. This model is replicable, offering insights for enhancing PMTCT programs.

EP0195

Capsid inhibition with lenacapavir in HIV-1 infection: real-life results from the French compassionate use program

C. Delaugerre[1], S. Mafi[2], A. Zenuni[3], K. Amat[4], S. Seang[3], C. Duvivier[4], D. Chirio[5], J.-P. Viard[4], L. Hocqueloux[6], E. Estrabaud[7], G. Peytavin[8], J. Ghosn[4], C. Charpentier[4], R. Landman[8], L. Assoumou[3], K. Lacombe[3]

[1]Université Paris Cité, Virologie, Paris, France, [2]Université de Limoges, Limoges, France, [3]Sorbonne University, Paris, France, [4]Paris Cité University, Paris, France, [5]CHU Nice, Nice, France, [6]CHRU Orléans, Orléans, France, [7]Gilead Sciences, Paris, France, [8]Bichat Hospital, Paris, France

Background: Lenacapavir is a first-in-class capsid inhibitor that showed substantial antiviral activity in a phase 3 study among participants with multidrug-resistant HIV-1. We aimed to evaluate the efficacy and safety of lenacapavir with an optimised background regimen (OBR) received through the compassionate access in France.

Methods: Participants with previous multidrug failure were prospectively enrolled between January 1st, 2021 and December 31st, 2023. Following a 2-week oral lenacapavir, they received subcutaneous lenacapavir every W26 with an OBR. A retrospective efficacy analysis was performed with the primary end point as the percentage of participants with HIV-1 viral load (VL) < 50copies/ml at W26. Secondary endpoints were virological outcomes at end of follow up, emergence of lenacapavir resistance in case of virological failure and tolerance.

Results: Thirty-three participants (11/33 females) were analysed with a median (IQR) age of 56 (41-59) years. At lenacapavir initiation, median CD4 cells count was 330 (106-500) cells/µL with 11/27 (41%) participants having less than 200 cells per µL. VL was 2.54 (1.48-4.27) $\log_{10}$ copies/ml with 14/33 (42%) having VL below 50 copies/ml. OBR included mainly darunavir/r (n=13), dolutegravir (n=11), cabotegravir (n=10), fostemsavir (n=12), maraviroc (n=8), ibalizumab (n=7) and enfuvirtide (n=4). At W26 (W22 to W30), a VL < 50 copies/ml was reported in 66.7% (CI95% 48.2-82.0) of the participants with a mean increase in the CD4+ count of +92 cells/µL.

	Baseline VL<50 copies/mL N=14	Baseline VL≥50 copies/mL N=19
HIV-1-RNA at week 26 window (W22 to W30)		
<50 copies/mL	12/14(85.7%)	10/19(52.6%)
≥50 copies/mL or virological failure definition	1/14(7.1%)	7/19(36.8%)
No data	1/14(7.1%)	2/19(10.5%)
HIV-1-RNA at last follow-up visit (12,2 (IQR11,5-15,7) months)		
<50 copies/mL	13/14(92.9%)	14/19(73.7%)
≥50 copies/mL	1/14(7.1%)	5/19(26.3%)

HIV-1 capside sequencing was performed in 7 participants with virological failure and the Q67H mutation conferring resistance to lenacapavir was evidenced in one case. There were no grade 3 or 4 treatment-related adverse events (included two deaths). Injection site reactions were reported for 11/33 (33%) participants without treatment discontinuation.

Conclusions: In this real-life cohort of highly treatment-experienced HIV-1 participants, lenacapavir in combination with an OBR resulted in a high level of virological suppression up to 26 weeks, even increasing throughout the end of follow-up.

EP0196

Reasons for choosing oral-lead-in versus direct-to-injection when switching to long-acting antiretroviral therapy in East and Southern Africa

V. Ankunda[1], U. Bahemuka[1], P. Kafeero[1], V. Tumusiime[1], C. Norcross[1], J. Kitonsa[1], N. Garrett[2], S. Mahomed[2], S. Kassim[3], L.A. Ombajo[4], E.L. Odongpiny[5], N. Owarwo[5], I. Yawe[6], D. Grint[7], A. Idahosa[8], I. Eshun-Wilsonova[9], W.v. Rein-van der Horst van[10], F.A. Boateng[11], E. Ruzagira[1,7], F. Cresswell[7]

[1]MRC/UVRI & LSHTM, Viral Pathogens Theme, Entebbe, Uganda, [2]Centre for the AIDS Programme of Research in South Africa, HIV Pathogenesis and Vaccine Research, Durban, South Africa, [3]Desmond Tutu HIV Foundation, Cape Town, South Africa, [4]University of Nairobi, Department of Medicine, Nairobi, Kenya, [5]Infectious Diseases Institute, Kampala, Uganda, [6]Joint Clinical Research Centre, Fort Portal, Uganda, [7]London School of Hygiene and Tropical Medicine, London, United Kingdom, [8]Johnson & Johnson, Lagos, Nigeria, [9]Johnson & Johnson, Cape Town, South Africa, [10]Johnson & Johnson, South Holland, Netherlands, the, [11]Johnson & Johnson, Accra, Ghana

Background: The benefits and risks of long-acting injectable (LAI) antiretroviral therapy are under investigation in ongoing clinical trials in Africa. Product labels for LAI cabotegravir (CAB) and rilpivirine (RPV) in USA and Europe include an optional one-month oral-lead-in (OLI) prior to initiating injections, despite data from high-income settings demostrating the saftey of direct-to-injection (DTI). We present the first data on reasons and factors associated with choice of OLI versus DTI in East and Southern Africa.

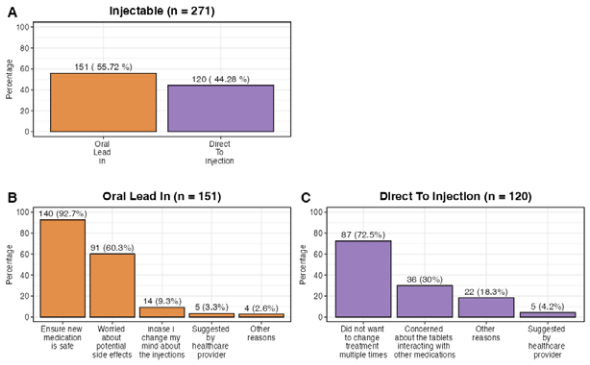
Methods: We analysed data from an ongoing trial (IMPALA, NCT05546242) that recruited adults living with HIV in Uganda, Kenya and South Africa. Eligible participants were randomised to either continue oral treatment or switch to two-monthly CAB+RPV LAI.

Participants randomised to LAI were given the option to choose between OLI or DTI, and reasons for their choice were documented. Participant characteristics were summarised by choice using descriptive statistics. Logistic regression was performed to identify factors associated with OLI preference.

Results: A total of 271 participants were randomised to LAI (01/Feb/2023–03/May/2024). The median age was 40.0 years (IQR:33.0–48.0), 62.4% (169/271) were female, 43.2% (117/271) were married/cohabiting, 45.4% (123/271) had secondary school education, 44.3% (120/271) were from Uganda, 29.9% (81/271) from Kenya and 25.8% (70/271) from South Africa. Most participants (55.7%, 151/271) chose OLI (Figure 1A), and the main reason given was to ensure medication safety (92.7%, 140/151) (Figure 1B).

The main reason for choosing DTI was to avoid multiple medication changes (72.5%, 87/120, Figure 1C).

Compared to participants in Uganda, participants in Kenya and South Africa had lower odds of choosing OLI (Adjusted odds ratio [AdjOR]: 0.33, 95% CI: 0.18–0.62, p-value=0.0006, and AdjOR: 0.08, 95% CI: 0.04–0.18, p-value<0.0001, respectively).



Conclusions: Preference for OLI versus DTI varied by country. Providing reassurance about safety and tolerability of CAB+RPV could increase DTI preference and simplify implementation in a public health setting.

EP0197

Real-world virologic outcomes of high BMI on CAB+RPV LA-I: a systematic review

C. Orkin[1,2], M. Boffito[3,4], M. Parczewski[5], K. Ring[1,2], A.M. Geretti[6,7,8]

[1]Queen Mary University of London, London, United Kingdom, [2]Barts Health NHS Trust, London, United Kingdom, [3]Chelsea and Westminster Hospital, London, United Kingdom, [4]Imperial College London, London, United Kingdom, [5]Pomeranian Medical University, Szczecin, Poland, [6]University of Rome Tor Vergata, Rome, Italy, [7]Free London NHS Foundation Trust - North Mid, London, United Kingdom, [8]King's College London, London, United Kingdom

Background: Multivariable analysis of pooled data from the ATLAS, FLAIR and ATLAS-2M RCTs associated the risk of virological failure (VF) with the presence of ≥2 baseline factors (highest to lowest predictive value): rilpivirine (RPV) resistance-associated mutations, subtype A1/A6 and/or body mass index (BMI) ≥30 kg/m^2. Pooled results from phase 3/3b studies of cabotegravir (CAB)+RPV long-acting injectable (LA-I) trials have demonstrated efficacy regardless of baseline BMI category. With growing numbers of observational cohorts (OCs) reporting clinical outcomes during routine clinical care, evaluating the impact of risk factors such as BMI is warranted.

We present an evidence synthesis of the VF outcomes in OCs by baseline BMI.

Methods: We performed a systematic review of electronic databases and HIV-related congresses from January 2020–July 2024 for OCs N≥10 evaluating CAB+RPV LA-I (Figure 1). We summarised all identified OCs reporting patient-level data on VF outcomes by baseline BMI status (≥30 or <30 kg/m^2).

The presence of combined baseline risk factors identified in the multivariable analysis is not accounted for in this summary. Data were summarised descriptively, as populations; VF definitions and follow-up times varied across studies.

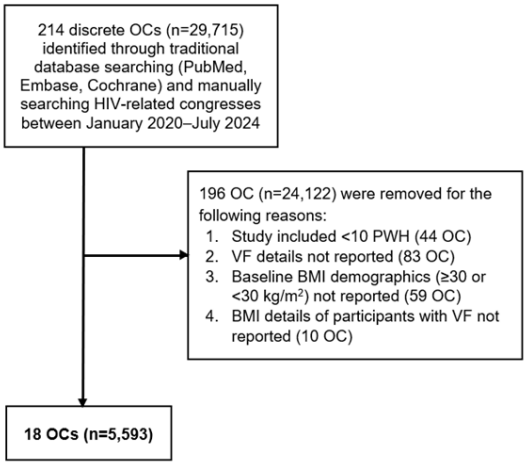


Figure 1. Flow diagram of search methodology.

Results: We identified 18 OCs which included 5,593 PWH; duration of follow up was ~3–54 months. Overall, BMI ≥30 kg/m^2 was reported for 1,248/5,593 (22.3%; range 0.9–51.0%)

participants. VF was reported for 66/5,593 (1.2%; range 0-2.5%) participants. In participants with BMI ≥30 kg/m^2, VF was reported for 17/1,248 (1.4%; range 0-60.0%) vs 49/4,264 (1.1%; range 0-40%) in those with BMI <30 kg/m^2.

Conclusions: In this evidence synthesis of OCs, VF rates were similar in those with and without high BMI; this is consistent with clinical trial data. However, ongoing monitoring of the relationship between BMI and VF is warranted.

EP0198

Crushing barriers beyond the pill: when people with HIV cannot swallow – a review

H. Abdessamad[1], C. Baroody[2], K. Pogorzelski[3], W. Jamaleddine[1], M.S. Kitonga[4], D. Dandachi[1,5]
[1]University of Missouri-Columbia, Internal Medicine, Division of Infectious Diseases, Columbia, Missouri, United States, [2]UT Southwestern Medical Center, Investigational Drugs Service Pharmacy, Dallas, Texas, United States, [3]University of Missouri-Columbia, Faculty of Medicine, Columbia, Missouri, United States, [4]Moi University College of Health Sciences, Faculty of Medicine, Eldoret, Kenya, [5]Columbia/Boone County Public Health & Human Services, Medical Director, Columbia, Missouri, United States

Background: Continuous lifetime treatment for HIV is essential to control the disease, prevent resistance and stop transmission. However, there exist scenarios where people with HIV (PLH) cannot swallow, and the only available form of ART is the pill. This causes treatment interruptions, especially that injectable antiretrovirals have specific indications, are coupled with oral medication or are challenged by cost and availability. Furthermore, there is minimal data to support administering oral antiretrovirals in alternative methods, especially in comatose, demented or intubated individuals.

Methods: We conducted this review in accordance with PRISMA guidelines to explore all the published data from 2010 to 2023 about alternative methods of administration of the antiretroviral pills in PLH who cannot swallow. (Figure 1)

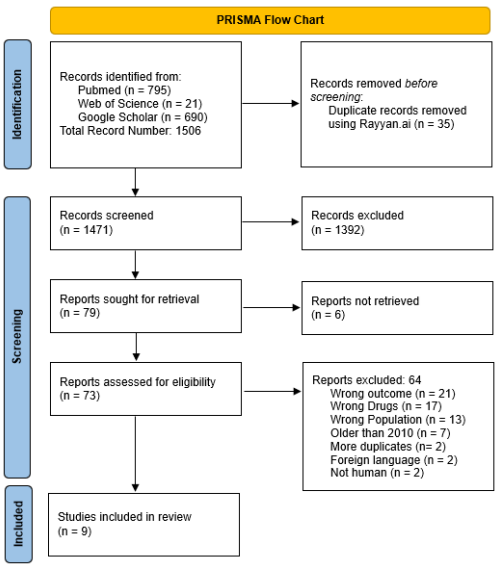

Figure 1: PRISMA Flowchart of this Review.

Results: Many of the available antiretroviral tablets were crushed, emulsified, dissolved or sprinkled over food in various preparations that can be given via enteral feeding tubes, whether nasogastric (NGT), percutaneous endoscopic gastrostomy (PEG) or jejunostomy tubes (JT). The review discusses these findings Table 1.

Class of ART	Drugs	Alternative Administration
PIs	Atazanavir, Indinavir, Saquinavir*	Capsules opened and mixed with food *Gelatin capsules heated and mixed with juice
	Ritonavir, Nelfinavir, Lopinavir/Ritonavir*, Fosamprenavir**, Darunavir+	Crushed *Significantly less bioavailability ** Only reported in PEG +Only reported in NGT
INSTIs	Raltegravir, Dolutegravir*	Crushed and mixed with water. *Use immediately. Also mixed with food.
NNRTI	Etravirine, Delavirdine (100mg tablets only)	Crushed and used with water
	Efavirenz, Rilpivrine*	Crushed. Water insoluble. Should not feed for 2 hours after administration. *Increase dose from 25 to 50mg if crushed. PEG (required acidic environments)
NRTIs	Abacavir, Lamivudine, Stavudine*	Crushed. Use immediately. Mixed with foods *Described in NGT and PEG
	Tenofovir	Tablets: dissolved in 100 ml of water or juice Powder: mixed with food and taken immediately. Clumps if mixed with liquids.
	Didanosine	Powder mixed with antacids; unstable in acid. Used in NGT
	Abacavir/lamivudine, Abacavir/Lamivudine/Zidovudine	
	Lamivudine/Zidovudine, Emtricitabine/Tenofovir	
	Bictegravir/emtricitabine/tenofovir alafenamide	
Combinations	Dolutegravir/abacavir/lamivudine	Viral suppression achieved with crushing and administering with water. *Bioequivalence/pharmacokinetics also studied and achieved. ** Water insoluble. To be taken with a meal of >533 calories
	Elvitegravir/cobicistat/emtricitabine/tenofovir*	
	Darunavir/cobicistat/emtricitabine/tenofovir alafenamide*	
	Rilpivirine/Emtricitabine/Tenofovir**	

Table 1: Summary of Findings Regarding Alternative Antiretroviral Formulations

Conclusions: This review offers an evidence-based backup on the use of ART pills in an alternative form when they are the only available options. This encourages further research on the use of crushed pills in HIV treatment when conscious swallowing is not an option.

EP0199

Long-acting ART (LEN/CAB and CAB/RPV) among viremic persons living with HIV

S. Chaudhuri[1], S. Olender[2], J. Eldib[3], J. Bosco[2], M. Saylor[3], M. Scherer[2]

[1]University of Miami School of Medicine, Miami, United States, [2]Columbia University, New York, United States, [3]New York Presbyterian, New York, United States

Background: Cabotegravir/rilpivirine (CAB/RPV) is approved for treatment of virologically suppressed HIV patients. There is growing interest in its use among those with viremia (VL >200 copies/mL). In cases of drug resistance, combination, fully active injectable therapy—i.e. lenacapavir (LEN) with CAB +/- RPV—is also of interest, but has not been formally studied.

Methods: We identified 27 viremic patients (VL >200copies/mL) interested in LAI-ART. They were initiated on off-label CAB/RPV or LEN/CAB +/- RPV between 2022 and 2024. Clinical factors of interest were last 3 viral loads, HIV risk factors, CD4 count, mental health diagnoses, substance use, resistance, opportunistic infections, hospitalizations, engagement, and reasons for switching. Outcomes were viral load suppression (VL <200 copies/mL), time to suppression, and CD4 count.

Clinical characteristics	n=27
CD4 (mean)	267
AIDS diagnosis (CD4<200)	15 (56%)
OI diagnosis in past year	10 (37%)
Recent hospitalizations?	11 (41%)
Mental health diagnosis	19 (70%)
Substance use history (recent)	12 (44%)

Treatment	VL at time of injection (copies/mL)	VL post-treatment (most recent)	Time to suppression (in weeks)	Baseline NRTI or INSTI Mutations	CD4 count pre-treatment (cells/mm3)	Most recent CD4 count
CAB 400/600mg QM+LEN Q6M	1,070,000	114	8	Y181C	102	N/A

	<20	<20	5.1	none	160	409
	3,480	<20	12.9	none	1011	1041

Results: 20 patients received CAB/RPV and 7 received combination LEN/CAB +/-RPV. 52% were male, 48% female and over half were younger than 35. 67% were Black and 30% Hispanic. The most common HIV risk factor was perinatal infection (41%). 56% had AIDS (CD4 <200 cells/mm3).

The most common resistance-associated mutations were Y181C, K103N, and E138Q. Most fell within a pre-treatment VL range of 1,000-50,000 copies/mL; values reached 2.8 million. Of those with ≥1 VL collected after initiating LAI-ART, 100% (26/26) achieved suppression. 1 patient expired before a VL was collected. Median time to suppression was 5.1 weeks. Of those on LEN/CAB +/- RPV, 100% (7/7) suppressed. 24/27 remain on LAI-ART and remain undetectable. 2 expired and one was lost to follow-up.

Conclusions: We saw high rates of viral suppression with CAB/RPV and LEN/CAB +/- RPV among viremic patients and showed they can be effective options, including in cases of resistance.

EP0200

Pregnancy and health outcomes among women living with HIV on different antiretroviral therapy in Malawi: a cohort study

A. Masano[1], M. Chagomerana[1], W. Kumwenda[1], S. Wallie[1], A. Jumbe[1], M. Maliwichi[2], J. Phulusa[3], M. Hosseinipour[1]

[1]UNC Project Malawi, Lilongwe, Malawi, [2]Kamuzu University of Health Sciences, Blantyre, Malawi, [3]Malawi Liverpool Wellcome Trust, Blantyre, Malawi

Background: The Option B+ strategy, introduced in Malawi in July 2011, provides lifelong antiretroviral therapy (ART) to pregnant and breastfeeding women with HIV. Despite successes, some women were failing treatment and some default from ART which may affect pregnancy or health outcomes.

We compared pregnancy and health outcomes between pregnant women who were failing treatment and were switched to second-line therapy during pregnancy and those who defaulted from care and resumed first-line therapy during pregnancy.

Methods: The prospective cohort study enrolled pregnant women at Bwaila Hospital and Area 18 clinic in Lilongwe, Malawi, from 2015 to 2018, with two years follow-up. Demographic characteristics, pregnancy outcomes, and clinical and laboratory adverse events were summarized using proportions. Chi-square or Fisher's exact tests were used to compare demographic characteristics between women in Cohort B and Cohort C. We compared the risk of preterm and low birthweight between infants delivered in these cohorts.

Results: A total of 321 pregnant women were enrolled: 171 in Cohort B and 150 in Cohort C. The median gestational age at delivery was 40 weeks (IQR: 38-41), and the median birth weight was 3.00 kg (IQR: 2.60-3.32).

Women in Cohort B were older (median age 31 vs. 26 years, $p < 0.001$), had more multiparous women (74% vs. 60%, $p = 0.03$), and a higher percentage in WHO stages ≥2 (19% vs. 10%, $p = 0.008$).

The risk of preterm delivery (RR = 1.11; 95% CI: 0.51-2.40) and low birthweight (RR = 0.92; 95% CI: 0.46-1.85) did not differ significantly between cohorts. Grade ≥ 3 clinical adverse events were reported in 26 women from Cohort B and 22 from Cohort C. Cohort B had more grade ≥ 2 laboratory events, including elevated bilirubin (43%), while low hemoglobin levels were observed in both cohorts (Cohort B: 32%, Cohort C: 51%).

Conclusions: Women in both cohorts had similar pregnancy outcomes, but Cohort B experienced a higher frequency of Atazanavir and Zidovudine- associated clinical and laboratory events compared to those in Cohort C.

These results emphasize importance of consistent ART management and monitoring to improve maternal and neonatal health outcomes.

EP0201

Prevalence and durability of viral suppression among adults living with HIV transitioned from boosted protease inhibitors-based to dolutegravir-based regimens as second-line therapy from 2019 to 2021 in Tajikistan

A. Nabidzhonov[1], P. Nadol[2], S. Vallabhaneni[3], J. Bacha[4], R. Teran[4], U. Talbov[5], D. Ali-Zade[6], S. Yusufbekova[6]
[1]US Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB, Dushanbe, Tajikistan, [2]US Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB, Bishkek, Kyrgyzstan, [3]US Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB, Windhoek, Namibia, [4]US Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB, Atlanta, United States, [5]Republican AIDS Center of the Ministry of Health and Social Protection of Population of Tajikistan, Dushanbe, Tajikistan, [6]ICAP at Columbia University Office in Tajikistan, Dushanbe, Tajikistan

Background: WHO recommends dolutegravir-based regimens (DBR) as preferred second-line therapy for those failing efavirenz-based regimens (EBRs) but there was no guidance on whether those who failed EBR and were switched to boosted protease inhibitor-based therapy (bPIBR) could be transitioned to DBRs. In Tajikistan, DBRs, primarily tenofovir/lamivudine/dolutegravir (TLD), became available in 2019. People living with HIV (PLHIV) on EBR and second-line bPIBRs were transitioned to TLD. We assessed durable viral suppression (DVS) among PLHIV transitioned from second-line bPIBRs to TLD.
Methods: Routine clinical and laboratory data were abstracted from electronic medical records of PLHIV ≥15 years, who were transitioned to TLD after bPIBRs from 2019 to 2020; had ≥3 viral load (VL) results recorded ≥6 months after TLD initiation. Viral suppression was defined as VL ≤1000 copies/ml; PLHIV having all (≥3) VLs suppressed ≥6 months after TLD initiation were considered to have DVS.
Results: Among 89 PLHIV ≥15 years transitioned from second-line bPIBRs to TLD, 80 had ≥3 VLs after TLD initiation; 76% (61/80) were suppressed on bPIBR. Median time on ART before TLD was 5 years (IQR:3-6) and on bPIBRs 1 year (IQR:1-2); 63% used lopinavir- and 35% atazanavir-based regimens; tenofovir was part of backbone regimen for 46% of PLHIV. After initiating TLD, 95% (76/80) were suppressed at first VL test, of which 92% (70/76) maintained DVS throughout follow-up (median=4 years: IQR:4-5). Among those suppressed before TLD initiation (n=61), 98% (60/61) remained suppressed at first VL and 93% of them (56/60) maintained DVS on subsequent VL tests (median 4 tests, IQR:3-5; median follow-up 4 years, IQR: 4-5). Among those not suppressed before TLD (n=19), 84% (16/19) achieved suppression on TLD at first VL (median 90 days, IQR:57-120) and 88% of them (14/16) maintained DVS throughout follow-up (median 4 tests, IQR:3-6; median follow up 4 years, IQR:3-5).
Conclusions: Transitioning from second-line bPIBRs to TLD resulted in high rates of DVS among most PLHIV, including those previously suppressed and unsuppressed on bPIBRs. Our results suggest that transition from second-line bPIBR to DBRs may be an effective practice. Further investigation is needed to identify reasons for non-suppression among some PLHIV transitioned from second-line bPIBRs to DBRs.

Antiretroviral therapies and clinical issues in adolescents and young adults

EP0202

Pilot testing of a smartphone-based self-management support programme for adolescents living with HIV in the Western Cape, South Africa

T. Crowley[1], C. Petinger[2], L. Tokwe[3], S. Ntanjana[1], L. Weyers[1]
[1]University of the Western Cape, School of Nursing, Belville, South Africa, [2]University of the Western Cape, School of Public Health, Cape Town, South Africa, [3]University of Cape Town, HIV Mental Health Research Unit, Cape Town, South Africa

Background: Adolescents living with HIV (ALHIV) represent a vulnerable population requiring enhanced healthcare support, as they face heightened risks of poor health outcomes stemming from a complex interplay of individual, environmental, and health system challenges. The Supporting Adolescents to be Resilient and Thrive (SSMART) programme is a 12-week smartphone-based intervention to enhance self-management among ALHIV.
This pilot study assessed the feasibility and acceptability of the programme among ALHIV aged 15–21 years attending antiretroviral therapy (ART) services at a primary care clinic in the Cape Metropole, Western Cape, South Africa.
Methods: Thirteen purposively selected ALHIV were provided smartphones, monthly data, and access to the SSMART app from September to December 2024. The intervention included individual activities (quizzes, videos), five peer group sessions, and three individual coaching sessions, delivered by two peer leaders and two lay coaches (all under 30 years old and living with HIV) and supported by the project team. Pre-implementation focus groups with participants (n=17) explored app usability and navigation, while post-implementation focus groups (n=12) evaluated user experiences.
Results: Participants engaged daily with the app, reporting high satisfaction with quizzes, medication adherence reminders, and peer interaction. Participants also noted how the quizzes improved their HIV and self-management knowledge, and the medication adherence reminders served as a tool to remain adherent. However, the language complexity of some activities posed a barrier, with participants recommending simpler language and more visual content. Both participants and facilitators reported

that the app improved the self-efficacy and self-esteem of ALHIV. Implementation challenges included limited communication via the app due to technological issues (e.g., lack of push notifications) and difficulty scheduling sessions, resulting in only some planned peer and coaching sessions being conducted. Facilitators expressed a need for more training. Despite these challenges, participants indicated they would engage with the programme even without the provision of smartphones and data.

Conclusions: The SSMART programme shows potential for supporting self-management among ALHIV. Content and delivery require refinement to improve health literacy and flexibility of delivery, and technological enhancements are needed to address communication barriers.

EP0203

The relationship of stigma on self-efficacy among adolescents and young adults with HIV enrolled in the Sauti ya Vijana Clinical Trial in Tanzania

E. Senkoro[1], D. Arthur[2], B.T. Mmbaga[1,2,3], E. Ketang'enye[4], L. Komba[5], G. Mollel[6], A. Shayo[3,7], L. Turner[2], J. Gallis[2], D. Dow[1,2,8]

[1]Kilimanjaro Christian Medical Center-Duke Collaboration, Moshi, Tanzania, the United Republic of, [2]Duke Global Health Institute, Durham, United States, [3]Kilimanjaro Christian Medical Centre, Department of Pediatrics, Moshi, Tanzania, the United Republic of, [4]Baylor College of Medicine Children Foundation of Tanzania, Mwanza, Tanzania, the United Republic of, [5]Baylor College of Medicine Children Foundation of Tanzania, Mbeya, Tanzania, the United Republic of, [6]Ifakara Health Institute, Ifakara, Tanzania, the United Republic of, [7]Kilimanjaro Christian Medical University College, Moshi, Tanzania, the United Republic of, [8]Duke University, Department of Pediatrics, Durham, United States

Background: Many adolescents and young adults with HIV (AYAWH) experience HIV-related stigma that may impact self-efficacy. Self-efficacy is important for AYAWH as it influences their ability to manage their HIV care, adhere to antiretroviral therapy (ART) and ultimately have viral suppression.

We hypothesized that increased stigma may be associated with lower self-efficacy and that self-esteem may mediate this effect.

Methods: Baseline data from AYAWH enrolled in the Sauti ya Vijana (SYV) randomized control trial between March-2021 and July-2024 were analyzed. SYV is a mental health intervention, participants were 10-24 years, on ART for ≥ 6 months and were aware of their HIV diagnosis. Measures included Coping Self-Efficacy (CSE) (range 0-130) (higher score is better CSE). Other were HIV stigma (range 12-48), Rosenberg self-esteem (range 0-30), adherence (% with good adherence), HIV RNA (suppression was <400 copies/mL).

Multivariate analysis was adjusted for age, sex, stigma, adherence, and HIV RNA. The mediation of self-esteem on the relationship between stigma and CSE was explored using R software.

Results: Participants (N=690) had a mean age of 17.5 years (SD = 2.5); 50% were female. Mean scores included HIV-related stigma 26.3/40 (sd = 4.5); CSE 79/130 (sd=25); self-esteem 21.2/30 (3.2); good adherence 77% (sd=17%) and HIV RNA <400 copies/mL (87%). Older age, viral suppression, and stigma were significantly associated with self-efficacy (Table 1).

Mediation analysis suggests that the association between stigma and CSE may operate through self-esteem (Table 2).

Variable	N (%) or Mean (SD)[1]	Unadjusted Model Estimate (95% CI)	Adjusted Model Estimate (95% CI)
Age	17.50 (2.47)	1.6 (0.87, 2.4)	1.7 (0.94, 2.4)
Biological sex Male Female	 343 (50%) 347 (50%)	 Ref - 0.31 (14, 3.4)	 Ref - 0.27 (- 3.9,3.4)
Self-reported adherence	77 (17)	- 0.038 (- 0.14, 0.069)	- 0.017 (- 0.18, 0.034)
Viral suppression Not suppressed (≥ 400) Suppressed (< 400)	 92 (13%) 598 (87%)	 Ref 6.8 (1.3, 12)	 Ref 6.8 (1.5, 12)
Total stigma score	26.3 (4.5)	- 0.89 (-1.3, -0.47)	- 0.92 (- 1.3, - 0.51)

Table 1: Estimates from regression models (unadjusted and adjusted).

*[1]Mean (SD); n (%); *HIV RNA includes samples from trial enrollment with missing results supplemented from the nearest standard of care result.*

Mediator	Effect of Stigma	Unadjusted	Adjusted
Self esteem	Total effect	-0.89	-0.92
Self esteem	Direct effect	-0.19	-0.27
Self esteem	Indirect effect	-0.70	-0.65

Table 2: Mediators of the association of stigma and self-efficacy.

Conclusions: Interventions aimed at reducing stigma and improving self-esteem may improve coping and self-efficacy. Interventions addressing stigma reduction and improving self-esteem may improve CSE and in turn HIV outcomes.

EP0204

Factors influencing viral non-suppression among adolescent and young people living with HIV in Lagos State, Nigeria; a focus on treatment-related factors

A. Ogunnaike[1], O. Salami[2], T. Ladi-Akinyemi[2]

[1]University of Ibadan, Ibadan, Nigeria, [2]University of Lagos, Idi-Araba, Nigeria

Background: Viral load suppression (VLS) is a key indicator of effective HIV treatment in adolescents and young people living with HIV (AYPLWH). Despite better access to antiretroviral therapy (ART) and related care, 80% of AYPLWH (aged 10-24 years) on ART in Lagos State remain virally unsuppressed (HIV RNA>1000copies/ml), reflecting poor treatment outcomes. This study aims to examine the treatment-related factors influencing VL non-suppression among AYPLWH in Lagos State, Nigeria.

Methods: This descriptive cross-sectional study involved 280 AYPLWH on highly active antiretroviral therapy (HAART) from four ART clinics in Lagos State. Only AYPLWH

with valid viral load results (most recent result used for clinical decision) were included in the analysis. Data were extracted from clinical records, focusing on treatment-related variables including VLS, duration on ART, ART regimen, tuberculosis preventive therapy (TPT) use, multi-month dispensing (MMD), body mass index (BMI), and CD4 count.

Bivariate (Chi-square) and multivariate (binary logistic regression) analyses were used to assess relationships between these variables and VLS, with significance set at $p<0.05$. Ethical approval was granted by the Lagos University Teaching Hospital Health Research Ethics Committee (ADM/DSCST/HREC/APP/6321) and the Lagos State Health Service Commission (LSHSC/2222/VOLIII/73).

Results: The mean age of the AYPLWH participants was 19.17 ± 3.35 years, with 52% being female. Nearly 18% of the AYPLWH had been on ART for more than 10 years. The majority were virally suppressed (84%), on a first-line ART regimen (98%), had completed TPT (95%), had a normal BMI (18.5–24.9 kg/m²) (81%), and had a normal CD4 count (>200 cells/mm³) (94%). In bivariate analysis, the duration on ART ($\chi^2 = 9.22$, $p = 0.027$) and MMD ($\chi^2 = 29.86$, $p < 0.00001$) were significantly associated with VLS.

Multivariate analysis showed that AYPLWH with less than 2 years on ART (adjusted odds ratio [aOR] = 2.98, $p = 0.042$) and those with less than 3 months of MMD (aOR = 14.27, $p < 0.00001$) were significant predictors of VL non-suppression.

Conclusions: Enhancing adherence counselling and providing targeted care for AYPLWH who are new on ART, while ensuring a minimum of 3 months of drug supply, will positively impact and improve VLS among AYPLWH.

EP0205

Extended travel-time and clinic wait-time as non-clinical predictors of viral non-suppression in adolescent and young-persons on ART in Lagos State, Nigeria

A. Ogunnaike[1], O. Salami[2], T. Ladi-Akinyemi[2]
[1]University of Ibadan, Ibadan, Nigeria, [2]University of Lagos, Idi-Araba, Nigeria

Background: The AIDS Virus Education Research Trust (AVERT) reported a decline in Nigeria's national viral load suppression (VLS) rate, from 81% in the 2018 National AIDS Indicator and Impact Survey (NAIIS) to 72% in 2020. There is limited information on the non-clinical factors influencing this poor VLS, particularly among adolescents and young persons (AYP). This study aims to address this gap.

Methods: This study was conducted with 280 AYP (aged 10-24 years) receiving antiretroviral therapy (ART) in selected ART clinics in Lagos State. Only consenting clients with valid viral load results were included.

Data on sociodemographic and psychosocial characteristics, transport costs, travel-time to the facility, and clinic wait-time were collected using a validated semi-structured questionnaire. Viral load data was obtained from facility electronic medical records. Bivariate (Chi-square) and multivariate (binary logistic regression) analyses were used to assess the relationships between these factors and viral load non-suppression (HIV RNA >1000 copies/ml), with significance set at $p<0.05$. Ethical approval was granted by the Lagos University Teaching Hospital Health Research Ethics Committee (ADM/DSCST/HREC/APP/6321) and the Lagos State Health Service Commission (LSHSC/2222/VOLIII/73).

Results: About half of the AYP were females (52%), with 50% aged 20-24 years, and 76% were still in secondary school. Most (94%) had treatment support partners, primarily parents (88%), and were members of support groups (87%). About half (48%) spent ≤1000 naira (~$1 at the time of data collection) on transport, while 39% and 48% reported travel-time and clinic wait-time exceeding 2 hours, respectively. The majority (84%) had high VLS. At bivariate analysis, only travel-time ($\chi^2 = 10.21$, $p = 0.006$) and clinic wait-time ($\chi^2 = 8.18$, $p = 0.017$) had significant association with viral load non-suppression.

Multivariate analysis revealed that AYP who spent ≤1 hour as – travel-time to the clinic (adjusted odds ratio [aOR] = 0.34, $p = 0.002$), and clinic wait times (aOR = 0.457, $p = 0.023$) were 3 times and 2 times less likely, respectively, to experience viral non-suppression.

Conclusions: This study posits that – reducing the distance to clinics and wait times, through appropriate differentiated services, for AYP attending ART clinics would improve VLS.

EP0206

Clinical and psychosocial factors associated with depression among adolescents and young people living with HIV in Rwanda (Aged 10-24) in 2024

J.B. Tugirimana[1], D. Mutambuka[2], G. Mujawamariya[3], G. N. RWIBASIRA[3], P. Mutesi[1]
[1]Rwanda Network of People Living with HIV /AIDS (RRP+), Community Engagement in HIV Responses, Kigali, Rwanda, [2]Rwanda Network of People Living with HIV/AIDS (RRP+), Community Engagement in HIV Responses, Kigali, Rwanda, [3]Rwanda Biomedical Center (RBC), HIV / AIDS and STIs Diseases, Kigali, Rwanda

Background: Depression is a major mental health issue among adolescents and young people living with HIV (AYPLHIV), affecting adherence to treatment and overall health outcomes. Identifying the clinical factors associated with depression in this population is crucial for developing effective mental health interventions.

This study aimed to identify HIV-related clinical factors and experiences associated with depression among AYPLHIV in Rwanda.

Methods: This cross-sectional study was conducted in Rwanda in 2024, involving 457 adolescents and young people aged 10–24 years living with HIV. Data were collected using structured interviews, focusing on clinical factors such as HIV transmission mode, ART treatment history, caregiver support, and trauma exposure (including forced sex and physical abuse). Depression was assessed using a Patient Health Questionnaire-9 (PHQ-9) for depression. Statistical analyses included bivariate and multivariable logistic regression to determine the clinical factors associated with depression.

Results: The study identified several clinical factors associated with depression among AYPLHIV. Female gender was associated with higher odds of depression compared to male participants (Adjusted OR=0.482, p=0.002). Younger adults aged 20-24 years were more likely to experience depression than those aged 10-14 years (Adjusted OR=2.785, p=0.064).

A history of orphanhood, particularly losing both parents, was strongly associated with depression (Adjusted OR=2.622, p=0.003). Living with both parents was found to be protective, with those in such households exhibiting lower odds of depression (Adjusted OR=0.308, p=0.001).

Trauma exposure was significantly linked to depression, with individuals who had experienced forced sex (Adjusted OR=2.072, p=0.035) or physical abuse (Adjusted OR=2.853, p=0.009) showing higher odds of depression.

Additionally, disclosure of HIV status was also significantly associated with depression (Adjusted OR=1.774, p=0.007). People with unknown viral load were at a higher risk of presenting with depression than those with known viral load (Adjusted OR=3.214, 95%CI:1.404-7.359, p=0.006).

Conclusions: The study underscores the importance of psychosocial factors such as gender, caregiver involvement, trauma exposure, and HIV-related history in the mental health of AYPLHIV in Rwanda.

These findings call for targeted mental health interventions that consider trauma and caregiver support to improve both mental health outcomes and HIV care in this population.

EP0207

Impact of significant depression symptoms (SDS) on adherence to Tenofovir-based Antiretroviral therapy (ART) in young women living with HIV (WLWH) in Kampala

M.E. Kasirye[1], E. Nakimuli Mpungu[2], J. Nakigudde[3], F. Matovu Kiweewa[4]

[1]MUJHU Care, Pharmacy, Mityana, Uganda, [2]Makerere University Kampala, Psychiatry, Kampala, Uganda, [3]Makerere University Kampala, Psychiatry Department, Kampala, Uganda, [4]MUJHU Care, Research Directorate, Kampala, Uganda

Background: After nearly 40 years of the HIV pandemic, Africa remains disproportionately affected, with women accounting for 54% of the cases. Addressing depression and its impact on ART adherence is crucial to ending the pandemic by 2030.

This study aimed to assess the longitudinal patterns of significant depression symptoms (SDS) and their association with ART adherence among 18–35-year-old women living with HIV (WLWH) on TDF-based regimens in Kampala. We hypothesized an association between SDS patterns and adherence.

Methods: A retrospective cohort study that analyzed secondary data from the BONECARE study files at MUJHU Care in Kampala was conducted. we involved 390 WLWH aged 18 to 35 years, recruited from 11 health facilities in Kampala between 2016 and 2017 and followed until 2020. SDS were scored using the Hopkins Symptom Checklist (HSCL-15) while ART adherence was measured with a 7-day self-report questionnaire. SDS was categorized as significant (HSCL-15 ≥ 1.75) or sub-clinical (< 1.75). The longitudinal patterns of SDS were modeled using mixed-effects logistic regression, with bivariate and multivariable analyses assessing the relationship between SDS and ART adherence over 24 months. Statistical significance was set at p<0.05.

Results: The graph shows higher ART adherence among participants without SDS, with steady improvement over time peaking at month 24. SDS had no statistically significant effect on baseline adherence (p=0.126) or adherence changes over time (p=0.61).

However, adherence improved significantly over time regardless of SDS status (p=0.004). Age and alcohol-use independently influenced baseline adherence.

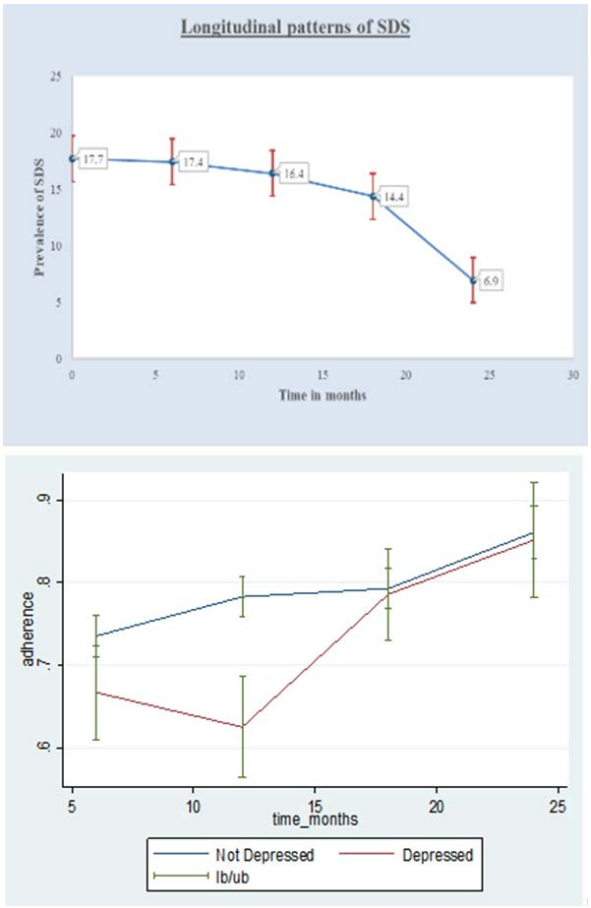

Figure 1: Longitudinal pattern of SDS and ART adherence grouped according to the presence or absence of SDS

Conclusions: In conclusion, SDS had no impact on ART adherence at baseline or over time. Conversely, ART adherence significantly improved over time regardless of SDS status. Alongside managing depression, monitoring ART adherence in people living with HIV is crucial.

EP0208

Diving into the life of Cameroonian adolescents living with HIV/AIDS and their interest for long-acting antiretroviral treatment: evidence from the CIPHER-ADOLA study

Background: Long-acting injectable antiretroviral therapy (LAI-ART) might be a potential game-changer in the treatment of adolescents living with HIV (ALWH). We aimed at delineating the profile of Cameroonian ALWH regarding their interest in receiving LAI-ART.

Methods: A cross-sectional study performed among participants of the CIPHER-ADOLA cohort which enrolled ALWH 10-19 years receiving tenofovir/lamivudine/dolutegravir (TLD) in four paediatric HIV treatment centres in Cameroon. Data was collected using medical records and questionnaires. Uni-multivariate logistic regression was performed to identify factors associated with interest of ALWH to LAI-ART.

Results: We enrolled 236 ALWH (male: 51.7%; median [IQR] age: 15 [13-17] years) mainly treated in urban-settings (84.3%), with a median-BMI of 19.3 (17.3-21.8); overweight: 10.6%; and underweight: 7.2%. Majority lived with biological parents [60.6%] and HIV status partially/fully disclosed in 76.7%; stigmatised and non-injectable drug-users represented 3.0% and 5.9%, respectively.

About 77.5% were in a multi-month ARV-dispensing differentiated service delivery model (M-DSD) and only 34.3% self-reported no missed ARV-dose since 30-days. About 30.9% were knowledgeable on LAI-ART; and 73.1%, 15.8% and 11.1% had respectively no-, moderate- and high-fear of injection/needle.

About 71.6% and 72.5% had a VL<50 copies/mL and CD4≥500 cells/mm^3 respectively. Globally, 92.4% (n=218) were LAI-ART interested. Compared to non-LAI-ART interested ALWH, they had a higher median-age (15 [13-17]) vs. 13 [11-15], p=0.010); higher BMI (19.4 [17.4-21.9] vs. 17.9 [16.7-19.3], p=0.041), mainly living with biological-parents (62.4% vs. 38.9%, p=0.096), mainly non-injection/needle fearing (74.5% vs. 55.6%, p=0.058), and knowledgeable on LAI-ART (32.6% vs. 11.1%, p=0.075).

Sex, immuno-virological status, ART-adherence and living in urban-settings were not significantly associated with interest in LAI-ART. In multivariate model, only injection/needle fear independently predicted LAI-ART interest.

Compared to ALWH with high fear, those without fear were about four-folds more interested (OR [95% CI]: 4.243 [1.089-16.527], p=0.037). Finally, concerning the preference between LAI-ART and M-DSD, 74.8%, 20.9% and 4.3% respectively preferred LAI-ART, M-DSD and no preference.

Conclusions: Cameroonian ALWH have many challenges to overcome during their therapeutic pathway. Despite their low knowledge of LAI-ART, they express a high interest in LAI-ART, particularly predicted by the absence of injections/needles fear. Providing data on their eligibility to this new strategy is essential to guide decision-making.

EP0209

Virological outcomes of adolescents switched to dolutegravir based regimens at Botswana-Baylor Children's Clinical Centre of Excellence (BBCCCOE), 2016 to 2023

J. Farirai[1], A. Avalos[2,3,4], G. Kings[2,3], L. Bewlay[5,3], K. Molebatsi[2], L. Ketumile[1], T. Regonamanye[1], T. Choga[2], D. Ramaabya[4], B. Nkomo[4], M. Matshaba[1], The Botswana Epidemiological ART Treatment Cohort Study II

[1]Botswana-Baylor Children's Clinical Centre of Excellence, HIV Medicine, Gaborone, Botswana, [2]Botswana Harvard Health Partnership, HIV Research, Gaborone, Botswana, [3]Careena Centre for Health, HIV Medicine, Gaborone, Botswana, [4]Botswana Ministry of Health, HIV/AIDS Treatment & Care, Gaborone, Botswana, [5]Tau Technology, Informatics, Gaborone, Botswana

Background: To address the unique challenges of adolescents adhering to anti-retroviral treatment (ART) and remaining in care, the BBCCCOE provides comprehensive HIV services to adolescents, including broad social and mental health support. As an alternative to more toxic

and difficult to administer ART, Dolutegravir (DTG) based regimens (DBRs) were introduced in ART-experienced adolescents, beginning in 2016. We now report real-world virological outcomes of treatment-experienced adolescents, switched to a DBR.

Methods: The BBCCCOE is a public-private facility located at Princess Marina Hospital in urban Gaborone. Retrospective data on 499 adolescents (≥13-<18 years) consecutively switched from 1st or 2nd line ART to DBRs, were drawn from the BBCCCOE Electronic Medical Records System (2016-2023). Descriptive statistics were used to report virological failure (VF) (two consecutive VL measurements >400 copies/mL), viral load suppression (VLS) <400, deaths and lost-to-follow up (LTFU), from the time of switch to DBRs until switched off DTG, were LTFU, transferred out or died, for up to 60 months.

Results: Median age of n=499 males and females, 16 years (52.5% female); Rates of VLS at 60 months, 88.2% (Table 1); 7.8% (39) experienced VF after VLS (5.4% females, 4.6% males); 16.2% (81) experienced transient viremia, 3.2% (16) re-suppressed on the same DBR. 94.8% (37/39) with VF occurred in adolescents ≥16 years, 71.7% failed by 36 months. No statistically significant differences of VF found upon disaggregation by gender, VLS at switch, 1st or 2nd line at switch (P=>0.05)

Months from time of Switch	# / % of Total Cohort	Number with Viral Loads Tests	% Viral Load Coverage	% Viral Load Suppression	Number Suppressed	LTFU	Deaths	Transferred out of the Cohort
0	N=499 / 100%	316	63.3%	82.3%	260	1	2	1
6	495 / 99.1%	380	76.8%	89.5%	340			3
12	492 / 98.5%	350	71.1%	89.4%	313			6
24	486 / 97.3%	366	75.3%	84.7%	310			3
36	483 / 96.7%	346	71.6%	88.4%	306	2		22
48	459 / 91.9%	351	76.5%	84.9%	298	7		22
60	430 / 86.1%	229	53.3%	88.2%	202			

Conclusions: High VLS of 88.2% at 60 months were achieved at a private-public facility providing extensive psychosocial support. Higher rates of VF were found in older adolescents. Lower than expected VL coverage (55.3%) at 60 months, likely reflected the SARS-COVID19 period when routine VL monitoring was suspended.

Remarkably, 16.2% adolescents experienced transient viremias and 3.2% adolescents with confirmed VF subsequently achieved VLS on their original DBR, reflecting the critical importance of on-going VL monitoring and comprehensive psycho-social support.

EP0210

Determinants of successful transition from paediatric to adult HIV care in Zambia, 2015-2023

T. Chabu[1], S. Funda[2], K. Sikwibele[3], P. Shabangu[3], P. Kawina[4], B. Chiteba[2], A. Kashoka[5], L. Saunyama[4], E. Mulenga[4], S. Kunene[4], J. Silupumbwe[4], O. Mwiinde[2]

[1]Institute for Health Measurements-Southern Africa, Capacity Building, Lusaka, Zambia, [2]CDC, Lusaka, Zambia, [3]Institute for Health Measurements-Southern Africa, Management, Lusaka, Zambia, [4]Institute for Health Measurements-Southern Africa, Health Information, Lusaka, Zambia, [5]Ministry of Health-Head Quarters, ICT, Lusaka, Zambia

Background: The transition from paediatric to adult HIV care is a critical phase for adolescents living with HIV, requiring structured support to maintain adherence and viral suppression. In Zambia, this process often faces challenges such as treatment fatigue, care discontinuity, and psychosocial barriers, leading to poor outcomes.

Understanding the determinants of successful transitions is vital to improving health outcomes in this vulnerable population.

Methods: A retrospective cohort study was conducted using data from Zambia's SmartCare electronic Health Record system. The study included adolescents aged 10–19 years who transitioned to adult HIV care between 2015 and 2023. Clinical and demographic data were analyzed. Key outcomes included ART adherence, viral load suppression(<1,000 copies/ml), and retention in care post-transition. Multivariable regression models were used to identify determinants of successful transitions.

Results: Among 5,500 adolescents, 85% achieved ART adherence, and 75% maintained viral suppression within 12 months of transitioning. Factors significantly associated with successful transitions included strong family and community support systems (adjusted OR: 2.3, 95% CI: 1.8–3.1), early transition preparation (adjusted OR: 1.9, 95% CI: 1.5–2.4), and access to structured transition programs (adjusted OR: 2.7, 95% CI: 2.1–3.5). Adolescents receiving psychological counselling were 1.8 times more likely to remain in care compared to those without.

Conclusions: Structured transition programs addressing both clinical and psychosocial needs can improve health outcomes for adolescents transitioning to adult HIV care. Family and peer support, mental health services, and improved healthcare accessibility can facilitate retaining adolescents in care.

Expanding such programs across Zambia may reduce care discontinuation and improve long-term outcomes for this population.

EP0211

Addressing mental health challenges to improve treatment adherence among children and adolescents living with HIV in Shiselweni, Eswatini

A.N. Sihlangu[1], M. Maseko[1], H. Mkhatshwa[1], H. Nxumalo[2]
[1]World Vision, Health & HIV, Mbabane, Eswatini, [2]World Vision, Program Development, Evidence & Impact (PDEI), Mbabane, Eswatini

Background: World Vision Eswatini (WVE) implements a community-based OVC/DREAMS program as part of the Kingdom of Eswatini's HIV response. This program focuses on preventing new HIV infections and reducing vulnerabilities among orphaned and vulnerable children (OVC) aged 0–17 years and adolescent girls and young women (AGYW) aged 15–29 years. By providing evidence-based interventions, WVE addresses HIV prevention, mobilizes subpopulations for clinical and family planning services, and offers adherence support for children and adolescents living with HIV (C/ALHIV) in collaboration with local healthcare facilities.

Recognizing the link between mental health challenges and treatment adherence, WVE introduced integrated mental health interventions in 2023. These interventions include group therapy sessions, household visits, psychological first-aid, and one-on-one counseling, aimed at addressing psychosocial barriers and improving health outcomes for vulnerable populations.

Description: Adherence support is provided through Linkages Officers who engage with C/ALHIV in households and health facilities. Project data from 2021 to 2023 demonstrated high viral load and treatment interruption among C/ALHIV. Verifications to establish the cause revealed that mental health challenges contribute to treatment interruption, as 98/1304 interrupted treatment and 72 recorded a high viral load.

Adolescents often express frustration, anger, and despair, stemming from their status, feelings of betrayal by parents, and concerns about living a "normal" life. Provision of psychosocial support to C/ALHIV and their parents addressed such challenges and have improved treatment adherence.

Routine implementation data show a marked improvement in adherence, with 99% of C/ALHIV in the program achieving viral suppression compared and 100% adhering to treatment in 2024. WVE also integrates clinical referrals for mental health services to psychologists, peer support groups or teen clubs, and caregiver education forums.

Lessons learned: Early disclosure of HIV status to children living with HIV helps in addressing their psychosocial challenges. Proactive psychosocial support equips children and adolescents with resilience and coping mechanisms, reducing the likelihood of treatment interruption.

Conclusions/Next steps: Mental health challenges are a significant barrier to treatment adherence among C/ALHIV. Strengthening early disclosure practices and embedding continuous, age-appropriate counselling within HIV care programs are vital for improving adherence and overall health outcomes.

EP0212

Improving viral load suppression rate among children and adolescents living with HIV (CALHIV), a continuous quality improvement project at Maanyi H.C.III, Mityana district, Uganda

M. Adolf[1], J. Mukuza[1], N. Resty[2], M. Catherine[2], N. Peter[2]
[1]Maanyi Health Centre III, Health, Mityana, Uganda, [2]Alliance for Youth and Adolescents Health Organization, Health, Mityana, Uganda

Background: At Maanyi H.C.III, only 43% of CALHIV had suppressed viral load results as of March 2024 which is against the Uganda Ministry of Health's standard of 95%. Contributing factors included missing scheduled appointments, lack of supportive caregivers, non-disclosure whereby some adolescents didn't know the reasons for taking medications, drug resistance, stigma, and discrimination.

A Continuous Quality Improvement (CQI) project was launched aiming at increasing the rate from 43% in March 2024 to 95% by February 2025.

Description: Several interventions were introduced in April 2024 to improve adherence and viral load suppression. Routine and timely viral load monitoring is conducted every six months among CALHIV, Intensive Adherence Counseling (IAC) one month apart for non-suppressed cases, and after achieving three consecutive goods, a repeat viral load test done together with a Drug resistance test to facilitate early identification of resistance and timely adjustments of ART regimens.

Peer support groups were strengthened to encourage adherence and engagement. Caregivers were trained on safe disclosure and provided mental health support. Adolescents participated in educational camps to share experiences and learn coping strategies from each other. Home visits and household assessments identified individual barriers to adherence and facilitated individualized interventions. Anti-stigma campaigns are being conducted through community radio towers and social media to address misconceptions and reduce discrimination. Some adolescents with good adherence were trained as peer educators to provide support and act as role models for their peers.

Lessons learned: Peer-led interventions proved essential in enhancing adherence, with adolescents fostering trust and engagement. Caregiver education created a supportive home environment, while community engagement reduced stigma. Routine monitoring and early drug resistance detection allowed timely ART adjustments. Addressing psychosocial factors like stigma proved to be crucial for sustained adherence.

Conclusions/Next steps: By December 2024, the viral load suppression rate had increased to 85%. Moving forward with the target of 95%, the project will scale up the peer education program, and expand home-based support, and anti-stigma campaigns.

Continued viral load monitoring and personalized support are essential to reach the 95% suppression target by February 2025 and improve long-term health outcomes for CALHIV.

EP0213

Neurotypical vs. neuroatypical development among school-aged and adolescent HIV-exposed children from Uganda: findings from a consensus group evaluation

J. Awadu[1], C. Abbo[2], S. Zalwango[3], A. Sikorskii[1], A. Arinda[2], J. Nakitende[2], B. Giordani[4], A. Ezeamama[1]

[1]Michigan State University, Psychiatry, East Lansing, United States, [2]Makerere University, Psychiatry, Kampala, Uganda, [3]Kampala Capital City Authority, Public Health and Environment, Kampala, Uganda, [4]University of Michigan, Psychiatry, Ann Arbor, United States

Background: We examine the hypothesis that children with perinatal HIV infection may be more likely to be clinically diagnosed with neurodevelopment disorders by school-age and adolescence when compared to HIV unexposed and uninfected children.

Methods: A sample of 164 children and adolescents (aged 6-18 years), based on their high, moderate, or low total score on the Social Responsiveness Scale, second edition (SRS-2), were enrolled with their respective primary caregivers from a larger ongoing study of 750 children. The 61 CPHIV, 54 CHEU, and 49 CHUU were then sent to a clinical consensus team including psychiatrists and psychologists blinded to children's HIV status and neurodevelopmental concerns for independent clinical neurodevelopmental disorder (ND) evaluation and diagnosis. Children were classified as neurotypical, if no disorder was flagged and neuroatypical, if diagnosed with ≥ one disorder.

Multivariable logistic regression models implemented in Statistical Analysis Software (v.9.4) estimated HIV-status associated odds ratio (OR) with 95% confidence intervals (CI) for the likelihood of neuroatypical diagnosis with adjustment for age and sex.

Results: Compared to CHUU, CPHIV had a significantly increased likelihood for being diagnosed as neuroatypical, (OR=2.4; 95% CI: 1.10, 5.45). The likelihood of being neuroatypical was similar among CHEU and CHUU (OR=0.79; 95% CI: 0.36, 1.74).

Further, CPHIV were more likely to be diagnosed with more than one developmental disorder relative to CHUU (OR=1.98; 95% CI: 0.94, 4.20). Most HIV-exposed children were clinically diagnosed with attention deficit hyperactivity disorder, intellectual disorder, stuttering and functional impairment.

Conclusions: When compared to CHUU, CPHIV are more likely to be clinical diagnosed with a developmental disorder (i.e., neuroatypical). It is reassuring to see that CHUU and CHEU are not different in their likelihood to be so diagnosed. There long-term development of CPHIV should be continuously monitored and interventions should be utilized that promote their long-term functioning.

Antiretroviral therapies and clinical issues in neonates, infants and children

EP0214

Proviral genotype and phenotype as predictors of broadly neutralizing antibody susceptibility

N. Jilg[1], A. Niesar[2], N.O. Moraka[3], Z. Hu[4], A. Gbolahan[3], M.D. Hughes[5], T. Mohammed[3], J.D. Reeves[6], C. Maphorisa[3], S. Moyo[3], R. Shapiro[7], M. Lichterfeld[2], D.R. Kuritzkes[4]

[1]Massachusetts General Hospital/ Harvard Medical School, Department of Medicine, Division of Infectious Diseases, Boston, United States, [2]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [3]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [4]Brigham and Women's Hospital/ Harvard Medical School, Department of Medicine, Division of Infectious Diseases, Boston, United States, [5]Harvard T.H. Chan School of Public Health, Department of Biostatistics, Boston, United States, [6]Monogram Biosciences LabCorp, South San Francisco, United States, [7]Harvard T.H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States

Background: The Tatelo study showed that broadly neutralizing antibodies (bNAbs) maintained HIV suppression in children with favorable reservoir characteristics. We investigated associations between treatment success and bNAb susceptibility as predicted by proviral genotype (GT) and phenotype (PT).

Methods: Children with vertically acquired HIV in Botswana were started on ART within the first week of life, on ART ≥96 wks, and virally suppressed ≥24 wks at inclusion in Tatelo. Participants received monthly infusions with 2 bNAbs (VRC01LS, 10-1074), initially with ART, then during a period when ART was held. At 24 wks, or earlier if viral rebound occurred, bNAbs were discontinued and ART was resumed.

Proviral DNA obtained from timepoints before Tatelo (bNAb naïve) was sequenced. The bNAb-ReP software (https://github.com/RedaRawi/bNAb-ReP) was used for GT interpretation and PhenoSense mAb Assay (Labcorp-Monogram Biosciences) for PT bNAb susceptibility testing. Fisher's exact test was used for associations of proviral GT/PT with treatment success (absence of viral rebound).

Results: The analysis included 202 intact env sequences from 18 participants. Eleven (61%) of these 18 experienced viral rebound. GT predicted 10-1074 susceptibility in 13 (72%), and VRC01LS susceptibility in 2 (11%) participants. For 10-1074, 6/13 (46%) with predicted susceptibility by GT and 5/5 (100%) with predicted resistance rebounded (p=0.10), suggesting a high negative predictive value (100% [0.57%-100%]).

There was no association between predicted VRC01LS susceptibility by GT and therapeutic success (1/2 with predicted susceptibility, 6/16 with predicted resistance, [p>0.99]). Proviral PT predicted susceptibility to 10-1074 in 8/14 (57%) with available results and this was associated with treatment success (2/8 with predicted susceptibility, 0/6 with predicted resistance [p<0.01]). PT predicted susceptibil-

ity to VRC01LS in 7/14 (50%), but this was not associated with treatment success (3/7 with predicted susceptibility, 3/7 with predicted resistance [p>0.99]). We found robust agreement between GT and PT predictions for 10-1074 (12/14, 86%), but not for VRC01LS (7/14, 50%).
Conclusions: The utility of PT and GT testing in the Tatelo Study was bNAb dependent. PT susceptibility testing was associated with treatment outcome for 10-1074, and GT testing aligned with the PT results. Neither PT nor GT testing proved useful for VRC01LS, but only few specimens showed preexisting susceptibility.

EP0215

Dolutegravir use in children: experiences of Newlands Clinic, Zimbabwe, 2016-2024

L. Mandikiyana Chirimuta[1], T. Shamu[2,1], A. Mandiriri[1,2,3], C. Chimbetete[1]
[1]Newlands Clinic, Harare, Zimbabwe, [2]University of Bern/Institute of Social and Preventive Medicine, Bern, Switzerland, [3]University of Bern/Graduate School of Health Sciences, Bern, Switzerland

Background: Dolutegravir has been rolled out for use in first, second- and third-line antiretroviral (ART) regimens among people living with HIV, including children and adolescents. This medicine was widely adopted due to its safety profile, tolerability, high genetic barrier to resistance and efficacy.
We describe the outcomes of children and adolescents who commenced dolutegravir containing regimens at Newlands Clinic (NC).
Methods: A cross-sectional study was conducted in which all children and adolescents living with HIV (CALHIV) who have ever commenced dolutegravir at NC before 15 October 2024 and <18 years old at dolutegravir commencement, were included.
Clinical data including Viral loads (VLs) taken at dolutegravir commencement and most recent VLs (within the last 24 weeks at analysis), were extracted from an electronic database using customized queries. Analysis was done using STATA Ver13.1 and descriptive statistics used.
Results: A total of 810 CALHIV were commenced on dolutegravir at NC between June 2016 to 15 October 2024. Of these 403 (49.8%) were female. Median age at dolutegravir commencement was 13.8 years (IQR 10.1 – 17.2). A total of 267 (31.7%) were orphaned (86 [10.6%] paternal, 102 [12.6%] maternal, 69 [8.5%] double).
At analysis, median duration on dolutegravir was 50 months (IQR 38 – 56) and 724 (89.4%) remained in care, 67 (8.3%) had been transferred out, 12 (1.5%) were lost to follow up, two (0.02%) had dolutegravir discontinued due to adverse events and seven(0.8%) deceased.
Of the deceased, three died from advanced HIV disease, two from accidental causes and two from non-communicable disease. At dolutegravir commencement, 771 (95.2%) were ART experienced, and of these, 86.6% had a viral load (VL) <1000 copies/mL at treatment switch.
Of those ART naïve at dolutegravir commencement and at least 24 weeks on dolutegravir containing regimen, 89.2% had a most recent VL <1000 copies/mL, and 67.6% had VL <50 copies/mL, and of those ART experienced 95.5% had VL <1000 copies/mL and 87.1% had VL <50 copies/mL.
Conclusions: We report excellent viral suppression rates on dolutegravir in this cohort of predominately ART experienced CALHIV as well as a very low mortality and high retention in care. Dolutegravir is safe and efficacious in CALHIV.

EP0216

Lessons learned from evaluation of final outcomes of HIV exposed infant cohorts of year 2022 in Ethiopia

M. Zeidan[1], G. Bantayehu[1], W. Perry[2], S. Ghosh[3], Z. Zewdie[4], M. Abdurahman[4], F. Negash[4], M. Kemal[5], A. Asmamaw[5], T. Assefa[6], Z. Melaku[7]
[1]CDC, DGHT, Addis Ababa, Ethiopia, [2]CDC, DGHT, Atlanata, United States, [3]CDC, DGHT, Atlanta, United States, [4]Federal Ministry of Health, HIV Prevention and Control LEO, Addis Ababa, Ethiopia, [5]ICAP, C&T, Addis Ababa, Ethiopia, [6]ICAP, Central Office Program Director, Addis Ababa, Ethiopia, [7]ICAP, Ethiopia Country Director, Addis Ababa, Ethiopia

Background: The National 2021 Prevention of Mother to Child Transmission (PMTCT) Guideline is implemented across all health facilities to identify and provide care for pregnant and lactating women living with HIV and their infants. However, health outcomes of HIV exposed infants (HEI) are not being longitudinally investigated or reported at the national level. The objective of this evaluation was to determine the documented HEI outcomes by identifying the number and percentage of HEIs at selected health facilities in Ethiopia.
Methods: We conducted a retrospective data review of a cohort of 3,844 infants across Ethiopia, encompassing 11 regions and two city administrations from January to February 2024 using registers, clients' charts, and aggregate reporting of key performance indicators for each infant. The infant cohort consists of the number of HEIs whose mothers were enrolled in PMTCT care and completed at least two years of HEI follow up. We selected 56 health facilities that implemented cohort monitoring for three years. We conducted descriptive analysis stratified by regions and analyzed six HEI outcome indicators: discharged negative, lost to follow-up (LTFU), transferred out, HIV-positive, died, and still exposed during follow-up care due to continued breast feeding.
Results: Out of the 3,844 HEI in the cohort, 3,181 (82.8%) were discharged negative, 281 (7.3%) were LTFU, 261 (6.8%) transferred out to other health facilities, 47 (1.2%) were HIV-positive, and 50 (1.3%) died. Regional disaggregation of HEI outcome for discharged negative showed that five regions achieved greater than 85% achievement; while three regions (Afar, Somali and Central Ethiopia) achieved less than 75% discharged negative. Central Ethiopia achieved the lowest result at 60%, with unknown status of 14.1%.
Conclusions: Although most of HEIs in the cohort had a known outcome, conducting cohort monitoring analysis could benefit the country's prevention of vertical trans-

mission of HIV program in addressing the regional variation of HIV positivity rate among the HEIs, reduce LTFU, and minimize unknown status at the end of HEI follow-up care. This would ultimately accelerate progress towards elimination of vertical transmission of HIV.

EP0217

Optimizing viral load services for children living with HIV: the quality improvement initiative to enhance viral load suppression in Southern Nigeria

C. Nwangeneh[1], E. Ugobo[2], E. Nwanja[3], O. Ogheneuzuzao[2], U. Akpan[3], I. Elechi[4], F. Agu[5], E. Effiong[5], O. Toyo[3], D. Carpenter[6], N. Persaud[6], N. Ezema[1], U. Omo-Emmanuel[7], B. Adebobola[8], D. Ogundehin[7], E. James[7], O. Onyedinachi[3], A. Adegboye[3], A. Eyo[3]

[1]FHI 360, Abuja, Nigeria, [2]Save the Children International, Abuja, Nigeria, [3]Excellence Community Education Welfare Scheme, Uyo, Nigeria, [4]Achieving Health Nigeria Initiative, Abuja, Nigeria, [5]Howard University Global Initiative, Abuja, Nigeria, [6]FHI 360, Washington DC, United States, [7]United States Agency for International Development, Office of HIV/AIDS and TB, Abuja, Nigeria, [8]National Agency for the Control of AIDS, Abuja, Nigeria

Background: Achieving viral load (VL) suppression among children living with HIV (CLHIV) is key to improving their health outcomes and preventing disease progression. The USAID/PEPFAR-funded Accelerating Control of the HIV Epidemic – Cluster 5 (ACE5) project launched a six-month "Operation-Go-Green" in March 2024 to reverse declining VL suppression among CLHIV in Southern Nigeria. This study appraises the outcome of the intervention.

Methods: The initiative focused on childhood (boarding school), caregiver (forgetfulness, herbal medications, change of caregivers, food insecurity), and clinical (child ailments, sub-optimal regimen) factors contributing to treatment failure.

Strategies employed were appointment scheduling outside boarding school calendar, treatment supporters, medication reminders, caregiver treatment literacy, management of childhood ailments, pediatric dosing charts, and household economic empowerment.

Program data (sex [male, female] and VL [≥1,000 copies/ml: unsuppressed, <1,000 copies/ml: suppressed, <50 copies/ml: undetectable=untransmittable [U=U]]) were extracted from the Lafiya Management Information System for CLHIV (<15 years) receiving antiretrovirals for ≥ six months in Akwa Ibom and Cross River States, from October 2023 to September 2024.

Data were grouped into fiscal-year quarters: October–December 2023 (Q1), January–March 2024 (Q2), April–June 2024 (Q3), and July–September 2024 (Q4).

We compared viral suppression (proportion of CLHIV with suppressed VL) and U=U rates (proportion of CLHIV with U=U VL) using linear regression in SPSS v26.

Results: CLHIV ranged from 5,100 in Q4 to 5,214 in Q1 (mean: 5,067; SD: 42.9) (Table 1). Across quarters, mean proportion of males was 50.2% (SD: 0.2).

Period	Sex	Eligible CLHIV	Viral Load >1,000 copies/ml	Viral Load <1,000 copies/ml	U=U	Coverage	Suppression Rate	% U=U
Q1	Female	2,602	136	1,954	1,814	80.3%	93.5%	86.8%
	Male	2,612	145	2,315	2,146	94.2%	94.1%	87.2%
Q2	Female	2,512	173	1,947	1,747	84.4%	91.8%	82.4%
	Male	2,507	184	1,953	1,741	85.2%	91.4%	81.5%
Q3	Female	2,523	123	2,231	2,008	93.3%	94.8%	85.3%
	Male	2,561	158	2,243	2,008	93.8%	93.4%	83.6%
Q4	Female	2,538	81	2,314	2,108	94.4%	96.6%	88.0%
	Male	2,562	79	2,354	2,122	95.0%	96.8%	87.2%

Table 1. Viral load summarized by quarter.

VL suppression improved from 93.8% (4,269/4,550) to 96.7% (4,668/4,828) (R^2=0.99, p=0.073), and U=U rate improved from 87.0% (3,960/4,550) to 87.6% (4,230/4,828) (R^2=0.96, p=0.121) from Q1 to Q4. VL suppression and U=U rates did not differ significantly (p >0.05) between sexes.

Conclusions: This initiative resulted in an upward trend in viral suppression among CLHIV. Further evaluation of longer-term outcomes is recommended.

EP0218

Effects of antiretroviral use by HIV-positive pregnant women on the birth weight of HIV exposed children

L.H. Mattos da Silva[1], L. Sales dos Santos[1], C. Andrade[1], G. Arakaki Faria[1], R.H. Oliveira[1], P. Gutman[1], T. Abreu[1], A.C. Cisne Frota[1], G. Pucarelli[1], C. B Hofer[1]

[1]UFRJ - Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Background: An association between the use of antiretroviral (ARVs) during pregnancy (mainly preconception or in the first trimester of pregnancy) and low birth weight was observed. This premise was not evaluated with integrase inhibitors.

The objective of this study is to evaluate the impact of exposure to ARVs on birth weight in a cohort of pregnant women living with HIV (GVH) and their newborns (NBs).

Methods: Cross-sectional study, nested within a cohort of GVH and their newborns. We selected newborns born in 2022 and 2023, followed at IPPMG-UFRJ, where demographic, clinical and laboratory data were collected. We categorized newborns as low birth weight (LBW, <2500g) and adequate weight, and also assessed variables possibly associated with thiscondition through logistic regression.

Results: Between 2021-2023, we followed 182 infants exposed but not infected with HIV. Of these, 90 (49%) were girls, 46 (25%) mothers reported white ethnicity, and the average maternal age was 27 years. A total of 176 (96%) of the mothers received prenatal care, which began on average at 11 weeks of gestational age (GA), and 171 (93%) used antiretroviral therapy (ART) during prenatal care, which began on average at 9 weeks of GA.

Furthermore, 68 (37%) mothers were already using ARVs when they became pregnant. 73 women (40%) had vaginal delivery, 12 NB were premature and 23 were LBW. The

variables statistically associated with LBW were NB whose mothers did not use dolutegravir during pregnancy (OR=2.63, CI95%= 1.08-6.47) and later initiation of prenatal care (OR=2.631.06 per GA, CI95%= 0.99-1.13).
Conclusions: Prenatal care as early as possible and the use of integrase inhibitors during pregnancy appear to protect newborns exposed to but not infected with HIV from possible
LBW.

EP0219

Clinical and virological outcomes among children and adolescents with HIV after initiation of antiretroviral therapy: a five-year cohort analysis in Cameroon, 2019–2024

B. Tchakounte Youngui[1], P. Tchendjou[2], S. Talla[2], R. Kana[1], E. Shu[1], J. Fokam[3], T. Djikeussi[1], R. Ajeh[3], S. Lekeumo[4], Y.M. Fadil[5], M. Mukaminega[6], E. Takem[5], M. Fabou[4], K.A. Bosh[5], N. Rakmaniana[6,7], Z. Bissemou[2], E. Muna[5], J. Ditekemena[8], G. Ndayisaba[2], A. Tiam[9,7], M.F. Jalloh[5], B.K. Tchounga[1]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Public Health Evaluation and Research, Yaoundé, Cameroon, [2]Elizabeth Glaser Pediatric AIDS Foundation, Programs, Yaoundé, Cameroon, [3]Ministry of Health, National AIDS Control Committee, Yaoundé, Cameroon, [4]Elizabeth Glaser Pediatric AIDS Foundation, Strategic Information & Evaluation, Yaoundé, Cameroon, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Yaoundé, Cameroon, [6]Elizabeth Glaser Pediatric AIDS Foundation, Technical Leadership and Program Optimization, 1350 I Street NW, Suite 400 Washington, DC 20005, United States, [7]George Washington University Milken Institute School of Public Health, Washington DC, United States, [8]Elizabeth Glaser Pediatric AIDS Foundation, Program Implementation & Country Management, Kinshasa, Congo, the Democratic Republic of the, [9]Elizabeth Glaser Pediatric AIDS Foundation, Technical Strategies and Innovation, 1350 I Street NW, Suite 400 Washington, DC 20005, United States

Background: While pediatric HIV care has advanced in resource-limited settings, achieving and maintaining undetectable viral load (VL) in children and adolescents living with HIV (CALHIV) remains a challenge. Real-word data are essential to inform strategies for improving pediatric HIV care outcomes.
We assessed mortality, time to death, and virological outcomes in CALHIV initiating antiretroviral therapy (ART) in two Cameroonian regions.
Methods: We conducted a retrospective cohort analysis using data from 46 HIV clinics. We included children (0–9 years) and adolescents (10–14 years) who initiated ART between October 2019 and September 2023, with follow-up until July 2024. We abstracted and de-identified individual-level data from facility data sources.
We analyzed mortality, time to death from ART initiation, and undetectable VL (<40 copies/mL) outcomes stratified by age, with comparisons using Chi-squared and Kruskal-Wallis tests.
Results: The cohort included 730 CALHIV (median age: 4 years; IQR: 1.2–8.5), with 367 (50.3%) males and 137 (18.8%) adolescents. Median follow-up time was 19.6 months (IQR: 10.7–32.7).
Overall, 42.9% (313/730) were initiated on a dolutegravir-based regimen with 38.5% in 0–2-year-olds, 39.1% in 3–9-year-olds, and 60.6% in 10–14-year-olds. Among 417 not initiated on dolutegravir, 264 (63.3%) switched to dolutegravir. Overall, 118 (16.2%) were lost to follow-up, with a median time from ART initiation to the last visit of 10.8 months (IQR: 5.6–18.4). Among 433 (59.3%) CALHIV on ART for ≥6 months with VL data, 313 (72.3%) achieved undetectable VL. Younger children (0–2-year-olds) had lower proportion of undetectable VL (61.8%,110/178) compared to 3–9-year-olds (75.4%, 126/167) and 10–14-year-olds (87.5%, 77/88), p<0.0001.
Of 112 participants with ≥1 year follow-up after their first undetectable VL, 85 (75.9%) maintained an undetectable level. Children showed lower maintenance (70.9%, 56/79) compared to adolescents (87.9%, 29/33), p=0.088. Crude mortality was 10.0% (73/730), with no age-group variations. Median time from ART initiation to death was two months (IQR: 0.8–5.0).
Conclusions: CALHIV in Cameroon, especially children, experienced suboptimal virologic suppression and significant mortality. Prioritizing viral load monitoring in young children and ensuring early initiation of optimized-ART regimen could significantly improve treatment outcomes and reduce mortality among children.

EP0220

Using a pediatric prescription tool for antiretroviral therapy optimization: improving treatment outcomes in children living with HIV in Tanzania

A. Temu[1], B. Benedicto[1], R. Van de Ven[1], S. Mgeleka[1], K. Selemani[1], F. Haraka[1], S.J. Kimambo[1]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Technical, Dar es Salaam, Tanzania, the United Republic of

Background: Pediatric HIV management poses unique challenges, particularly with respect to dosage accuracy and regimen selections, which are critical to achieving pediatric viral load suppression (VLS). We introduced a pediatric antiretroviral therapy (ART) prescription tool to improve ART optimization and present here lessons learnt from its implementation in Tanzania.
Description: The ART prescription tool was piloted to optimize dosages and regimen choices, aiming to improve prescribing accuracy, adherence, and treatment outcomes for children living with HIV (CLHIV). We provided capacity building for clinic workers on how to use the tool. A tailored ART prescription tool was utilized for each CLHIV at every visit. Chart review of the care and treatment cards was conducted for all CLHIV aged 0-14 years to review the accuracy of the ART (regime and dosage) and viral load monitoring. Descriptive analysis was done on aggregated routine programmatic data between April 2024 – September 2024 at 12 care and treatment clinics at Ikungi District in Singida Region.

Lessons learned: A total of 171 children aged 0-14 years old receiving care and treatment services from 12 facilities were administered the ART prescription tool. At the start of the intervention in April 2024, there were 11/171(6.4%) CLHIV with dosing and /or regimen errors, 21/171(12.3%) CLHIV with unknown HIV viral load status, and 17/171(9.9%) CLHIV with high HIV viral load results. By September 2024, the dosing and/or regimen errors had decreased to 0% errors. We observed improved treatment outcomes in this cohort of CLHIV by improved clinical markers, i.e. viral load coverage (VLC) increased from 87.7% in May 2024 to 97.6% in September 2024, and viral load suppression (VLS) improved from 90.1% to 97.9% within the same period.
Conclusions/Next steps: We observed a reduction in prescription errors and improvement of viral load suppression among children after the introduction of prescription tool. It will be important to monitor the cohort of children for a longer period. In addition, this strategy should be expanded to additional sites to see if the results are sustained.

EP0221

Comparative adherence and effectiveness of Dolutegravir vs Lopinavir in Tanzanian children with HIV: retrospective cohort study

D. Panga[1], A. Marealle[2], H. Mlyuka[2], A. Kamuhabwa[2]
[1]Muhimbili University of Health and Allied Science, Clinical Pharmacy and Pharmacology, Dar es Salaam, Tanzania, the United Republic of, [2]Muhimbili University of Health and Allied Science (MUHAS), Clinical Pharmacy and Pharmacology, Dar es Salaam, Tanzania, the United Republic of

Background: Tanzania faces a significant HIV burden, with approximately 85,000 children living with the virus as of 2012. The global 95-95-95 targets aim to achieve high rates of diagnosis, treatment, and viral load suppression by 2030. Effective pediatric medications are crucial for achieving these goals. Current management practices are shifting from lopinavir-based to dolutegravir-based regimens; however, there is limited data on the adherence and effectiveness of dolutegravir in Tanzania.
The main objective was to compare the adherence and effectiveness of a dolutegravir 10mg based regimen verses Lopinavir based regimen among HIV-infected children in Tanzania.
Methods: A retrospective cohort study was conducted from January 2021 to October 2023 across three clinics: Muhimbili National Hospital, Mbeya Zonal Referral Hospital, and Baylor College of Medicine in Bugando. The study included 340 children who had been on either dolutegravir (DTG) or lopinavir/ritonavir (LPV/r) regimens for at least 6 to 12 months. Adherence was assessed via medication refill schedules, while effectiveness was defined as viral load suppression (VL < 50 copies/ml). Data were analyzed using SPSS version 23, with categorical variables summarized using frequencies and proportions, and continuous variables summarized using the median. Inverse probability treatment weighting (IPTW) was employed to balance baseline characteristics between the two groups.
Results: Adherence was significantly better in the DTG group (95.9%) compared to the LPV/r group (85.1%) (P < 0.001). The DTG group also experienced fewer reports on adverse drug events (ADEs) (8.7%) compared to the LPV/r group (22.0%) (P < 0.001). Factors associated with better adherence included being aged ≥ 5 years, having an active caregiver, and the absence of ADEs. Viral load suppression rates were higher in the DTG group at both 6 and 12 months compared to the LPV/r group.
Conclusions: The DTG regimen demonstrates significantly better adherence and effectiveness compared to the LPV/r regimen in pediatric HIV patients. These findings support the adoption of DTG as the preferred regimen for children in Tanzania.

EP0222

Enhancing paediatric HIV treatment outcomes through Community Adolescent Treatment Supporters (CATS) model in Zimbabwe

L. Moyo[1], E.T. Mudiwa[2], B. Tapesana[1], V. Chitiyo[3], N. Willis[4], A. Mutsinze[3], T.P. Sibanda[5], A. Mushavi[6]
[1]Zvandiri, Service Delivery, Harare, Zimbabwe, [2]Zvandiri, SIE, Harare, Zimbabwe, [3]Zvandiri, Knowledhe and Evidence, Harare, Zimbabwe, [4]Zvandiri, Executive Director, Harare, Zimbabwe, [5]Zimbabwe Health Interventions, Programs, Harare, Zimbabwe, [6]Ministry of Health and Child Care, Health, Harare, Zimbabwe

Background: Viral load (VL) monitoring is the cornerstone of HIV management. The Zvandiri model responds to the specific needs of Children, Adolescents and Young People living with HIV and their families to ensure the prevention and control of HIV through peer led, Community Adolescent Treatment Supporter (CATS) intervention. The intervention was implemented since 2022 together with Ministry of Health and Child Care (MoHCC) and Zimbabwe Health Interventions (ZHI) in 36 health facilities in Manicaland and Midlands provinces of Zimbabwe. At baseline, significant gaps in VL monitoring were noted, attributed to lack of adequate caregiver support, stigma, low treatment literacy, lack of treatment monitoring and follow up, and limited access to health care services.
Description: Zvandiri, ZHI and MoHCC implemented a multifaceted intervention centred on the CATS package of services. Key components included peer facilitation of paediatric and adolescent support groups, caregiver treatment literacy and support meetings, adherence counselling during home visits, mental health screening, support and referral, and disclosure support.
Enhanced Adherence Counselling (EAC) clinics were conducted to facilitate learning and sharing for children with detectable VL. We utilised age and developmentally appropriate tools including Zvandiri interactive counselling games, animated books and videos. We descriptively analysed program data from 2022 to 2024.
Lessons learned: A total of 1,869/1869 (100%) 0-14 years, received the CATS package of services in the supported health facilities. Viral load coverage increased from 60% (726/1,212) in 2022 to **92% (1,685/1,823) in 2024.** In 2024, 734 (87% improvement from 2023) had VL samples collected

in the in hard-to-reach communities. 126/136 and 63/63 EAC clinics were held in 2023 and 2024, respectively, reaching 238 paediatrics and adolescents and 189 caregivers. The viral suppression rose from 87% (635/726) to **96% (1,613/1685).** The successes were attributed to regular adherence monitoring, caregiver support, access to support groups, and community-based peer intervention.

Conclusions/Next steps: These findings suggest that comprehensive, peer led, community-centred approaches can substantially improve VL monitoring and outcomes for children living with HIV, offering valuable insights for healthcare interventions in similar contexts.

This significant enhancement highlights the effectiveness of the community-based support model in improving HIV treatment outcomes for children and adolescents.

EP0223

Intergrated Mother Baby Course (IMBC) model in action: a comprehensive approach to HIV diagnosis and prevention in Zimbabwe Maternal Health

J. Mukondwa[1], S. Rusakaniko[1], T. Sanyatwe[2], V. Mubaiwa[2], B. Bero[1], T. Chimbidzikai[2]
[1]Zimbabwe AIDS Preventing Project ZAPP, Programs, Harare, Zimbabwe, [2]Family AIDS Caring Trust Zimbabwe (FACT), Programs, Mutare, Zimbabwe

Background: In 2020, Zimbabwe's Mother-to-Child Transmission (MTCT) rate stood at 8.7%, exceeding the World Health Organisation (WHO) target of 5%. Contributing factors include inadequate follow-up for PMTCT mothers with high viral loads, delayed final PMTCT outcome testing, and prolonged Nucleic Acid Test (NAT) result turnaround times (6–8 weeks).

To address these issues, an integrated model combining maternal health and infant care interventions is essential for improving both maternal and child health outcomes, ultimately reducing MTCT rates.

Description: Through the USAID funding, Zimbabwe AIDS Preventing Project (ZAPP) is implementing the SPACE FOR OVC program which aims to contribute and sustain PEPFAR epidemic control efforts by enhancing HIV prevention, care and treatment service provision to most at-risk sub-populations in 9 districts. This includes maternal engagement in IMBC sessions through 105 mentor mothers in 9 districts trained on IMBC facilitation. Mentor mothers are MCT champions who enrol HIV-positive pregnant and lactating women in support groups (IMBC).

In these groups, they discuss stress management, adherence, and coping strategies for raising an HIV-exposed infant, with the primary goal of ensuring the child remains HIV-negative.

Lessons learned: Between October 2023 to September 2024, 2,012 women living with HIV on ART with children under 2 years were enrolled in IMBC sessions. Among HIV-exposed infants, 715 underwent final outcome testing within the recommended timeframe (post-weaning), with 702 testing negative, achieving a 98.2% success rate within the World Health Organization (WHO) target for MTCT. Among HIV-positive infants 13 (1.8%), ART was initiated within the first month. Of note maternal participation in IMBC sessions was significantly associated with improved HIV testing rates and ART initiation. And independently associated with a lower likelihood of vertical transmission.

Conclusions/Next steps: Maternal engagement in IMBC sessions significantly improved health literacy and care retention, contributing to reduced vertical transmission rates. The IMBC model demonstrated substantial success in improving HIV outcome testing rates among HIV-exposed infants and reducing MTCT rates in the targeted districts. These findings support the scale-up of integrated care models to enhance prevention efforts and minimize vertical transmission in resource-limited settings.

EP0224

Time to undetectable viraemia among children newly initiating dolutegravir-based antiretroviral therapy: a programmatic analysis

E. Nwanja[1], U. Akpan[1], O. Onwah[1], O. Toyo[1], C. Nwangeneh[2], C. Okolo[1], O. Igboelina[3], D. Ogundehin[3], M. Katbi[3], C. Obiora-Okafo[3], A. Idemudia[3], U. Omo-Emmanuel[3], B. Adebobola[4], E. James[3], J. Pius[3], O. Oyelaran[3], O. Onyedinachi[1], A. Adegboye[1], A. Eyo[1]
[1]Excellence Community Education Welfare Scheme, Uyo, Nigeria, [2]FHI360, Abuja, Nigeria, [3]United States Agency for International Development (USAID), Office of HIV and TB, Abuja, Nigeria, [4]National AIDS, STI and Viral Hepatitis Control Program, Abuja, Nigeria

Background: Undetectable viraemia reduces the likelihood of clinical disease and transmission. WHO recommends viral load (VL) testing within six months of initiating ART. This study assessed the time to undetectable viraemia among children newly initiating ART in Southern Nigeria.

Methods: This retrospective cohort study used data from electronic medical records of children aged below 15 years who initiated ART between October 2021 and September 2023 at 88 health facilities in Akwa Ibom and Cross River States. Data extracted at ART initiation includes sex, age, regimen type (Abacavir-Lamivudine-Dolutegravir [ALD] or Tenofovir-Lamivudine-Dolutegravir [TLD]), and VL test results with dates (extracted quarterly until September 2024).

Viral load tests were routinely done every six months. VL results were categorised as undetectable (<50 copies/mL), otherwise detectable. Kaplan–Meier estimator was used to assess the time to undetectable viraemia (days between ART initiation and first undetectable VL), stratified by age (categorised into 0-4 years, 5-9years and 10-14 years) and regimen type, at a 0.05 significance level.

Results: During the study period, 1816 children initiated ART; 51.3% (932) were female, 37.3% (677) were aged 0-4 years, 28.5% (518) were aged 5-9 years and 34.2%(621) were 10-14 years. 72.5% (1316) were initiated on ALD regimen.

Overall median time to undetectable viraemia was six months (IQR: 4-9) and differed by age (0-4 years: 7 months [IQR: 5-10]; 5-9 years: 6 months [IQR: 4-6]; 10-14 years: 6 months [IQR: 4-9], log-rank p-value =0.05). Median time

was comparable by regimen type (ALD: 6 months [IQR: 4-10]; TLD: 6 months [IQR: = 4-9months], log-rank p-value =0.621).

Conclusions: While the majority of children attained undetectable viraemia within six months of ART initiation, children 5 years and older attained undetectable viraemia earlier. Attention should be given to children <5 years to attain optimal treatment outcomes.

EP0226

The practice of delayed cord clamping does not increase the risk of HIV mother-to-child-transmission: an Italian experience

F. Sabbatini[1], S. Ornaghi[2,3], E. Salmoiraghi[3,2], G. Scandella[2,3], N. Viaro[3], A. Locatelli[2,3], P. Bonfanti[4,1]

[1]Foundation IRCCS San Gerardo dei Tintori, Infectious Diseases, Monza, Italy, [2]Foundation IRCCS San Gerardo dei Tintori, Obstetrics, Monza, Italy, [3]University of Milano-Bicocca, Obstetrics, Monza, Italy, [4]University of Milano-Bicocca, Internal medicine, Monza, Italy

Background: Delayed cord clamping (DCC) refers to the practice of waiting 60 seconds after birth before clamping the umbilical cord, in order to increase the amount of blood that goes from the placenta to the newborn. DCC has become a routine practice since its proven association with several neonatal benefits, including higher red blood cell flow to vital organs with better cardiopulmonary adaptation, higher hemoglobin concentrations, additional iron stores, and reduced rates of anemia later in infancy. However, in the context of maternal HIV infection, DCC has been scarcely used due to the lack of specific recommentations by scientific societies on the topic and the fear of potentially increasing the risk of mother-to-child-transmission (MTCT).

Methods: We conducted a retrospective study at a single center in Northern Italy (Foundation IRCCS San Gerardo dei Tintori, Monza) to analyze the rate of MTCT in HIV-positive mothers in whom DCC was performed.

Results: 77 pregnancies were observed between 2008 and 2023 among 58 women living with HIV (WLWH), and for each of these the DCC practice was implemented. Regarding the mode of delivery, 45 women underwent cesarean section (33 planned pre-labor and 12 urgent in labor), whereas 32 gave birth vaginally. All mothers were on combination antiretroviral therapy (cART) and showed an undetectable HIV viral load at delivery. There were no cases of HIV MTCT among the 77 newborns.

Conclusions: Thanks to cART, pregnant WLWH can be managed according to several standard interventions followed for HIV-negative women, such as accessto vaginal birth. Some practices that have shown beneficial effects on the general population are still precluded to WLWH due to fear or lack of data on the safety of the practice with respect to HIV-MTCT. Our study provides additional evidence regarding the safety of DCC and supporting its implementation in pregnant WLWH, as long as they arrive at the time of delivery with a stably suppressed HIV viral load.

Clinical issues specific to key populations

EP0227

Central and Eastern European migrants living with HIV in two different European regions: Polish and Italian cohorts

C. Bieńkowski[1], M.D. Di Trapani[2], M. Menozzi[2], S. Antoniak[3], O. Samsonova[4], A. Cozzi-Lepri[5], J. Kowalska[1], C. Mussini[2]

[1]Medical University of Warsaw, Department of Adults' Infectious Diseases, Warsaw, Poland, [2]University Hospital of Modena, Department of Infectious Diseases and Tropical Medicine, Modena, Italy, [3]Gromashevsky Institute of Epidemiology and Infectious Diseases, Viral Hepatitis and AIDS Department, Kyiv, Ukraine, [4]Ministry of Health, Public Health Centre, Kyiv, Ukraine, [5]University College London, Centre for Clinical Research, Epidemiology, Modelling and Evaluation (CREME) Institute for Global Health, London, United Kingdom

Background: Migration in Europe has undergone notable acceleration in recent years, driven by multifaceted factors. The aim of the study was to perform a comparative analysis of the two cohorts of migrants from Eastern and Central Europe living with HIV being linked to care in Modena (Italy), and Warsaw (Poland).

Methods: It was a cross-sectional analysis of data collected from medical records of the Eastern European migrants living with HIV being linked to care in the HIV Outpatient Clinic in the Hospital for Infectious Diseases in Warsaw and in the Department of Infectious Diseases and Tropical Medicine at the University Hospital of Modena.

Results: In total, 301 migrants living with HIV were included in the analysis. The median age of the population was 38 years, mainly consisting of women (n=170, 56.5%). The most common HIV transmission mode was heterosexual (n=175, 58.1%). Most of the population was virologically suppressed when linked to care (n=174, 57.8%), with a median CD4 count of 484.5 cells/uL (IQR: 321.6–714.1 cells/uL). In 49 (16.3%) persons there was the HBV co-infection, and in 81 (26.9%) the HCV co-infection. Risk factors for HIV viral load detectability were male sex (p=0.011), being linked to care in Italy (p<0.0001), and having the HBV co-infection (p=0.002). Risk factors for undetectability were older age (0.002), longer HIV infection duration (p<0.0001), higher CD4 cell count (p<0.0001), being on antiretroviral treatment (p<0.0001). The multivariable analysis showed that being linked to care in Italy was a factor independently associated with HIV VL detectability (OR 0.2, 95% CI 0.06–0.68, p=0.01). Factors independently associated with HIV VL undetectability were higher CD4 cell count (OR 1.00, 95% CI 1.00–1.00, p<0.0001) and being on antiretroviral treatment (OR 8.85, 95% CI 1.75–44.61, p=0.008).

Conclusions: To conclude, our results remark the importance of a careful taking care of migrants in our countries, through prompt HIV screening and ARV treatment beginning, in order to ensure their health status and prevent HIV transmission. HIV testing, together with HBV/HCV screening, must be done not only at the time of arrival in another country, but also later in time.

EP0228

Active tuberculosis case finding and treatment outcomes among key populations living with HIV in Delta State, Nigeria: a retrospective study

S.C. Wilson[1], B. Ukoaka[1], C. Ifedigbo[1], I. Omogun[1], H. Udenenwu[1], L. Unazi[1], S. Okon[1], R. Agbonregbe[1], I. Awajinor[1], E. Mbaba[1], U. Usoro[2], O. Aliu[1], J. Bako[1], M. Tingir[1], I. Onyekwelu[1], G. Orji[1], A. Inyang[1], G. Jimbo[1], O. Ekele[1], A. Inedu[1], O. Onyedinachi[1], A. Eyo[1], M. Moemeke[3], A. Omoigberale[3]

[1]Excellence Community Education Welfare Scheme (ECEWS), Delta, Nigeria, [2]Family Health International - 360 (FHI360), Delta, Nigeria, [3]State AIDS and STI Control Program, Delta, Nigeria

Background: Diagnosing and managing tuberculosis (TB) among key populations (KP) living with HIV remain significant healthcare challenges. This cohort faces barriers to healthcare access due to stigma and social marginalization. Targeted testing and prompt linkage to care hold promise for improved treatment outcomes.

This study assessed TB incidence and treatment outcomes among KPs living with HIV in Delta State between July 2023 and June 2024.

Methods: A retrospective study design was used to evaluate TB program implementation among KPs. Incidence data were extracted from TB registers across 5 KP One Stop Shops (OSS). Evaluation methods included clinical assessment, laboratory tests with TB-LAM or GeneXpert, and Chest X-ray. Treatment followed national guidelines and outcome data were obtained from TB-DOT registers and analyzed using Excel.

Results: Approximately 19,690 KPs, including new and returning clients, were screened for TB, with a mean age of 36 (±8.49) years. About 143 presumptive cases were identified among new (16.49%) and returning clients (0.42%) (Figure 1).

76% and 24% were identified in the community and OSS respectively. 21 cases (15 F, 6 M), including men who have sex with men (2), female sex workers (8), and people who inject drugs (11), were diagnosed using diverse diagnostic modalities. The diagnostic yield was 14.69% for both new (80.95%) and returning (14.29%) clients, while the overall treatment success rate averaged 43%, with 6 deaths (29%), 2 lost to follow-ups (10%), and 4 (19%) on treatment.

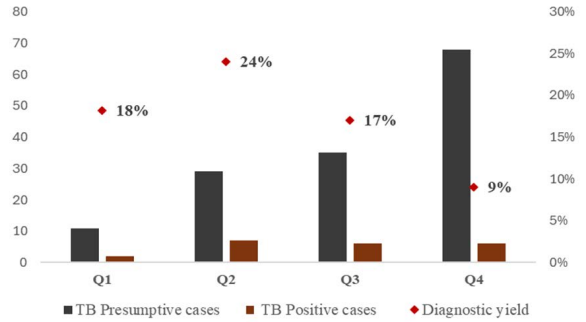

Figure 1.

Conclusions: The study shows increasing TB presumptive cases among KPs, and moderate treatment success due to frequent interruptions among mobile KPs. Strengthening community interventions and expanding access to diagnostic services are essential to improve the current national 80% average.

EP0229

Demographic and HIV characteristics of priority female population living with HIV accepting cervical cancer screening services in resource limited settings

T. Adeyanju Shola[1], P. Faison Oliver[1], T. Zakka Babah[2], C. Ukanwa[3], A. Aikhomokhor[4], J. Anenih[5], F. Agbo[5], J. Pius[6], M. Katbi[6], O. Oyedeji[7], W. Fajemisin[8], K. Erechalu[9], A. Idemudia[6]

[1]Society for Family Health, Strategic Information, Maiduguri, Nigeria, [2]Society for Family Health, Programs, Maiduguri, Nigeria, [3]National AIDS and STDs Control Programme, Prevention Program, Abuja, Nigeria, [4]National AIDS and STDs Control Programme, Advocacy, Communication & Social Mobilization, Abuja, Nigeria, [5]National Agency for the Control of AIDS, Abuja, Nigeria, [6]United States Agency for International Development, HIV AIDS and Tuberculosis, Abuja, Nigeria, [7]Society for Family Health, Programs, Abuja, Nigeria, [8]Society for Family Health, Strategic Information, Abuja, Nigeria, [9]Society for Family Health, Program Delivery, Abuja, Nigeria

Background: Cervical-cancer is a leading cause of death among Key Population Women Living with HIV (KPWLHIV). According to WHO, women diagnosed with HIV are six times more likely to develop cervical-cancer than HIV-negative-women. Despite the importance of early cervical-cancer detection through screening, service-uptake among KPWLHIV in Sub-Saharan-Africa (Nigeria) is abysmally low. To improve service-uptake, we investigated demographic and some HIV-related characteristics of KPWLHIV to ascertain their association with uptake of cervical-cancer screening services.

Methods: Society for Family Health (SFH) Nigeria, an indigenous non-governmental organization intervening for priority-populations through USAID funded KP-CARE-2 project, conducted a secondary data analysis using routine program data across eight KP-CARE-2 programming states.

Variables of interests include; Women-Who-Inject-Drugs (WIDUs), Female-Sex-Workers (FSW) and Women-In-Prisons-and-Enclosed Settings (WIPES), age, duration in HIV-care, viral-load (VL) status were extracted from Electronic-Medical-Records platform and analyzed. A logistic regression analysis was employed to evaluate the odds of cervical-cancer screening.

Results: Data was abstracted from 6,197 KPWLHIV-records screened for cervical-cancer: 1,817 (29.32%) WIDUs, 4,372 (70.55%) FSW and 8 (0.13%) WIPES. WIDUs show significantly lower odds of being screened (OR=0.79; p<0.001; 95% CI: 0.74–0.85) than FSW (OR=1.00; p=0.906) or WIPES (OR=1.40; p=0.459). From total records abstracted, 1,732 (28%), 2,869, (46.3%), 1,351 (22%) and 245 (4%) were between ages 20–29, 30–39, 40–49 and >49years. Age groups 30–39 (OR=1.17; p<0.001; 95% CI: 1.10–1.24) and 40–49 (OR=1.14; p=0.001; 95% CI: 1.05–1.23) have higher odds of screening than those

>49years (OR=0.82; p=0.005; 95% CI: 0.72–0.94). Individuals in care between 1–4years are more likely to be screened (OR=5.37; p<0.001; 95% CI: 4.51–6.40), with even higher odds for those in care for >5years (OR=14.75; p<0.001; 95% CI: 12.03–18.07).
Similarly, individuals with a suppressed-VL, 6,007 (96.93%) have much higher odds of being screened (OR=4.29; p<0.001; 95% CI: 3.69–4.98).
Conclusions: This study provided insights about cervical-cancer screening uptake among KPWLHIV. We therefore recommend cervical-cancer screening programs in similar settings to explore innovative strategies to improve uptake among WIDUs.
Similarly, innovative strategies are required to reach older women (above 49years), those <1year in care and women that are virally unsuppressed.

EP0230

Impact of a comprehensive support program on retention in care and viral load suppression among female sex workers living with HIV at WE-ACTx for hope Kigali, Rwanda

P. Ishimwe[1], M. Cohen[2], C. Benekigeri[1], C. Dusabe[1], J. Tuyishime[1], O. Uwimana[1]
[1]WE-ACTx For Hope, Clinical, Kigali, Rwanda, [2]Boston Health Care for the Homeless Program, Clinical, Boston, United States

Background: Female sex workers living with HIV (FSWLH) faces challenges such as stigma, financial insecurity, and limited health literacy, which hinder engagement in care and ART adherence. In response, the WE-ACTx for hope (WFH) Clinic in Kigali_Rwanda has developed a comprehensive intervention to address these challenges through integrated medical care, psychosocial support, health literacy education, and economic assistance to promote retention in care and achieve viral load (VL) suppression among FSWLH.
Description: From 2021 to 2024, 134 FSWLH participated in this program at the WFH clinic in Kigali_Rwanda. The interventions included free-of-charge general medical care, monthly group therapy for health education, peer support, and psychological counselling; financial support including transport stipends, health insurance for all family members, nutritional support, and child school sponsorship; and cooperative initiation to reduce financial stressors. ART adherence and VL suppression were tracked through VL monitoring and pharmacy refill data.
Retention in care was assessed through clinic appointments and group therapy attendance. Semi-structured interviews explored overall health impact, experiences, and perceptions of the program.
Lessons learned: Of the 134 participants, 130 (97.0%) achieved VL suppression (<200 copies/ml) within six months of joining, with 128 (95.5%) attained undetectable viral loads (<20 copies/ml). Sustained VL suppression over 2021–2024 was observed in 125 (93.3%) participants. Nine participants (6.7%) experienced intermittent treatment failure (>200 copies/mL), six of which attributed to intermittent incarceration.By December 2024, two participants had passed away, and one participant was completely lost to follow-up. Among the remaining 132 live participants, 131 (99.2%) were retained in care with undetectable VL, except for one individual with a recorded VL of 220 copies/mL. Appointment adherence, pharmacy refill, and group therapy attendance were 97.0%, 98.0%, and 97.3%, respectively.
Qualitative findings revealed improved health literacy, reduced stigma, financial relief, and enhanced mental health in general as contributors to better care engagement.
Conclusions/Next steps: The WFH comprehensive intervention effectively addressed key barriers to VL suppression and care retention among FSWLH.
These findings support the implementation and scale-up of holistic, targeted interventions to improve HIV outcomes in vulnerable populations in resource-limited settings.

EP0231

Partners of Transgender Women in Buenos Aires, Argentina: a key population for targeted HIV and syphilis prevention strategies

J.L. Garcia[1], C. Cesar[1], M. Ceschel[1], D. Salusso[1], C. Petriglieri[1], F. Bilbao[1], L. Maldonado[1], C. Perez[1], I. Aristegui[1], M.I. Figueroa[1], P. Cahn[1]
[1]Fundación Huésped, Research Department, Buenos Aires, Argentina

Background: Transgender women (TGW) have high HIV/syphilis prevalence, but the role of their partners (PTGW) in transmission is unclear. Characterizing sexual behavior of PTGW could clarify how they contribute to HIV/syphilis transmission among TGW and other populations.
We aimed to compare sexual behavior and HIV/syphilis prevalence of PTGW to other populations at high risk.
Methods: We analysed cross-sectional data from a voluntary HIV-testing centre in Argentina (June 2023-January 2025). PTGW refers to individuals self-reporting sex with TGW, regardless of their own gender or other partner's gender. HIV/syphilis prevalence among repeat testers was based on their first test. Group comparisons were performed with Kruskal-Wallis, chi-squared, and Fisher's exact tests, and post hoc Wilcoxon rank-sum and Fisher's exact tests with Bonferroni correction, when appropriate. Bivariate analyses were conducted in PTGW to determine associations between age, gender, receptive anal/vaginal sex, cocaine use, transactional sex, and HIV/syphilis diagnosis.
Results: Of 3110 individuals included: 211 PTGW, 1715 men who have sex with men (MSM), 1032 heterosexual cisgender men (h-cis-men) and 152 TGW. Among PTGW, median age was 30 years; 65% self-identified as cisgender men, 13% cisgender women, 8% non-binary, 8% TGW, 4% transgender men and 2% other.
Table-1 shows sexual behavior and HIV/syphilis prevalence by group. PTGW had lower HIV/syphilis prevalence compared to TGW (3%vs.10.5% for HIV, p<0.05; and 5%vs.27% for syphilis, p<0.01). However, no significant differences were observed between PTGW and MSM(p>0.05). Syphilis

prevalence was associated with transactional sex and cocaine use($p<0.05$) while no variables were associated with HIV prevalence.

Characteristics	Overall N = 3,110	PTGW N = 211	MSM N = 1,715	p-value (PTGW vs MSM)	h-cis-men N = 1,032	p-value (PTGW vs h-cis-men)	TGW N = 152	p-value (PTGW vs TGW)
Gender of sexual partners, n (%): - Cisgender woman	1,374 (44.2%)	158 (74.9%)	175 (10.2%)	< 0.01	1,032 (100.0%)	-	9 (5.9%)	< 0.01
- Cisgender man	1,962 (63.1%)	113 (53.6%)	1,715 (100.0%)	-	0 (0.0%)	-	134 (88.2%)	< 0.01
- Transgender man	121 (3.9%)	73 (34.6%)	38 (2.2%)	< 0.01	6 (0.6%)	< 0.01	4 (2.6%)	< 0.01
- Non-Binary	126 (4.1%)	70 (33.2%)	40 (2.3%)	< 0.01	10 (1.0%)	< 0.01	6 (3.9%)	< 0.01
Number of sexual partners in the last 6 months, Median (IQR)	3.0 (2.0, 6.0)	4.0 (2.0, 7.5)	4.0 (2.0, 6.0)	1	2.0 (1.0, 3.0)	< 0.01	6.0 (2.0, 15.0)	< 0.01
Sexual practices, n (%): - Anal and/or vaginal receptive sex, n (%)	2,060 (71.4%)	149 (75.6%)	1,400 (85.1%)	< 0.01	380 (41.7%)	< 0.01	131 (99.2%)	< 0.01
- Consistent condom use in anal and/or vaginal receptive sex, n (%)	855 (41.5%)	59 (39.6%)	602 (43.0%)	0.8	141 (37.1%)	< 0.01	53 (40.5%)	1
- Anal and/or vaginal insertive sex, n (%)	2,779 (93.3%)	188 (93.1%)	1,510 (90.7%)	1	962 (98.8%)	< 0.01	119 (86.9%)	0.2
- Consistent condom use in anal and/ or vaginal insertive sex, n (%)	1,045 (37.6%)	63 (33.5%)	609 (40.3%)	0.2	325 (33.8%)	< 0.05	48 (40.3%)	< 0.05
Transactional sex, n (%)	367 (12.2%)	46 (22.1%)	155 (9.3%)	< 0.01	55 (5.6%)	< 0.01	111 (76.0%)	< 0.01
Drugs use in last month, n (%)	1,448 (47.9%)	138 (66.0%)	801 (47.9%)	< 0.01	414 (41.6%)	< 0.01	95 (66.0%)	1
HIV, n (%)	143 (4.6%)	7 (3.3%)	105 (6.1%)	0.3	15 (1.5%)	0.2	16 (10.5%)	< 0.05
Syphilis, n (%)	172 (6.9%)	9 (5.2%)	116 (8.7%)	0.4	27 (3.0%)	0.5	20 (27.0%)	< 0.01

Table1. Sexual behavior and HIV/syphilis prevalence by group.

Conclusions: PTGW represents a gender-diverse population at high risk for HIV and syphilis. Their HIV prevalence is similar to other at-risk groups, such as MSM. Targeted strategies to reduce risk behaviors among PTGW are needed, warranting further research to inform interventions.

EP0232

Unveiling the hidden reality: First-ever prevalence estimates of sexually transmitted and blood-borne infections in Canadian provincial prisons

N. Kronfli[1], A. Mambro[1], F. Laprise[1], N. Popovic[1], P. Sandstrom[2], J. Kim[2], S. Kiazyk[2], P. Lecap[2], A. Coates[2], A. Harris[2], E. Huerta[1], J. Cox[1]
[1]Research Institute of the McGill University Health, Montreal, Canada, [2]National Microbiology Lab, Winnipeg, Canada

Background: Incarcerated individuals are disproportionately affected by sexually transmitted and blood-borne infections (STBBI) and are a key population to the global STBBI response.
As Canadian data on this population are lacking, we aimed to determine the prevalence of blood-borne (HIV, hepatitis B virus (HBV), and hepatitis C virus (HCV)) and bacterial sexually transmitted infections (chlamydia, gonorrhea, and syphilis) among people incarcerated in Quebec provincial prisons.
Methods: Convenience sampling of participants from seven representative provincial prisons (where individuals are sentenced for <2 years) was undertaken. Participants were offered self- or peer-collected dried blood spot (DBS) testing for HIV and HCV antibodies, syphilis enzyme immunoassay (EIA), hepatitis B surface antigen (HBsAg), and HIV and HCV viral loads.
PCR testing was conducted on urine samples collected in participants' cells for *Chlamydia trachomatis* and *Neisseria gonorrhoea.* While recruitment is ongoing (desired sample size: 1,176), preliminary results are presented.
Results: From October 7, 2024 to January 20, 2025, 379 participants were recruited from L'Établissement de Détention de Montréal (100% male; median age: 36 years; 56 (18%) ever injected drugs; median sentence: 160 days). Among these, 262 (69%) chose a peer-collected DBS method. Prevalence estimates were 0.7% (2/305) for anti-HIV antibodies (0/2 undetectable viral load), 1.0% (3/305) for HBsAg, 5.2% (16/305) for anti-HCV antibodies (1/16 detectable viral load), and 5.2% (16/305) for syphilis EIA. The median turnaround time from DBS collection to results was 22 days [range 18-28 days]. Urine prevalence estimates were 1.5% (5/343) and 0.6% (2/343) for *Chlamydia trachomatis* and *Neisseria gonorrhoea*, respectively.
The median turnaround time from urine collection to results was 10 days [range 7-12 days]. One-quarter (24.0%; 71/296) of participants were released from prison prior to test results, among whom 43.7% (31/71) could not be reached post-release.
Conclusions: Preliminary results among people in Quebec provincial prisons demonstrate high hepatitis B, C, and syphilis prevalence estimates compared to the general population, underscoring significant public health concerns and unmet needs.
While enhanced testing and treatment for STBBI both within and beyond carceral settings is imperative to curb transmission and meet Canada's elimination goals, point-of-care testing should be prioritized to improve linkage to care.

EP0233

Improving HIV care for female adolescents and young people in Rwanda's rehabilitation centers: insights from Gitagata, Nyamagabe, and Iwawa

J.B. Tugirimana[1], D. Mutambuka[2], G. Rwibasira[3], M. Ribakare[4], A. Pirotte[5], F. K. Rubuga[6]

[1]Rwanda Network of People Living with HIV /AIDS (RRP+), Community Engagement in HIV Responses, Kigali, Rwanda, [2]Rwanda Network of People Living with HIV/AIDS (RRP+), Community Engagement in HIV Responses, Kigali, Rwanda, [3]Rwanda Biomedical Center (RBC), HIV / AIDS and STIs Diseases, Kigali, Rwanda, [4]World Health Organization (WHO), HIV Responses, Kigali, Rwanda, [5]Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ), Rights Based Approach, Kigali, Rwanda, [6]Centre for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition (CIIC-HIN), Research, Kigali, Rwanda

Background: Adolescents and young people (AYP) aged 10-24 in Rwanda's rehabilitation centers (RCs) face significant challenges in accessing HIV services. This study, led by the Rwanda Network of People Living with HIV (RRP+) in collaboration with the Rwanda Biomedical Center (RBC), aimed to assess HIV prevalence and the quality of HIV services provided to AYP in Gitagata, Nyamagabe, and Iwawa RCs.

Description: From March to July 2024, the study covered 7,537 residents, including 925 females (12.2%), across three RCs. Routine health screenings were conducted, and quantitative surveys and qualitative interviews with healthcare providers and residents were used to collect data. The study mapped HIV services, identified gaps in service delivery, and explored barriers to care.

Lessons learned: The HIV prevalence among the 7,537 residents of the RCs was 5.4% (n=402), exceeding the national prevalence rate of 3%. Gitagata had the highest prevalence at 13.6% (n= 925), predominantly among females, followed by Iwawa with 257 (5.1%, n= 5,037), and Nyamagabe with 19 (1.2%, n= 1,575). Despite the high HIV burden, only one RC (33.3%) had a dedicated HIV care space, and one (33.3%) could initiate antiretroviral therapy (ART). None of the centers employed medical doctors. Healthcare providers lacked specialized HIV care training. HIV prevention services were underutilized due to stigma and confidentiality concerns. Qualitative findings revealed significant gaps in mental health support and post-discharge follow-up. Participants highlighted the need for better coordination between RCs and external health services to ensure continuity of HIV care, especially for female residents at Gitagata.

Conclusions/Next steps: Critical gaps in HIV care exist in Rwanda's RCs, particularly at Gitagata, where the high prevalence among female residents requires urgent attention. Establishing a dedicated HIV care space, offering gender-sensitive interventions, enhancing staff training, improving mental health services, post-discharge follow-up, and strengthening coordination with external health services are essential next steps. Scaling these efforts across all RCs is crucial for comprehensive HIV prevention and treatment to improve health outcomes for AYP.

EP0234

Testosterone effects on sexual health in transgender men: feasibility study of an oral intervention (TEST-F)

A. Radix[1,2], A.B. Harris[1], A.-C. Uhlemann[2], B. Esquivel[1], A. Guerra[1], M. Jace[1], J. Mandell[2], C.-S. Leu[2], H. Park[2], S.Z. Moscovitz[2], R. Shivakoti[2]

[1]Callen-Lorde Community Health Center, Medicine, New York, United States, [2]Columbia University Irving Medical Center, New York, United States

Background: Transgender men (TM) have a disproportionately high incidence of STIs compared with cisgender women (CW). Nearly half of TM use testosterone treatment (TT). Preliminary studies suggest that TT leads to a low Lactobacillus (LL) microbiota profile in TM, which may contribute to elevated HIV/STI risk.

However, longitudinal studies and interventional trials targeting vaginal health in TM on TT are lacking. TEST-F aimed to provide additional data about TT effects on vaginal microbiota and assess feasibility and acceptability of an oral Lactobacillus probiotic complex to improve vaginal health.

Methods: Healthy TM, ages 18–45 years, receiving TT for ≥6 months and no genital surgery were enrolled. We collected sociodemographic, clinical, and sexual history data. Baseline testing included HIV screens and vaginal swabs (gonorrhea, chlamydia, Nugent score, Molecular-BV based on 16S rRNA sequencing).

Participants were 1:1 randomized to a daily oral probiotic (L. acidophilus GLA-14 and L. rhamnosus HN001) or placebo (maltodextrin) for 4 weeks with repeated vaginal testing, clinical and acceptability assessments.

Results: 29 TM enrolled between 8/14/2024 and 11/21/2024, mean age 26.7 (20-37); 38% queer, 14% gay, 21% bisexual, 10% pansexual. Race/ethnicity: 62% White, 21% African-American and, 21% Hispanic/Latinx.

In the 6 months prior to enrollment, 32% reported receptive anal, 34% receptive vaginal sex and 72% reported vaginal symptoms (dryness, itching, discharge, pain).

At baseline only 8 (27.6%) had normal Nugent scores (0-3), and 25 (86%) had a LL microbiota (i.e. molecular-BV). 14/29 received active drug.

Although not powered for efficacy, we noted 15% increase in Lactobacillus relative abundance in the intervention group and increase in proportion with normal Nugent scores from 28.6% to 35.7%.

Adjusting for baseline scores, treatment group demonstrated higher odds of normal Nugent scores OR 2.19 (0.34-14.3) p=.411 after 1 month intervention.

Conclusions: TEST-F confirmed the LL microbiota in TGM receiving TT and the need for novel, effective interventions to reverse these effects. The probiotic intervention was well tolerated and study procedures acceptable to participants.

We showed a trend to improved Nugent scores, although limited by small sample size. We propose a larger clinical trial to investigate the efficacy of the Lactobacillus probiotics intervention on BV and STI outcomes.

EP0235

Clinical and epidemiological analysis of community-acquired bacterial pneumonia in people living with HIV in Argentina: impact of a history of freebase cocaine use

A. Zampetti[1], C.B. Alves[1], M.P. Alurralde[1], T. Rosella[1], A. Benchetrit[1], R. Rollet[1], J. García[1]
[1]Hospital F. J. Muñiz, Buenos Aires, Argentina, Ciudad Autónoma de Buenos Aires, Argentina

Background: Drug use, including freebase cocaine (paco), is associated with higher HIV incidence and poor antiretroviral therapy (ART) adherence. In Argentina, 0.5% of the population uses paco. Its respiratory and psycho-neurological damage leads to health risks for people living with HIV (PLHIV).
This study aimed to compare clinical and etiological characteristics of community-acquired bacterial pneumonia (CABP) in PLHIV who use paco versus non-users.
Methods: Descriptive, retrospective analysis of medical records from PLHIV with CABP during 2022 treated at a tertiary-level hospital in Buenos Aires, Argentina. CABP was defined as compatible clinical and imaging findings, bacterial isolation from respiratory and/or blood samples, and no hospitalization in the preceding 30 days.
Statistical analysis: categorical variables: absolute values and proportions; continuous variables: median and interquartile range. Comparative analysis: Mann-Whitney U test, t-test, Chi-square test, and Fisher's test. Significance level: p<0.05.
Results: Users of paco had a median CD4 of 167 cel/ml; 39.3% abandoned ART and 16% had viral load <40 cop/ml; no significant difference was observed between groups. Users of paco experienced greater socioeconomic vulnerabilities: 36.8% of homelessness and 21.4% being transgender women.
In *Table 1:* sociodemographic characteristics and habits; *Table 2:* clinical and etiological attributes.
Streptococcus pneumoniae was more frequently isolated in users of paco. *M. catarrhalis* and *S. aureus* had similar incidence in both groups. Vaccination rates were very low: 3.7% fully vaccinated for *S. pneumoniae* and 6% for influenza; no significant difference was observed between groups.

	History of paco use: no (n = 58)	History of paco use: yes (n = 28)	p value
Age median (IQR)	43 (35 - 48.75)	36 (30 - 42)	0.015
Gender			0.069
- Cisgender men n (%)	35 (60.3)	12 (42.9)	
- Cisgender women n (%)	20 (34.5)	10 (35.7)	
- Transgender women n (%)	3 (5.2)	6 (21.4)	0.053
People experiencing homelessness n (%)	3 (7.7)	7 (36.8)	0.001
Alcohol consumption n (%)	21 (36.8)	15 (57.7)	0.124
Tobacco use n (%)	37 (64.9)	23 (88.5)	0.050

Table 1.

	History of paco use: no (n = 58)	History of paco use: yes (n = 28)	p value
Bacterial isolation:			
- Streptococcus pneumoniae n (%)	14 (24.1)	16 (57.1)	0.006
- Haemophilus influezae n (%)	40 (69.0)	13 (46.4)	0.076
Management:			
- Required admission n (%)	40 (69)	20 (71.4)	0.999
- General ward n (%)	33 (56.9)	17 (60.7)	
- ICU n (%)	7 (12.1)	3 (10.7)	
- Total admission days median (IQR)	15 (10.5 - 34)	9 (3.75 - 20.5)	0.030
- Required mechanical ventilation n (%)	4 (6.9)	2 (7.1)	0.999
Deaths n (%)	3 (5.2)	3 (10.7)	0.622

Table 2.

Conclusions: This is the first study to describe CABP in PLHIV who use paco in whom socioeconomic vulnerabilities are highlighted. *S. pneumoniae* was the main etiological agent, emphasizing the urgent need for improved vaccination coverage strategies. Research efforts need to be directed towards a better understanding of key population characteristics, enabling the design of more effective public health interventions.

EP0236

Prevalence and determinants of depressive symptoms among key population on ART at Gobabis Walvis Bay Corridor Group (WBCG) clinic, in Omaheke region - Namibia. A cross-sectional prospective study

K.F. Lumbala[1], M. Taderera[2], L. Kaavara[3], J. Tshimwanga[4], N. Ruswa[5]
[1]Ministry of Health and Social Services, Omaheke Health Directorate, Gobabis, Namibia, [2]Intrahealth Namibia, Walvis Bay Corridor Clinic, Gobabis, Namibia, [3]Intrahealth Namibia, Data clerk/Monitoring and Evaluation, Gobabis, Namibia, [4]Ministry of Health and Social Services, Otjizondupa Regional Health Directorate, Otjiwarongo, Namibia, [5]Ministry of Health and Social Services, Directorate of Special Programmes, Windhoek, Namibia

Background: Globally it's estimated that 1 in every 8 people experiences a mental disorder and the risk is twice higher among PLHIV with depression and anxiety disorders commonest among them. Undetected mental health problems can have a profound effect on adherence, clinic attendance, and disease progression in PLHIV. In Namibia, data on mental health in PLHIV are scarce although the Ministry of Health introduced screening tools in the latest ART care booklet.
We aimed to estimate the prevalence and factors associated with depressive symptoms among clients attending this facility, which offers specialized care to PLHIV members of key populations (female sex workers -FSW, transgender-TG, and men who have sex with men -MSM).
Methods: We conducted a cross-sectional quantitative study at Gobabis WBCG clinic. We extracted socio-demographic and clinical characteristics in medical records including the PHQ 9 and alcohol screening scores of clients seen at the facility between December 2023 and June 2024. Only results of the first encounter with clients during

the study period were considered and depressive symptoms were considered positive in clients who scored ≥ 5 on the PHQ-9.

Collected data were analyzed using Stata software version 18. The occurrence of depressive symptoms in different demographic categories was assessed using chi-square tests, with the level of significance set at 0.05.

The multivariate logistic regression model was used to estimate the associations between variables and depressive symptoms presentation.

Results: All 98 clients from key populations seen during the study period were enrolled. 62(63.3%) females and 36(36.7%) males, 53(54%) were FSW, and 28(28,6%) MSM. In total, 15(15.3%;95CI9.3%-24%) had depressive symptoms. Among them, 8(53.3%) were females, and 7 (46.7%) males. Being married (p= 0.015), TG (P=0.031), and moderately harmful alcohol risk (p=0.033) were significantly associated with having depressive symptoms in univariable analysis. In the multivariable logistic regression model being married OR 8 (95CI;1.2-56) and TG OR 11(95CI;1.8-64) remained significantly associated to depressive symptoms.

Conclusions: Presentation with depressive symptoms is common among key populations on ART at this clinic associated with being married, TG, and having moderate-harmful alcohol risk behavior. These results underscore the need to strengthen screening and management of mental health in these special populations.

EP0237

Viral load suppression among key populations: Who is left behind? Evidence from a retrospective study in Zimbabwe

M. Munjoma[1], J. Mavudze[1], M. Pako[1], A. Chiumburu[1], T. Moga[1], B. Mutede[1], N. Taruberekera[1]

[1]Population Solutions for Health, Harare, Zimbabwe

Background: The World Health Organization reports that Zimbabwe has achieved HIV epidemic control, with at least 95% of individuals on antiretroviral therapy (ART) achieving viral suppression. However, there are evidence gaps on whether all key demographics meet viral load (VL) suppression targets. Population Solutions for Health (PSH), funded by the United States Agency for International Development (USAID) and in collaboration with the Ministry of Health and Child Care (MoHCC), conducted a retrospective study among female sex workers (FSW), men who have sex with men (MSM) and transgender persons (TG) to measure viral load suppression of the PEPFAR-funded program cohort and ascertain factors influencing this outcome.

Methods: We analyzed a cohort of key populations living with HIV enrolled in care between October 2021 and September 2024, using data from an electronic management system (BAHMNI). Data were analyzed using STATA 17, starting with calculation of VL suppression as a point estimate and plotting 95% confidence intervals.

Logistic regression modeling was employed to evaluate factors associated with VL suppression, adjusting for sex, residence, age, key population status, and duration on ART.

Results: A total of 15,157 unique individuals underwent at least one VL test during the study period, with 627 (4.1%, 95% CI: 3.8-4.5) being virally unsuppressed. Among those 15 years and under, 17.8% were unsuppressed, compared to 8.8% in the 20–24 years and only 1.2% among those 50 years and older. We found that older individuals were more likely to be suppressed, with 20–24-year-olds six times more likely to be unsuppressed than those 50 years and older (p<0.001).

Also, individuals who have been on ART for 1-2 years were 2.39 times more likely to be unsuppressed than those on ART for at least 7 years (p=0.006). VL suppression did not vary by sex, residence, or key population type.

Conclusions: Viral load suppression was significantly lower in younger age groups, who are more likely sexually active and at higher risk for HIV transmission, potentially jeopardizing epidemic control gains.

Strengthening ART adherence especially among the younger age groups and those with fewer years on treatment, and expediting ART linkage, is essential to sustain this critical milestone.

EP0238

Prevalence of STI symptoms and access to healthcare among female sex workers in Rwanda: findings from the IBBSS 2023

J.B. Tugirimana[1], C. Kayitesi[2], D. Mutambuka[1], A. Gasozi Ntwali[3], M. Ribakare[4], F. K. RUBUGA[5]

[1]Rwanda Network of People Living with HIV /AIDS (RRP+), Community Engagement in HIV Responses, Kigali, Rwanda, [2]Rwanda Biomedical Center (RBC), HIV/AIDS and STIs Diseases, Kigali, Rwanda, [3]UNAIDS, HIV Responses, Kigali, Rwanda, [4]World Health Organization (WHO), HIV Responses, Kigali, Rwanda, [5]Centre for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition (CIIC-HIN), Research, Kigali, Rwanda

Background: Female sex workers (FSWs) in Rwanda face a significant burden of sexually transmitted infections (STIs), which increases their vulnerability to adverse health outcomes. This study, part of the Integrated Bio-Behavioral Surveillance Survey (IBBSS) 2023, aimed to assess the prevalence of STI symptoms and healthcare-seeking behaviors among FSWs in Rwanda.

Methods: The IBBSS 2023 was a cross-sectional study involving 2,541 FSWs aged 15 years and above. Data on STI symptoms within the past 12 months and associated healthcare-seeking behaviors were collected through structured interviews. Prevalence estimates were calculated with 95% confidence intervals (CIs), and the data were disaggregated by symptom type and healthcare access.

Results: Overall, 60.4% (95% CI: 56.8–63.8) of FSWs reported experiencing STI symptoms in the 12 months preceding the survey. Among them, 32.3% reported having an ulcer or sore and 40.3% experienced abnormal vaginal discharge.

Among those who reported ulcers or sores, only 69.9% (95% CI: 64.0–75.3) sought healthcare services, highlighting barriers to healthcare access.

Additionally, 12.1% (95% CI: 10.0–14.6) reported noticing ulcers or sores on their partners during the same period. Despite the high prevalence of STI symptoms, significant gaps remain in healthcare utilization. Approximately 30.1% (95% CI: 24.7–36.0) of FSWs who experienced ulcers or sores did not seek care, underscoring the urgent need for targeted interventions.

Conclusions: The high prevalence of STI symptoms and suboptimal healthcare-seeking behaviors among FSWs in Rwanda indicate critical gaps in STI prevention, access to and condom use and other care services.

Interventions should focus on improving access to affordable, stigma-free healthcare, increasing awareness of STI symptoms and addressing barriers to healthcare-seeking behaviors.

These efforts are essential to mitigate the STI burden and enhance overall health outcomes for FSWs in Rwanda. Further research should explore the underlying reasons for limited healthcare access and develop evidence-based strategies to improve STI management among this vulnerable population.

EP0239

Evaluating social support, psychological distress, and HIV-related stigma in a cohort of ART-experienced migrant adults living with HIV switched to B/F/TAF in Montreal, Canada – the ASAP-Switch Study

A. Godin[1], M.A. Chalati[2], D. Lessard[2], S. Yaphe[3], K. Engler[2], D. Chu[1,2,4], M. Laymouna[1,2,4], J. Ishak[2], J.-P. Routy[3], A. De Pokomandy[3,4], S. Landry[3], S. Vicente[5], R.-P. Lorgeoux[6], B. Lebouché[2,3,4]

[1]McGill University, Faculty of Medicine and Health Sciences, Montreal, Canada, [2]Research Institute of the McGill University Health Centre, Centre for Outcomes Research and Evaluation, Montreal, Canada, [3]McGill University Health Centre, Chronic Viral Illness Service, Division of Infectious Disease, Department of Medicine, Montreal, Canada, [4]McGill University, Department of Family Medicine, Faculty of Medicine and Health Sciences, Montreal, Canada, [5]École de technologie supérieure, Université du Québec, Département des enseignements généraux, Montreal, Canada, [6]Gilead Sciences Canada, Inc., Mississauga, Canada

Background: In Canada, many migrant people living with HIV (MLWH) are referred for HIV care with limited known clinical history and antiretroviral treatments (ART) that are either unavailable or incompatible with local guidelines. MLWH often face important psychosocial challenges that interfere with their care. We evaluated the degree of social support, psychosocial distress, and HIV-related stigma among MLWH enrolled in a cohort testing the feasibility of free-of-charge ART switch.

Methods: In May 2024, we initiated a 52-week prospective cohort at a hospital-based clinic in Montreal (Canada) – Antiretroviral Speed Access Program Switch Study (ASAP-Switch). ART-experienced MLWH recently arrived in Quebec (<2 years) were switched free-of-charge to Bictegravir/Emtricitabine/Tenofovir-Alafenamide (B/F/TAF). The rapidity of the switch was measured as the time to B/F/TAF initiation from first clinic visit. We measured social support with the 8-item Medical Outcomes Study Social Support Survey (MOS-SSS), with higher scores on an averaged 0–100 scale indicating better support. The 6-item Kessler Psychosocial Distress Scale (K6) was used to assess absence (0-18) or presence (9-30) of serious mental illness. HIV-related stigma was measured using the 6-point AIDS-Related Stigma Scale, with higher scores indicating greater internalized stigma. We computed descriptive statistics of socio-demographic and psycho-social variables collected at baseline.

Results: As of December 2024, 20/50(40%) participants have been recruited, prescribed B/F/TAF in a median (m) of 6 days from first clinic visit (Interquartile range [IQR]=0-19), and completed at least 4/72 weeks of follow-up.

Among these, 17/20(85%) are active participants (3 withdrawals); 9/17(53%) are female; 13/17 (76%) are aged <50 years; and 10/17 (59%) are heterosexual. At baseline, concerning social support, mean score on the MOS-SSS was 31 (Standard Deviation=14.2).

Most participants did not meet criteria for serious mental illness on the K6 scale (m=10; IQR=6-14) and HIV-related stigma median score was 2/6 (IQR=1-3).

Conclusions: Psychological distress and stigma were low in 17 MWH rapidly switched to B/F/TAF, despite limited reported social support. Monitoring these mental health indicators along the HIV care cascade and offering tailored mental health interventions could improve their care.

EP0240

Strengthening the continuum of care for key populations: insights from female sex workers (FSWs)

D. Ndagijimana[1], L. Ngabonzima[1], N. Kabanyana[1], J.P. Ayingoma[1], G. Rwibasira[2], C. Ndinda[2]

[1]Rwanda NGOs Forum on HIV/AIDS and Health Promotion, Kigali, Rwanda, [2]Rwanda Biomedical Center, Kigali, Rwanda

Background: Female Sex Workers (FSWs) face barriers to accessing healthcare, which exacerbates their vulnerability to HIV and other sexually transmitted infections (STIs). Despite targeted services, gaps remain in healthcare engagement, linkage to care, and treatment adherence.

This study investigates factors associated with healthcare engagement and its impact on viral suppression among FSWs in Rwanda, leveraging respondent-driven sampling (RDS) to ensure representative findings.

Methods: A cross-sectional study was conducted in 2023 among 2,541 FSWs recruited through respondent-driven sampling in 10 urban districts of Rwanda. Data were collected through structured interviews and validated with clinical records. Variables included peer support, access to health facilities, economic empowerment programs, and stigma experiences. Weighted multivariable logistic regression and structural equation modeling (SEM) were employed to explore associations and pathways between predictors, healthcare engagement, and viral suppression.

Results: Among participants, 80.1% (95% CI: 77.0-82.8) engaged to use healthcare services, while 19.9% experienced interruptions. Peer support (adjusted odds ratio [aOR]: 3.45, 95% CI: 2.12-5.62, p < 0.001) and access to health facilities (aOR: 2.98, 95% CI: 1.88-4.72, p < 0.001) were the strongest predictors of healthcare engagement. Economic empowerment also contributed positively (aOR: 1.92, 95% CI: 1.12-3.28, p = 0.016).
Consistent engagement significantly improved viral suppression rates (84.6% vs. 43.2%, p < 0.001). SEM analysis demonstrated that stigma indirectly influenced viral suppression through reduced engagement in care (β = -0.39, p < 0.001).
Conclusions: Strengthening the continuum of care for FSWs requires scaling up peer-led interventions, enhancing access to community-based services, and integrating economic empowerment initiatives. Addressing stigma through targeted programs is critical to improving healthcare engagement and viral suppression rates. These findings underscore the need for scalable, context-specific interventions to close gaps in care for FSWs in resource-limited settings.

Epidemiology of HIV

EP0241

Establishment of non-invasive diagnostic prediction model for HIV positive asymptomatic neurosyphilis patients

H. Guan[1], X. Di[2], C. Zou[1], J. Peng[2], Z. Xia[2], Q. Wang[2], R. Cai[2], C. Chen[2], H. Wei[1,2]
[1]Department of Infectious Diseases, The School of Public Health of Nanjing Medical University, The Second Hospitalof Nanjing, Nanjing, China, [2]Department of Infectious Diseases, The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, Nanjing, China

Background: Due to the invasive nature of lumbar puncture, this makes it challenging to perform comprehensive neurosyphilis (NS) screening in HIV-infected patients with a positive serum syphilis test, especially in asymptomatic patients, and it is critical to construct an effective NS diagnostic prediction model to improve diagnostic accuracy and reduce missed diagnoses. To develop a non-invasive method for diagnosing asymptomatic neurosyphilis in HIV-infected patients to reduce unnecessary trauma in patients.
Methods: This study included persons with HIV admitted at the Second Hospital of Nanjing from January 2013 to September 2024, who had a positive syphilis serology and underwent a lumbar puncture (LP) for NS screening. Missing data were replaced using a multiple imputation. The data was randomly divided into training and testing groups at a 7:3 ratio. Logistic regression and LASSO regression analysis were used to determine independent risk factors.
Validation methods for training and testing models included ROC, approximately equal index, sensitivity, specificity, calibration curve, Decision curve analysis(DCA), and Clinical impact curves(CIC).
Results: From 718 participants initially identified for the study, we excluded 158 who reported symptoms attributable to NS and 16 who had other central nervous system conditions. The final sample included 544 participants. Multivariable logistic regression analyses showed that sero-TRUST, CD4+T lymphocyte percentage, and Magnetic resonance imaging shows lacunar infarction (MRI-lacunar infarction) increased the risk of NS, while the CD4/CD8 ratio decreased the risk of NS.LASSO regression analysis included age, VL, CD4/CD8, CD4 percentage, and MRI-lacunar infarction into the diagnostic prediction model. Area under the ROC values showed moderate discrimination for both the test model (AUC:0.752) and the training model (AUC:0.795). The calibration curve and Hosmer-Lemeshow test indicate that both models were well-calibrated. The results of decision curve analysis and clinical impact curve showed that the application of this model could achieve clinical benefits, and it was found that the model was stable in different subgroups (syphilis treatment, ART) in different subgroups
Conclusions: NS is highly influenced by age,SERO-TRUST, VL,CD4/CD8, CD4+T lymphocyte percentage, and MRI-lacunar infarction. Our model can support clinicians in identifying ANS among persons with HIV even when a LP is not available.

EP0242

Evaluation of characteristics and clinical outcomes in advanced HIV disease patients: insights from the USAID *Fahari ya Jamii* Project – a retrospective study

P. Maiya[1], G. Ruttoh[1], S. Mwangi[1], E. Kubo[1], R. Marima[1], J. Mecha[1], F. Otieno[1], D. Achwoka[2], T. Simiyu[2], I. Yonga[2]
[1]University of Nairobi, Department of Medicine and Therapeutics, Kenyatta National Hospital, Nairobi, Kenya, [2]United States Agency for International Development, HIV Programming, Nairobi, Kenya

Background: About 20-35% of people living with HIV (PLHIV) present with advanced HIV disease (AHD) in Sub-Saharan Africa. PLHIV with AHD have worse outcomes than those presenting well due to severe opportunistic diseases and other comorbidities. The common causes of mortality include Tuberculosis, Cryptococcal meningitis, severe bacterial infections, and end-organ damage.
Many determinants of health comprising age, sex, socio-economic status, access to health, and health-seeking behaviors, influence the promptness of HIV diagnosis. *Fahari ya Jamii* (FYJ) project sought to evaluate the characteristics and clinical outcomes of clients presenting with AHD.
Methods: We conducted a retrospective cohort study in Nairobi and Kajiado County health facilities supported by USAID FYJ project among PLHIV older than 15 years and newly started on anti-retroviral therapy (ART) between

October 2022 and September 2024. Identified clients were categorized as having AHD if they had CD4+ count less than 200 cells/ml or World Health Organization (WHO) clinical stage 3 or 4. Data was extracted from electronic medical records (EMR) using a table created in Microsoft Excel. The clinical outcomes of interest included linkage to ART, treatment adherence, viral load testing, and viral load suppression We compared socio-demographic and clinical characteristics of the two categories of patients using multivariate regression and survival analysis.

Results: A total of 9654 PLHIV records were extracted from the EMR and the prevalence of AHD was 21%. Clients with AHD were more likely to be older than 35 years, have lower than high school education, be males, and reside in rural zones. Those with AHD had more than double the odds for developing chronic kidney disease and mental illness (OR=2.52, p<0.001). AHD clients took longer to initiate ART (χ^2=72.241, p=0.001) and had lower viral load suppression (p<0.001). No significant difference was noted in occupation, time to viral load testing, adherence level, and ART regimen type.

Conclusions: Both socio-demographic and clinical characteristics are associated with AHD. People with AHD are at a higher risk for poorer outcomes due to comorbidities and delayed linkage to ART. All AHD clients should receive the WHO-recommended package of care to ensure rapid initiation of ART and intensified monitoring for complications.

EP0243

Incidence of renal insufficiency and chronic kidney disease in people living with HIV: findings from South Africa's National Health Laboratory Services Multi-morbidity Cohort

E.M. Kileel[1,2], S. Khoza[3], N. Crowther[3], J. Bor[4,1,2], M.P. Fox[4,1,2], S. Rosen[4,1], P. Hibberd[1], F. Raal[5], K. Mlisana[6], J. George[6,7,3], A. Brennan[4,1,2]

[1]Boston University School of Public Health, Department of Global Health, Boston, United States, [2]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [3]University of the Witwatersrand, Department of Chemical Pathology, National Health Laboratory Service, Faculty of Health Sciences, Johannesburg, South Africa, [4]Health Economics and Epidemiology Research Office, Faculty of Health Sciences, University of the Witwatersrand, Parktown, South Africa, [5]University of the Witwatersrand, Division of Endocrinology and Metabolism, Department of Internal Medicine, Faculty of Health Sciences, Johannesburg, South Africa, [6]National Health Laboratory Service, Johannesburg, South Africa, [7]University of the Witwatersrand, Wits Diagnostic Innovation Hub, Johannesburg, South Africa

Background: Kidney disease is a global health challenge with high morbidity and mortality. People living with HIV (PLWH) are at increased risk of renal insufficiency (RI) and chronic kidney disease (CKD) due to HIV viral effects, inflammation, immune dysfunction, and antiretroviral therapy (ART) toxicity. Data on RI and CKD incidence are scarce, especially in low- and middle-income countries.

Methods: Using South Africa's National Health Laboratory Services (NHLS) Multi-morbidity Cohort (2012-2016), we examined incident RI and CKD rates in PLWH (18–85 years) with normal baseline creatinine (eGFR >60 mL/min/1.73m²). RI was defined as one eGFR <60, and CKD as two eGFRs <60, 3–12 months apart. Follow-up spanned 1–6 years, ending at CKD, RI, or the last NHLS lab result of any type. Crude incidence rates (per 1000 PYs) were calculated overall and by HIV severity (VL >1000 copies/mL; CD4 <350 cells/mm³). Cox regression models were used to estimate RI and CKD risk adjusted for age, sex, TB, diabetes, and province.

Results: Among 1,370,095 PLWH, 158,879 (11.6%) experienced RI and 3,479 (0.3%) developed incident CKD (Table). Over a median follow-up time of 1.8 years (Q1, Q3: 0.003, 3.8), the crude rate of RI was 57 per 1000 PYs (95% CI: 56.9, 57.5) and the crude rate of CKD was 1.2 per 1000 PYs (95% CI: 1.21, 1.30). HIV severity did not affect RI risk, but incident CKD risk was 7% higher in PLWH with CD4 ≤350 cells/mm³ (vs. >350) and 53% higher in those with VL ≥1000 copies/mL (vs. <1000).

Table. Risk of incident renal insufficiency (RI) and chronic kidney disease (CKD) among people living with HIV in South Africa, overall and by HIV severity.

	Total N	N (%) events	Total person-time (years)	Incidence rate per 1000 PY (95% CI)	Crude HR (95% CI)	Adjusted HR[3] (95% CI)
Outcome: RI event[1]						
Overall	1,370,095	158,876 (11.6)	2,776,046	57 (56.9, 57.5)	-	-
HIV severity						
CD4 > 350 cells/mm³	922,406	106,759 (11.6)	1,869,686	57 (56.8, 57.4)	ref.	ref.
CD4 < 350 cells/mm³	447,689	52,118 (11.6)	906,360	57 (57.0, 58.0)	1.01 (1.00, 1.03)	1.02 (1.00, 1.03)
Viral load < 1000 copies/mL	124,474	14,282 (11.5)	253,443	56 (55.4, 57.3)	ref.	ref.
Viral load ≥ 1000 copies/mL	1,245,594	144,594 (11.6)	2,522,603	57 (57.0, 5.7.6)	1.01 (1.00, 1.02)	1.00 (0.99, 1.01)
Outcome: Incident CKD[2]						
Overall	1,370,095	3,479 (0.3)	2,776,046	1.2 (1.21, 1.30)	-	-
HIV severity						
CD4 > 350 cells/mm³	922,406	2,281 (0.3)	1,869,686	1.2 (1.17, 1.23)	ref.	ref.
CD4 < 350 cells/mm³	447,689	1,198 (0.3)	906,360	1.3 (1.25, 1.40)	1.08 (1.01, 1.16)	1.07 (1.00, 1.16)
Viral load < 1000 copies/mL	124,474	214 (0.2)	253,443	0.8 (0.74, 0.96)	ref.	ref.
Viral load ≥ 1000 copies/mL	1,245,594	3,265 (0.3)	2,522,603	1.3 (1.25, 1.34)	1.53 (1.34, 1.76)	1.53 (1.34, 1.76)

[1]Incident Renal Insufficiency (RI) defined as a singular eGFR < 60 mL/min/1.73m².
[2]Incident CKD defined as two eGFRs < 60 mL/min/1.73m² taken 3-12 months apart.
[3]Adjusted for sex, age at first CKD, diabetes mellitus status, tuberculosis status, and province.

Conclusions: In our South African NHLS cohort >10% of PLWH with normal kidney function at baseline developed RI over follow-up. CKD risk was higher in those with low CD4 counts or high VLs. Routine monitoring, early detection, and effective ART are crucial to managing CKD and improving outcomes, especially in immunosuppressed individuals.

EP0244

Prevalence and determinants of viral suppression in Young People Living with HIV on antiretroviral therapy in Southern Africa: a cross-sectional analysis of HIV survey data of 2020 and 2021

T. Msosa[1,2], A. Kabaghe[3], H. Twabi[1], S. Mpinganjira[4], W. Mzumara[5], M. Sumari-de Boer[6], R. Aarnoutse[7], T. Rinke de Wit[8], G. Chipungu[1,6], K. Ngowi[6], N. Kalata[3], M. Mukoka[1], C. Msefula[1], I. Swai[6,2], B. Zimba[9], R. Semphere[1], G. Makhumba[1], M. Nliwasa[1]

[1]Kamuzu University of Health Sciences, Pathology, Blantyre, Malawi, [2]Amsterdam University Medical Centers, Department of Global Health, Amsterdam, Netherlands, the, [3]US Centers for Disease Control and Prevention, Division of Global HIV and TB, Lilongwe, Malawi, [4]University of Washington, Department of Global Health, Seattle, United States, [5]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [6]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, the United Republic of, [7]Radboud University Medical Center, Nijmegen, Netherlands, the, [8]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, the, [9]The World Health Organisation, Malawi Country Office, Lilongwe, Malawi

Background: Young People Living with HIV (YPLHIV, 15 – 24 years) are an important demographic of Persons Living with HIV (PLHIV) globally and in Southern Africa. However, YPLHIV experience poor outcomes across the HIV diagnostic and treatment cascade due to multiple factors. Therefore, we estimated the prevalence and determinants of HIV viral suppression in YPLHIV on antiretroviral therapy (ART) in selected Southern African countries.

Methods: We used publicly available data from Malawi, Zimbabwe, Mozambique, Lesotho, and Eswatini collected during the Population-based HIV Impact Assessments (PHIAs) of 2020 to 2021.

Weighted proportions, and 95% confidence intervals (CI) were computed to estimate the prevalence of viral suppression (<1000c/ml) and bivariate and multivariate logistic regression analyses were conducted to identify determinants of viral suppression.

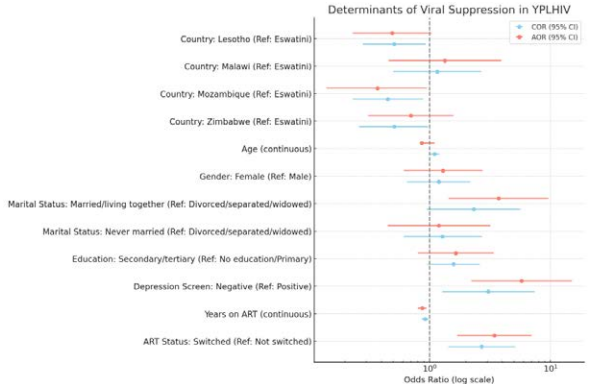
Variables that had a p-value of <0.2 in the bivariate analyses were specified in the multivariate logistic regression model.

Significant determinants were based on post-adjustment confidence intervals in the regression model.

Results: A total of 855 records of YPLHIV on ART were included in the analysis. The prevalence of viral suppression in YPLHIV on ART was 82.4% (95% CI: 76.7, 86.9).

Residing in Mozambique and duration on ART were inversely associated with viral suppression; adjusted odds ratios (AORs) of 0.37 (95% CI: 0.14, 0.95), and 0.87 (95% CI: 0.80, 0.94), respectively.

A negative result in the depression screen, being married/cohabitating, and ever switching an ART regimen were positively associated with viral suppression: AORs of 5.78 (95% CI: 2.21, 15.11), 3.72 (95% CI: 1.44, 9.63), and 3.44 (95% CI: 1.69, 7), respectively.



Conclusions: Our analysis showed that YPLHIV had sub-optimal viral suppression prevalence. Therefore, evidence informed interventions such as expanding mental health care access and screening programs in low-resource settings for YLPHIV on ART could be implemented to potentially improve viral suppression in this demographic.

EP0245

Characterizations of mobile populations and their HIV outcomes in Rakai, Uganda, 2021-23

A. Khalifa[1], R. Ssekubugu[2], J. Mpagazi[2], L.W. Chang[2,3,4], D.T. Duncan[1], M. Lamb[1,5], H. Nakawooya[2], A. Ndyanabo[2], G. Kigozi[2], S.J. Reynolds[4,6], G. Kigozi[2], G. Nakigozi[2], Q. Abdool Karim[1,7], B. Mathema[1], M.K. Grabowski[2,3,8], F. Nalugoda[2]

[1]Columbia University, Department of Epidemiology, New York, United States, [2]Rakai Health Sciences Program, Kalisizo, Uganda, [3]Johns Hopkins University, Department of Epidemiology, Baltimore, United States, [4]Johns Hopkins University, Department of Medicine, Baltimore, United States, [5]ICAP at Columbia University, New York, United States, [6]National Institute of Allergy and Infectious Disease, Division of Intramural Research, Bethesda, United States, [7]University of KwaZulu-Natal, Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [8]Johns Hopkins University, Department of Pathology, Baltimore, United States

Background: Mobility can come in many forms that may differentially affect access to health services and HIV transmission. We characterized mobility patterns and HIV outcomes in Uganda to identify gaps and opportunities in HIV programs.

Methods: This cross-sectional study utilized population-based Rakai Community Cohort Study data (2021-2023). Latent class analyses identified migrant (changed residence in the past 1-2 years) and traveler (spent >1 night away from home in the past year) subclasses based on social, spatial, and temporal mobility metrics. Age-adjusted prevalence ratios compared HIV-related outcomes (prevalence, viremia >200 copies/mL, HIV testing in the past year, status awareness, ART/PrEP use, and circumcision) between mobile and non-mobile groups by gender. Estimates were corrected for selection bias using inverse probability weights informed by enhanced tracing of survey-eligible mobile participants away during the survey.

Results: Of 27,294 eligible participants, 15,464 (57%) completed interviews and HIV testing. Of 10,732 away during interviews, 1,664 (16%) were successfully traced and informed weighted analyses. Among initial participants, migrants included 753 (4%) who moved between households in their local community, 2,353 (15%) who moved within the broader Rakai region, 1,057 (7%) who in-migrated to the region, 847 (5%) who returned to their household after living elsewhere, and 308 men (2%) who moved between households for polygamy.
Travelers included those who were away <1 week (n=2,029, 13%), 1-4 weeks (1,468. 9%), >1 month for social reasons (1,984, 13%), >1 month for opportunity (work or school) (1,224, 8%), and in Kampala for opportunity (568, 4%). With 30.3% (95% CI: 25.1-35.5%) HIV prevalence, women moving within their community had double the prevalence of non-migrant women (PR: 2.03 [1.63-2.52]); this was not true for men. Women and men in-migrating from outside the region had 4.20 (2.65-6.64) and 2.06 (1.19-3.59) times higher viremia prevalence than non-migrants, respectively. Women traveling for opportunity had 26% (15-35%) lower HIV testing coverage than non-travelers, while most classes of male travelers had higher coverage than non-travelers.
Conclusions: Mobile populations had heterogenous HIV burdens that varied by gender. Populations with high HIV prevalence and viremia should be prioritized to reduce transmission. Tailored strategies for mobile populations may be needed to close service gaps.

EP0246

Sex differences in cardiovascular disease and associated factors in people with HIV among underrepresented population

H. Zhang[1], X. Yang[1], H. Xia[2], F. Shi[1], Q. Li[3], S. Weissman[4], X. Li[1], B. Olatosi[1]
[1]University of South Carolina, Health Promotion, Education and Behavior, Columbia, United States, [2]University of South Carolina, South Carolina SmartState Center for Healthcare Quality, Columbia, United States, [3]Oklahoma State University, Stillwater, United States, [4]University of South Carolina, Department of Internal Medicine, Columbia, United States

Background: People with HIV (PWH) face a higher risk of cardiovascular disease (CVD). Sex differences in CVD risk are especially important given its historical disparities in cardiovascular care. However, sex-specific mechanisms of HIV-associated CVD are incompletely understood.
Using a nationwide database, our study aimed to compare the sex differences in CVD events among PWH and investigate the factors driving such differences in CVD events.
Methods: We utilized data from All of Us program,which includes a diverse group of historically underrepresented US populations in biomedical research. We used computational phenotyping to identify the HIV cohort. CVD was defined as a composite of coronary artery disease or stroke, which was identified by the presence of corresponding ICD-9 and ICD-10 codes or affirmative responses in survey questions. Logistic regression models were used to investigate associated factors and biomarkers on sex differences in CVD events.
Results: A total of 4,374 PWH were included, with females having a higher CVD prevalence than males (25.8%, 340/1,318 vs 21.9%, 670/3,056). Regression results showed among female PWH higher CD4 counts (≥500 cells/mm^3: OR=0.26, 95% CI: 0.14-0.48; 350-500 cells/mm^3: OR=0.30, 95% CI: 0.13-0.64) were associated with a lower CVD risk, while Black or African American race (OR=1.68, 95% CI: 1.04-2.79) was associated with a higher CVD prevalence.
No such associations were found in male PWH. Hypertension, hyperlipidemia, and not being employed for wages were associated with a higher CVD risk in both sexes.
For male PWH, obesity (OR=0.66, 95% CI: 0.49-0.88) and no insurance (OR=0.29, 95% CI: 0.13-0.56) were associated with lower CVD risk, while age groups 45-54, 55-64, and $25k-$50k annual income were correlated with a higher CVD risk. In terms of biomarkers, low High-Density Lipoprotein Cholesterol (HDL-C) levels were associated with higher CVD risk in males (OR=1.67, 95% CI: 1.25-2.23) but not in females.
Conclusions: There are common risk factors (e.g., hypertension, hyperlipidemia) for CVD development in both sexes. However, HIV-specific factors seem to play an important role for female PWH, while unfavorable inflammatory biomarker (HDL-C) was more likely to exist in male PWH. It is essential to implement targeted strategies to reduce CVD risk among PWH of different sexes.

EP0247

Impact of antiretroviral therapy on liver fibrosis and survival among people with HIV in an ethnic minority prefecture, Southwestern China: a 20-year retrospective cohort study

X. Li[1,2], R. Ye[3], Y. Yang[3], S. Yao[3], S. Duan[3], N. He[1,2]
[1]School of Public Health, and The Key Laboratory of Public Health Safety of Ministry of Education, Fudan University, Shanghai, China, [2]Shanghai Institute of Infectious Diseases and Biosecurity, Fudan University, Shanghai, China, [3]Dehong Prefecture Center for Disease Control and Prevention, Yunnan Province, China

Background: Liver complications have emerged as significant burden and causes of death for people with HIV (PWH) in the era of antiretroviral therapy (ART). Little is known regarding the role of ART in liver fibrosis among PWH prone to liver injury in underdeveloped regions.
Methods: We conducted a retrospective cohort study of PWH receiving ART in Dehong Prefecture of Yunnan Province, Southwestern China, where comprehensive AIDS care programs including free ART have been implemented since 2004. All PWH on ART with available serostatus of HBsAg and anti-HCV antibody during 2004-2024 were subject to analysis. Demographic data and laboratory measurements were extracted from the electronic medical database. Liver fibrosis (LF) was determined by FIB-4 score (age [years]×AST [IU/L]/(PLT count [10^9/L]×ALT$^{1/2}$[IU/L])) with three categories: Class 1 (normal), <1.45; Class 2 (medium), 1.45-3.25; Class 3 (heavy), >3.25.

Results: Of 6774 participants, 40.7% aged over 50 years, 61.8% were male, 61.2% were ethnic minorities, 60.8% were illiterate or educated at primary school and 24.9% acquired HIV through injecting drugs. The proportion of living with mono-HIV, HIV/HBV, HIV/HCV and HIV/HBV/HCV was 69.9%, 5.5%, 22.6%, and 2.0%, and the proportion of LF at normal, medium and heavy status was 60.2%, 27.4% and 12.4%, respectively. The median follow-up period was 8.73 years (IQR: 3.68-11.72).

Improvement to a lower LF class was observed in Class 2 (55.4%) and Class 3 (85.5%), respectively. Progression to a higher LF class was observed in Class 1 (47.9%) and Class 2 (11.0%), respectively. 1343 deaths occurred and the all-cause mortality was 2.2 per 100 PY.

Multiple Cox regression analysis showed that participants who were older, male, ethnic minors, lower educated, HIV/HCV co-infected, drug users, with low CD4 levels and LF had higher risks of death.

Conclusions: More improvement than progression of liver fibrosis was gained in PWH following ART. The effect of ART on liver fibrosis improvement in individuals living with HIV/HCV fell short compared to that in other co-infection status. It is warranted to provide direct-acting antiviral (DAA) therapy for PWH with HCV coinfection, especially for ethnic minority men with a low educational level in underdeveloped regions.

EP0248

Trends in HIV-1 incidence among adolescent girls and young women (AGYW): a longitudinal population-based cohort in Mid-Western and Central Uganda

A. Daama[1], A. P. Miller[2], S. Mugamba[1], E. Kyasanku[1], F. Nalugoda[3], J. Nkale Menya[4], G. Nakigozi[4], G. Kigozi Nalwoga[5], J. Kagaayi[6], N. Kiwanuka[6], R. Bulamba[1], S. Watya[4], J. Madihah Nakakande[7], B. Magada[7], D. Denis Mpanga[7], A.M. Ekström[8,9], W. Byansi[10], D. Kiwanuka[4], V. Nkwanzi[11], Y. Tozan[12], G. Alvarez[12], G. Kigozi[4]

[1]Africa Medical & Behavioral Sciences Organization, Epidemiology & Behavioral Studies, Kampala, Uganda, [2]San Diego State University, Department of Epidemiology and Biostatistics, Califonia, United States, [3]Africa Medical & Behavioral Sciences Organization, Grants, Science and Training, Kampala, Uganda, [4]Africa Medical & Behavioral Sciences Organization, Research Programs, Kampala, Uganda, [5]Africa Medical & Behavioral Sciences Organization, Quality Control and Compliance, Kampala, Uganda, [6]Makerere University School of Public Health, Department of Epidemiology and Biostatistics, Kampala, Uganda, [7]Africa Medical & Behavioral Sciences Organization, Clinical Trials, Kampala, Uganda, [8]Karolinska Institutet, Global Public Health, Stockholm, Sweden, [9]Karolinska Institutet, Department of infectious Diseases/Venhälsan, Södersjukhuset, Stockholm, Sweden, [10]Boston College, Social Work, Boston, United States, [11]East Tennessee State University, Social Work, Virginia, United States, [12]New York University, School of Global Public Health, Global Public Health, New York, United States

Background: Adolescent girls and young women (AGYW) account for the majority of new HIV infections in sub-Saharan Africa. HIV prevention interventions such as Determined Resilient AIDS-free Mentored Safe woman/girl (DREAMS) and Pre-Exposure Prophylaxis (PrEP) services have been implemented to reduce HIV risk in this population.

However, there are a few direct estimates of HIV-1 incidence among AGYW from high-burden countries in the region exist. We estimated the incidence of HIV-1 infections among AGYW.

Methods: We conducted a longitudinal population-based study, the Africa Medical and Behavioral Sciences Organization (AMBSO) Population Health Surveillance (APHS), Hoima and Wakiso districts of Uganda. Data on AGYW aged 15-24 years collected from four successive survey rounds were analyzed to determine trends in the incidence of HIV-1 infections using on the basis of observed sero-conversion data using Cox proportional hazards models.

Results: Between 2018 and 2023, 2,619 study participants who were HIV negative at baseline contributed 1,083-person years. Mean age was 19.8 years (SD 2.8).

A total of 14 sero-conversions were observed. By 2023, the overall incidence of HIV infection was 1.29 cases per 100 person-years of observation (pyo), HIV incidence increased from 0.90 per 100 pyo (95% CI 0.29- 2.79) in 2018-2019 to 2.41 per 100 pyo (95% CI: 1.21- 4.83) in 2019-2020; and further dropped to 0.71 cases per 100-person years (95% CI 0.23- 2.22) in 2022/2023.

HIV testing service coverage decreased from 85.7% in 2018/2019, 83.5% in (2019/2020), to 78.4% in (2021/2022) and later rebounded to 80.8% by 2022/2023 (p=0.012).
Conclusions: To effectively combat HIV risk among AGYW in Uganda, comprehensive and sustained strategies are required. These should focus on enhancing access to consistent testing services, addressing barriers to prevention (including barriers in uptake of novel biomedical prevention approaches), and implementing targeted interventions that address the unique vulnerabilities of this population.

EP0249

Title: Prevalence and factors associated with advanced HIV Disease (AHD) in "Treat all" era among newly diagnosed PLHIV at Epako clinic, Omaheke region in Namibia—a retrospective cross-sectional study

K.F. Lumbala[1], H. Andreas[2], L. Mabhura[3], G.H. Muulu[3], J. Tshimwanga[4], N. Ruswa[1]
[1]Ministry of Health and Social Services, Directorate of Special Programmes, Windhoek, Namibia, [2]Intrahealth Namibia, Monitoring and Evaluation, Gobabis, Namibia, [3]Ministry of Health and Social Services, Epako Clinic/ Omaheke Health Directorate, Gobabis, Namibia, [4]Ministry of Health and Social Services, Otjizondupa Regional Health Directorate, Otjiwarongo, Namibia

Background: In 2016 Namibia adopted the" Treat all" strategy which implies ART initiation regardless of baseline CD4 count value and WHO clinical stage. Despite this strategy, it is still common to encounter newly diagnosed PLHIV with advanced HIV disease (AHD) in the Omaheke region. However, the magnitude and characteristics of these clients are unknown.
We aimed to determine the prevalence and factors associated with AHD at Epako Clinic the main ART facility in the region.
Methods: We conducted a cross-sectional observational study using programmatic data of clients aged ≥ 15 years enrolled in ART between January 2023 and December 2024 at Epako Clinic. The client's socio-demographic and clinical characteristics were extracted from the electronic medical records. The prevalence of AHD defined as a presentation with CD4 count < 200 cells/mm^3 or WHO stage or 4 was estimated. Collected data were inputted and analyzed with the STATA software version 18. Proportions of AHD in different demographic variables were assessed using chi-square tests, with p value< 0.05 set as a statistically significant level. A multivariate logistic regression model was used to estimate the associations between variables and AHD.
Results: Among 317 newly diagnosed PLHIV, 302 were enrolled, with 161(53.3%) females, and 141(46.7%) males, clients had 35 years mean age and 20.5 kg/m^2 mean BMI. 236 clients were classified based on both CD4 and WHO staging while 66 were classified based on WHO staging only due to missing baseline CD4. In total, AHD was present in 140 (46.4%) (95CI;40%-52%); with males more affected than females (62 % Vs 38%) P<0.001.
In univariate analysis, males, 35 to 44 years age group (37%), underweight (56.4%), and TB diagnosis (51.4%) were significantly associated with AHD(P<0.001). In the logistic regression model, male gender OR 2.7; (95 CI;1.31-5.42) and being underweight OR2.7;(95CI;1.3-5.7) remained significantly associated with having AHD.
Conclusions: Presenting with advanced HIV remains common at the Epako clinic. Being male, age, and nutritional status were associated with an increased risk of having AHD. Strategies addressing males' poor health-seeking behaviors and increasing testing in males and other high-risk populations should be strengthened in the Omaheke region to reduce the rate of AHD.

EP0250

Prevalence, trends, and correlates of HIV, syphilis, and HCV among male attendees at STD clinics in Southwest China: a 13-year cross-sectional study (2010-2022)

C. Tao[1], B. Liang[1], J. He[1], L. Ye[1], H. Liang[1], J. Che[2], Z. Wu[2], J. Cai[2], Y. Ou[2], L. Bao[2], A. Nong[2], R. Huang[3], F. Liang[3], Z. Lin[3]
[1]Guangxi Medical University, Nanning, China, [2]Chongzuo Center for Disease Control and Prevention, Chongzuo, China, [3]Qinzhou Center for Disease Control and Prevention, Qinzhou, China

Background: Sexually transmitted infections (STIs) pose a significant health threat, especially among high-risk groups, but data on their long-term patterns in these populations are limited. This study aimed to assess the prevalence, trends, and factors associated with HIV, syphilis, and HCV among male individuals attending STD clinics in Southwest China.
Methods: From 2010 to 2022, annual cross-sectional surveys were conducted among male individuals attending STD clinics in Southwest China. Blood samples were collected to test for HIV, syphilis, and HCV. The Mann-Kendall test was used to analyze trends in the prevalence of these conditions, and rare event logistic regression (relogit) identified factors associated with them.
Results: This study included a total of 23,964 male individuals attending STD clinics. The prevalence of HIV, syphilis, and HCV among participants was 0.98%, 2.16%, and 0.61%, respectively. While the prevalence of syphilis and HCV decreased from 3.64% and 1.81% in 2010 to 1.05% and 0.38% in 2022, the HIV prevalence did not show a downward trend. Participants with a history of STDs had significantly increased risks of acquiring HIV (aOR = 1.90, 95% CI: 1.14-3.15) and HCV (aOR = 4.91, 95% CI: 3.22-7.49).
Participants who had ever engaged in homosexual behavior had significantly increased risks of acquiring HIV (aOR = 14.66, 95% CI: 5.49-39.14) and syphilis (aOR = 3.95, 95% CI: 1.41-13.71). Those aged 50 years and above having a higher likelihood of acquiring HIV (aOR = 2.55, 95% CI: 1.91-3.39), while those under 50 years were more likely to acquire HCV (aOR = 1.94, 95% CI: 1.19-3.16). Being married or cohabiting increased the likelihood of syphilis (aOR = 1.40, 95% CI: 1.09-1.80), and a history of injecting drug use (IDU) significantly increased the risk of acquiring HCV (aOR = 10.97, 95% CI: 5.21-23.12).

Conclusions: This study found a low prevalence of HIV, syphilis, and HCV among male individuals attending STD clinics. While syphilis and HCV prevalence declined, HIV prevalence remained stable. These findings highlight the need for ongoing, targeted prevention, especially for MSM and individuals with a history of IDU.

EP0251

Early sexual debut and HIV sero-prevalence among adult females (18-50 years): evidence from a rural and urban longitudinal cohort study in Uganda

J. Kato[1], A. Daama[2], R. Bulamba[3], E. Kyasanku[4], S. Mugamba[5], F. Nalugoda[6], G. Kigozi[7], D. Kiwanuka[7], P. Kato[1], S. Watya[7], J. Nkale[7], G. Kigozi[7], G. Nakigozi[7]

[1]Africa Medical and Behavioral Sciences Organization, Epidemiology and Behavioral Studies, Kampala, Uganda, [2]Africa Medical and Behavioral Sciences Organization, Head Epidemiology and Behavioral Studies, Kampala, Uganda, [3]Africa Medical and Behavioral Sciences Organization, Data Manager Epidemiology and Behavioral Studies, Kampala, Uganda, [4]Africa Medical and Behavioral Sciences Organization, Programs Director, Kampala, Uganda, [5]Africa Medical and Behavioral Sciences Organization, Head of Research Programs, Kampala, Uganda, [6]Africa Medical and Behavioral Sciences Organization, Scientific Officer, Head Grants, Science and Training, Kampala, Uganda, [7]Africa Medical and Behavioral Sciences Organization, Research Directorate, Kampala, Uganda

Background: Early sexual debut (<18 years of age) is linked to strong pointers for future poor sexual health and risky behavioral patterns. The continued decline in the median age at first sex among females in a number of countries raises a serious concern regarding associated negative health outcomes and effectiveness of HIV prevention efforts.

We present findings on early sexual debut and HIV sero-prevalence among adult females in Wakiso and Hoima Districts, Uganda.

Methods: Female participants 18-50 years participated in the AMBSO Population Health Surveillance (APHS) in 2020-2021. Sociodemographic and behavioral data including; age, education, sexual behaviors, sexual debut etc. were collected using same-sex interviewer administered questionnaires. HIV testing was done using the Uganda Ministry of Health algorithm for HIV screening and testing. Bivariate analysis assessed differences in age at sexual debut and key socio- demographic variables. Modified Poisson regression was used to assess association of age at sexual debut, HIV infection, and other covariates.

Results: The study sample was 1,802 females, HIV prevalence was 13%, mean age 30.3, (SD=8.5). More than half (60%) reported early sexual debut and 8.8% (154/1760) reported coercion at first sex. HIV prevalence was higher in women reporting early sexual debut (15.5% vs. 9.3%, P<0.001). Females who reported early sexual debut and those who reported coercion at sex debut were more likely to be HIV positive compared to their counterparts (PR=1.70, P<0.001), and (PR=1.60, P=0.007, 95% CI 1.14, 2.25) respectively. Compared to agriculture, participants doing other jobs (mining, fishing, military work etc., had a lower prevalence of HIV. PR: 0.54 (P-value =0.002, 95% CI: 0.37–0.80).

Conclusions: Early sexual debut among females is a key predictor of HIV prevalence in urban and rural Uganda. Targeted interventions for adolescent girls and young women are required for HIV prevention in this setting.

EP0252

Syndemic interactions between HIV, mental health, and non-communicable diseases in Africa: a scoping review of contributing factors

C. Iloegbu[1], A. Karbasi[1], C. Ruan[1], N. Osei-Tutu[1], K. Patel[1], L. Frerichs[1], J. Patena[1], D. Vieira[1], D. Adenikinju[1], L. Samuels[1], J. Gyamfi[1], E. Peprah[1]

[1]New York University, Global Public Health, New York, United States

Background: The syndemic framework provides a critical lens to examine the interwoven challenges of HIV, mental health (MH), and non-communicable diseases (NCDs) in Africa. This scoping review highlights how these conditions synergistically affect individuals living with HIV. Contextual factors such as stigma, poverty, gender disparities, and fragmented healthcare systems exacerbate these conditions, posing significant challenges to individual and public health.

Methods: A scoping review was conducted to explore syndemic interactions between HIV, MH, and NCDs across Africa. Following the PRISMA framework, literature searches were conducted in March 2024 across PubMed/Medline (OVID), Web of Science (all databases), CINAHL, Global Health, and Psychinfo.

Articles were screened independently by two reviewers, with conflicts resolved by a third. Data were extracted to summarize study characteristics, prevalence rates, and contextual factors underpinning these syndemic interactions.

Results: Of 2,706 articles screened, 207 underwent full-text review, with 17 studies included. Hypertension, diabetes, and depression were the most prevalent co-morbidities among individuals living with HIV, disproportionately affecting women and older adults. Stigma, socioeconomic barriers, and fragmented healthcare systems consistently exacerbated these conditions, hindering effective care. Many NCDs and MH conditions were undiagnosed or poorly managed, complicating HIV treatment and reducing quality of life. Resource limitations and poor healthcare integration further impeded comprehensive care delivery.

Conclusions: This review underscores the urgent need for integrated healthcare approaches to address the syndemic of HIV, NCDs, and MH in Africa. Interventions should prioritize stigma reduction, capacity building, and comprehensive care while addressing underlying socioeconomic determinants of health among individuals living with HIV. Strengthening healthcare systems and promoting person-centered care are vital to reducing disparities

and achieving Sustainable Development Goals. Future research should expand geographic and demographic coverage to capture the full scope of these syndemic relationships in diverse African contexts.

EP0253

The association between low birth weight and neurocognitive development and the impact of exposure to HIV in Utero

C. Mdhluli[1], N. Nampota-Nkomba[2], F. Mkandawire[1], O. Nyirenda[1], L. Maliwichi[3], M. Crespo Llado[4], M. Gladstone[4], M.K. Laufer[2], A.G. Buchwald[2]
[1]Blantyre Malaria Project, Blantyre, Malawi, [2]University of Maryland School of Medicine, Baltimore, United States, [3]University of Malawi, Zomba, Malawi, [4]University of Liverpool, Liverpool, United Kingdom

Background: Neurodevelopment in early childhood has long-term impacts on quality of life and economic achievement. HIV infection in pregnant women is associated with low birthweight (LBW) and neurodevelopmental delay in the infant, even among children born HIV-exposed but uninfected (CHEU). LBW is associated with developmental delays, but few studies have assessed whether the impact of LBW among CHEU is different compared to HIV unexposed children (CHU). Due to progress in preventing mother-to-child HIV transmission, there is an urgent need to understand the pathways leading to developmental delay in CHEU.
Methods: We conducted a longitudinal cohort study in Malawi, recruiting pregnant women in their second trimester, and followed their infants to two years of age. Neurodevelopment was assessed using the Malawi Developmental Assessment Tool. Delays (Z-scores <-1) were assessed across gross motor, fine motor, language, and social domains. Children were categorized by birthweight (LBW < 2500g vs normal (NBW)) and HIV exposure. We used Chi-squared tests to examine the frequency of delay by group and logistic regression models to determine the odds ratio (OR) for delay by birthweight, accounting for interaction with HIV exposure and other confounders.
Results: Among 604 children, 49.5% were CHEU, and 13.9% of the total population were LBW. LBW was significantly associated with delays in fine motor (p=0.002), language (p=0.01), and overall MDAT scores (p=0.005). CHEU with LBW had the highest prevalence of overall delays (25% vs 11% among CHU with NBW). There was significant interaction between LBW and HIV exposure with a strong association between LBW and developmental delay among CHEU in the gross motor domain (OR among CHEU = 2.28, 95% CI:1.05, 4.97) but no association between LBW and gross motor delay among CHU (OR = 1.07, 95% CI:0.13, 8.83). Interaction was also seen in the fine motor domain (OR for CHEU = 3.27, 95% CI:1.28, 8.34; vs OR for CHU= 2.17, 95% CI:0.24, 20.03).
Conclusions: The effect of LBW on child development is more pronounced among CHEU than their CHU counterparts. This study highlights the significant long-term impacts of HIV exposure in utero and the urgent need for targeted interventions to improve CHEU health.

EP0254

Mortality and engagement patterns of People Living with HIV (PLHIV) during the first 12 months of antiretroviral treatment (ART)

E. Viola[1], C. Mtumodzi[1], T. Kumwenda[1], D. Kathumba[1], J. Huwa[1], E. Rambiki[1], A. Thawani[1], T. Heller[1,2]
[1]Lighthouse Trust, Lilongwe, Malawi, [2]International Training and Education Center for Health, University of Washington, Seattle, United States

Background: The first 12-months of ART is associated with poor treatment outcomes. Advanced HIV Disease (AHD) screening is recommended for new initiations, and psychosocial support to prevent disengagement. In 2020, Lighthouse clinic established a "buddy system" that pairs newly initiating people living with HIV (PLHIV) with expert clients (ECs) for the first 12-months, to ameliorate transition to ART and offer adherence support. We assessed treatment outcomes during the first 12-months among PLHIV initiating ART.
Methods: We retrospectively analyzed engagement and mortality of PLHIV in the first 12-months of ART initiation (Jan 2021–Jun 2023) using EC diaries data. Engagement at 6 and 12-months was categorized as "continuous care" (no missed visits), "cyclers" (missed appointment and returned), or "disengaged" (not in care at month-6 and 12). PLHIV who "transferred out" or "died" were censored for the engagement analysis. Kaplan-Meier plots were generated in STATA.
Results: Among 1,168 PLHIV paired with ECs (median age 36 [IQR 28–43]; 55% female), AHD screening was done in 1,042 (89.2%), with 43.7% having CD4<200. Among these, serum-CrAg was positive in 4.4% and urine-LAM in 17.4%. Engagement at 6 and 12-months was 82% and 85%. Continuous care was 737 (87%) in the first 6 months, while 115 (13%) were cyclical. Twenty-six (4%) of the continuous PLHIV disengaged in the second half, and 23 (20%) of cyclers disengaged permanently.
Mortality was 7.2/100 person-years (95% CI: 5.6–9.1), highest in the first 3 months (17.2, 95% CI: 12.5–23.0) and declining thereafter. AHD was associated with higher mortality (10.2 vs. 4.1, p<0.01); no sex differences were found.
Conclusions: Our large cohort of PLHIV initiating ART shows continuing high early mortality. Patients with AHD are at higher risk despite 70-80% coverage of recommended testing for opportunistic infections (OIs).
Pairing PLHIV with an expert buddy leads to improved retention in the first year of ART compared to previous retention rates of 73%. Cyclical disengagement is a well observed pattern and is associated with increased risk of permanent disengagement later.

EP0255

Predictors of mortality among people living with HIV in Northern Nigeria: a four-year retrospective analysis of verbal autopsy cause of death

O. Airaoje[1], O. Ogorry[1], I. Abah[1], D.S. Dauda[2], M. Li[2], L. Claussen[2], O. Oyelaran[3], J. Pius[3], E. James[3], C. Obiora-Okafo[3], D. Ogundehin[3], D. Kimanga[3], R. Eneogu[3], A. Idemudia[3], M. Katbi[3], P. Gado[3], A. Bashorun[4], M. Morka[4], P. Nwaokenneya[4], C. Ukanwa[4], T. Ilori[5], J. Anenih[5], F. Agbo[5]

[1]Data.FI|Palladium International, Abuja, Nigeria, [2]Data.FI|Palladium International, Washington, DC, United States, [3]United States Agency for International Development, Abuja, Nigeria, [4]National AIDS, Sexually Transmitted Infections Control and Hepatitis Programme (NASCP), Federal Ministry of Health, Abuja, Nigeria, [5]National Agency for the Control of AIDS (NACA), Abuja, Nigeria

Background: HIV-related mortality remains a significant challenge in Northern Nigeria, where healthcare access and service delivery models vary. Identifying the predictors of mortality is crucial for improving survival outcomes. Verbal autopsy, an established method in low-resource settings, provides valuable insights into the causes of death. This study examines predictors of mortality among people living with HIV (PLHIV).

Methods: A four-year (202-2024) retrospective study analyzed electronic medical records (EMRs) and verbal autopsy data from 202 health facilities across 10 states. Inclusion criteria for the study were documented HIV related deaths, time to mortality (defined as time from ART initiation to death) as the dependent variable determined through verbal autopsy. Mortality predictors were analyzed using univariable and multivariable Cox proportional hazards models. Variables included sex, current-age, recent-clinical stage, recent-viral load, facility ownership, service levels, and differentiated service delivery (DSD) models.

Results: Among the 24,885 PLHIV cohort, 13,774 (55.4%) were female and 11,111 (44.6%) were male. The median age was 40 years (IQR: 32 – 48). The mortality rate was 23.9 deaths per 1000 person-years (95% CI: 2.37 – 2.43). Some factors were significantly associated with a higher risk of deaths: male sex (aHR = 1.14, 95% CI: 1.04 – 1.24, p = 0.004), viral load (≥1000 copies/mL), age <15years (aHR = 1.13, 95% CI: 0.87–1.47, p<0.03), clients receiving services in private for-profit facilities (aHR = 1.38, 95% CI: 1.12 – 1.70, p <0.003), and facility-based DSD models (aHR = 1.20, 95%CI:1.08 – 1.33, p <0.001). Unexpectedly, clinical stage II (aHR = 0.74, 95%CI:0.65 – 0.84, p <0.0001) showed a significantly decreased likelihood of mortality while tertiary-level facilities showed a significantly lower mortality risk (aHR = 0.64, 95%CI:0.53 – 0.77, p <0.001) compared to primary health facilities

Conclusions: This study reveals key predictors of mortality among PLHIV: sex, age, viral load, facility type, and DSD model. To reduce mortality, targeted interventions should focus on improving care for individuals <15years, male, virally unsuppressed, those in private health facilities and clients receiving ARVs through facility-based DSD models. Future research should explore the unexpected link between Stage II HIV and lower mortality risk.

EP0256

Characteristics and prevalence in HIV, hepatitis B/C, and STDs among sexual minority men who inject drugs in the US, 2021-2023

X. Li[1], S. Bornstein[1], B. Altman[1], Y. Xiang[2], V. Umutoni[3], J.Q. Freeman[3], Y.G. Lee[4]

[1]The Geroge Washington University, Milken Institute School of Public Health, Washington, United States, [2]University of Southern California, Department of Population and Public Health Sciences, Los Angeles, United States, [3]University of Chicago, Department of Public Health Sciences, Chicago, United States, [4]University of Hong Kong, Department of Social Work and Social Administration, Pokfulam, Hong Kong, SAR of China

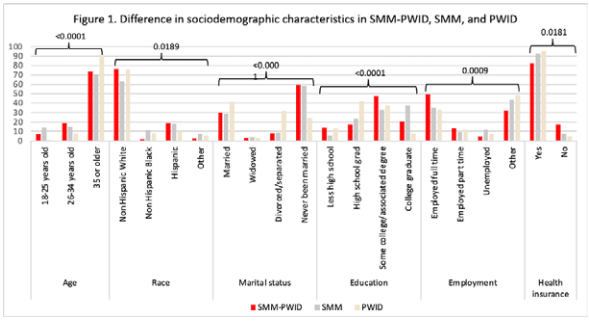
Background: Sexual minority men who use injection drugs (SMM-PWID) might face a heightened risk of HIV infection compared to non-injecting SMM and other male PWID due to dual HIV risks. Given advancements in HIV prevention and shifts in the opioid epidemic, this study provided an updated assessment of SMM-PWID's characteristics and the prevalence of HIV, hepatitis B/C, and STDs.

Methods: We analyzed the 2021-2023 National Survey on Drug Use and Health data, including adults who were assigned male at birth and heterosexual, gay, or bisexual. Participants who were gay or bisexual and never injected drugs were categorized as SMM, those who were gay or bisexual and ever injected drugs as SMM-PWID, and those who were heterosexual and ever injected drugs as PWID. Participants were asked about their life history of HIV, hepatitis B/C, and STDs in the past year.

We compared weighted percentages using Rao-Scott Chi-Squared tests and performed weighted logistic regression, controlling for sociodemographic characteristics and time.

Results: The sample (n=2,214, weighted n=15,336,498) included 4% SMM-PWID, 60% SMM, and 36% PWID. Selected sociodemographic differences are shown in Figure 1. In SMM-IDU, the prevalence of HIV was 34.5%, hepatitis B/C was 22.9%, and past year STDs was 7.6%. SMM-PWID had higher odds of having HIV compared to SMM (adjusted odds ratio [AOR]: 2.68, 95%CI: 1.13, 6.33) or to PWID (AOR: 22.10, 95%CI: 7.84, 62.33).

Additionally, SMM-PWID had higher odds of having hepatitis B/C compared to SMM (AOR: 6.30, 95%CI: 1.90, 20.88). No difference was found in STD prevalence.



Conclusions: The high prevalence of HIV and hepatitis B/C in SMM-PWID indicated that their engagement in multiple risk behaviors may have a synergistic effect on disease

transmission. The findings underscore the urgent need for targeted interventions that address the compounded risks faced by SMM-PWID, emphasizing the importance of incorporating their unique characteristics into intervention design.

EP0257

HIV/AIDS epidemiological patterns in Western and Central Africa: a decade-long analysis of 21 nations (2014-2023)

O.J. Okesanya[1,2], M.M. Ahmed[3], B.M. Ukoaka[4], D.E. Lucero-Prisno III[5]
[1]Neuropsychiatric Hospital, Medical Laboratory Science, Abeokuta, Nigeria, [2]University of Thessaly, Department of Public Health and Maritime Transport, Volos, Greece, [3]SIMAD University, Mogadishu, Benadir, Somalia, [4]First On-Call Initiative, Community and Clinical Research Division, Abuja, Nigeria, [5]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom

Background: Western and Central Africa (WCA) is the epicenter of the HIV/AIDS epidemic in Africa, affecting 5.1 million people and causing 190,000 new infections at a 0.31 incidence per 1000 uninfected populations among critical groups: young women, girls, and their sexual partners. WCA accounts for an outsized share of HIV-related burdens and deaths in Africa. We examined HIV/AIDS epidemiological patterns in WCA between 2014 and 2023.
Methods: We conducted a longitudinal retrospective study using UNAIDS surveillance data spanning 2014-2023, examining HIV/AIDS patterns across WCA nations. We performed analyses at the national and regional scales on HIV prevalence (ages 15-49), incidence rate among 1000 uninfected adults, total adult cases (15+ years), and associated mortality rates. For consistency in reporting, we applied a standardized age criterion of ≥ 15 years across all analyses.
Results: The decade-long analysis of HIV prevalence across WCA nations varies significantly. Gabon (3.5 ± 0.35%) and Guinea-Bissau (2.88 ± 0.39%) had the highest prevalence, while Mauritania (0.24 ± 0.05%) and Niger (0.21 ± 0.03%) recorded the lowest. Regional prevalence has consistently declined over the decade, dropping from 1.7% in 2014 to 1.27% in 2023, with an overall mean of 1.48 ± 0.14%. Despite reductions, countries like Congo and Côte d'Ivoire remain heavily impacted. The average HIV incidence rate in WCA regions was 0.79 per 1,000 uninfected persons with a gradual decrease from 1.0 in 2014 to 0.59 in 2023 (mean annual rate ± SD: 0.79 ± 0.14). The number of adults living with HIV in WCA was 200,895.24 ± 3931.05. Nigeria had the highest burden (1,830,000 ± 48,304.59); Angola and DR Congo experienced gradual increases, while Burkina Faso and Guinea-Bissau showed stability. The HIV-related deaths in WCA were 6,321.67 ± 1,211.18, with the highest mortality rate in Nigeria.
Conclusions: Over the past decades, HIV prevalence, incidence, and burden have consistently decreased across WCA, indicating a controlled epidemic. Nevertheless, significant variations continue to exist.

EP0258

Late HIV testing in delivery rooms of Bukavu referral maternity wards for HIV vertical transmission prevention in the Democratic Republic of the Congo: a retrospective study

F.K. Maneraguha[1], J. Côté[2], G. Rouleau[3], G.W. Utshudienyema[4]
[1]Université de Montréal, Faculté des Sciences Infirmières, Montréal, Canada, [2]Chaire sur les Nouvelles Pratiques en soins Infirmiers, Université de Montréal, Montréal, Canada, [3]Université du Québec en Outaouais, Department of Nursing, Montréal, Canada, [4]Université de Kinshasa, École de santé Publique, Kinshasa, Congo, the Democratic Republic of the

Background: Vertical transmission of the human immunodeficiency virus (HIV) remains a major challenge for sustainable development and global health. One contributing factor is the significant proportion of delivering women who are HIV status unaware. In Bukavu, little is known at present about delivering women unaware of their status, HIV prevalence among these women, the determinants of status unawareness, and the impact of unawareness on neonatal outcomes.
Methods: This observational, multi-site study used delivering women's the obstetric records data of women who delivered in eight referral maternity wards in Bukavu over the period from January 2020 to June 2021. Descriptive statistics were computed, and multivariate logistic regression analyses were run with the statistical significance threshold set at 5%.
Results: The proportion of delivering women who were status unaware was 3.2% (520/16,469). Of these, 14.0% (73/520) were HIV positive. The women had an average age of 23 years and were mostly primigravida and primiparous. In multivariate analysis, HIV positive status was associated with place of residence.
All newborns of HIV-positive mothers received antiretroviral prophylaxis postpartum. Early and late neonatal mortality rates were 9.4% and 9.2%, respectively, though no significant statistical association emerged with mother's positive status.
Conclusions: In Bukavu, high HIV prevalence among status-unaware women at childbirth challenges the objective of ensuring an HIV-free generation, compromises neonatal outcomes, and raises maternal and child health concerns.
This underscores the need for increased initiatives in Congolese health policy to enable early HIV testing for pregnant women and implement effective interventions to prevent HIV vertical transmission.

EP0259

Achieving high 25-year retention in women's HIV research: Chicago Women's Interagency HIV Study (WIHS)

M.H. Cohen[1], S. Urwin[2], E. Daubert[2], M. Santiago[2], C. Winston[2], C. Thomas[2], D. Johnson[2], K.M. Weber[2]
[1]Stroger Hospital, Medicine, Chicago, United States, [2]Hektoen Institute, Chicago MWCCS, Chicago, United States

Background: Socioeconomically vulnerable women of color are underrepresented in HIV research and described as "hard to retain." Obstacles include rigid protocols, transportation, childcare, inflexible employment, medical mistrust, disclosure/confidentiality concerns, and inaccessibility of information.
We describe long-term retention and semiannual visit attendance over 25 years (1994-2019) in Chicago WIHS, the longest running women's HIV study.
Methods: Retention strategies included community advisory boards planning with researchers, renumeration (for time, transportation, child-care), flexible scheduling, confidential, respectful, and culturally competent staff/environment, frequent care coordination/referrals, health education, peer support, and celebratory events/appreciation gifts. We report retention (seen in last year) and visit attendance censored at study endpoint (death, relocation, inability to consent, or withdrawal).
We compared women retained to those lost to attrition (met a study endpoint or unretained). Primary reasons for continued participation were ascertained; top three motivators were identified.
Results: At baseline, 581 women with/without HIV (78% WWH/22% WWoH), 71% African American (AA), median age 36 years; 73% unemployed, 61% ≤ high school education, 73% ≤ $18,000 annual household income; 38% unstably housed; 61% reported abuse history, 34% reported ever injecting drugs (IDU) and 64% used crack/cocaine/heroin (CCH). As of 2019 (Visit 49/50), 296 (50.9%) of women met a study endpoint [226 (38.9%) due to death]. Among 285 remaining, 246 (86.3%) were retained and 39 (13.6%) were unretained.
Retained women, compared to those lost to attrition were more likely to be Black, older at last visit, stably housed, employed, have higher income and more education but less likely to report recent CCH/IDU and cigarette use (all p<.01). Attrition was higher among WWH primarily due to deaths. Visit attendance was exceptional: 86% attending >90% visits with 61.4% attended *ALL* semiannual visits.
Women's top three reasons for study continuation were compassionate staff, personal health information, helping others by contributing to research.
Conclusions: High long-term engagement among poor marginalized women of color with/and at risk for HIV is achievable with an inclusive approach that addresses woman-specific challenges. Exceptional semiannual visit attendance over 25 years contributed to robust longitudinal data, ensuring high validity and generalizability of study findings that will advance our multidimensional understanding of women aging with HIV.

EP0260

HIV virological outcomes among children less than 15 years on dolutegravir in Rwanda, 2023

L.I. Ntawunga[1], A. Habimana[2], A. Tuyisenge[3], S. Malamba[4], G.N. Rwibasira[5]
[1]Rwanda Biomedical Center, HIV/AIDS Disease Prevention and Control Department, Kigali, Rwanda, [2]Mount Kigali University, Public Health, Kigali, Rwanda, [3]University of Rwanda, Medicine and Health Science, Kigali, Rwanda, [4]Consultant, Strategic Information, Kigali, Rwanda, [5]Rwanda Biomedical Center, Head of (IHDPC) Institute of HIV/AIDS Disease Prevention and Control, Kigali, Rwanda

Background: HIV significantly impacts global health, with 39 million acquired HIV, including 25.6 million in Africa. While antiretroviral therapy (ART) improves survival, some clients do not achieve viral load suppression. Dolutegravir (DTG) is effective and cost-efficient and has become preferred in low- and middle-income countries since 2018. However, it may not ensure adequate virological suppression. In Rwanda, pediatric clients receive DTG-based treatments, and this study examines risk factors for virological non-suppression.
Methods: Secondary Data from the national viral load sample management (VLSMS) and laboratory information system (LIS) were analyzed in a cross-sectional study of children living with HIV (CLHIV) on DTG-based ART. Logistic regression analyses were conducted using Stata 17 to assess relevant variables.
Results: Children aged 10-14 have a lower viral load than those 0-9, with significant odds ratios (OR) of 0.714 and 0.697 (p: 0.020, 0.006), indicating younger children are more susceptible to non-suppression. Males showed a higher unsuppressed rate (9.40%) than females (7.29%), but the difference was not significant (aOR 1.319, p=0.059). The Western Province had the highest unsuppressed rate (9.05%), but no significant regional variations were found. Therapy adherence was critical; children with poor adherence (<85%) had a higher unsuppressed rate (30.77%) versus those with good adherence (≥95%, aOR 0.178, p < 0.001).
No differences in unsuppressed rates were observed among various DTG regimens, and no significant changes were noted for therapy initiations between 2019 and 2023, suggesting treatment timing is not a major risk factor within the first year. Interventions must enhance support for younger children to address adherence.
Conclusions: Virological failure varies by age and gender, with adherence being the primary outcome determinant. The absence of geographic disparities implies equitable healthcare access nationwide.
Further research should explore local healthcare. Infrastructure and social determinants impacting initial inequality. Promoting excellent adherence is essential for optimizing DTG regimens and improving long-term health in among children.

EP0261

One-year incidence and causes of mortality among persons living with HIV who initiated antiretroviral therapy (ART) at an HIV clinic in Kampala

M. Magololo Fiona[1], P. Kateme[1], J.V. Kigongo[1], S. Ouma[1], Y. Miya[1], A. Kazibwe[1], B.M. Etukoit[1], TASO Mulago Clinical Team
[1]The Aids Support Organization, Programs & Operations Research, Kampala, Uganda

Background: Mortality among PLHIV in Uganda is still higher than national targets to achieve the global End-HIV goals. Advanced HIV disease, characterized by low CD4 counts and stage III or IV disease, contributes to high mortality among persons living with HIV (PLHIV).
Following the roll-out of Dolutegravir as the preferred anchor drug for first-line therapy, there is a need to monitor changes in mortality among PLHIV. We aimed to determine the one-year incidence and causes of mortality among this cohort.
Methods: We conducted a retrospective cohort study using data from Uganda Electronic Medical Records at TASO Mulago HIV clinic in Kampala, Uganda. We included all PLHIV newly identified and initiated lifelong ART between January 2020 and January 2024. Using Logistic regression, we computed all-cause mortality, and then computed mortality rate as the total number of deaths divided by total person-time. Cox-proportional hazard models predicted the association between baseline CD4 category and death.
Results: Overall, there were 1922 PLHIV started on ART during the period, 67.7% (1304) were female, and the median age was 31 years (IQR: 13). Of these 67.8% (1304) had a baseline CD4 result, with 77.3% (1009) having CD4 above 200 cells/ul. In the cohort, 94.8% (1785) didn't have any signs or symptoms of tuberculosis (TB), 1.8% (34) were presumed to have TB, and 3.4% (103) were diagnosed with TB at baseline.
All-cause mortality at 1 year for this cohort was high at 3.6% (p<0.001). Seventy percent (49) of all deaths were due to opportunistic infections, TB inclusive. The one-year mortality rate for this cohort was 24 deaths per 10000-person months. Baseline CD4 <200 cells, compared to CD4≥200 cells/ul was associated with higher mortality at 1 year (HR = 8.1, p <0.001).
Conclusions: The proportion of PLHIV with low CD4 counts was low in this cohort. One-year mortality rate was high, and low CD4 was associated with a higher risk of mortality. TB and other infectious diseases accounted for more than two-thirds of mortality causes.
Advances in ART potency should be accompanied by advances in management of AHD and infectious diseases.

EP0262

Aging with HIV in Rwanda: navigating the dual burden of managing HIV and comorbidities

G. N.Rwibasira[1], G. Gatete[1], G. Mujawamariya[1], D. Mutambuka[2], A. Tuyishime[1]
[1]Rwanda Biomedical Centre, National HIV Program, Kigali, Rwanda, [2]Rwanda Network of People Living with HIV, Kigali, Rwanda

Background: With improved access to antiretroviral therapy (ART), Rwanda has seen an increase in the life expectancy of people living with HIV (PLHIV), resulting in a growing population of older PLHIV. Aging with HIV presents challenges due to the dual burden of HIV and age-related comorbidities.
This study examined the prevalence of comorbidities among older PLHIV and their associations with age, time on ART, and health outcomes.
Methods: A cross-sectional study was conducted in 2023-2024 across 115 health facilities in Rwanda, including 7,449 PLHIV aged 15years and older. Data on demographics, duration of ART, comorbidities (e.g., high bool pressure, hyperglycemia, Asthma, and cervical cancer), and viral suppression were collected through structured interviews and medical record reviews.
Multivariate logistic regression was used to assess associations between age, time on ART, and accurence of comorbidity, with adjusted odds ratios (aOR) and 95% confidence intervals (CI) calculated.
Results: The study found that 40 % of PLHIV in Rwanda are aged 50 years and older. Among this group, 5.6 % had at least screened positive to one comorbidity, with the most common condition being High blood pressure (33.9%), Hyperglycemia (1.8 %), cervical cancer lesions (18%) and Asthma(1.4 %).
Additionaly, 30.8% of PLHIV with a longer duration on ART (≥20 years) and 20% of those with viral load non-suppression had at least one cormobidity. Older age (35-49 and ≥50 years) was significantly associated with comorbidities (aOR: 1.8, 95% CI: 1.5-2.3) and (aOR:3.8, 95%CI:3.0-4.7) respectivey.
Conclusions: Rwanda's aging PLHIV population faces a growing burden of comorbidities linked to age and long-term ART use. Integrated care models addressing HIV and chronic conditions, along with targeted interventions such as early screening and management of comorbidities, are essential to improving health outcomes and quality of life for this vulnerable population.

EP0263

Factors explaining high HIV prevalence among women compared to men in people who use drugs (PWUD)

F.Z. Mwumvaneza[1], C. Ndinda[1], B. Ikuzo[1], G. N. Rwibasira[1]
[1]Rwanda Biomedical Centre, HIV, Disease Prevention Control, Kigali, Rwanda

Background: Women who use drugs show appreciably higher HIV prevalence (47.1%) compared to men (6.2%), representing a 7.6 times higher HIV infection rate. Contributing risk behaivors include exchanging sex for drugs or money and struggling to negotiate condom use with sexual partners.
This study aimed to explore the vulnerability of women who use drugs to HIV infection and identify associated factors in Rwanda.
Methods: A cross-sectional approach and Respondent Driven Sampling (RDS). 1,113 individuals, aged 18+ from ten predetermined sites in Rwanda. Eligible participants had injected drugs within the last 12 months before the study, held a valid recruitment coupon, and consented to interviews and biological tests for HIV, HBV, and HCV screening. Data collection involved interviews and screening tests with analysis conducted using the Python program to focus on the prevalence of HIV infection and associated factors among women who use drugs.
Results: A total of 137 women who use drugs participated in the survey, regression analysis indicated that unemployed women were 2.86 times more likely to acquire HIV infection than unemployed men (OR = 2.86, 95% CI: [1.51, 5.37]), whereas women who used drugs more than four times daily were 1.47 times more likely to acquire HIV infection compared to men (OR = 1.47, 95% CI: [1.07, 2.03]). Furthermore, women who shared needles with over five individuals demonstrated a 1.92-fold increased likelihood of acquiring HIV infection as opposed to males (OR = 1.92, 95% CI: [1.33, 2.77]), and women who attempted suicide demonstrated a double increased likelihood of acquiring HIV infection compared to men (OR = 2.00, 95% CI: [1.19, 3.35]). Married women were 1.88 times more likely to acquire HIV infection than married men (OR = 1.88, 95% CI: [1.35, 2.61]).
Conclusions: The higher HIV incidence among women is primarily due to increased vulnerability associated with unemployment, substance abuse, needle-sharing, suicidal ideation, and marital circumstances.
This underscores the importance of developing gender-specific public health interventions to address these vulnerabilities and reduce HIV infections.

EP0264

Orphanhood and HIV risk among adolescents and young adults in Rakai, Uganda: a prospective cohort study, 1998-2022

D. Malden[1], A. Khalifa[1], O. Ratmann[2], Y. Chen[2], K. Grabowski[3], L. Chang[3], F. Nalugoda[4], G. Kigozi[4], T. Lutalo[4], N. Sewankambo[5], A. Ndyanabo[4], D. Serwadda[4], P. Kreniske[1], F. Makumbi[4], R. Ssekubugu[4], J. Kagaayi[4], A. Settuba[4], H. Nakawooya[4], J. Santelli[1]
[1]Columbia University, Department of Population and Family Health, New York City, United States, [2]Imperial College London, Department of Mathematics, London, United Kingdom, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [4]Rakai Health Sciences Program, Kalisizo, Uganda, [5]Makerere University, Kampala, Uganda

Background: Orphanhood decreased considerably in Rakai, Uganda, after the rollout of combination HIV treatment and prevention programs. However, the potentially evolving influence of orphanhood on risk for HIV infection as children become adolescents and young adults (AYA) remains unclear.
This study describes behaviors and HIV incidence among AYA who have lost one or both parents in Uganda.
Methods: Persons aged 15-24 years were surveyed approximately every 1-2 years from 1995 through 2022 in 28 communities. Orphanhood was defined as loss of a parent before age 18 years, categorized as single (lost either their mother or father), or double orphanhood (lost both mother and father).
We assessed risk of HIV acquisition by orphanhood status using Poisson regression to estimate incidence rate ratios (IRR) of new-onset HIV and 95% confidence intervals during 1998-2022. We also describe the cross-sectional associations between orphanhood and social and behavioral HIV risk factors using logistic regression to control for baseline age, sex and socio-economic status.
Results: Among 21,399 AYA without HIV at first interview, 3,228 (15.1%) single orphans and 1,468 (6.9%) double orphans were identified over the study period. Of these, 342 incident cases of HIV infections were identified during 1998-2022. Both orphanhood and HIV incidence fell over time. Orphans had higher HIV incidence rates than non-orphans at ages 15-19 years (IRR: 2.01, 95% CI: 1.09-3.69) but not at 20-24 years (IRR: 1.36, 95% CI: 0.91-2.00). Compared with non-orphans, orphans were more likely to have ever had sex (OR: 1.52, 95% CI: 1.38-1.67), and were less likely to have secondary education (OR: 0.78, 95% CI: 0.68-0.90). Orphanhood was not associated with other well known risk factors such as multiple partners. HIV risk among orphans did not change over time.
Conclusions: Despite recent declines, orphans represent an important risk group for targeted HIV prevention and treatment programs such as PrEP and programs that provide social support such as access to education and family strengthening.

EP0265

CD4 testing and occurrence of advanced HIV disease among PLHIV initiating treatment: insights from the PEPFAR monitoring, evaluation, and reporting system – October 2023-September 2024

P. Marks[1], A. Jones[1], G. Saemisch[2], M. Grande[1], A. Mbunda[3], I. Aitmagambetova[4], A. Nabidzhonov[5], N. Usmanova[6], C.D. Nyagatare[7], J. Kabanda[8], R.E. Morales Siliezar[9], F.d.B. Perini[10], R.R. Allam[11], P. Martynov[12], R. Prasad[13], D. Tesfaye[14], C. Mbelwa[15], F. Ntuuyo[16], S. Prohow[17], H.T. Wolf[1], E.K. Dokubo[1], E.A. Agyemang[18]

[1]U.S. President's Emergency Plan for AIDS Relief. Bureau of Global Health Security and Diplomacy, U.S. Department of State, Washington, United States, [2]United States Agency for International Development, Office of HIV/AIDS, Washington, United States, [3]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, the United Republic of, [4]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Almaty, Kazakhstan, [5]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Dushanbe, Tajikistan, [6]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Bishkek, Kyrgyzstan, [7]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Kigali, Rwanda, [8]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Kampala, Uganda, [9]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Guatemala City, Guatemala, [10]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Brasilia, Brazil, [11]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, New Delhi, India, [12]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Kyiv, Ukraine, [13]United States Agency for International Development, Office of HIV/AIDS, New Delhi, India, [14]United States Agency for International Development, Office of HIV/AIDS, Kigali, Rwanda, [15]United States Agency for International Development, Office of HIV/AIDS, Dar es Salaam, Tanzania, the United Republic of, [16]United States Agency for International Development, Office of HIV/AIDS, Kampala, Uganda, [17]United States Agency for International Development, Office of HIV/AIDS, Central and South America, Washington, United States, [18]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Atlanta, United States

Background: Despite the adoption of Test and Start, many persons living with HIV (PLHIV) present late to care increasing their risk for opportunistic infections and mortality. CD4 cell count is the gold standard for identifying PLHIV who have advanced HIV disease (AHD; defined as PLHIV ≥ 5+years with CD4 count<200 cells/mm³) that may benefit from interventions that reduce death. In October 2023, PEPFAR began incorporating CD4 data into monitoring, evaluation, and reporting (MER) indicators to understand the prevalence of AHD among PLHIV, including those newly initiated on treatment in PEPFAR-supported countries and region (OUs). This analysis leverages MER CD4 testing data to estimate AHD prevalence by age and sex, aimed at guiding programming to prevent and address AHD.

Methods: Cumulative CD4 data were extracted from PEPFAR's MER system for PLHIV ≥ 5 years initiating treatment (TX_NEW) between October 2023 and September 2024 (FY24) across 32 of 33 PEPFAR OUs. Those with CD4 testing coverage of 60% or higher among TX_NEW were included, representing the top 20% of OUs in reporting completeness. Proportions of AHD among TX_NEW with CD4 results were disaggregated by age and sex across OUs meeting inclusion criteria. Nigeria was excluded due to ongoing data quality improvement efforts.

Results: CD4 results were documented for 639,012 of 1,515,064TX_NEW clients (42.2%) across 32 PEPFAR OUs. Seven OUs—Central Asia, India, Rwanda, Tanzania, Uganda, Central and South America, and Ukraine—documented CD4 results in ≥60% of their TX_NEW.

The proportions of TX_NEW with known CD4 results presenting with AHD in these seven OUs was 24.7% (range: 22.5% (Tanzania) – 45.1% (Ukraine)).

Among females, 32,572 of 153,601 (21.2%) had AHD, compared to 30,633 of 101,903 males (30.1%). Estimated AHD prevalence was highest (32.5%) among PLHIV aged ≥40 years.

Conclusions: These findings demonstrate low CD4 reporting rates across most PEPFAR OUs and indicate gaps in identifying PLHIV with AHD, limiting access to life-saving interventions. Substantial proportions of PLHIV continue to present with AHD, particularly among men and individuals aged ≥40 years.

These results underscore the importance of enhanced efforts to improve access to CD4 testing, early identification of PLHIV, and initiate ART to prevent AHD.

EP0266

Intentional horizontal transmission of HIV: narratives from people living with HIV in Nigerian hospitals – a mixed-method study

J.C. Onyehalu[1], J.E. Agbo[2], C.B. Nwankwo[1,3], M.M. Abubakar[1,4], C. Nwachuya[1], G. Ezenri[1], A. Ngige[1], C. Idabor[1], E.J. Ugochukwu[1,5], A. Isah[1,5]

[1]Person-Centered HIV Research Team, Department of Clinical Pharmacy and Pharmacy Management, University of Nigeria, Nsukka, Enugu state, Nigeria, [2]ESUT Teaching Hospital Parklane, Enugu state, Nigeria, [3]Lagos University Teaching hospital, Lagos state, Nigeria, [4]Directorate of Therapeutic Services, Medical Services Branch, Nigerian Air Force, Abuja, Nigeria, [5]Department of Clinical Pharmacy and Pharmacy Management, University of Nigeria, Nsukka, 410001, Enugu state, Nigeria

Background: Horizontal HIV transmission remains a major contributor to the HIV prevalence. People living with HIV (PLWHIV) face psychosocial distress, including anger and resentment, which influence their actions and promote HIV transmission.

The aim of this study was to assess the prevalence and factors associated with intentional HIV transmission among PLWHIV in Nigerian teaching hospitals.

Methods: A mixed-method cross-sectional design was utilized in obtaining responses from PLWHIV in two tertiary health facilities: Lagos University Teaching Hospital and Enugu State University Teaching Hospital, Nigeria. Responses were sought from a randomly sampled 300 PLWHIV from December 2024 to January 2025.

The 23-item questionnaire assessed socio-demographics, personal experience and thoughts, acts of intentional HIV transmission, and personal narratives and perspectives. Descriptive, inferential, and thematic analyses were conducted, with significance set at $p < 0.05$.

Results: With a response rate of 74.0%, 222 PLWHIV participated in the study. Of this, 110 (49.5%) were within the ages of 25 and 44 years, 134 (60.4%) were female, and 106 (47.7%) were married. Less than half of the participants [52 (23.4%)] reported experiencing stigma and discrimination, and 110 (49.5%) acknowledged feelings of anger or resentment due to their HIV status.

The participants [28 (12.6%)] admitted to having considered transmitting HIV intentionally. About a third of the respondents, [70 (31.5%)], reported engaging in condom-less sex without disclosing their HIV status.

However, only 22(9.9%) admitted having condom-less sex with the intent of transmitting HIV. Participants' motivation included retaliation and stigma. A participant clearly responded, "*I was so sad; I felt others should experience it too.*". The most reported support systems were families and healthcare providers.

On measures to prevent negative behaviors such as intentional transmission, the most common themes were proper awareness and education. Of the 196 participants who adhered to their ART, 70 (35.7%) engaged in condom-less sex without disclosing their HIV status ($p = 0.009$).

Conclusions: The findings from this study showed that while the prevalence of intentional HIV transmission was low, the practice of condom-less sex remained high among PLWHIV.

Feelings of resentment, stigma, and discrimination, were major factors driving intentional HIV transmission. There is a need for targeted interventions to address stigma, discrimination, and intentional HIV transmission.

EP0267

Identifying key multimorbidity patterns in PWH with moderate and severe CKD using network analysis

M. Byrne[1], A. Monroe[1], B. Braffett[2], M. Horberg[3], A. Castel[1]

[1]George Washington University, Epidemiology, Washington, United States, [2]George Washington University, Biostatistics Center, Rockville, United States, [3]Kaiser Permanente Mid-Atlantic Permanente Medical Group, Rockville, United States

Background: Chronic kidney disease (CKD) in people with HIV (PWH) often co-occurs with other conditions, contributing to multimorbidity (presence of >2 chronic conditions). We used network analyses to explore multimorbidity patterns among PWH with eGFR<60 or eGFR<30.

Methods: We used DC Cohort data (2011-24) from participants with an initial eGFR<60 or eGFR<30 mL/min/1.73m^2 during observation. Covariates included demographic factors (age, sex, race/ethnicity, e.g.) and tenofovir disoproxil (TDF) exposure. Comorbidities were identified with diagnostic codes. We used prevalence and partial correlations between comorbidities to quantify strength of association between two conditions. Mixed graphical models identified multimorbidity patterns and centrality (importance) of each condition.

Results: A total of 3728 participants with an eGFR<60 were included in the analysis. Median age at enrollment was 53.6 years (IQR:46.9–60.0); majority were male (71.9%) and identified as Black (84.2%). Most participants (N=2903;77.9%) had a comorbidity concurrently with reduced eGFR, and the majority had TDF exposure (N=1749;46.9%). Of those, 2080 participants had an eGFR <30. Most common comorbidities were hypertension (67.7% and 64.1%), dyslipidemia (43.5% and 43.9%) among eGFR<30 and eGFR<60, respectively.

The network analysis included 1466 participants with >2 comorbidities and 43 individual conditions. Hypertension had the highest centrality in both networks, indicating its prominent role in multimorbidity, followed by alcohol abuse and chronic obstructive pulmonary disease (COPD) for eGFR<60 and dyslipidemia and COPD for eGFR<30 *[Figure]*.

The steep decline in centrality highlights key conditions influencing multimorbidity patterns among PWH with reduced eGFR. Diabetes, depression, and tobacco use are also relatively central in the network, suggesting strong associations to many conditions.

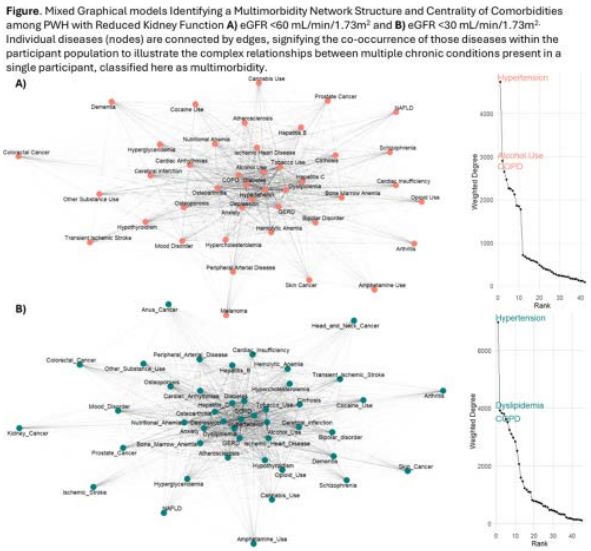


Figure. Mixed Graphical models Identifying a Multimorbidity Network Structure and Centrality of Comorbidities among PWH with Reduced Kidney Function **A)** eGFR <60 mL/min/1.73m^2 and **B)** eGFR <30 mL/min/1.73m^2. Individual diseases (nodes) are connected by edges, signifying the co-occurrence of those diseases within the participant population to illustrate the complex relationships between multiple chronic conditions present in a single participant, classified here as multimorbidity.

Conclusions: We identified relevant multimorbidity patterns among PWH across a spectrum of kidney function. The network analysis results offer a unique approach to identifying influential conditions in highly dimensional data, enabling the prioritization of these conditions for routine screenings in public health strategies and interventions.

EP0268

Is it feasible to eliminate mother-to-child transmission of HIV (MTCT) in Mexico by 2030?

E. Bravo-García[1], H. Ortiz-Pérez[2]
[1]Universidad Nacional Autónoma de México. Facultad de Medicina, Departamento de Salud Pública, Mexico, Mexico, [2]Universidad Autónoma Metropolitana. Unidad Xochimilco, Departamento de Atención a la Salud, Mexico, Mexico

Background: Eliminating MTCT of HIV is a global priority established by the World Health Organization (WHO), with the goal of achieving it by 2030. In accordance with this goal, the Mexican government considers it a fundamental objective within the current health program for the period 2019-2024. The aim was to analyze the evolution of HIV cases related to perinatal transmission during the period between 1986 and 2023.
Methods: An analysis of the historical trend of HIV cases reported as a result of perinatal transmission was carried out, using the data provided by the National Registry of HIV/AIDS Cases of the Ministry of Health.
Results: During the period from 1986 to December 2023, a total of 4,255 cases of HIV associated with MTCT were recorded, representing 1.3% of the total reported cases. The trend in the number of cases was upward until 2006, reaching its peak with 277 diagnosed cases. From 2007 onwards, a general downward trend was observed until 2020. However, in 2021 there was an increase to 63 cases, followed by a decrease in 2022 and 2023, with 51 and 46 cases respectively *(Figure 1)*.

Figure 1. HIV cases by mother-to-child transmission of HIV by year of diagnosis, Mexico 1986-2023.

Conclusions: At the current rate of decline, Mexico will not achieve the MTCT of HIV by 2030. It is unacceptable that, despite having the necessary preventive measures and free and universal access to antiretroviral therapy against HIV, dozens of minors acquire HIV from their mothers every year. Guaranteeing the right of children to be born free of HIV is an ethical imperative that must be an absolute priority.

EP0269

Understanding drivers of HIV infections among men who have sex with men: opportunity for effective and efficiency use of HIV prevention services

Z. Nzeyimana[1], B. Ikuzo[1], G. Nshogoza Rwibasira[1], C. Mambo Muvunyi[2]
[1]Rwanda Biomedical Centre, HIV, Viral Hepatitis, and STIs Division, Kigali, Rwanda, [2]Rwanda Biomedical Centre, Director General, Kigali, Rwanda

Background: Men who have sex with men (MSM) continue to experience a disproportionate burden of HIV infections globally. In 2024, Rwanda Biobehavioural Survey (BBS) among MSM reported that about 5.8% MSM were living with HIV in Rwanda. Understanding the key drivers of HIV transmission in this population is essential for developing effective prevention strategies.
This study determined factors that are linked with HIV infections among MSM in Rwanda.
Methods: We analyzed 2024 BBS among MSM data. The BBS was a cross-sectional study which Respondent Driven Sampling (RDS). The data were weighted using Gile's Successive Sampling (SS) estimator. To determine the drivers, we analyzed variables on participants' sociodemographic, use of HIV pre-exposure prophylaxis (PrEP), sexual behaviors including sex work information, condom use, lubricant use, circumcision, experience of discrimination and violence, and history of sexually transmitted infections. Using STATA 17, logistic regression model was built on factors associated with HIV infections.
Results: Of the 3757 MSM aged from 18 to 67 years with mean age 27. Of them, 53.1% were in Kigali city, 88.5% circumcised, 13% had ever been paid by a woman for sex, 22.5% had ever taken PrEP while about 5.8% (n=239) were tested HIV positive. Of those living with HIV, 70% were aware of their status.
Significantly higher likelihood of having HIV infection (p value<0.05) was among MSM aged 31 years and older [aOR: 23.1 with 95% C.I: 2.8-188.3], living in Northern province [aOR: 59.0 with 95% C.I: 2.9-1203.9], usually using petroleum Jelly as lubricants [aOR: 15.8 with 95% C.I: 1.3-193.9], and Syphilis infection [aOR: 21.0 with 95% C.I: 2.0-224.5].
Conclusions: This study reveals that HIV infections are strongly associated with increasing age, syphilis co-infections, and the frequent use of petroleum jelly as a lubricant. The use of petroleum jelly may damage condom during use, leading to protection failure. HIV prevention interventions should prioritize raising awareness and ensuring MSM have access to appropriate water or silicone based lubricants.
Nevertheless, further research with larger sample sizes is necessary to gain deeper insights into the contributing factors.

Monitoring and population-level interventions for non-HIV outcomes

EP0270

Understanding the intersection of HIV and aging

C. Himabala[1]

[1]Center for Infectious Disease Research in Zambia, Clinical, Lusaka, Zambia

Background: The intersection of HIV and aging in Zambia presents critical challenges for healthcare systems, policymakers, and communities. Advancements in antiretroviral therapy (ART) have enabled longer lives for people living with HIV (PLHIV), leading to an increasing population of individuals aged 50 and above. This demographic faces complex health, social, and economic challenges, including higher prevalence of non-communicable diseases (NCDs), mental health issues, and stigma.

The study aimed to explore these challenges, evaluate healthcare systems, and propose strategies to improve the quality of life for older PLHIV.

Methods: A mixed-methods study was conducted in Lusaka District, encompassing 512 quantitative interviews, 47 key informant interviews, and facility assessments at 11 healthcare centers. Quantitative data were analyzed using STATA and Excel, while thematic analysis of qualitative data was performed with NVivo. The study adhered to ethical standards, securing informed consent and approvals from relevant authorities.

Results: The results reveal that 57.2% of participants reported comorbidities alongside HIV, with hypertension being the most common. Mental health challenges were prominent, with 44.7% experiencing social isolation. Only 36.4% of healthcare facilities had age-specific HIV care plans, and 45.5% offered home-based care services.

Economic barriers significantly affected healthcare access, with 42.4% consistently facing transportation challenges. While support group participation was low at 37.1%, 73.6% of participants expressed willingness to join such groups. Employment was limited, with 28.9% self-employed and many reliant on family support or pensions.

Conclusions: The findings highlight the urgent need for integrated, age-specific healthcare that addresses physical, mental, and economic barriers. Recommended interventions include training healthcare workers in geriatric HIV care, enhancing NCD management, and expanding support systems.

Addressing stigma and promoting community-based care are critical for improving outcomes. These strategies will support healthy aging for PLHIV, align with global health goals, and ensure no one is left behind in the fight against HIV.

EP0271

A novel approach to weight loss: helping People Living with HIV to live well

E. Hamlyn[1], F. Burns[1,2], J. Ferreira[1]

[1]Royal Free Hospital, Ian Charleston Day Centre, London, United Kingdom, [2]University College London, Institute for Global Health, London, United Kingdom

Background: Overweight and Obesity are increasing globally, with associated morbidity and mortality. Helping People living with HIV (PLHIV) who want to lose weight is integral to helping them live well with HIV.

The Imperial Satiety Protocol (I-Satpro) is an evidence-based, holistic approach to weight loss. Participants learn the scientific rationale behind making sustainable changes to eating habits, movement, sleep and self-care - resulting in clinically meaningful weight loss (≥. 10% body weight loss in previous work) and improvements in cardio-metabolic health.

We present results from 2 cohorts of I-SatPro participants from a large urban HIV clinic. There were no specific referral criteria.

Methods: Baseline data were collected on all participants including weight, lipid profile, HBA1C, and demographics.

The programme was delivered (online) in Spring and Summer 2024.

Participants were asked to register weekly weights by email.

Daily emails were sent to reinforce learning.

Results: 41 participants enrolled and engaged with the programme across the 2 cohorts.

	Participants	Age: (yrs)	Age: mean (yrs)	Weight: range (kg)	BMI: range	BMI: mean	Ethnicity: Black African	Ethnicity: White
Women	22	37-66	50.8	61.2-123.8	25.8-45.7	34.01	86%	14%
Men	21	40-68	54.6	87-135	29.1-39.4	34.37	10%	90%

Table 1: Baseline demographics.

1 woman and 3 men were discounted from analysis because they were taking a GLP-1 receptor-agonist. 1 man and 1 woman did not return any follow up weights.

The mean weight loss in women was 5.71Kg (range 2.1-11) and 6.54Kg (range 2-18) in men.

Women lost on average 6.17% of their baseline body weight (range 1.6-12.5) and men lost 6.48% of their baseline weight (range 1.6-17.1). The greatest weight loss was observed in those who engaged fully with the programme until completion.

	HbA1c mmol/mol	LDL mmol/L	Triglycerides	HDL
Women – mean	-0.63	-0.01	-0.18	0
range	(-4 to +3)	(-0.7 to + 0.6)	(–1.3 to +1.1)	(-.9 to+0.4)
n	n = 11	n = 17	n = 17	n = 17
Men - mean	-5.9	-0.59	-0.73	-0.03
range	(-27 to +1)	(–2 to +0.1)	(–2.4 to +0.2)	(-0.5 to +0.2)
n	n = 10	n = 8	n = 10	n = 10

Table 2. Differences in metabolic biomarkers measured before and after the programme. n = number of participants for whom these data were available.

Conclusions: These PLHIV participating in I-SatPro lost a clinically meaningful amount of weight.
In these real world data, greater improvement in metabolic markers was seen in men, however significance is not possible and interpretation is limited by sample size.
Participant feedback indicated significant positive impact on quality of life. These results suggest significant potential benefits of I-SatPro for PLHIV.

EP0272

Effect of nicotine metabolism on risk of myocardial infarction in cigarette smokers with

D. Ahmed[1], W. Bilker[1], X. Han[1], J. Merlin[2], S. Kimmel[3], J. Martin[4], M. Plankey[5], K. Christopoulos[6], L. Hojat[7], L. Bamford[8], S. Napravnik[9], R. Ashare[10], R. Gross[1]
[1]University of Pennsylvania, Department of Biostatistics, Epidemiology and Informatics, Philadelphia, United States, [2]University of Pittsburgh, Department of Medicine, Pittsburgh, United States, [3]University of Florida, Department of Epidemiology, Gainesville, United States, [4]University of California San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [5]Georgetown University, Department of Medicine, Washington, DC, United States, [6]University of California San Francisco, Department of Medicine, San Francisco, United States, [7]Case Western Reserve University, Cleveland, United States, [8]University of California San Diego, San Diego, United States, [9]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [10]University at Buffalo, SUNY, Department of Psychology, Buffalo, United States

Background: The prevalence of smoking in people with HIV (PWH) is 2 to 3 times the general population. Smoking increases risk of myocardial infarction (MI). Faster nicotine metabolism, quantified by the nicotine metabolite ratio (NMR; 3-hydroxycotinine/cotinine), is associated with nicotine dependence and lung cancer, but its causal effect on MI is unknown.
Methods: We conducted a nested case-control study within the Center for AIDS Research Network of Integrated Clinical Systems (CNICS) cohort. Cases were cigarette-smoking PWH with incident adjudicated MI between 1989 and 2020 who had available plasma samples; cigarette-smoking controls were selected by incidence density sampling (goal of 2 controls per case), with individual-level matching on age, race, birth sex, and plasma HIV RNA level.
NMR components were measured by liquid chromatography–tandem mass spectrometry. Conditional logistic regression was used to estimate odds ratios (OR) for the determinants of MI.
Results: We identified 135 cases with MI and 252 controls. Median (IQR) NMR was greater in those with MI [0.51 (0.36 0.73)] than controls [0.47 (0.30, 0.70)]. In conditional logistic regression, higher NMR was associated with greater odds of developing an MI, but the difference did not reach conventional statistical significance (OR: 1.4, 95% CI: 0.97-1.9). History of statin use (OR: 2.5, 95% CI: 1.5-4.1), hypertension (OR: 4.1, 95% CI: 2.5-6.6), and diabetes (OR: 2.2, 95% CI: 1.2-3.9) were associated with MI. Adjusting for these determinants did not substantively change the NMR-MI relationship (OR: 1.4, 95% CI: 0.92-2.0).
Conclusions: Among cigarette-smoking PWH, there was a small-magnitude association between NMR and MI which did not achieve conventional statistical significance. NMR therefore remains a potential biomarker for MI risk among PWH.
Further investigation is needed to estimate the precise effect of NMR on MI in PWH as well as to extend knowledge of NMR's effect on smoking cessation in this population.

EP0273

Associations between serum fatty acids and executive function among a prospective cohort of children with and without perinatal HIV exposure or acquisition from Kampala, Uganda

V. Cardino[1], S. Zalwango[2], J. Fenton[1], A. Ezeamama[3]
[1]Michigan State University, Food Science and Human Nutrition, East Lansing, United States, [2]Kampala Capital City Authority, Kampala, Uganda, [3]Michigan State University, Psychiatry, East Lansing, United States

Background: The relationship between fatty acids and executive function is understudied in child populations affected by HIV in Sub-Saharan Africa, where malnutrition and neuroinflammation persist.
The objectives of this study were to determine associations between serum fatty acids and proxy-reported executive function in Ugandan children and evaluate modification by perinatal HIV status. It was hypothesized that polyunsaturated fatty acids (PUFAs) associated with better executive function, while saturated fatty acids (SFAs) associated with worse executive function, especially among those affected by HIV.
Methods: 6-10-year-old children with perinatally acquired HIV (CPHIV; n=84), children HIV exposed but uninfected (CHEU; n=78), and children HIV unexposed and uninfected (CHUU; n=81) were recruited for a prospective cohort study in Kampala, Uganda. Serum fatty acids were measured at baseline, and caregivers reported child executive dysfunction via the Behavior Assessment System for Children-3 (BASC-3) and the Behavior Rating Inventory of Executive Function (BRIEF) at baseline, 6, and 12 months.
Adjusted linear mixed models assessed mean differences (MDs) and 95% confidence intervals (CIs) in age/sex standardized executive dysfunction z-score by fatty acid tertile. Results are presented by perinatal HIV status for significant fatty acid*HIV interactions ($p<0.10$).
Results: Among all adolescents, a high v. low ω-6:ω-3 ratio (MD [95% CI]: 0.35 [0.04, 0.66]) predicted increased executive dysfunction per BRIEF. Moderate SFA myristic acid (-0.34 [-0.64, -0.05]) and high SFA stearic acid (-0.33 [-0.63, -0.03]) associated with decreased executive dysfunction per BRIEF. CHEU with moderate and high ω-6 linoleic acid levels displayed strong increases in executive dysfunction per both tests (moderate BASC-3: 0.86 [0.11, 1.62]; high BRIEF: 0.66 [0.01, 1.31]), whereas high long-chain PUFAs predicted decreased dysfunction. High SFA arachidic acid

associated with increased executive dysfunction per BRIEF among CHUU (0.62 [0.00, 1.24]) but decreased dysfunction among CHEU (-0.99 [-1.65, -0.33]).

Conclusions: These results support the benefits of a low ω-6:ω-3 ratio for executive function but also highlight a positive association between SFAs and executive function. CHEU may be especially sensitive to long-chain PUFA and SFA intake.

Future studies should explore how fatty acids differentially influence cognitive processing, including scholastic outcomes, in populations affected by HIV and how in-utero/peripartum ART exposure may complicate this relationship.

EP0274

Information-based approach increases vaccine uptake among people living with HIV in the Paris region

A. Kolakowska[1,2], A. Maka[1], E. Krastinova[3,4,2], A. Cros[5], C. Duvivier[6,2], P. Caraux-Paz[7,2], G. Melica[8,2], P. Leroy[9,2], F. Caby[3,10], D. Zucman[11], D. Salmon[12,2], A. Chéret[13,14,2]

[1]Bastia Hospital, Infectious Diseases, Bastia, France, [2]CORESS Île-de-France Sud, Paris, France, [3]Sorbonne Université, INSERM U 1136, Pierre Louis Institute of Epidemiology and Public Health (IPLESP), Équipe de Recherche en Épidémiologie Sociale (ERES), Paris, France, [4]Creteil Hospital, Prevention and Community Health, Creteil, France, [5]COREVIH Île-de-France Sud, Paris, France, [6]Paris Cité University, Necker Hospital, AP-HP, Infectious Diseases, Paris, France, [7]Villeneuve Saint Georges Hospital, Villeneuve-Saint-Georges, France, [8]Henri Mondor Hospital, Créteil, France, [9]Groupe Hospitalier Sud Île-de-France, Infectious Diseases, Public Health Unit, Melun, France, [10]Victor-Dupouy Hospital, HIV and STI Department, Argenteuil, France, [11]Foch Hospital, Internal Medicine, Suresnes, France, [12]Institut Fournier, Infectious Diseases, Paris, France, [13]University Hospital, Service de Plateforme de Diagnostic et Thérapeutique Pluridisciplinaires, Pointe-à-Pitre, Guadeloupe, [14]Inserm U 1016, CNRS UMR 8104, Université Paris Descartes, Institut Cochin, Paris, France

Background: A two-phase, cross-sectional multicenter prospective COVAVIH study was conducted among people living with HIV (PLWH) across 16 hospitals in the Paris region, France (2020-2021). During the initial phase, vaccination coverage was assessed, and participants underwent an intervention providing toolkits on vaccination guidelines for healthcare providers, vaccination counselling, and information leaflets for PLWH.

The study revealed low vaccination coverage despite regular follow-up and free of charge access to vaccines. The primary reason for vaccine reluctance was the lack of vaccination proposals or reminders. Nevertheless, 71% of participants expressed a willingness to get vaccinated. The findings were published (Kolakowska et al. *Vaccine* **42**, 3655–3663 (2024)).

Methods: Three years later, a follow-up survey took place to evaluate the impact of this awareness-raising strategy. Data from both phases were collected through questionnaires completed by participants, healthcare providers, and from medical records. Statistical analysis was performed using R software.

Results: Out of 338 PLWH participating in the 1st phase, 242 were included in the 2nd phase (71.5%). Vaccination coverage increased for all vaccines: DTP 83.9% vs. 56.2%, pneumococcus 75.2% vs. 59.9%, seasonal influenza 56.2% vs. 42.6%, hepatitis B 81.9% vs. 61.6%, hepatitis A 81.7% vs. 57.3%, and MMR 69.6% vs. 37%. However, the increase in vaccine uptake for DTP, hepatitis B and pneumococcus was observed only shortly after the intervention, with the effect diminishing in the following months.

Multivariable analysis in the 2nd phase revealed the following factors associated with vaccine uptake: BMI>30 (aOR=1.96; 1.03-3.8), older age (aOR=1.03; 1.01-1.06), being born in a Sub-Saharan Africa country (aOR=0.3; 0.13-0.7), and a low CD4 nadir (aOR=0.5; 0.26-0.96).

VACCINE	Indication to vaccine	Assessed in the 1st phase as vaccinated/immunized		Assessed in the 1st phase as not vaccinated/immunized	
		still up to date	no more up to date (including unknown status)	currently up to date	still not up to date
DTP	242	128	8	75	31
Pneumococcus	242	130	15	52	45
Seasonal influenza	242	80	23	56	83
MMR (born after 1980)	46	17	0	15	14
Hepatitis B (all uninfected)	138	84	1	29	24
Hepatitis A (when indicated)	213	122	0	52	39

Conclusions: Educational interventions through this multifaceted approach, are essential for increasing vaccine uptake among PLWH. Priority should be given to targeting vulnerable populations, particularly migrants and immunocompromised individuals. To achieve a sustainable result, such interventions should be repeated periodically.

EP0275

Early signals of language delays among preterm children who are HIV-exposed uninfected in Botswana

K. Thankane[1], M.A. Bulterys[2], I. Kitsi[1], S. Schenkel[3], S. Kgole[1], G. Masasa[1], K. Neya[1], A.R. Cassidy[4], K. Powis[3]

[1]Botswana Harvard Health Partnership, Gaborone, Botswana, [2]University of Washington, Global Health, Seattle, United States, [3]Mass General Hospital, Boston, United States, [4]Mayo Clinic, Departments of Psychiatry & Psychology and Pediatric & Adolescent Medicine, Rochester, United States

Background: Children who are HIV-exposed uninfected (CHEU) may still be at greater risk of neurodevelopmental deficits than children who are HIV-unexposed uninfected (CHUU). We evaluated early neurodevelopment among infants with and without perinatal HIV exposure in Gaborone, Botswana.

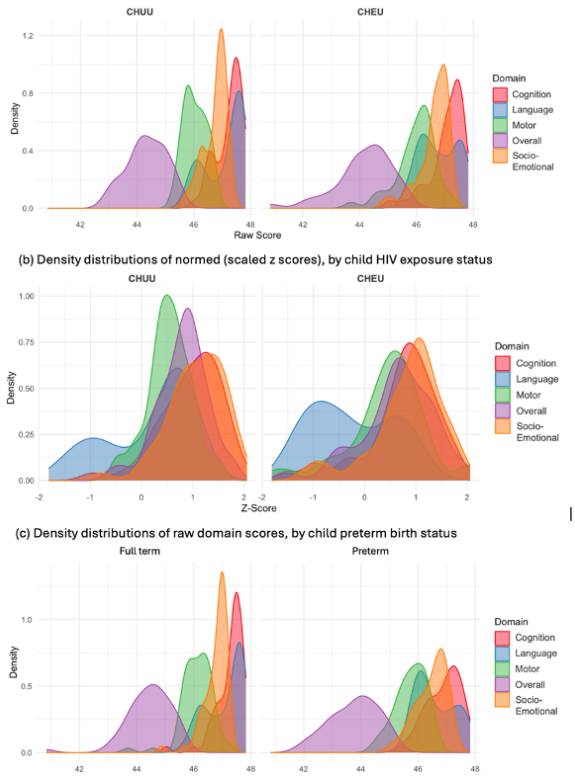
Methods: From October 2023 – June 2024, we enrolled mother-infant pairs, half of whom were mothers living with HIV and their CHEU. As infants reached 6-months of age, mothers were administered the Caregiver Reported Early Developmental Instruments (CREDI), which evaluated infants' overall, motor, language, cognition, and socio-emotional status.

Multivariable linear regression models compared infant raw and scaled z-scores by child HIV exposure status, adjusting for maternal education, marital status, and infant age and sex.

Results: A total of 86 mother-infant pairs were enrolled in Gaborone, Botswana, including 42 CHEU and 44 CHUU. Overall, 57% of children were male and 28% were born prematurely, which was comparable across groups. Compared to CHUU, CHEU were more likely to have older mothers (30 vs. 26 years), and fathers who were not financially supportive (29% vs. 9%) or present in the child's life (21% vs. 16%).

In unadjusted and adjusted models, CHEU scored significantly lower than CHUU in the language domain using both raw scores (coefficient: -0.30; 95% CI: -0.58, -0.01; p=0.04) and scaled z-scores (coefficient: -0.38 (-0.74, -0.02; p=0.03), with no significant differences identified in other domains. Preterm birth was significantly associated with poorer language outcomes among all children, and especially among CHEU.

Figure 1. Density distribution curves of CREDI scores



Conclusions: We saw an unusually high prevalence of preterm births in our cohort of CHEU and CHUU in Botswana. CHEU, and especially those born prematurely, may be at heightened risk of poor early language development. Interventions are urgently needed to identify children exhibiting these risk factors, screen for early developmental delays, and improve language stimulation among children in families affected by HIV.

EP0276

Utilization of prostate cancer screening services and reason for not screening among men living with HIV in Wakiso and Hoima districts, Uganda

V. Ofumbi Olwa[1], A. Daama[1], E. Kyasanku[1], R. Bulamba[1], J. Nkale[1], M. K. Ssebakumba[2], D. Kiwanuka[1], J. Kagaayi[1], F. Nalugoda[3], G. Nakigozi[1], G. Kigozi[1], S. Watya[1,3]

[1]Africa Medical and Behavioural Science Organization, Research, Kampala, Uganda, [2]Uro Care Hospital, Research, Kampala, Uganda, [3]Uro Care Hospital, Clinical, Kampala, Uganda

Background: Prostate cancer, the second leading cause of cancer-related deaths among men worldwide, is a non-AIDS-defining cancer (NADC) with rising incidence among men living with HIV (MLWH). Improved life expectancy in the antiretroviral therapy era increases age-related prostate cancer risk. Early detection through screening can significantly reduce morbidity and mortality but faces substantial challenges.

This study investigates the utilization of prostate cancer screening services and factors influencing their uptake among men aged 40 years and above living with HIV in Wakiso and Hoima districts, Uganda.

Methods: We utilized cross-sectional data from Round 4 of a population health surveillance study conducted by the Africa Medical and Behavioural Science Organization (AMBSO). The ongoing AMBSO cohort study (APHS) implemented in Wakiso and Hoima communities follows up participants annually to monitor disease trends particularly HIV. The communities are stratified into rural, semi-urban, and urban settings. Men aged 40 years and above living with HIV were surveyed at baseline and follow-up using a standardized questionnaire to assess their prostate cancer screening status and identify factors influencing service uptake.

Results: A total of 468 men aged 40 years and above were enrolled in the study, with a mean age of 52 years (SD = 10.02). Of these, 10.8% (50/464) were living with HIV and on antiretroviral therapy. Among MLWH, only 4% (2/50) had ever undergone prostate cancer screening. Among those who had never been screened, 66.7% (32/48) were unaware of the services, 29.2% (14/48) cited unavailability of services, 2% (1/48) reported fear, and the remainder felt they did not need the services.

Conclusions: The study reveals that prostate cancer screening among men living with HIV (MLWH) in Wakiso and Hoima districts remains critically low, with only 4% having ever been screened, compared to the national average of 5%. The primary barriers to uptake include lack of awareness, unavailability of services, fear, and perceived lack of necessity.

These findings emphasize the need for targeted interventions to raise awareness, improve service availability, and address misconceptions. Integrating prostate cancer screening into HIV care programs could enhance early detection, timely treatment, and ultimately reduce morbidity and mortality among MLWH.

EP0277

Scaling the uptake of mental health services and integration into primary health care for people living with HIV in Kenya

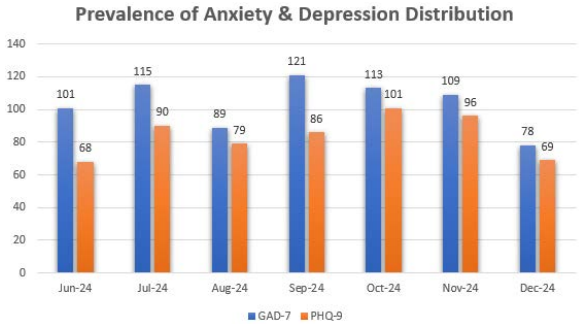
J. Kamau[1], P. Macharia[2], J. Maina[3], J. Mathenge[4], A. Onyango[5]

[1]HOYMAS KENYA, HIV Lead Clinician, Nairobi, Kenya, [2]HOYMAS KENYA, Programs, Nairobi, Kenya, [3]HOYMAS KENYA, Grants, Nairobi, Kenya, [4]HOYMAS KENYA, Executive Director, Nairobi, Kenya, [5]HOYMAS KENYA, Monitoring, Evaluation , Research & Learning, Nairobi, Kenya

Background: Mental health care in Kenya is under-prioritised, mainly addressed at higher care levels. Nearly 50% of adolescents face mental health issues, with depression and anxiety being major causes of disability among youths aged 10-24. One in four Kenyans struggles with mental disorders, yet there is a severe shortage of mental health professionals and facilities and minimal funding.

Description: HOYMAS Kenya, a community-led organization in Nairobi serving Men who have Sex with Men (MSM) and Male Sew Workers (MSW) , has integrated mental health services into its programs to address the mental health gap between June and December 2024. This initiative aimed to improve adherence to ART, reduce substance abuse, and tackle suicide. By centralising de-stigmatized mental health care. Healthcare workers were trained to screen, support, treat, and refer clients for mental health services, ensuring comprehensive integration. Clients were screened using Ministry of Health-approved tools (PHQ-9 and GAD-7).

Lessons learned: Programmatic data collected involving 1027 MSM/MSWs showed a higher prevalence of anxiety compared to depression. There was a surge between July and September owing to the hostility around LGBTQI+ in the country and the high cost of living. 726 clients had a varying degree of anxiety accounting for 70.69% while 589 (57.35%) had varying degree of depression.



Programmatic data collected involving 1027 MSM/MSWs showed a higher prevalence of anxiety compared to depression. There was a surge between July and September owing to the hostility around LGBTQI+ in the country and the high cost of living. 726 clients had a varying degree of anxiety accounting for 70.69% while 589 (57.35%) had varying degree of depression.

Conclusions/Next steps: Mental disorders and substance abuse often lack visible symptoms, complicating diagnosis and intervention. While more clients are seeking mental health services, barriers such as reluctance to engage with peer or clinical support persist. Capacity building for health care workers is crucial to successful service integration.

Recommendations:

- Promote mental health literacy to reduce stigma.
- Increase staffing in primary healthcare to improve service quality.
- Integrate telehealth to reduce wait times in overburdened facilities.
- Implement suicide prevention measures, including policy changes to decriminalize suicide.
- Secure adequate funding for mental health programs.
- Advocate for workplace policies that promote mental health.

EP0278

Trends in alcohol use among people living with HIV in South Central Uganda (2015-2020): divergent patterns by sex and concurrent substance use

A. Kasango[1], H. Nakawooya[1], V. Ssempijja[2], A. Ssettuba[1], E.N. Kankaka[1], A. Ndyanabo[1], M. Wawer[3], D. Serwadda[1], R. Gray[3], J. Kagaayi[4], S. Reynolds[2], T. Lutalo[1], L.W. Chang[3], K. Grabowski[3], R. Ssekubugu[1], R.M. Galiwango[1], G. Nakigozi[1], G. Kigozi[1], F. Nalugoda[1]

[1]Rakai Health Sciences Program, Kalisizo, Uganda, [2]National Institutes of Health, Bethesda, United States, [3]Johns Hopkins University, Baltimore, United States, [4]Makerere University School of Public Health, Kampala, Uganda

Background: Among people living with HIV (PLHIV) in Africa, alcohol use is associated with several detrimental health outcomes, including reduced adherence to antiretroviral therapy, poor viral load suppression, increased susceptibility to chronic conditions, and higher morbidity and mortality. However, population-level data on trends in alcohol use and associated consequences are rare among African PLHIV.

Methods: Data of PLHIV aged 15-49 in the Rakai Community Cohort Study (RCCS), a population-based HIV surveillance cohort were analyzed for periods 2015–2016 (n=3621), 2016–2018 (n=3641), and 2018-2020 (n=3350). Socio-demographic and behavioral characteristics were analyzed. Alcohol use was defined as any self-reported use in the past 12 months. Consequences of alcohol use were assessed using the Alcohol Use Disorder Identification Test (AUDIT). We used the $\chi 2$ test for trend to compare proportions of alcohol use across survey rounds, and modified Poisson regression, through a generalized linear model, to assess predictors of alcohol use. Variables with a cutoff $p<0.1$ were included in the model.

Results: Alcohol use decreased from 57.5% (2083/3621) in 2015–2016 to 54.4% (1823/3350) in 2018–2020 ($p=0.018$). Among females, it declined from 50.0% in 2015–2016 to 43.8% in 2018–2020 ($p<0.001$). However, among males, an increase from 70.6% to 73.2% was observed over the same period ($p<0.001$).

In the multivariable analysis, alcohol consumption was significantly higher among males, previously married, smokers, illicit substance users (marijuana and khat), and those working in bars, truckers or boda riders.

Significant declines in adverse outcomes of alcohol use were observed between 2015–2016 and 2018–2020: unsteady gait (28.9% to 17.1%, p<0.001), blackouts (14.3% to 11.2%, p=0.012), violence (14.1% to 10.3%, p<0.001), shaky hands (10.2% to 7.6%, p=0.017) and feelings of shame following what was done under the influence of alcohol (14.9% to 11.5%, p=0.008). These declines were more pronounced among the females.

Conclusions: While overall alcohol consumption and associated effects decreased, higher use among men, already more likely to be viremic than women, remains a concern. Notably, there are high rates of concurrent alcohol and substance use irrespective of gender.

These findings underscore the urgent need for integrated alcohol and substance use screening in routine HIV care.

EP0279

Accelerating progress in WHO 70-90 global cervical cancer screening and treatment targets for women living with HIV through PEPFAR support: achievements of the go Further partnership in 12 countries

B. Odion[1], C. LoVullo[1], T. Bingham[2], E.K. Dokubo[1], M. Chevalier[1]
[1]Bureau of Global Health Security and Diplomacy, Program Quality, Washington DC, United States, [2]Centers for Disease Control and Prevention (CDC), Atlanta, United States

Background: Women living with HIV (WLHIV) develop cervical cancer (CC) at sixfold higher risk. In 2021, the World Health Organization (WHO) launched its 90-70-90 strategy targeting the elimination of cervical cancer (CC) as a public health threat by 2030. The United States President's Emergency Plan for AIDS Relief (PEPFAR) through the Go Further (GF) partnership, supports 12 African countries with CC screening and the treatment of precancerous lesions (PCLs) among WLHIV on antiretroviral therapy (ART). We examined progress in achieving WHO 70-90 targets for CC screening and treatment of PCLs, respectively, between fiscal years 2021-2024 in PEPFAR GF countries.

Methods: We reviewed semi-annual PEPFAR programmatic data on CC screening and treatment of PCLs among WLHIV (15+ years) in 12 PEPFAR-supported GF countries between October 2020 (FY2021) and June 2024 (FY2024). Screening methodologies included visual inspection with acetic acid and Human Papillomavirus (HPV) testing, and treatment of PCLs was by cryotherapy, thermal coagulation or Loop Electrosurgical Excision procedure. The Joint United Nations Programme on HIV/AIDS (UNAIDS) aidsinfo data was used to estimate the number of WLHIV (15+ yrs) in the 12 GF countries. We calculated CC screening and PCL treatment rates from FY21 to FY24 to assess progress towards WHO targets.

Results: As of FY2024, PEPFAR screened 6.9 of 7 million WLHIV (15+ years) in 12 GF countries (98% screening coverage). From FY2021 to FY2024, there was a 146% increase in the number of WLHIV who received CC screening (2.8 million to 6.9 million). Of the 424,646 who screened positive for PCL, 300,661 were first-time screens, representing 5.34% of all WLHIV on ART screened from FY2021-FY2024. First-time screenings dropped from 82% in FY2021 to 50% in FY2024, while rescreening rates increased from 15% to 47%, respectively. As of FY2024, five (Ethiopia, Lesotho, Mozambique, Namibia and Tanzania) of the twelve GF countries surpassed the WHO target of 90% treatment rate for PCLs.

Conclusions: PEPFAR has made substantial progress in reaching WHO 70-90 targets among WLHIV in the 12 Go-Further countries, with screening and PCL treatment services. To sustain the gains, continued national and donor investments are needed to integrate CC/HIV prevention services into health systems.

EP0280

Prevalence, characteristics, and correlates of physical frailty among people with HIV over 50 in clinical care in Kumasi, Ghana

P. Tawiah[1], D. Opoku Aninng[1], M. Addae[1], E. Konadu[1], B. Hansel Sambian[1], N.A. Abruquah[1], K. Faka-Gyan[1], E. Oduro[1], G. Twumasi[1], Y.T. Boadu[1], B. Barnie[1], A. Werekuu[2], N. Tagoe[1], K. So-Armah[3], N.K. Ayisi-Boateng[1], The Kwame Nkrumah University of Science and Technology Aging and HIV Outcome Study Team
[1]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [2]Lawrence General Hospital, Lawrence, United States, [3]Boston University, Boston, United States

Background: The globally aging population of people with HIV (PWH) is at increased risk for discrete multi-morbidity associated with aging (e.g., hypertensive, metabolic, and renal diseases) as well as nonspecific aging health deficits embodied as frailty. Recent advances in frailty research in aging PWH in sub-Saharan Africa where majority of PWH live suggests frailty prevalence ranging from 5-20%. These studies have not included data from West African countries. We assessed the prevalence, characteristics and sociodemographic and morbidity correlates of physical frailty among PWH presenting for clinical care in Kumasi, Ghana.

Methods: PWH 50 years and older with at least 6 months of HIV antiretroviral therapy were enrolled during routine clinic visit to the Kwame Nkrumah University of Science and Technology Infectious Disease Unit.

We defined physical frailty as meeting three out of the 5 following criteria: impaired grip strength and walking speed, fatigue, falling physical activity levels, and BMI in the lowest 20% (as a proxy for unintentional weight loss). We defined pre-frailty as having 1-2 of these criteria. Demographics and socioeconomics were self-reported; clinical data was abstracted from medical records; physical and mental health assessments were performed and compared by frailty levels.

Results: Of 160 participants (68% female, 78% HIV diagnosis duration ≥5 years), 56% were aged 50-59, 35% were aged 60-69 and 9% were aged 70+ years. Frailty prevalence was 13%; 70% were prefrail with exhaustion being the most prevalent pre-frailty criterion (Figure).

Uncontrolled hypertension prevalence was 57% (55%, 56%, and 61% in frail, pre-frail and robust groups, respectively). Diabetes (8%) and dyslipidemia (4%) prevalence were low

though 51% had obesity/overweight (40%, 51%, and 60% in frail, pre-frail and robust groups, respectively). Almost all (99%) reported full function in activities of daily living. Moderate or higher depression (7%) or anxiety (5%) were uncommon.

Conclusions: Frailty and exhaustion related pre-frailty are important clinical considerations in aging PWH in Ghana, where functional impairment appears rare. Integrating geriatric care or principles into HIV care may be an important way to continue to extend quality and quantity of life for aging PWH.

Methodology to support epidemiological studies

EP0281

Overcoming barriers to biometric registration for PLHIV, insights from EpiC project implementation achieving over 99.4% across Arusha CC and Meru DC

R. Kimaro[1], M. Gwerino[1]

[1]Youth Wings Organization, Program, Arusha, The United Republic of Tanzania

Background: This study examines factors enabling successful biometric registration among People Living with HIV (PLHIV) under the EpiC project, aimed at enhancing healthcare outcomes and client tracking efficiency.

Supported by FHI360 in partnership with Tanzania's Ministry of Health, YOUTH WINGS Organization implements the project in Meru DC and Arusha CC, funded by PEPFAR-USAID. Operating in 10 regions, the initiative strengthens healthcare systems and ensures effective care delivery for PLHIV through improved registration and tracking mechanisms.

Description: Biometric registration ensures accurate tracking of Recipients of Care (RoC) within healthcare systems, enabling the delivery of appropriate treatment and care. This system eliminates RoC who may appear in records but are not actively in care, allowing health providers to allocate resources effectively based on actual needs. Since its introduction, biometric registration has improved client tracking transparency and clarified the true number of active RoC.

However, achieving full coverage remains challenging due to barriers such as fear of stigma, privacy concerns, and suspicions about government data use. Understanding the factors driving the high biometric registration rates in Arusha CC and Meru DC is crucial to replicating this success.

Lessons learned: The combination of mentorship, personalized client engagement, and targeted outreach proved effective in addressing client concerns and misconceptions about biometric registration.

The role of peer navigators was crucial in building trust and ensuring that clients understood the benefits of registration while respecting their autonomy.

The success of this initiative demonstrates the importance of flexibility in service delivery and the need for client-centered approaches in healthcare interventions for PLHIV.

Conclusions/Next steps: Achieving over 99.4% biometric registration for RoC in Arusha CC and Meru DC highlights the success of mentorship, tailored outreach, and decentralized health services for PLHIV. This approach effectively tackled client resistance and misinformation, ensuring nearly all eligible clients were registered. By prioritizing client-centered care and community involvement, the initiative offers a model for improving tracking and care under the EpiC project in other regions. Future efforts should focus on addressing remaining barriers and sustaining a robust registry system, vital for enhancing health outcomes and long-term support for PLHIV. This success underscores the importance of adaptive and inclusive strategies.

EP0282

Modeling retention in care and final outcomes among infants born to Mothers living with HIV in Rwanda: a survival analysis

N. Christian[1], R. Gallican[1], U. Djemima[1], A. Taofeek Tope[2], G. Gaetan[1], M. Mireille[1], T. Isabelle[1], M. Fatima[1], K. Claude[1], N. Philemon[1]

[1]Rwanda Biomedical Centre, HIV/AIDS, STI and OBBI, Kigali City, Rwanda, [2]University of Rwanda, Microbiology & Parasitology, Butare, Rwanda

Background: Retention in care among infants born to mothers living with HIV is a critical metric for the success of Prevention of Mother-to-Child Transmission (PMTCT). While Rwanda has made significant progress in reducing vertical HIV transmission, gaps remain in long-term infant retention, particularly during the early postnatal period.

This study aimed to predict retention rates in HIV care and HIV positivity rates at various intervals of routine follow-up to inform targeted interventions.

Methods: This study analysed data from 9,776 mother-infant pairs in Rwanda, recorded between June 2016 and July 2021 in all health facilities across the country, utilizing longitudinal clinical records. Retention rates were assessed at 6 weeks, 9 months, 18 months, and 24 months using Kaplan-Meier survival curves. Predictors of retention and HIV positivity were examined using Cox proportional hazards models, with maternal variables such as ART regimens, maternal viral load, and clinical outcomes included.

Results: Retention declined sharply within the first five months, stabilizing around the fifth month. By 24 months, the retention rate was approximately 68.1%, with most losses occurring early. HIV positivity rates declined across intervals, starting from 0.48% at 6 weeks, decreasing to 0.22% at 9 months, 0.11% at 18 months, and reaching 0.05% at 24 months.

Maternal age significantly impacted retention; the maternal median age was 36 years (IQR 31–40 years). For every 1-year increase in maternal age, the likelihood of

retention increased by 1% (Exp(coef) = 0.99, p < 0.005). Regional disparities were observed, with Kigali City showing a 19% higher likelihood of retention compared to the Eastern Province (Exp(coef) = 1.19, 95% CI: 1.06–1.33, p < 0.005).
Conclusions: Retention in care for HIV-exposed infants remains a challenge, particularly during the early postnatal period, underscoring the need for targeted interventions within the first five months.
The decline in HIV positivity rates highlights the effectiveness of Rwanda's PMTCT programs, though further efforts are needed to address retention gaps and regional disparities.
Strengthening maternal ART adherence, optimizing postnatal follow-up, and tailoring region-specific strategies can enhance retention and reduce transmission. These findings offer actionable insights to refine PMTCT programs in Rwanda and similar settings.

Surveillance: Measuring the HIV pandemic

EP0283

Outcomes from phase 1 implementation of recent HIV infection surveillance in the North and West regions of Cameroon, 2022-2024

T. Kingsly Nkwoh[1], A. Rogers Awoh[2], J. Fokam[3], Z. Albert Meka[3], G. Loni Ekali[4], T. Gladys[4], E. Pascal Roland[4], N. Elong[4], M. Agathe[4], K. A. Bosh[1], Y. Moussa Fadil[1], L. Eno[1], T. Ebako[1], C. Keleko[1], D. Nembot Fabrice[1], T. Ayukotabe[1], A. Carrine[1], T. Dobbs[5], R. Domaoal[5], E. Yufenyuy[5], C. Owens[5], M. F. Jalloh[1]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Yaounde, Cameroon, [2]Cameroon Ministry of Public Health, Coordination Unit for HIV, TB, and Malaria, Yaounde, Cameroon, [3]Cameroon Ministry of Public Health, National AIDS Control Committee, Yaounde, Cameroon, [4]ICAP at Columbia University, Maroua, Cameroon, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States

Background: Although Cameroon is nearing HIV epidemic control, over 12,000 new infections are reported annually. With the goal to inform policies on public health interventions to prevent HIV transmission, we established and implemented recent HIV-1 infection surveillance in the North and West regions of Cameroon.
Methods: A cross-sectional surveillance investigation was conducted to monitor recent HIV-1 infections in 30 facilities in the West and North Regions of Cameroon from October 2022 through September 2024. HIV-1 recency testing was systematically offered to all eligible clients aged ≥15 years with newly diagnosed HIV-1 infection.
A rapid test for recent HIV-1 infection was performed and viral load testing was used to improve the accuracy of classification, with results classified as either "recent" (acquired within 12 months) or "long-term" (over 12 months). Descriptive statistical analysis was performed to show the distribution of new HIV-1 infections by demographic characteristics.
Multivariable logistic regression was used to identify correlates of recent HIV-1 infection.
Results: A total of 3,746 clients aged 15 years and older with newly diagnosed HIV-1 were offered recency testing and 3,528 (94.2%) consented. Recent HIV-1 infection was confirmed in 114 (3.3%) clients using recent infection testing algorithm.
The proportion of recent infections was higher in the North versus the West region (3.9% vs. 2.4% p=0.023), in clients aged 15-24 versus those 25 years and older (5.3% vs 3.0% p=0.007), and in people who self-identified with key populations (KP) versus non-KP (7.3% vs. 2.9% p<0.001).
The odds of recent infections were 69% greater in the North compared to the West region (AOR 1.69; 95% CI: 1.03-2.76). Moreover, the odds of recent infections were doubled in KP compared to non-KP clients (AOR: 2.33, 95% CI 1.37-3.96) and doubled among those who were divorced or separated compared to those who were married or living together (AOR: 2.17, 95% CI: 1.24-3.80).
Conclusions: We successfully implemented and differentiated outcomes of HIV-1 recency surveillance in two Cameroonian regions. The findings can inform more targeted public health and social responses to tackle new infections. Additional qualitative investigations would help explore the association between recent infections and divorce/separation.

EP0284

Trends in TB/HIV co-infection and TB treatment outcomes in selected tertiary facilities in North Central Nigeria: a 5-year review

O. Salau[1], P. Opara[2], C. Ogbudebe[3], L. Ugochukwu[3], T. Bot[4], J. Diara[5], R. Kifasi[6], B. Odume[7]
[1]KNCV Nigeria, Strategic Information, Lafia, Nigeria, [2]KNCV Nigeria, Programs, Lafia, Nigeria, [3]KNCV Nigeria, Strategic Information, FCT Abuja, Nigeria, [4]KNCV Nigeria, Programs, Jalingo, Nigeria, [5]KNCV Nigeria, Programs, Makurdi, Nigeria, [6]KNCV Nigeria, Programs, Jos, Nigeria, [7]KNCV Nigeria, Executive Directorate, FCT Abuja, Nigeria

Background: Tuberculosis (TB) remains a leading cause of morbidity and mortality among people living with HIV (PLHIV). TB/HIV co-infection poses challenges to treatment outcomes, requiring analysis of favourable (treatment success) and unfavourable (death, failure, loss to follow-up) outcomes to inform programmatic improvements.
This study reviews trends in TB treatment outcomes among TB/HIV co-infected individuals in tertiary facilities in North Central Nigeria over five years.
Description: A retrospective analysis of clinical and programmatic data was conducted for TB/HIV co-infected individuals treated at DOT units in tertiary facilities across Benue, Plateau, Nasarawa, and Taraba States from 2020 to 2024. Data sources included TB treatment registers, treatment cards, and laboratory records. Treatment out-

comes were categorized as favourable (treatment success) or unfavourable (death, failure, or loss to follow-up), with trends analyzed descriptively.

Lessons learned: Over five years, 1,005 pulmonary TB cases were identified among PLHIV (53% female; 4% children). Of these, 988 (98%) were enrolled in care. Favourable treatment outcomes improved from 65% in 2020 to 73% in 2024. Mortality rates declined from 12% to 8%, while loss to follow-up decreased from 17% to 6%, driven by enhanced DOT services. Loss to follow-up constituted 56% of unfavourable outcomes, predominantly among male patients by 2%.

Five-year Trend of TB/HIV Co-infection and TB Treatment Outcomes

		TB Treatment Outcomes									
Sex/Age Disaggregation		Sum of TB/HIV Patients Diagnosed	Sum of TB/HIV Patients on Treatment	Sum of TB/HIV Patients Cured	Sum of TB/HIV Patients Treatment completed	Sum of TB/HIV Patients Died	Sum of TB/HIV Patients Treatment Failure	Sum of TB/HIV Patients Loss to Follow up	Sum of TB/HIV Patients still on treatment	Favourable outcomes (Treatment successes)	Unfavourable outcomes
Sex	Male	471	463	141	193	47	1	69	12	334 (74%)	117 (26%)
	Female	534	525	148	243	57	0	65	12	391 (76%)	122 (24%)
Age	Children (0-14 yrs)	36	36	4	18	4	0	10	0	22 (61%)	14 (39%)
	Adult (>14 yrs)	969	952	285	418	100	1	124	24	703 (76%)	225 (24%)
Total TB/HIV Clients		1005	988	289	436	104	1	134	24	725 (75%)	239 (25%)
Proportion of children		4%	4%	1%	4%	4%	0%	7%	0%	22 (3%)	14 (6%)

Table 1: Showing Five years trend of the Favourable and Unfavourable TB treatment outcome cascade among TB/HIV co infected Patients.

Conclusions/Next steps: The findings reveal significant progress in achieving favourable TB treatment outcomes among TB/HIV co-infected individuals, with improvements in treatment success and reduced mortality. Persistent challenges with loss to follow-up underscore the need for strengthened DOT services and integrated TB/HIV care to sustain these gains. These insights are crucial for optimizing TB/HIV co-management in high-burden settings.

EP0285

Coverage gaps in HIV recent infection testing in community settings in Lusaka, Zambia, October to December 2022

Y. Bwalya[1], M. Nsofu[1], L. Phiri[1], S. Nyimbili[1], M. Mubanga[1], K. Moomba[1], M. Lumpa[1], K. Kamalonga[2], D. Nsofwa[2], K. Nkwemu[2], J. Mzyece[3], M. Herce[1], T. Savory[1], I. Sikazwe[1], L. Mulenga[3]

[1]The Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [2]Division of Global HIV and TB, Global Health Center, U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, [3]Ministry of Health Zambia, Lusaka, Zambia

Background: The Zambia recent HIV infection surveillance (recency) program was launched in 2020 in high HIV incidence districts. Blood specimens for recent HIV infection and baseline viral load are collected from individuals newly testing HIV-positive to follow a recent infection testing algorithm (RITA). RITA results help map areas of potential HIV transmission to inform a targeted, public health response. A cornerstone of the program is the timely collection of standardized and accurate data. Here we evaluate coverage gaps in recency testing in community settings within Lusaka Province, Zambia and describe barriers to comprehensive surveillance.

Methods: We collected cross-sectional data between October-December 2022 from five community-based HIV testing sites attached to five general hospitals and primary health centers. Clients found HIV-positive in the community received recency testing from the respective health facilities. We evaluated coverage by comparing the number of community HIV positive tests vs facility recency tests.

Data were collected through a review of facility-level records and assessed for completeness and accuracy using community HIV testing records as source documentation. Feedback on challenges and gaps in processes was gathered from healthcare providers during routine data quality audits.

Results: Out of 295 HIV-positive individuals that tested positive in the community, 194 (66%) underwent recency testing at health facilities. Coverage varied significantly across sites, between 28% (13/46) and 100% (20/20).

Missed sample collection was the driver of the variance in coverage and was primarily attributed to a lack of clinical staff accompanying community teams and the logistical challenges of testing clients who opted to start ART at other facilities.

Community HIV Recent Infection Testing Coverage in Lusaka, Zambia, October to December 2022.

	Kanyama Genral Hospital	Matero General Hospital	Chelstone Urban Health Center	Chipata General Hospital	Bauleni Urban Health Center
Community HTS Pos	104	82	46	43	20
Recency Test Done	74	48	13	21	20
Recency Test Not Done	30	34	33	22	0
Coverage	71%	59%	28%	49%	100%

Conclusions: The findings highlight the impact of missed sample collection, which hinder the integration of recent infection testing into community-based HIV testing sites. Routine assessment of coverage gaps can inform the development of targeted interventions.

EP0286

Geospatial analysis of recent HIV infection in Zambia, April 2023 to September 2023

M. Mubanga[1], S. Fwoloshi[2], C. Nkwemu[1], L. Phiri[1], M. Mulabe[1], J. Mzyece[2], S. Nyimbili[1,3], J. Mutale[1], K. Kamalonga[4], S. Mwape[2], M. Lumpa[1], K. Moomba[1], M. Arons[5], L. Mulenga[2], T. Savory[1], J.M. Pry[6,1]

[1]The Centre for Infectious Disease Research in Zambia, Strategic Information, Lusaka, Zambia, [2]Ministry of Health, Lusaka, Zambia, [3]New York University, Department of Population Health, Grossman School of Medicine, New York, United States, [4]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Global Health Center, Lusaka, Zambia, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Global Health Center, Atlanta, United States, [6]University of California, Division of Epidemiology, School of Medicine, Davis, United States

Background: HIV recency assays have been used in the identification of populations and geographic areas that are at high risk of new infection. The Zambia recent HIV infection surveillance program began in early 2020. Here, we present results from surveillance data that mapped HIV hotspots from 27 districts across 6 provinces in Zambia.

Methods: We conducted a geospatial analysis using HIV recent infection surveillance data collected from April through September 2023 Data were obtained from the Zambian national laboratory surveillance system, and routine monthly HIV testing information. Recent HIV infection (acquired ≤12 months) was defined based on a positive rapid test for recent infection (RTRI; Asante™) and unsuppressed baseline viral load (VL) with ≥1000 copies RNA/ml which forms the basis of the rapid test for recent infection algorithm (RITA). Hotspot areas were defined using discrete Poisson scan statistics using SaTScan v10.3 with a radius of 10 kilometers, and clusters of recent HIV infection described using sex (male/female), age (<30, ≥30) and health facility geocodes.

Results: Out of 31,435 eligible HIV positive tests, 22,897 (72.8%) Asante™ tests were performed, and 2,984 (13.0%) tested RTRI-recent, and 1,132 (4.9%) RITA-recent. Of the 1,132, 69.5% were female, with individuals aged 20-34 comprising most cases (63.6%; 720/1,132). Geographical hotspots were identified in 3 provinces – Lusaka, Copperbelt and Eastern Provinces, Figure 1.

Figure 1. Geospatial Map of Zambia showing High HIV Acquisition Areas Between April and September 2023. Figure 1a1c Enlarged Views of Hotspot Areas Identified in Figure 1

Figure 1a. Copperbelt Province

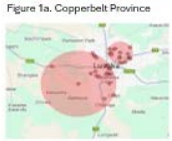


Figure 1b. Lusaka Province

Figure 1c. Eastern Province

Conclusions: Using the Asante™ rapid test, it was possible to identify HIV acquisition hotspots. Although the provinces identified are commercial hubs, they are diverse in environment, socio-economic context and cultural diversity. Results from recency surveillance along with other program data were key to understanding and responding to the current context.

EP0287

Recent HIV infection in urban and rural settings among pregnant and breastfeeding women in Zambia: a comparative analysis

M. Mulabe[1], C. Nkwemu[1], S. Nyimbili[2], K. Chiyenu[1], L. Phiri[1], M. Mubanga[1], K. Moomba[1], M. Lumpa[1], J. Mzyee[3], T. Savory[1], S. Fwoloshi[3]

[1]Center for Infectious Diseases Research in Zambia, Lusaka, Zambia, [2]New York University Grossman School of Medicine, New York, United States, [3]Ministry of Health Zambia, Lusaka, Zambia

Background: Women of reproductive age (15-49 years) in Zambia remain at high risk of acquiring HIV, posing significant challenges to efforts aimed at eliminating mother-to-child transmission (MTCT) of HIV. In high-prevalence settings, without intervention, the risk of vertical transmission ranges between 15% and 45%, with contributions of 5%-10% during pregnancy, 10%-20% during labor and delivery, and 5%-20% through breastfeeding.

This study compares recent HIV infections among pregnant and breastfeeding women (PBFW) in urban and rural settings in Zambia.

Methods: Data were analysed from the recent HIV surveillance (recency) program covering February 2020 to December 2023. We included PBFW aged between 15-49 years, tested in Lusaka and Copperbelt provinces, at 112 health facilities in two urban districts and 33 health facilities in two rural districts. Outcomes were compared using chi-squared tests.

Results: During the follow-up period, 33,857 recency tests were conducted of which 18% (6,238) were PBFW. Among the 6,238, 9.6% (599) were breastfeeding, and 90.3% (5,639) were pregnant. A total of 201 (3.2%) tests were from rural areas, and 6,037 (96.7%) were from urban areas. The proportion of recent infections was higher in rural settings at 17.4% (35/201) compared to 11.3% (685/6,081) in urban settings ($\chi^2 = 7.24$, $p = 0.007$).

When comparing groups, recent infections were higher among breastfeeding women, 17% (100/599), compared to pregnant women 11% (620/5639). Age distribution showed that younger women (15–24 years) accounted for a larger proportion of recent infections in rural settings (54% [109/201]) compared to urban settings (39% [2372/6081]). In both settings, antenatal care was the most common entry point into HIV services.

Conclusions: Despite differences in recency testing coverage driven by population density, the findings emphasize the need for targeted age-specific interventions in urban and rural areas to reduce HIV acquisition among PBFW, a critical step in preventing MTCT. Rural areas may require strengthened intervention programs, and expanded ac-

cess to testing services among the PBFW. Our study was limited to two high-burden provinces; however, expansion to more sites may provide more representative data and new insights in other regions of the Country.

EP0288

Tanzania bio-behavioral survey and population size estimation among women at high risk for HIV and sexually exploited girls in Dar es Salaam and Tanga, 2023

K. Kakulu[1]

[1]East African Sex Workers Alliance (EASWA), Program, Dar es Salaam, Tanzania, the United Republic of

Background: The Tanzania Biobehavioral Survey and Population Size Estimation (BBS and PSE), conducted by ICAP at Columbia University in partnership with the Tanzania Ministry of Health, CDC, NASHCoP, NIMR, NPHL, and MUHAS, aimed to evaluate progress towards the UNAIDS 95-95-95 targets.

The study focused on estimating the population size of women at high risk (WHR) for HIV and sexually exploited girls (SEG), identifying health and social challenges, and gathering data to guide HIV prevention strategies. I played a pivotal role as the community technical expert, ensuring ethical implementation, cultural relevance, and community trust throughout the survey.

Methods: From August to November 2023, the study used respondent-driven sampling (RDS) to recruit 1,009 WHR/SEG—776 from Dar es Salaam and 233 from Tanga City Council. Participants underwent behavioral interviews and biomarker testing for HIV, hepatitis B, hepatitis C, and syphilis. Emphasis was placed on community oversight to ensure ethical standards and culturally sensitive methodologies.

Achievements included strengthening referral systems, refining outreach strategies, and improving stakeholder engagement to boost community support.

Results: HIV prevalence among WHR/SEG was 17.0% in Dar es Salaam and 12.9% in Tanga. Incidence rates were 193 and 564 per 100,000 person-years, respectively. Viral suppression rates were 80.2% in Dar es Salaam and 58.4% in Tanga. The survey revealed high rates of physical and sexual violence (53.2% in Dar es Salaam, 37.4% in Tanga) and limited PrEP uptake (43.4% in Dar es Salaam, 43.9% in Tanga), especially in Tanga, where access to prevention and care services was significantly lacking.

Conclusions: This study highlights the value of multi-stakeholder partnerships in addressing HIV among vulnerable groups. It underscores the need for improved outreach, increased PrEP access, and integrated programs to combat gender-based violence.

By addressing these gaps, Tanzania can make significant strides toward achieving the UNAIDS 95-95-95 targets and improving health outcomes for WHR/SEG.

EP0289

Recent HIV infections and hotspot identification among key populations and their sexual partners in Ukraine, October 2021 to September 2024

M. Michalak[1], E. Barzilay[2], N. Podolchak[2], L. Dobrovolska[2], I. Doan[2], O. Lebega[2], M. Martin[1], D. Miller[1], K. Decker Pulice[1], U. Ijeoma[1]

[1]United States Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Atlanta, United States, [2]United States Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Kyiv, Ukraine

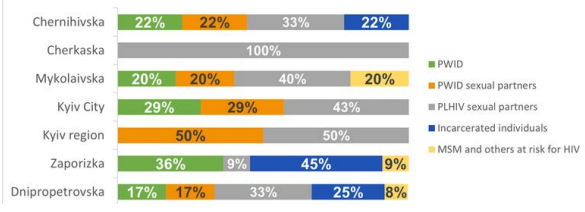
Background: Surveillance of recent HIV infection (RHI), infections occurring within the preceding 12 months, is critical for identifying active transmission, including among Key Populations (KP) and their sexual partners. In Ukraine, RHI surveillance is conducted in 13 of 24 regions.

Methods: RHI is defined by a first-time HIV diagnosis with a positive rapid test for recent infection and viral load >1000 copies/mL. Using RHI surveillance and demographic data, from October 2021 to September 2024 in 52 sites across 13 regions, U.S. Centers for Disease Control and Prevention (CDC) Ukraine and the Ukraine Public Health Center (PHC) identified hotspots using the following criteria:

- Local: Facilities reporting ≥ 2 new RHI cases within 30 days
- Regional: RHI comprising ≥ 5% of all newly diagnosed HIV cases within a quarter
- National: ≥ 2 standard deviations increase in RHI cases over 6 months

Results: During the surveillance period, 11,960 individuals were tested for RHI across 13 regions, with 0-7 hotspots identified per region. The percentage of RHI among newly-diagnosed cases was greater among Key Populations (KP); men who have sex with men (MSM) at 4.8% (438) and people who inject drugs (PWID) at 3.1% (2,962), versus 2.6% (8,506) among the general population. In 6 of the 7 regions with the most identified hotspots, at least 33% of RHI were among sexual partners of people living with HIV (PLHIV) (Figure 1).

Figure 1: Distribution of populations with RHI in regions with the most identified hotspots



Conclusions: The identification of hotspots demonstrates the influence of localized drivers of transmission, which may include displacement, disruptions in healthcare, and varying wartime risk behaviors. The high percentage of RHI among sexual partners of PLHIV highlights the importance of prevention, index testing, partner notification, and treatment services. RHI, with other surveillance and programmatic data, can allow CDC Ukraine and PHC to identify regions and populations with active transmission and tailor public health responses.

EP0290

Prevalence and factors associated with Advanced HIV Disease (AHD) among newly diagnosed people living with HIV in Rwanda, 2020-2023: implications on screening, prevention, and management

B. Kwizera[1], S. Karera[1], V. Mugisha[1], G. Rwibasira[2], G. Mujawamariya[2], S. S. Malamba[3], R. C.N. Mwesigwa[3], C. Nyagatare[3], J. Sebeza[3], T. Oluoch[3], E. Agyemang[4]
[1]ICAP at Columbia University, Mailman School of Public Health, Kigali, Rwanda, [2]Rwanda Biomedical Center, Kigali, Rwanda, [3]Centers for Disease Control and Prevention (CDC), Division of Global HIV & TB, Kigali, Rwanda, [4]Centers for Disease Control and Prevention (CDC), Division of Global HIV & TB, Atlanta, United States

Background: In 2017, the World Health Organization (WHO) introduced Advanced HIV Disease (AHD) package of care to facilitate early identification and management of opportunistic infections, rapid antiretroviral therapy (ART) initiation and adherence support among people living with HIV (PLHIV) with AHD. Despite improvements in ART coverage and early initiation, AHD remains a challenge. This study aimed to assess the prevalence of AHD and associated factors among newly diagnosed PLHIV in Rwanda.

Methods: We retrospectively reviewed HIV case-based surveillance (CBS) data of newly diagnosed PLHIV ≥18 years enrolled within 30 days of ART initiation from January 2020 to December 2023. We determined the prevalence of AHD (CD4<200 cells/mm3, WHO stage 3 or 4), determined factors associated with AHD in the first year of ART using odds ratios, Chi-square test and p-values reported.

Multivariable logistic regression was applied to determine predictors of unfavorable outcomes (alive on ART, treatment interruption, death, viral load non-suppression (VLS≥1000 copies/ml) and the implications of delayed diagnosis of AHD on morbidity and mortality.

Results: Among 19,512 newly diagnosed clients, 10,042 enrolled in CBS within 30 days of ART initiation and had outcome data available. Of these, 6500 (65%) were female, with a median age of 33 years (IQR: 27, 41).

AHD prevalence was 12.4% (1,246), significantly higher in males (16.2%) than females (10.3%) (p<0.001). Of those with AHD, 85.7% (1,068/1246) screened by CD4 had <200 cells/mm³, while those staged using WHO clinical stage, 22.1% (275/1246) were stage 3 or 4.

AHD prevalence increased with age: 5.6% in those aged 18–24 years, 9.8% in 25–34 years, 15.5% in 35–49 years, and 21.9% in ≥50 years (p for trend<0.001). PLHIV with AHD were 46% less likely (OR: 0.54, CI:0.36–0.81) to achieve VLS by 12 months; after 12 months, 97% had similar outcomes to those without AHD.

Conclusions: These findings highlight opportunities for granular AHD monitoring using CBS. In Rwanda, AHD disproportionately affects older individuals and is associated with lower likelihood of VLS before 12 months, despite similar care outcomes after 12 months. Lower CD4 testing coverage highlights missed opportunities for early AHD diagnosis that may exacerbate unfavorable outcomes.

EP0291

Community involvement in improving compliance among children and adolescents treated at the Donka outpatient treatment centre: the experience of the Fondation Espoir de Guinée

A.I. Bah[1], J. Balath[1], B.S. Wakou[1], M.D. Kanté[2], M.S. Diallo[2], T.M. Tounkara[2], M. Cissé[2]
[1]Hôpital Nationale de Donka, Conakry, Guinea, [2]Université Gamal Abdel Nasser, Conakry, Guinea

Background: Disclosing the HIV status of a child living with HIV is a delicate situation requiring a different approach to that used for adults.

The aim of this study was to determine the reasons for sharing serostatus with children and adolescents undergoing antiretroviral (ARV) treatment.

Methods: A descriptive cross-sectional study was conducted at the Donka CTA over a 36-month period, from January 2020 to December 2022. All HIV-infected children and adolescents undergoing ARV treatment and who explained the reason for their daily treatment were included.

Results: Of 367 patients monitored during this period, 44 were identified, representing a prevalence of 11.9%. The average age of the participants was 14 years, with extremes of 11 and 18 years. The majority of patients were female (56.8%). The main reasons for sharing HIV status were: misunderstandings with the guardian after the death of the parents (36.4%), the onset of active sexuality (13.6%), neglect of ARV treatment (18.2%).), categorical refusal to take the treatment (22.7%) and abandonment of the children by the family after the death of both parents (9.1%).

Despite these initial challenges, all participants adhered to treatment after learning their HIV status. They complied with the medical appointments prescribed, thus guaranteeing their continued care.

Conclusions: The adherence of HIV-infected children and adolescents was optimal after disclosure of their serostatus. These results highlight the need to develop intervention strategies tailored to the paediatric context.

Such approaches will better meet the specific needs of these young patients and improve their future health and quality of life.

EP0292

Assessing the impact of maternal art adherence and associated factors on perinatal HIV outcomes: a retrospective study in Rwanda (2016-2021)

N. Christian[1], R. Gallican[1], A. Taofeek Tope[2], U. Djemima[1], G. Gaetan[1], M. Mireille[1], T. Isabelle[1], M. Fatima[1], K. Claude[1]
[1]Rwanda Biomedical Centre, HIV/AIDS, STI and OBBI, Kigali City, Rwanda, [2]University of Rwanda, Microbiology & Parasitology, Butare, Rwanda

Background: Maternal adherence to antiretroviral therapy (ART) during pregnancy and postpartum is crucial in determining perinatal HIV outcomes. In resource-limited settings like Rwanda, understanding factors associated with infant HIV outcomes is vital for improving prevention of mother-to-child transmission (PMTCT) programs.
This retrospective study evaluates the impact of maternal ART adherence, ART regimens, and associated clinical and demographic factors on infant HIV status and retention at 24 months.
Methods: This study analyzed data from 9,776 mother-infant pairs recorded between June 2016 and July 2021 across health facilities in Rwanda. Maternal ART adherence was assessed at 6, 12, 18, and 24 months postpartum, alongside infant HIV status and retention rates at 24 months. Predictive variables included maternal age, ART regimens, opportunistic infections, and viral load (VL) at 24 months. Cox proportional hazard models and ordinary least squares regression were used for analysis.
Results: Adherence to ART declined from 82.8% at 6 months to 54.4% at 24 months. Poor adherence at 24 months was significantly associated with increased odds of infant HIV positivity (+0.50%, $p < 0.005$).
Maternal age was negatively associated with infant HIV positivity (1-year increase reduced odds by 0.19%, Exp(coef) = 0.998, $p < 0.005$). Absence of maternal opportunistic infections reduced infant HIV positivity odds by 0.20% (Exp(coef) = 0.998, $p = 0.018$). ART regimen ABC+3TC+DTG showed a modest effect, increasing odds by 0.24% (Exp(coef) = 1.0024, $p < 0.005$). Retention rates at 24 months were 68.1%.
Conclusions: This study highlights the importance of maternal ART adherence in reducing infant HIV transmission. Improved adherence interventions during postpartum stages and strengthening retention programs are essential for improving perinatal HIV outcomes in Rwanda.

EP0293

Qualitative assessment of health system barriers to access of HIV services by men who have sex with men (MSM) in Rwanda

K. Collins[1], M. Veronicah[1], C. Steiner[2], R. Gallican[3], I. Basile[3], M. Giselle[3]
[1]ICAP at Columbia University, MSPH, Kigali, Rwanda, [2]ICAP at Columbia University, MSPH, Lusaka, Zambia, [3]Rwanda Biomedical Center, IHDPC, Kigali, Rwanda

Background: In 2022, Rwanda became one of the first five country to achieve the UNAIDS 95 targets. However, despite national initiatives such as PrEP, KP-friendly services and same-day ART initiation, MSM have much lower achievements against the UNAIDS targets, compared to the general male population. HIV prevalence is 6.5% among MSM compared to 2.2% in the general male population. Compared to the general male population, MSM have higher new infection rates (9% vs. 0.09%), poor awareness of HIV status (43.4% vs. 80.4%), and lower viral suppression (76% vs. 85.4%).
This study, conducted in 2023, aimed at identifying barriers in the health system that impede MSM's utilization of HIV services in Rwanda.
Methods: This qualitative study used in-depth interviews with 98 MSM (46 who did access HIV services and 52 who did not access HIV services between July 2021 and June 2022). Interviews were also conducted with 18 healthcare providers and 8 staff from implementing partners supporting MSM programs. Using purposive sampling, 6 health facilities were selected, and MSM participants were recruited via health facility registers and snowballing sampling method. Participants were recruited based on age and geographic diversity. Data were analysed thematically to identify barriers.
Results: Limited MSM-tailored services, lack of trained healthcare workers, and low MSM awareness on the availability of HIV services impeded access. Community and self-stigma, coupled with poor health-seeking behaviour, fear of confidentiality breaches, stigma from healthcare providers, and inflexible service hours limited access to services.
Finally, pervasive stigma at the community, family, and facility levels eroded trust in services among MSM.
Conclusions: Addressing these barriers requires expanding MSM-competent services, involving MSM in program planning, training providers, and offering confidential, flexible care.
Collaborating with MSM networks, integrating mental health support, and ensuring consistent availability of prevention commodities like PrEP are crucial for improving HIV outcomes and achieving UNAIDS targets.

EP0294

Trends and predictors of mortality within the first year in care among people living with HIV on antiretroviral therapy in Tanzania

F. Haraka[1], S. Kimambo[1], J. Mkumbo[1], S. Mathias[2], T. Machalo[1], C. Genge[1], R. Van de Ven[1], F. Lyimo[1], G. Antony[1], C. Mbelwa[2], W. Maokola[3], M. Bateganya[2]
[1]Elizabeth Glaser Pedatric AIDS Foundation, Research, Dar es Salaam, Tanzania, the United Republic of, [2]USAID Tanzania, Dar es Salaam, Tanzania, the United Republic of, [3]National AIDS, STIs, and Hepatitis Control Programme, Ministry of Health, Dodoma, United Republic of Tanzania

Background: The test-and-treat all approach was adopted in 2016 and scaled in Tanzania in 2017. First-line antiretroviral therapy (ART) regimen included tenofovir, lamivudine, and efavirenz combination therapy and in 2019 was switched to dolutegravir (DTG) plus, (efficacious regimen). We evaluated trends of mortality within the first year on ART in people living with HIV (PLHIV) in five regions in Tanzania.
Methods: We conducted a retrospective cohort analysis of records and included all PLHIV who initiated ART between 2018 and 2022, followed from the date of ART initiation and censored on the date of death or 12 months since initiation. De-identified routinely client-level data were abstracted from the national HIV treatment database. Data abstracted included socio-demographics, clinical comorbidity, and outcome. Poisson regression was conducted to determine predictors of mortality. Analysis was done using STATA v17.
Results: A total of 119,544 PLHIV newly on ART with median age 35.8 (27.5, 45.3) were included. Overall 4.9% were under 15 years and 66.7% were female. The proportion of death among PLHIV in 2018, 2019, 2020, 2021, and 2022 were 5.5% 5.2%, 5.5%, 5.7%, and 5.3% respectively.
Overall, 79% (5,065) of all deaths occurred within the first six months of ART. The mortality rate was highest among children under 5 years, 12 per 100 person years (PY) (10.6-13.5); and for elderly above 50 years, 12.4 per 100 PY (11.8 – 13). Mortality was higher in males (10.5 per 100 PY (10.1 – 10.9)) compared to females (6.12 per 100 PY (5.93 – 6.34)).
Predictors of mortality within the first year on ART were: any opportunistic infections (OI) at start of ART (incident rate ratio (IRR) 1.3 (1.1 - 1.5)), poor treatment adherence (IRR 1.2 (1.1 - 1.3)), WHO stage 3 or 4 (IRR 2.2 (2.1 - 2.4)), being widowed (IRR 1.2 (1.1 - 1.3)), or being male (IRR 1.3 (1.2 - 1.4).
Conclusions: Twelve-month mortality rates among PLHIV newly on ART remained constant, 2018-2022, majority of deaths occurred within six months. Predictors of mortality included age <5 years, being male and OI diagnosis at initiation. There is need to optimize care of new PLHIV and closely monitor the first six months.

EP0295

Optimizing HIV surveillance for key populations in Nigeria: Insights from the 2023 size estimation and 2024 programmatic review

R. Aliyu Magaji[1], R. Aguolu[1], A. Andrew[1], G. Ashefor[2]
[1]National Agency for the Control of HIV/AIDS, Research, Monitoring and Evaluation, Abuja, Nigeria, [2]Dure Technologies Nigeria, Abuja, Nigeria

Background: Key populations (KPs) in Nigeria, including female sex workers (FSWs), men who have sex with men (MSM), transgender individuals (TG), and people who inject drugs (PWID), are disproportionately affected by HIV. The 2023 Key Population Size Estimation and the 2024 Key Population Programmatic Review (KPPR) provide a critical opportunity to refine surveillance systems and improve interventions for KPs.
These reports combine data on HIV prevalence, transmission dynamics, and service access to identify key gaps in the national HIV response.
Methods: The 2023 size estimation employed programmatic mapping across 20 states, with a focus on hard-to-reach KPs. Geospatial mapping identified HIV transmission hotspots. The 2024 KPPR utilized this data to analyze program reach, retention, and effectiveness of HIV prevention interventions across key populations.
A mixed-methods approach was employed, integrating surveillance data, program monitoring, and HIV outcome indicators to assess service access and retention.
Results: The Size Estimation identified 64,200 KPs, with FSWs (28.8%), MSM (25.0%), TG (15.5%), and PWID (10.9%) representing the highest HIV burden. GIS analysis showed spatial clustering of KPs, with significant HIV transmission in urban and peri-urban areas. The KPPR revealed that only 42% of KPs accessed prevention services, with gender disparities, particularly among TG and MSM. Retention rates in care were low, with a 30% drop among female KPs due to stigma and access barriers.
Conclusions: The findings highlight the importance of integrated surveillance systems for monitoring HIV transmission and assessing the effectiveness of interventions. Data from the 2023 Size Estimation and 2024 KPPR call for targeted, data-driven interventions in high-transmission areas and among under-served KPs.
To improve retention and care, geospatial monitoring, dynamic surveillance, and continuous program evaluation are essential for optimizing resource allocation and intervention strategies.

EP0296

Demographic and geographic disparities in the prevalence of advanced HIV disease among newly diagnosed people living with HIV in Nigeria: a cross-sectional study across sixteen states

I. Abah[1], G. Ayo-Jatto[1], O. Ogorry[1], O. Airaoje[1], D. Sulaiman Dauda[2], M. Li[2], A. Idemudia[3], U. Omo-Emmanuel[3], O. Oyelaran[3], J. Pius[3], E. James[3], D. Ogundehin[3], R. Eneogu[3], M. Katbi[3], C. Obiora-Okafo[3], D. Kimanga[3], B. Adebobola[4], M. Morka[4], T. Ileri[5], F. Agbo[5]

[1]Palladium, Abuja, Nigeria, [2]Palladium, Washington DC, United States, [3]United States Agency for International Development (USAID), Abuja, Nigeria, [4]National AIDS and STI Control Programme (NASCP), Abuja, Nigeria, [5]National Agency for the Control of AIDS (NACA), Abuja, Nigeria

Background: Advanced HIV Disease (AHD) is a significant threat to public health in Nigeria, contributing to increased opportunistic infections and mortality among people living with HIV (PLHIV). This study aims to determine the prevalence of AHD among newly identified PLHIV in Nigeria and explore opportunities for targeted interventions to improve health outcomes.

Methods: A cross-sectional study was conducted using de-identified data from 220,805 newly identified PLHIV, aged above five years, who were screened for AHD across 601 facilities in 16 states between January 2022 and November 2024. The primary outcome was AHD prevalence, defined as the percentage of clients diagnosed with AHD (CD4 count ≤ 200 cells/mm³ or WHO stage 3 or 4). Prevalence was analyzed using inferential statistics, including the Kruskal-Wallis test, Wilcoxon-Mann-Whitney test, and Kendall's tau correlation, across geographic locations, population settings (urban vs. rural), sex, age, care entry points, and target groups.

Results: 22,538 of the total 220,805 newly diagnosed PLHIV were diagnosed with AHD, yielding a prevalence of 10%. The median age was 32 years (IQR: 26–40). The highest prevalence was in Niger State (20%, 1,814/9,000). A weak positive correlation was observed between age and prevalence (tau = 0.0457, p < 0.001), with the highest prevalence among clients aged 65 and above (17%). There was a slight difference in prevalence by sex, with females at 10.4% and males at 9.9%. TB-DOT entry points recorded the highest prevalence at 38%. By ART enrolment, facility-based clients had a higher prevalence (14%, 16,678/116,069) than community-based clients (6%, 5,860/104,736). Among target groups, children of key populations recorded the highest prevalence (7%), followed by transgender individuals (5%). Differences in prevalence across states, entry points, ART settings, and target groups were statistically significant (p < 0.001).

Conclusions: These findings demonstrate an unexpectedly high proportion of PLHIV in Nigeria can be found to have advanced HIV disease, a problem that has been particularly concerning in those starting care via TB-DOT services, facility clients, older individuals, and children of key populations.. This underscores the urgent need for tailored interventions to improve early HIV diagnosis and linkage to care to reduce AHD-related morbidity and mortality.

EP0297

Factors associated with high HIV prevalence among females sex workers in Rwanda: a cross-sectional survey using respondent-driven sampling technique, 2023

G. Gatete[1], C. Kayitesi[1], V. Mupenzi Umubyeyi[1], B. Ikuzo[1], G. N.Rwibasira[1]

[1]Rwanda Biomedical Centre, National HIV program, Kigali, Rwanda

Background: Since the start of key populations program in Rwanda in 2013, HIV prevention services for high-risk groups have expanded. However, HIV prevalence among Female Sex Workers (FSWs) remains high, with 10 times those of females in the general population.

This study aimed to assess the HIV prevalence and associated factors among FSWs in Rwanda.

Methods: A cross-sectional biological and behavioral survey was conducted among FSWs aged 15 years and above in Rwanda from May to June 2023, using respondent-driven sampling with an expected sample size of 2,489. Consented participants were interviewed and tested for HIV following Rwandan national guidelines.

Descriptive analysis and multivariable logistic regression were performed in STATA_17 to identify factors associated with HIV infection. Results are presented as adjusted odds ratios (aOR) with 95% confidence intervals (CI) and a p-value < 0.05.

Results: Of 2,541 surveyed FSWs, 854 were HIV-positive, resulting in a prevalence of 35.2% [31.8, 38.7]. Prevalence was highest in Kigali city (43.5%) [37.0-50.2] and lowest in the Northern Province (21.6%) [17.6-26.2].

Multivariable logistic regression model showed higher odds of HIV acquisition among widowed (aOR=2.77, 95% CI:1.06-7.20, p=0.037), and divorced (aOR=1.48, 95% CI:1.00-2.19, p=0.045), those with no formal education (aOR=1.96, 95% CI:1.21-3.17, p=0.006), lacking health insurance (aOR=2, 95% CI:0.37-0.88, p=0.012), and those with negotiation power over condom usage (aOR=0.13, 95% CI:0.02-0.87, p=0.035), and FSWs working in other public places (aOR=5.27, 95% CI:1.56-17.79, p=0.007) than those in hotels or bars.

FSWs aged ≥40 years also had higher HIV odds compared to younger age groups: 15-19(aOR=0.11, 95% CI:0.01-0.61, p=0.012), 20-24(aOR=0.1, 95% CI:0.05-0.20, p=<0.001), 25-29(aOR=0.2, 95% CI:0.12-0.35, p=<0.001), 30-34(aOR=0.35, 95% CI:0.21-0.59, p=<0.001), and 35-39(aOR=0.55, 95% CI:0.33-0.89; p=0.016).

Conclusions: HIV prevalence among FSWs in Rwanda is influenced by diverse socio-demographic and behavioral factors, underscoring the need for targeted outreach, education, and access to prevention resources to reduce transmission in this vulnerable group.

EP0298

Data quality assessment on recent HIV acquired cases (Recency) surveillance data in nine districts of the Copperbelt Province, Zambia

M. Nsofu[1], C. Nkwemu[1], L. Phiri[2], M. Mubanga[1], D. Siakavuba[1], R. Chiinda[2], M. Lumpa[1], T. Savory[1], S. Fwoloshi[3], L. Mulenga[3], J. Mzyeche[3]
[1]Centre for Infectious Disease Research in Zambia (CIDRZ), Strategic Information, Lusaka, Zambia, [2]Centre for Infectious Disease Research in Zambia(CIDRZ), Lusaka, Zambia, [3]Ministry of Health, Lusaka, Zambia

Background: Recent HIV acquisition (recency) surveillance aims to identify areas of high HIV transmission to inform precision public health interventions. Surveillance data is important as it helps monitor disease trends and effectively guide resource allocation. Given that this data is used for planning, implementation and performance evaluation, data quality is important.
We evaluated the impact of data quality audits (DQAs) on the quality of recency data in the Copperbelt Province of Zambia.
Methods: DQAs were conducted in 24 randomly selected health facilities reporting recency data across nine districts between program quarters spanning (January-September 2024).
We extracted surveillance data from PCR laboratories, non-PCR (hub) laboratories, sample requisition forms, and the central laboratory data repository on the following variables: clients aged <15 years (clients ineligible for recency testing), missing data for age, gender, breastfeeding status, pregnancy status, modality of entry into HIV care, inconclusive and invalid recency assay results, missing baseline viral load results, sample collection date and recency test date. During DQAs, capacity building and mentorship were conducted at facility, district, and provincial level.

Data Issues	Total Recency Tests Done Quarter 1	Number of Errors Quarter 1	Percentage of Errors out of total tests	Total Recency Test Done Quarter 2	Number of Errors Quarter 2	Percentage of Errors out of total tests	Total Recency Test Done Quarter 3	Number of Errors Quarter 3	Percentage of Errors out of total tests
Unknown Gender	3619	1	0.03%	3149	1	0.03%	3594	0	0.00%
Missing Age	3619	15	0.41%	3149	6	0.19%	3594	16	0.45%
Below 15yrs	3619	32	0.88%	3149	25	0.79%	3594	29	0.81%
Missing Gender	3619	32	0.88%	3149	24	0.76%	3594	38	1.06%
Missing Sample Collection Date	3619	66	1.82%	3149	40	1.27%	3594	33	0.92%
Missing Baseline Viral Load results	3619	176	4.86%	3149	149	4.73%	3594	205	5.70%
Missing Modality	3619	265	7.32%	3149	210	6.67%	3594	221	6.15%
Missing Recency test date	3619	974	26.91%	3149	408	12.96%	3594	530	14.75%
Missing Pregnancy status	3619	1695	46.84%	3149	1317	41.82%	3594	1183	32.92%
Missing breastfeeding status	3619	2233	61.70%	3149	2044	64.91%	3594	1769	49.22%

Results: After the DQA interventions, we observed a reduction in the proportion of recency tests with missing data and errors. Missing pregnancy status among female clients reduced from 46.84% (Q1), to 41.82% (Q2), to 32.92% (Q3) respectively.
Missing pregnancy status among female clients reduced from 64.91% (Q2) to 49.22% (Q3). Unknown gender reduced from 0.03% (Q1), maintained 0.03% (Q2) to 0.00% (Q3). Missing sample collection data reduced from 1.82% Q1),to 1.27% (Q2), to 0.92% (Q3). Missing Recency test date also reduce from 26.91% (Q1), 12.96% (Q2), to 14.75% (Q3).
In contrast, we saw an increase in missing baseline viral load results from 4.86 (Q1) to 5.70% (Q3), missing gender from 0.88% (Q1) to 1.06% (Q3) and missing age from 0.41% (Q1) to 0.45% (Q3) respectively.
Conclusions: Data quality assessment processes improved surveillance data completeness and reliability. Variations observed after our interventions emphasize the need for continuous routine data quality assessments.

EP0299

Rates, causes, and determinants of mortality among HIV-positive orphans and vulnerable children in Tanzania

A. Exavery[1], R. Fovo[1], A. Barankena[1], J. Charles[1], A. Ally[1], R. Mseya[1], T. Mbwambo[1], B. Amani[1], C. Shao[1], T. Ventimiglia[2], E. Kuhlik[2], J. Mulik[2], E. Lema[3], L. Kikoyo[1]
[1]Pact Tanzania, Dar es Salaam, Tanzania, the United Republic of, [2]Pact Inc., Washington DC, United States, [3]USAID, Dar es Salaam, Tanzania, the United Republic of

Background: Child mortality remains a critical issue, particularly in low- and middle-income countries (LMICs), where children, especially those living with HIV, face higher risks of death due to inadequate healthcare access, malnutrition, and poor ART adherence. In Tanzania, despite significant advancements in HIV treatment, children, particularly orphans and vulnerable children (OVC), continue to face major health challenges. This study investigates the rates, causes, and determinants of mortality among HIV-positive OVC receiving ART in Tanzania.
Methods: Data were obtained from the ACHIEVE project (2020-2026), a USAID-funded project in Tanzania. The project followed OVC living with HIV aged 0-19 years and receiving ART and enrolled in the project. Mortality data for the children including cause of death were collected by community volunteers at household level and verified at the health facility. During October 2023–September 2024, ACHIEVE reported 81 deaths of HIV-positive OVC, while 19,854 remained alive at the end of the year. Data analysis involved calculating mortality rate, reviewing causes of death, and performing multivariate logistic regression to identify factors associated with mortality among OVC.
Results: A total of 19,935 OVC living with HIV (51.2% female) were analyzed, with 81 deaths observed, resulting in annual mortality rate of 4 deaths per 1,000 children. The main causes of death included malaria (21%), measles (13%), pneumonia (10%), tuberculosis (TB) (8.3%), fever (8%), diarrhea (8%), and anemia (6%). In the multivariable analysis, significant determinants of mortality in children were being on non-DTG-based regimens with a 14-fold higher risk of death compared to their DTG counterparts (aOR=14.04, 95% CI 7.21–27.33, p<0.001), while children with HIV-negative caregivers had a 3.46 times higher risk (aOR=3.46, 95% CI 1.46–8.25, p=0.005). Additionally, urban residence was protective, reducing mortality risk by 49% (aOR=0.51, 95% CI 0.31–0.84, p=0.008).

Conclusions: Although the annual mortality rate is relatively low, significant risks were observed among OVC on non-DTG regimens and those with HIV-negative caregivers. Malaria, measles, pneumonia, and TB were the leading causes of death. Urban residence was a protective factor. To reduce mortality risk, efforts should focus on increasing access to DTG-based regimens, strengthening caregiver support, and addressing healthcare disparities, particularly in rural areas.

EP0300

Determinants of sustained HIV viral suppression among pregnant and breastfeeding mothers enrolled in prevention of mother-to-child transmission program in Rwanda

P. Nisignizwe[1,2], D. Umutesi[1], Z. Nzeyimana[1], F. Mwumvaneza[1], B. Ikuzo[1], G. N. Rwibasira[1]
[1]Rwanda Biomedical Center, Institute of HIV/AIDS Disease Prevention and Control (IHDPC), Kigali, Rwanda, [2]University of Rwanda, Kigali, Rwanda

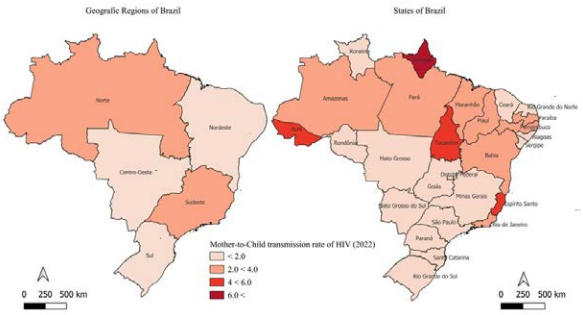
Background: HIV viral suppression among pregnant and breastfeeding mothers is critical for eliminating mother-to-child transmission (MTCT) of HIV. The transmission can occur during pregnancy, during delivery and breastfeeding period. Maintaining viral suppression throughout these stages is critical for reducing HIV transmission to infants. This study aimed to identify key determinants of sustained HIV viral suppression among mothers enrolled in Prevention of Mother-to-Child Transmission (PMTCT) program in Rwanda.
Methods: This retrospective cohort study was conducted across 283 health facilities in Rwanda on pregnant and breastfeeding mothers living with HIV who were enrolled in the PMTCT program. The study included mothers who were followed from pregnancy through the end of the breastfeeding period between July 2016 and June 2020. Viral suppression was defined as a viral load of <200 copies/mL, while non-suppression was defined as a viral load ≥200 copies/mL. Sustained viral suppression was achieved if a mother maintained a suppressed viral load throughout pregnancy and breastfeeding. Data were analyzed using Stata version 17, logistic regression were used to identify determinant of sustained viral suppression throughout the PMTCT follow-up period.
Results: A total of 5,454 mothers were included in the analysis. Among, 83% had maintained viral suppression during follow-up. The majority of mothers with suppressed viral loads were aged 35–44 years (50.5%). Mothers who were HIV positive before pregnancy and on treatment showed 85% suppression rate ($p < 0.001$). In multivariate analysis, identified determinant of sustained viral suppression were age 25–34 years (aOR: 2.36, 95% CI: 1.35–4.15), living in northern province (aOR: 3.25, 95% CI: 1.78–5.9), adherence to antiretroviral therapy at 6, 12, 18, and 24 months (aOR ranging: 10.1 –17.64), and male partner support during antenatal care (aOR: 1.4, 95% CI: 1.00–1.83).
Conclusions: Maintaining viral suppression throughout the PMTCT period is essential for ensuring good health outcomes for both mothers and their infants. Key determinant of sustained viral suppression include being aged 25–34 years, living in rural province, consistent adherence to antiretroviral therapy, and receiving male partner support during antenatal care. Interventions should be focus on these determinants to enhance viral suppression among mothers enrolled in the program.

EP0301

Mother-to-child transmission rate and the progress of Brazil towards elimination to HIV

Í.V. Albuquerque Diniz[1], L. Henriette de Lannoy[1], A.P. Betaressi da Silva[1], P. Cristina Gaspar[1], D. Barreira Cravo Neto[1]
[1]Ministry of Health of Brazil, Department of HIV/AIDS, Tuberculosis, Viral Hepatitis and Sexually Transmitted Infections, Brasília, Brazil

Background: Brazil has a universal healthcare system with over 30 years of experience in implementing HIV/AIDS policies. The national goal of eliminating of HIV mother-to-child transmission (MTCT) is a key component of efforts to address socially determined diseases. The country's disease reporting system, the mortality information system, access to the national universal antiretroviral distribution network and CD4 and viral load testing contribute to robust epidemiological surveillance. These systems allow for comprehensive tracking of MTCT cases across both public and private sectors, ensuring accurate monitoring of the MTCT elimination goal. This study aims to estimate MTCT rates in Brazil, following the implementation of routine case identification and confirmation of HIV MTCT cases through different national information systems.
Methods: The HIV-MTCT rate was calculated by dividing the number of children acquiring with HIV from public and private sectors, by year of birth, and by the total number of pregnant women infected with HIV, by year of delivery, within the same period.
Results: In 2019, 254 children were diagnosed with HIV; 190 in 2020; 180 in 2021 and 146 in 2022. The respective HIV MTCT rates were: 3% (2019); 2.3% (2020); 2.2% (2021) and 1.9% in 2022. In 2022, the North (2.6%) and Southeast (2.2%) regions had the highest MTCT rates in the country.



Conclusions: The availability of several reliable national information systems, together with a routine support from the Ministry of Health for timely case notification at the state level. strengthens surveillance efforts. The HIV-MTCT rate serves as a key indicator for evaluating MTCT. The most recent data indicates that Brazil has achieved

the goal for elimination set by PAHO/WHO. Brazil is also advancing in consolidating information for the process indicators required for MTCT certification.

EP0302

Trends in HCV testing and data reporting across EECA: insights from the COBATEST Network (2017–2023)

M. Gogishvili Asanishvili[1,2], J. Aceitón Cardona[1,2], M. Alarcón Gutierrez[1,2], J. Casabona Barbarà[1,2,3], L. Fernàndez-López[1,2,3]
[1]Centre of Epidemiological Studies of HIV/AIDS and STI of Catalonia (CEEISCAT), Health Department, Generalitat de Catalunya, Badalona, Spain, [2]Germans Trias i Pujol Research Institute (IGTP), Badalona, Spain, [3]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain

Background: Monitoring and evaluation (M&E) of Hepatitis C (HCV) testing are essential for informed decision-making and improving intervention effectiveness. Eastern Europe and Central Asia (EECA) are experiencing rising HCV incidence, driven by factors like injection drug use and limited harm reduction services. Fragmented data collection hinders accurate tracking of prevalence and intervention impact. Strengthening data processes is crucial for understanding the epidemic and targeting interventions. The COBATEST network, a European network of community testing centers, supports standardized data collection in EECA. This study highlights the progress of network members in reporting HCV data and presents key findings from the data reported.
Methods: Only COBATEST member centers from EECA that submitted data from 2017 to 2023 were included. Persons aged <16, previously diagnosed, or with missing test results were excluded. Only the most recent record per client each year was kept. Descriptive analysis of the data and key indicators was performed.
Results: From 2017 to 2023, 26 centers from 17 EECA countries reported 73,290 HCV tests. Except for 2017, when only 3 centers reported data, between 7 and 11 centers reported each subsequent year. However, only 7 centers consistently reported annually. Testing dropped by 44.5% in 2020 but increased by 34.8% in 2021. Excluding 2017, the lowest number of tests was 7,032 in 2020, and the highest was 17,646 in 2022. In 2023, tests declined by 9.7% to 15,930. The proportion of reactive tests rose from 8.6% in 2017 to 29.8% in 2023, peaking at 46.2% in 2022. The total proportion of reactive test results from 2017 to 2023 was 26%.
Conclusions: This study highlights trends in HCV testing across COBATEST members from EECA. While testing numbers fluctuated, with a significant decline in 2020 and recovery in 2021, the data emphasizes the need for consistent HCV testing. Despite a decrease in reported tests in 2023, the proportion of reactive tests increased, suggesting more individuals at risk are being identified. However, only a few members consistently report data, highlighting the need for stronger support in data collection. Strengthening data reporting is essential for targeted interventions and improving HCV prevention and treatment strategies in the region.

EP0303

Evaluation of the surveillance system for children who acquired HIV by mother-to-child transmission, Brazil from 2018 to 2022

Í.V. Albuquerque Diniz[1], L. Henriette de Lannoy[1], A.P. Betaressi da Silva[1], P. Cristina Gaspar[1], D. Barreira Cravo Neto[1]
[1]Ministry of Health of Brazil, Department of HIV/AIDS, Tuberculosis, Viral Hepatitis and Sexually Transmitted Infections, Brasília, Brazil

Background: HIV/AIDS surveillance in Brazil was established in 1986 and is within the scope of actions of the universal health system. The notification/investigation is relatively complete, based on the natural history of the disease, being the main source of information for planning and evaluation of public policies. Several factors are related to the quality of the surveillance system.
The study aimed to evaluate the HIV/AIDS surveillance system in children acquiring by mother-to-child transmission (MTCT), reported between 2018 and 2022 in Brazil.
Methods: An evaluative, retrospective descriptive study following the guidelines of the Guide for the Evaluation of Public Health Surveillance Systems of the Centers for Disease Control and Prevention.
The data were analyzed from the perspective of the Notifiable Diseases Information System (SINAN), in the quantitative attributes (opportunity), qualitative (simplicity, quality of data) and utility. Data analyzed with descriptive statistics.
Results: The surveillance system was considered complex due to the need for laboratory diagnostic confirmation, patient follow-up in the health service, and use of other information systems for monitoring, screening and reporting new cases.
The completeness of mandatory and essential variables in the notification was good (93.6%), however it does not reflect the adequate filling of the data, having ignored filling in 43% for schooling and 23.6% in maternal race/color. Data consistency was good in 91.3% of the database. There is still a low chance of diagnosis (37%), notification (27.3%) and typing (44.1%) of the data in SINAN.

Variables	2018 (n=385)	2019 (n=562)	2020 (n=249)	2021 (n=290)	2022 (n=301)	Average	Classification
Completeness							
Mandatory							
Sex	100.0	100.0	100.0	100.0	100.0	100.0	Excellent
Schooling	97.1	97.7	98.0	97.2	98.3	97.7	Excellent
Federative Unity	100.0	99.8	100.0	100.0	99.3	99.8	Excellent
Municipality of residence	100.0	99.8	100.0	100.0	99.3	99.8	Excellent
Mother's schooling	100.0	100.0	100.0	100.0	100.0	100.0	Excellent
Mother's race/color	100.0	100.0	100.0	100.0	100.0	100.0	Excellent
Evolution of the case	100.0	100.0	100.0	100.0	100.0	100.0	Excellent
Essential							
Race/color of the child	99.0	99.1	99.6	97.8	99.0	98.9	Excellent
Name of the mother	97.2	99.3	100.0	100.0	100.0	99.3	Excellent
Neighborhood	88.3	90.9	94.4	94.5	96.3	92.9	Good
Type of address	95.8	96.3	98.0	99.0	94.4	96.7	Excellent
Area of residence	95.6	84.3	92.8	95.2	95.7	92.7	Low
Complementary							
Age of the mother	75.1	66.9	79.9	69.7	73.4	73.0	Regular
Federative Unit where the treatment is carried out	84.7	79.5	90.4	90.3	87.7	86.5	Regular
Municipality where the treatment is carried out	81.3	76.2	85.1	86.2	83.4	82.4	Regular
Health Unit where the treatment is performed	73.8	70.8	81.9	80.7	78.4	77.1	Regular
Final classification of completeness						93.6	Good
Consistency							
Age of mother equal to 10 years or less than 49 years	99.1	99.1	100.0	100.0	99.5	99.5	Excellent
Date of diagnosis 8 weeks Date of birth (except death) (N=1,712)	95.7	96.1	95.8	89.3	90.7	93.5	Good
Death variable with completion of the date of death variable	100.0	100.0	100.0	100.0	100.0	100.0	Excellent
Reported cases of children under 13 years old (N= 2,156)	78.1	87.7	85.3	86.8	88.3	85.2	Regular
Case classified with criteria 100.600 and 901 (N=2,711)	80.1	87.5	74.4	74.5	75.3	78.3	Regular
Final Consistency Rating						91.3	Good
Opportunity							
Diagnostic opportunity ≤ 18 months	27.3	39.9	37.8	39.3	40.5	37.0	Low
Opportunity for notification ≤ 7 days	28.3	20.6	26.9	27.9	32.6	27.3	Low
Typing opportunity ≤ 7 days	39.0	52.7	51.0	33.8	44.2	44.1	Low
Final classification of the opportunity						36.1	Low

Conclusions: The surveillance system was considered useful. Good consistency of the database implies data reliability and good acceptance of the system for surveillance purposes. The low opportunity for notification and

typing directly impacts on indicators used to formulate policies and technologies in confronting HIV-MTCT. It is recommended to strengthen the training of professionals for early diagnosis and data quality in notifications.

EP0304

Evolving patterns of mortality causes and associated factors among people living with HIV (PLHIV) with unsuppressed viremia in Southern Nigeria: a retrospective cross-sectional study

U. Akpan[1], E. Nwanja[1], M. Umunike[1], O. Esosuakpo[1], M. Etim[1], O. Ogheneuzuazo[1], C. Okolo[1], A. Aikhomokhor[2], U. Omo-Emmanuel[3], D. Ogundehin[3], C. Obiora-Okafo[3], A. Idemudia[3], E. James[3], J. Pius[3], O. Oyelaran[3], O. Onyedinachi[1], A. Adegboye[1], A. Eyo[1]

[1]Excellence Community Education Welfare Scheme (ECEWS), Uyo, Nigeria, [2]National AIDS, STI and Viral Hepatitis Control Program, Abuja, Nigeria, [3]Office of HIV and TB, United States Agency for International Development, Abuja, Nigeria

Background: Antiretroviral therapy has transformed HIV from a fatal to a chronic manageable condition. However, unsuppressed viremia elevates the risk of disease progression and death.

This study assessed the causes of death (COD) and factors associated with mortality among PLHIV with unsuppressed viraemia in southern Nigeria.

Methods: This retrospective cross-sectional study analysed mortality data of people living with HIV (PLHIV) with unsuppressed viral load (>1000copies/ml) from July 2023 to September 2024 across 255 health facilities in Akwa Ibom and Cross River states. The COD was determined using verbal autopsy (VA) by interviewing the client's relatives using the WHO verbal autopsy tool and analysing the responses using the WHO SmartVA algorithm. The COD derived from this process was then entered into the electronic medical records.

Data was abstracted from the electronic medical records including sex, age (children: 0-14years, adults:>14 years), comorbidities, and viral load (VL) counts (High-VL (HVL)):1001–100,000, Very-High-VL (VHVL):>100,000 copies/ml) as of the last clinic visit. COD was categorised into AIDS-related (AIDS or tuberculosis), non-communicable disease (NCD)-related, and others. Chi square statistic was used to assess factors associated with mortality at a significant p-value set at <0.05 using STATA version 14.

Results: A total of 3,078 PLHIV were virally unsuppressed, with a mean age of 36 years (SD±13) and mean duration on ART of 5 years (SD ± 4); 66.7% (n=2053) were females, 3.5% (n=108) had comorbidities, and 24.3% (n=749) had VHVL.

Over 5.1% (n=157) PLHIV with unsuppressed viraemia died within the period assessed, with mortality significantly higher among males (6.7% vs. 4.3%, p=0.004), those with shorter ART duration (6.4% vs. 3.4%, p<0.001), comorbidities (19.4% vs. 4.6%, p<0.001), and VL >100,000 copies/ml (9.9% vs. 4.3%, p<0.001). Of the 67 records with a documented COD, 25.4% (17/67) were specifically AIDS-related, 19.4% (13/67) were NCD-related and 55.2% (37/67) were due to combination of other factors,. There was no significant difference in AIDS-related deaths across demographic and clinical characteristics.

Conclusions: While AIDS-related deaths contributed significantly to deaths among PLHIV with unsuppressed viral load, over half of the documented causes were due to non-AIDS-related factors, underlining the growing importance of addressing broader health determinants and comorbidities among PLHIV.

EP0305

The use of Kenya's primary care networks to scale up detection and monitoring of HIV recent infection in resource limited settings

G. Kotewas[1], G. Osoti[1], M. Okidi[1]

[1]MoH - Homa Bay, Department Health, Kendu Bay, Kenya

Background: The surveillance of HIV recent infection has been well characterized in the developed world, but limited surveillance is available in resource-constrained settings facing the largest burden of HIV infection. In Rachuonyo North, we adopted the primary care network model to scale up the detection and monitoring of HIV recent infection.

Description: In collaboration with MOH and Partners LVCT and UCSF, all the HIV Testing sites were marked for recency surveillance (RS). Recent infection was defined as infection acquired within the last 12 months. The HIV testing site were the spoke and two Hubs were then set where rapid test for recent infection (RTRI) and data entry to the national would be conducted. Trained riders were used to transport samples and the Laboratory request forms between the Hub and the spoke sites.

Lessons learned: Before the adoption of primary care network model, only two facilities were involved in recency surveillance, and thereafter between August 2022 and June 2023, 31 (72%) of the 43 HIV testing sites were enrolled to RS. Within the period under review, 495 participants were legible and enrolled to recency surveillance, 85% (423/495) of the participants had sample sent to the hub for RTRI testing, 33 missed phlebotomy due to commodity stock out and 20 participants declined sample collection. Out of the 423 samples collected, 8% (33/423) were of recent infection and there Viral load samples were taken for further testing as per the recent infection testing algorithm, whereas 89% (376/423) were long term infection. Three samples tested negative for RTRI, while 11 samples were not tested due to stock out of test kits.

Conclusions/Next steps: Recent HIV infection surveillance should be enhance to cover all the HIV testing site including home based testing and outreaches since the identification of recent HIV infection is important for two main public health reasons: It helps detect people during a period of increased transmissibility, which can guide intervention efforts making better use of scarce resources, and it allows real-time tracking of trends in new infections at the population level, which helps with the timely evaluation of prevention efforts.

EP0306

Prevalence of acquired HIV drug resistance in Pakistan: a national clinical-based survey

S.H. Abidi[1,2], S.F. Mahmood[1], R. Tafveez[1], N. Nasir[1], M.S. Jamil[3], M.S. Kamal Pasha[4], H. Ji[5], P. Sandstrom[5], C. Munyuza[5]
[1]Aga Khan University, Medicine, Karachi, Pakistan, [2]Nazarbayev University School of Medicine, Biomedical Sciences, Astana, Kazakhstan, [3]World Health Organization Regional Office for the Eastern Mediterranean, Cairo, Egypt, [4]WHO Pakistan Regional Office, Islamabad, Pakistan, [5]University of Manitoba, Manitoba, Canada

Background: The World Health Organization recommends that HIV antiretroviral therapy (ART) scale-up be accompanied by routine monitoring and surveillance of HIV drug resistance (HIVDR) to improve the quality of ART services. This includes monitoring of acquired HIVDR in populations receiving ART. In Pakistan, overall, ART coverage is low; however, most adults have been transitioned to a DTG-based regimen Among individuals receiving ART, viral load suppression is estimated at 23%. To date, no national clinical-based survey of acquired HIVDR has been conducted.
We conducted the first nationally representative clinic-based survey of acquired HIVDR in Pakistan. Here we report the prevalence of acquired HIVDR towards ART drugs among adults and children with viral non-suppression.
Methods: A nationally representative clinic-based cross-sectional survey was conducted using WHO-recommended protocol. Adults and children (age <15 years) were enrolled if they had been on treatment for at least 6 months. A sample size 771 was determined to be sampled across 58 ART centers via probability proportional to proxy size (PPPS). Blood plasma samples were subjected to viral load (VL) testing; specimens with unsuppressed VL (≥1000 copies/ml) were genotyped (RT, PR, and INT regions) using PCR and a Sanger-based sequencing strategy to identify HIVDR-associated mutations.
Results: Between date and date, 785 individuals (435 adults and 350 children) were enrolled; 103 samples (22 adults; 81 children) were found to be virally non-suppressed. Fifty-one individuals (18 adults and 33 children) were on a DTG-based regimen.
In adults, DRMs K103N (36.6%), V179VE (n=13.6%) against RT-inhibitors and R263K against INSTIs were the most prevalent DRMs. Efavirenz (63.6%), Nevirapine (36.36%), Emtricitabine (72.7%), Lamivudine (27.27%), Doravirine (13.6%) were the drugs most affected by the DRMs.
In children, DRMs K103N (55.5%), E138A (20.9%), M184V (54.2%), L74M (7.4%) and L74IM (7.4%), were the most prevalent DRMs. Nevirapine (24.6%), Efavirenz (25.9%), Emtricitabine and Lamivudine (38.2%) and Doravirine (59.2%) were the drugs most affected by the DRMs
Conclusions: The results highlight resistance rates for different ART inhibitors, especially RT inhibitors and INSTIs , among adults and children in Pakistan. This warrants ongoing monitoring of acquired HIVDR and optimized regimens and/or resistance testing within ART programs for virally non-suppressed individuals.

EP0307

Assessing viral suppression in Pakistan: insights from the first national HIV survey

S.F. Mahmood[1], R. Tafveez[1], S.H. Abidi[1,2], N. Nasir[1], M.S. Jamil[3], M.S. Kamal Pasha[4]
[1]Aga Khan University, Medicine, Karachi, Pakistan, [2]Nazarbayev University School of Medicine, Biomedical Sciences, Astana, Kazakhstan, [3]World Health Organization Regional Office for the Eastern Mediterranean, Cairo, Egypt, [4]WHO Pakistan Regional Office, Islamabad, Pakistan

Background: As of June 2024, 46,991 of estimated 290,000 people living with HIV were registered for HIV treatment in Pakistan, representing only 16% treatment coverage. Viral load testing coverage among those receiving treatment is 29%, and 77% of them achieved suppression according to programme data. To better understand viral suppression rates, we present a sub-analysis of a national acquired HIV drug resistance survey
Methods: Using WHO's clinic-based methodology, we employed a two-stage cluster design. ART clinics were selected via probability proportional to proxy size, and eligible individuals were sampled consecutively. Participants underwent viral load testing, and non-suppressed cases (≥1000 copies/mL) underwent HIV drug resistance genotyping at a WHO-designated laboratory.
Results: A total of 785 participants were enrolled from 37 centers across 5 provinces, with 58.2% adults and 41.8% children. Among adults, 68.3% identified as male, 28.5% female, and 3.2% transgender, while among children, 57.2% were boys and 42.8% girls. The mean age of participants was 25.2 years (adults: 38.8 years (range 18–73); children: 8.4 years (range 1–16)).
Sexual exposure was the most commonly reported mode of transmission in adults (63.2%), while mother-to-child transmission was the most common in children (40.4%).
Nosocomial transmission (unsafe injections or blood transfusion in healthcare) was reported in 14.3% of adults and 22.6% of children. Almost all the adults (94.5%) and half the children (47.4%) were on a DTG-based regimen.
Overall, 86.6% of participants achieved viral suppression, and 70.8% had undetectable viral loads (<50 copies/mL). Viral suppression was significantly higher in adults than in children (94.5% vs 76.9%, p < 0.001).
In adults, suppression was associated with the province (p=0.0082), self-reported adherence (p=0.0081), DTG-based regimens (97.7% vs 47.8%, p=0.0045), and prior viral loads <1000 copies/ml (97.8% vs 85.7%, p < 0.0002). In children, suppression was higher on DTG-regimens (90.6% vs 54.5%, p < 0.0002), with prior viral loads <1000 copies/ml (93.0% vs 61.5%, p=0.006), and urban dwellers (84.9% vs 72.3%, p=0.011).
Conclusions: Viral suppression rates in Pakistan are higher than previously estimated, especially in adults. However, suppression rates and slow transition to DTG in children remain low, highlighting the need for targeted interventions tailored to pediatric populations.

EP0308

The association between maternal HIV and stillbirths in an era of universal ART in pregnancy in the Western Cape, South Africa

E. Lubinda[1,2], F. Phelanyane[2], A. Heekes[2], U. Mehta[3], A. Boulle[4], E. Kalk[2], S. Maswime[5]

[1]University of Capetown, Epidemiology and Biostatistics, CapeTown, South Africa, [2]University of Cape Town, Centre for Infectious Disease Epidemiology & Research,, CapeTown, South Africa, [3]University of Cape Town, School of Public Health and Family Medicine, CapeTown, South Africa, [4]University of Cape Town, Health Intelligence Directorate, Western Cape Government Department of Health & Wellness, Cape Town, South Africa, CapeTown, South Africa, [5]University of Capetown, Faculty of Health Sciences Division of Global Surgery, CapeTown, South Africa

Background: This study investigates the relationship between maternal HIV and stillbirths within the framework of universal antiretroviral therapy (ART) during pregnancy in the Western Cape, South Africa.

Methods: Data from the Western Cape Pregnancy Exposure Registry (PER) spanning January 2017 to December 2021 was analysed, including 15,123 participants aged 18 or older with documented HIV status and pregnancy outcomes beyond 20 weeks. Key variables included maternal HIV status and the quality of antenatal care (ANC) according to WHO guidelines.

Descriptive and logistic regression analyses were performed to evaluate stillbirth rates and odds ratios among women living with HIV (WLHIV) compared to those without HIV, considering clinical and demographic factors, ANC quality, and visit frequency

Results: WLHIV had a median age of 31 years (IQR: 26-35), which was higher than that among women without HIV, 26 years (IQR: 22-31). Stillbirth rates were higher among WLHIV, at 17 per 1000 births (95% CI: 13.34-20.66), compared to 14 per 1000 births (95% CI: 11.75-16.25) for women without HIV. Maternal HIV-positive status was not significantly associated with stillbirths (AOR = 1.15, 95% CI: 0.87-1.52, p = 0.34).

However, longer ART duration was linked to a 47% reduction in stillbirth odds (AOR = 0.53, 95% CI: 0.33-0.93, p = 0.01). Poor-quality ANC showed a non-significant trend toward increased stillbirth odds.

Conclusions: The study found no significant association between maternal HIV and stillbirths, differing from findings in other low- and middle-income countries. The overall stillbirth rate was 15/1000 births, above the WHO target of ≤12/1000 by 2030 but lower than previous South African rates. Prolonged ART use was associated with a notable reduction in stillbirth odds.

Despite non-significant findings regarding ANC quality, our results highlight the importance of continued improvements in ART access and ANC quality to enhance maternal and fetal health outcomes.

Modelling the HIV pandemic

EP0309

Understanding the impact of PrEP adherence on HIV incidence through community-level drug concentrations: mathematical modeling analysis of the Monitoring PrEP in Young Adult women (MPYA) study in western Kenya

D. Kaftan[1], J. Haberer[2], E. Irungu[3], A. Roberts[4], N. Musinguzi[5,6], N. Mugo[7], E. Bukusi[8], K. Ngure[9,4], R. Barnabas[2], A. Bershteyn[1]

[1]New York University Grossman School of Medicine, Population Health, New York, United States, [2]Massachusetts General Hospital and Harvard Medical School, Boston, United States, [3]JHPIEGO, Nairobi, Kenya, [4]University of Washington, Seattle, United States, [5]Global Health Collaborative, Mbarara, Uganda, [6]University of Minnesota, Minneapolis, United States, [7]Kenya Medical Research Institute, Thika, Kenya, [8]Kenya Medical Research Institute, Kisumu, Kenya, [9]School of Public Health Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Background: Despite high HIV incidence among women in East Africa, oral pre-exposure prophylaxis (PrEP) adherence varies widely. The Monitoring PrEP in Young Adult Women (MPYA) study offered PrEP to 18–24-year-old women in central and western Kenya, measured effective PrEP use through tenofovir-diphosphate (TFV-DP) concentrations in dried blood spots (DBS), and assessed self-reported sexual behavior.

We modeled PrEP effectiveness in MPYA, PrEP scale-up in western Kenya, and community-level TFV-DP concentrations indicative of reaching incidence goals.

Methods: We estimated relationships between having multiple sexual partners and detectable (>100 fmol/punch) or high (>400 fmol/punch) TFV-DP concentrations with mixed-effects regression. We translated concentrations into HIV incidence reductions using a recent meta-analysis of pooled PrEP trials. Using a network-based transmission model, EMOD-HIV, we simulated expanding PrEP, with adherence as observed in MPYA, to various proportions of young women (ages 18–24) in western Kenya. Finally, we determined community-level TFV-DP concentrations indicative of achieving <0.1% incidence among young women by 2040.

Results: In MPYA, 21% of DBS had detectable TFV-DP concentrations; 14% had high concentrations, corresponding to 43.5% and 85.7% reductions in HIV acquisition. Having multiple sexual partners correlated with detectable TFV-DP concentrations (OR: 2.18, 95% CI: 1.22–3.90, p<0.01), but had no significant association with high concentrations among those with detectable TFV-DP (p=0.69).

Expanding PrEP to all sexually active young women in western Kenya (corresponding to high TFV-DP concentration in ≥9% of young women) would avert 1 HIV acquisition/926 person-years on PrEP (95% CI: 851–1007) and reach <0.1% incidence among young women by 2040 vs. 2046 without the intervention (*Figure*).

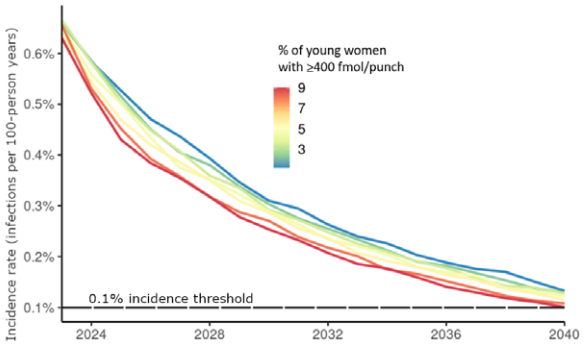


Figure. HIV incidence among young women with varying proportions having high TFV-DP concentrations.

Conclusions: Oral PrEP as observed in MPYA could achieve <0.1% incidence by 2040 if scaled widely to young women in western Kenya. Community TFV-DP measurement provides novel assessment of progress toward HIV incidence goals.

EP0310

The role of safe space model in increasing uptake of HIV Oral Pre-Exposure Prophylaxis among adolescent girls and young women in Malawi DREAMS Program (2021-2024)

V. Thonyiwa[1,2], U. Roxo[1], A. Abubakar[3], V. Kanje[3], K. Norwood[1], C. Mablekisi[4], L. Chewere[5]
[1]United States Government, Department of State - PEPFAR, Lilongwe, Malawi, [2]Amref Internationl University, Nairobi, Kenya, [3]United States Agency for International Development, Lilongwe, Malawi, [4]National AIDS Commission, Lilongwe, Malawi, [5]Ministry of Health, Department of HIV, STI, and Viral Hepatitis, Lilongwe, Malawi

Background: Adolescent Girls and Young Women (AGYW) continue to be vulnerable to HIV acquisition compared to their male counterparts. In 2024, the HIV Incidence for AGYW in Malawi was 4 times higher than that of ABYM. The United States Government through PEPFAR implemented Determined, Resilient, Empowered, AIDS-free, Mentored and Safe (DREAMS), an HIV prevention program, in 15 countries including Malawi from 2016 to 2024. DREAMS aimed at reducing HIV incidence among Adolescent Girls and Young Women (AGYW) aged 10-24 with higher risk of HIV acquisition. DREAMS program used safe space model to provides a private, youth friendly, safe and supportive environment where AGYW access information, built social networks, discussed issues regarding their overall health and needs without fear of judgment.
Examples of safe spaces were empty classrooms, church halls and community centers for AGYW weekly gatherings. The program provided HIV biomedical prevention services including oral Pre-exposure prophylaxis (PrEP) in safe spaces to increase access and reduce distance to facilities.
Methods: Retrospective data for 93,427 and 128,822 AGYW aged 15-24 enrolled in 2021 and 2024 respectively were extracted from Malawi's DREAMS Database representing before and after implementation of safe space model PrEP service delivery. Data were analyzed using Wilcoxon Signed-Rank Test, to compare oral PrEP service uptake by AGYW after the introduction of the safe space model for oral PrEP service delivery.
Results: Results showed a 96% increase in oral PrEP uptake in 2024 when community safe space model was used for delivery of this biomedical service compared to 2021 when AGYW were referred to health facilities. Oral PrEP service uptake was statistically significant [p-value < 0.05 (0.03125)]. HIV incidence reduced from 0.23 in 2021 to 0.15 in 2024 among AGYW.
Conclusions: The DREAMS safe space model, an essential prevention-focused investment, contributes to increasing HIV biomedical services uptake, including PrEP among AGYW at higher risk of HIV acquisition. The model bridges the gap to service access and uptake created by distance, transport money and time. The model remains central for curbing new HIV acquisition.

EP0311

Predicting ART interruptions: a machine learning approach among PLHIV in Haiti

J. Wu[1], B. Shaw[1], N.R. Labbe[2], M.A. Bien Aime[2]
[1]Georgetown University, Center for Global Health Practice and Impact, Washington, United States, [2]Georgetown University, Center for Global Health Practice and Impact, Port au Prince, Haiti

Background: Long-term retention on antiretroviral therapy (ART) is essential to improving clinical outcomes and reducing HIV transmission among people living with HIV (PLHIV). However, interruption in treatment (IIT) remains a persistent barrier. Machine learning (ML) models have shown promise in predicting adverse health events and, when integrated into health information systems, enable proactive, targeted interventions.
This study developed and integrated a classification model to predict IIT among PLHIV within 28 days in Haiti's ART program.
Methods: PLHIV were classified as IIT if they failed to return for a refill within 28 days of their scheduled follow-up date. Data were obtained from the national Electronic Medical Records (EMR) system for the period January 1, 2016, through October 7, 2024. After data cleaning, the final dataset included 72,070 PLHIV: 55,181 with active treatment status and 16,889 with IIT status. Given the unbalanced nature of the dataset, class imbalance techniques were applied during training, including weighting the loss function to penalize misclassification of the minority class. Eight ML classification models were trained and evaluated, with XGBoost emerging as the best-performing model. A cross-validation strategy (K-folds = 10) and an 80/20 train-test split were applied alongside hyperparameter tuning. Model performance was assessed using accuracy, sensitivity, specificity, precision, F1-score, and area under the receiver operating characteristic curve (AUC).
Results: The final XGBoost model achieved an accuracy of 90.02%, specificity of 70.43%, sensitivity of 96.02%, and an AUC of 0.938. The model was successfully integrated into

the national EMR system to generate weekly risk updates for healthcare workers at selected facilities. Key predictors of IIT included years of continuous ART engagement, the total number of historical viral load tests, and recent viral load results. Gender and time since HIV diagnosis contributed minimally to prediction outcomes.

Conclusions: The integration of an ML-based IIT prediction model into Haiti's EMR system provides an efficient tool for identifying PLHIV at risk of treatment interruption, facilitating early interventions such as targeted outreach via phone calls or in-person visits.

Future research should explore the inclusion of additional sociodemographic and behavioral predictors to further enhance model performance and address barriers to ART continuity.

EP0312

Incorporating non-communicable diseases into HIV care to strengthen health policy in Eswatini: a modeling study

N. Yamamoto[1], K. Bhamidipati[1], A. Osei-Ntansah[1], G. Ferrara[1], C. Kerr[2], R. Stuart[2], A. Bershteyn[1]

[1]New York University Grossman School of Medicine, Department of Population Health, New York, United States, [2]Institute for Disease Modeling, Seattle, United States

Background: Among people living with HIV (PLHIV) in low- and middle-income countries, especially as the average age of PLHIV rises, chronic inflammation from viral infection persists, and cardiometabolic side effects of HIV treatment accumulate. Studies show that PLHIV are 1.95 times more likely to develop Type 2 diabetes than HIV-negative individuals.

This study aims to develop an infectious and non-communicable diseases (NCDs) co-modelling tool and evaluate an illustrative intervention integrating HIV and Type 2 diabetes care in Eswatini.

Methods: We developed the Model of Inter-Generational Health, Transmission, and Interventions (MIGHTI), a dynamic agent-based simulation built on the Starsim disease modeling framework (starsim.org), which represents major sources of morbidity and mortality.

The model includes sexual transmission via relationship networks and inherited and vertically transmitted conditions (e.g., mother-to-child transmission).

It also captures HIV-NCD interactions by incorporating the increased susceptibility of PLHIV to Type 2 diabetes, alongside screening/testing sensitivity, specificity, and intervention effectiveness.

We calibrated MIGHTI to demographic, HIV prevalence, and NCD prevalence data in Eswatini and simulated HIV care alone and in combination with Type 2 diabetes screening and treatment from 2025 to 2050.

Results: Our preliminary results suggest that in the absence of integrated NCD care, Type 2 diabetes prevalence among in-care PLHIV aged 18+ will increase from 5.29% in 2025 to 19.43% in 2050.

In 2025, we estimate that 41.6% of all Type 2 diabetes cases will occur in PLHIV aged 50+, rising to 69.9% by 2050.

By 2050, Type 2 diabetes prevalence is expected to remain higher among PLHIV than in HIV-negative individuals, with PLHIV having 2.94 times higher T2D prevalence than HIV-negative individuals in 2025, and 4.68 times higher in 2050.

Conclusions: Integrating Type 2 diabetes screening and treatment into HIV care could avert a large proportion of diabetes-related mortality in Eswatini.

Future research should extend to additional NCDs and assess the cost-effectiveness and feasibility of interventions to support decision-making. Multi-disease simulators such as MIGHTI provide a useful platform for these analyses.

EP0313

How will delays in the scale-up of long-acting HIV pre-exposure prophylaxis impact health benefits and cost-effectiveness in South Africa? A mathematical modeling study

E. Mudimu[1,2], D. Kaftan[3], M. Sharma[4], D. Bridenbecker[5], A. Bershteyn[3]

[1]University of South Africa, Decision Sciences, Pretoria, South Africa, [2]Africa Health Research Institute, DurbanSouth, South Africa, [3]New York University, Department of Population Health, New York, United States, [4]University of Washington, Department of Epidemiology, Seattle, United States, [5]Institute for Disease Modelling, Seattle, United States

Background: Long-acting pre-exposure prophylaxis (LA-PrEP) represents a potentially transformative innovation in HIV prevention that is much-needed in South Africa, home to the world's largest HIV-positive population, with >1 in 6 adults living with HIV. Despite growing recognition of its potential, LA-PrEP scale-up has been delayed in South Africa due to factors including limited product supply allocated for African countries.

We aimed to estimate the effect of delayed introduction on the health benefits and cost-effectiveness of LA-PrEP over the next 35 years.

Methods: We adapted a stochastic individual-based network model, EMOD-HIV, to simulate LA-PrEP scale-up in South Africa beginning in 2025, 2030, 2035, 2040, nor never. Primary outcomes were (1) averted HIV deaths by 2060, and (2) the maximum amount that could be paid to deliver one person-year of LA-PrEP while remaining cost-effective at <US$500 per disability-adjusted life-year (DALY) of averted HIV burden, which we estimated through 2060 with 3% annual discounting.

We varied the extent to which LA-PrEP use would concentrate in populations with elevated HIV incidence, using as a proxy the risk score derived from the Vaginal and Oral Interventions to Control the Epidemic (VOICE) clinical trial, versus broadly used by sexually active adults across all population segments.

Results: Delaying LA-PrEP introduction substantially reduced health benefits regardless of the population segments assumed to uptake LA-PrEP over the next 35 years. In a maximal scenario of LA-PrEP across all sexually active adults in South Africa, scale-up in 2025 could avert 146,000

HIV-related deaths in South Africa by 2060, compared to 76,000 deaths if scale-up began in 2040. Delaying LA-PrEP introduction also greatly reduced the maximum amount that could be paid per person-year of LA-PrEP delivered, on average, over the period of analysis.
Scale-up in 2025 to those with VOICE score ≥5 allowed for up to US$106 per person-year of LA-PrEP delivered, while delaying scale-up to 2040 reduced this to US$70.
Maximum allowable costs were lower when LA-PrEP use included lower-risk populations, but with similar effects from delaying introduction.
Conclusions: Delaying LA-PrEP scale-up would reduce its health benefits and limit the populations and settings where its use could be cost-effective.

HIV prevention research

EP0314

Increased HIV case finding from pre-exposure prophylaxis rollout in Liberia

H. Reeves[1], R. Lyimo[1], C. Kerbay[1], F. Thomas[1], D. Kalapelee[1], D. Mulbah[1], N. Scott[1], Y. Gbeh[1], J. Garway[1], D. Nyanplu[2], G. Kamanga[1]
[1]FHI 360, Epic, Monrovia, Liberia, [2]National HIV and STI Control Program, NACP, Monrovia, Liberia

Background: Liberia has made significant progress in HIV prevention through the implementation of Pre-Exposure Prophylaxis (PrEP) via the FHI 360-led EpiC project. Collaborating with the National AIDS and STI Control Program and County Health Teams, this initiative has improved access to HIV services and enhanced case detection among vulnerable populations.
Description: In April 2022, six health centers—Steven Tolbert Memorial Hospital, Clara Town Health Center, Nyehn Health Center, Saclepea Comprehensive Health Center, Sister Barbara Ann Health Center, and ELWA Hospital—began providing PrEP services. Utilizing a "hub and spoke" model, these centers served as the core of PrEP initiation and refills, while civil society organizations reached at-risk adults through peer networks.
Community outreach events were crucial in facilitating PrEP access for those who tested negative for HIV and linking individuals with confirmed HIV diagnoses to treatment at the hub.
Lessons learned: HIV testing uptake at the six health facilities improved greatly, contributing to a corresponding increase in HIV-positive cases identified. Data were compared before and after the intervention (October 2021–September 2022 vs. October 2022–September 2023).
Overall, HIV testing increased from 20,654 to 26,750 (29%) (Table 1).
At one facility (Stephen Tolbert), HIV testing increased markedly, from 220 to 1,836 (734%). The number of new HIV cases identified also rose significantly, from 702 to 1,352, reflecting a 93% increase. HIV case finding increased from 700 (3.39%) to 1,349 (5.05%).

Health Facility	Number of tests		% Change	Number of reactive results (case-finding rate)	
	2021–2022	2022–2023		2021–2022	2022–2023
Steven Tolbert Memorial Hospital	220	1,836	734%	10 (5%)	26 (1%)
Clara Town Health Center	4,475	7,905	77%	192 (4%)	422 (5%)
Nyehn Health Center	559	816	46%	40 (7%)	61 (7%)
Sacleapea Comprehensive Health Center	2,015	2,456	22%	60 (3%)	95 (4%)
Sister Barbara Ann Health Center	5,165	5,631	9%	183 (4%)	428 (8%)
ELWA Hospital	8,220	8,106	-1%	217 (3%)	320 (4%)
Total	**20,654**	**26,750**		**702 (26%)**	**1,352 (29%)**

Conclusions/Next steps: Although one facility experienced a decline in testing, the overall trend indicated improved access to preventive measures and greater community engagement with HIV services. This initiative illustrates the essential role of PrEP in Liberia's response to HIV and offers critical insights for future public health efforts.

EP0316

PrEP offer and uptake among HIV-negative testers in public primary health care facilities in Malawi: a cross-sectional study

W. Phiri[1], T. Tchereni[1], I. Mokhele[2], N. Mutanda[2], F. Birhanu[1], A. Gunda[1], R. Nyirenda[3], L. Chewere[3], S. Rosen[2,4], S. Pascoe[2], A. Huber[2]
[1]Clinton Health Access Initiative, Sexual Reproductive Maternal and Neonatal Health, Lilongwe, Malawi, [2]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]Malawi Ministry of Health, Directorate of HIV/AIDS and Viral Hepatitis, Lilongwe, Malawi, [4]Boston University, School of Public Health, Massachusetts, United States

Background: Uptake of pre-exposure prophylaxis (PrEP) for HIV prevention has not met targets in many African countries. Malawi began providing free oral PrEP at public sector clinics in April 2019 and long-acting injectable PrEP in March 2024. Little is known about the extent to which eligible clinic attendees are offered PrEP, how many accept it, and the reasons for acceptance or refusal.
Methods: From 8-31 May 2024, we interviewed up to 50 adults (≥16) seeking HIV testing at each of 12 public sector clinics in Malawi's Chiradzulu, Blantyre, and Lilongwe districts. Participants were enrolled sequentially as they arrived at the clinics.
Those who tested HIV-negative were asked about their experiences with testing services, information provided about HIV prevention, whether they were screened for or offered PrEP, and whether they accepted PrEP if offered.
We used descriptive statistics to summarize participant demographic characteristics, and testing experiences. Continuous variables were described using medians and interquartile ranges (IQR) where appropriate.
Categorical variables are described using frequencies and percentages. Analysis was conducted using STATA version 14 (Stata Corp, College Station, Texas, USA).
Results: We enrolled 555 HIV-negative participants. Two-thirds (66%, 365) of those who tested negative were aware of PrEP, but only 8% (42/555) had previously been offered it. Most (79%, 440) were asked for were asked questions

about HIV transmission risk, but only a quarter (26%, 143) reported that PrEP was discussed with them, of which, 41 (29%) were offered PrEP. Over half (59%, 24) who were offered PrEP accepted it.
For those who did not accept PrEP, the reasons offered included perceived low risk of HIV exposure, belief that it was not necessary, not being sick, risk of perception of infidelity in a stable relationship, and not being ready to take PrEP.
Conclusions: Most negative testers were aware of PrEP and reported being asked about HIV transmission risk, indicating that healthcare providers are increasingly incorporating HIV risk screening into routine care.
However, direct communication about PrEP between providers and clients remains limited despite this. Enhancing provider-client dialogue is essential to bridge the gap between PrEP awareness, offer and actual uptake.

EP0317

PrEP preferences, acceptability and utility of a decision support tool to inform PrEP choices among young African women in the INSIGHT cohort

C.P. Aluoch Auma[1,2], S. Delany-Moretlwe[3], D. Donnell[1,4], E. Bukusi[2,1], K. Mugwanya[1], B. Gati Mirembe[5], R. Heffron[6], C. Celum[1]
[1]University of Washington, Global Health, Seattle, United States, [2]Kenya Medical Research Institute, Center for Microbiology Research, Kisumu, Kenya, [3]University of the Witwatersrand, Johanessburg, South Africa, [4]Fred Hutchinson Cancer Center, Seattle, United States, [5]Makerere University-Johns Hopkins University (MU-JHU), Kampala, Uganda, [6]University of Alabama at Birmingham, Birmingham, United States

Background: African adolescent girls and young women (AGYW) experience high HIV incidence but their adherence and persistence with pre-exposure prophylaxis (PrEP) is often low. AGYW's PrEP use may be improved if their risk perception, motivation, and knowledge about PrEP were higher. A decision support tool (DST) could inform AGYW's perceived risk and need for PrEP.
We assessed PrEP preferences, and the acceptability and utility of a PrEP DST, "*MyPrEP*", in increasing AGYW's interest and knowledge about PrEP.
Methods: From August-December 2022, we enrolled sexually active, HIV-negative AGYW ages 16-30 from six African countries (15 South African sites, and 1 each in Eswatini, Kenya, Malawi, Uganda, and Zambia) into the INSIGHT cohort. AGYW were offered daily oral PrEP at enrollment, months 1, 3 and 6 and adherence assessed using a qualitative urine tenofovir assay.
The *MyPrEP* DST was administered at month 6 and participants were asked about PrEP preferences, knowledge and interest in different PrEP formulations and acceptability of the *MyPrEP* DST.
We assessed factors influencing interest in daily oral PrEP, 2-monthly injectable cabotegravir (CAB-LA) and monthly dapivirine vaginal ring (DVR) using multivariable logistic regression models.
Results: 3087 AGYW enrolled with 2795 (90.5%) attending the month 6 visit, a median age (IQR) of 24 years (21,27), 74.9% were South African, 95.6% had a primary sex partner, and 99.2% initiated oral PrEP. PrEP preferences were CAB-LA (52.8%), monthly oral PrEP (31.5%), daily oral PrEP (25.5%), weekly oral PrEP (12.3%), and DVR (5.4%).
There was increased interest (56.4%, 53.8%, 40.3%) and knowledge (66.3%, 67.3%, 58.8%) about CAB-LA, oral PrEP and DVR, respectively, after using *MyPrEP*. A positive urine tenofovir result was associated with increased interest in daily oral PrEP (aOR 1.64, 95% CI: 1.36, 1.98) and CAB-LA (aOR 1.21, 95% CI: 1.01, 1.45). Overall, 90% indicated strongly liking getting information from *MyPrEP*.
Conclusions: AGYW indicated a strong preference for long-acting oral and injectable PrEP despite only having actual experience with daily oral PrEP.
The *MyPrEP* DST was highly acceptable, increasing participants' interest and knowledge about PrEP formulations. DSTs could facilitate AGYW's assessment of their HIV risk and informed choices about PrEP options.

EP0318

PEPFAR-supported HIV pre-exposure prophylaxis coverage among female sex workers and gay, bisexual, and other men who have sex with men in 26 sub-Saharan Africa countries, October 2021– September 2024

D. Philpott[1], V. Lee[1], R. Nelson[1], A. Lyn[1], C. Corcoran[1], P. Bastani[1], A.M. Beyene[2], T.F. Weldemariam[2], V. Singano[3], F. Zulu[3], G. Maibaze[4], V. Adamu[5], S. Adamu-Oyegun[5], A. Abutu[6], M. Foster[6], J. Gunn[7], H. Savva[7], A.G. Fitzmaurice[8,7], J.M. Grund[9], A. Katale[9], M. Baluku[8], B. Bongonyinge[8], O. Chituwo[10], J. Mandisarisa[11], T. Mharadze[11], M. De Klerk[12], G. Tidwell[13], U. Ijeoma[1], S. Davis[1], R. Bhatia[1], Key Population PrEP Coverage Collaborators

[1]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Atlanta, United States, [2]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Addis Ababa, Ethiopia, [3]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Lilongwe, Malawi, [4]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Maputo, Mozambique, [5]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Abuja, Nigeria, [6]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Freetown, Sierra Leone, [7]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Pretoria, South Africa, [8]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Kampala, Uganda, [9]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, the United Republic of, [10]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Lusaka, Zambia, [11]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Harare, Zimbabwe, [12]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Windhoek, Namibia, [13]Health Resources and Services Administration, U.S. Department of Health and Human Services, Washington, D.C., United States

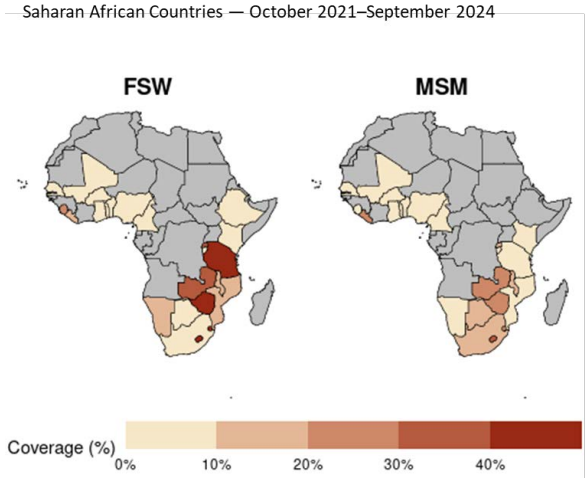
Background: Female sex workers (FSW) and men who have sex with men (MSM) are disproportionately affected by HIV and prioritized for HIV preexposure prophylaxis (PrEP), but current estimates of PrEP coverage among these populations are unavailable. We estimated PrEP coverage supported by the United States President's Emergency Plan for AIDS Relief (PEPFAR) for these populations in sub-Saharan African (SSA) countries by leveraging program data and population size estimates.

Methods: We extracted the number of quarterly PrEP users, including those initiating and continuing, from October 2021–September 2024 for 26 countries from PEPFAR's Monitoring, Evaluation, and Reporting system and calculated the population of FSW and MSM aged 18–49 years without HIV by country using recent population size estimates.

We estimated the proportion accessing PrEP services each quarter, PrEP coverage, by dividing quarterly PrEP users by the population without HIV and calculated 95% confidence intervals (CIs) using a Monte Carlo method.

Results: From October 2021–September 2024, PrEP coverage among FSW increased from 5.4% (95% CI: 4.0–6.9) to 13.9% (95% CI: 10.3–17.7). Coverage among MSM increased from 3.8% (95% CI: 3.1–4.5) to 8.9% (95% CI: 7.5–10.7). Coverage ranged widely across countries (Figure): By July–September 2024, the median country-level coverage among FSW had reached 8.7% (range 0.1–49.4%), while the median country-level coverage among MSM had reached 7.3% (range 0.0–33.5%). Growth in coverage ranged widely between countries, with a median country-level increase of 4.7% (range: -0.1–37.7%) among FSW and 4.5% (range: -0.2–20.3%) among MSM.

Figure: HIV Preexposure Prophylaxis Coverage (Proportion of Female Sex Workers and Men Who Have Sex with Men Accessing PrEP Services) Supported by the President's Emergency Plan for AIDS Relief in 26 Sub-Saharan African Countries — October 2021–September 2024



Conclusions: PEPFAR-supported PrEP coverage among FSW and MSM without HIV in SSA was low and growth was modest. These findings suggest a need for renewed commitment, enabling policies, non-discriminatory laws, and resources to fill gaps in programming. Additional options, including more dosing schedules and long-acting products, may support higher coverage.

EP0319

Expanding PrEP access through a community-based refill model in Kajiado West sub-county, Kenya

A. Mwangi[1], E. Kubo[1], C. Odhiambo[1], S. Arodi[1], R. Marima[1], J. Mecha[1], C.F. Otieno[1], E. Simiyu[1]

[1]University of Nairobi, Clinical Medicine and Therapeutics, Nairobi, Kenya

Background: Differentiated service delivery (DSD) for pre-exposure prophylaxis (PrEP) provides a novel approach to HIV prevention that is flexible and client-centered. Existing models of PrEP implementation do not adequately address barriers around stigma, frequent clinic visits and rigid scheduling that hinder good adherence and PrEP accessibility.

Methods: Starting April 2022, UoN-USAID *Fahari ya Jamii* project collaborated with Kajiado County to implement a DSD model for PrEP clients that involved community distribution of commodities through a peer and health care worker led model. Five out of eight low-volume facilities in

Kajiado West were selected. Clients chose pick-up points upon PrEP initiation. These included satellite dispensaries, shopping centres and *Manyattas,* with on-site HIV re-testing for those eligible. Implementation was spearheaded by facility clinicians, and monitoring of the intervention done monthly by monitoring and evaluation officers from the subcounty and the project.

We performed a retrospective review of the pre- and post-implementation data from PrEP registers and electronic medical records. All patient records from April 2022 to April 2024 were included. Descriptive and bivariate analyses were performed.

Results: Of 92 clients that were enrolled in this model, 48 (52%) were female. Forty-eight (52%) were discordant couples, 2 (2%) were key populations (KPs), adolescent girls and young women (AGYW) were 16 (17%), 1 (1%) was a breastfeeding woman and 23 (25%) were general population in the high-risk category.

Overall, 84% (67/80) of the clients were retained on PrEP at 6+ months, compared to 68% (19/28) pre-implementation. The percentage of patients continuing treatment was consistently high from 2022 to 2024, with 62.5%, 64.5%, and 100%, respectively, resulting in an overall rate of 72.8%. Ten to 19-months discontinuation without ongoing risk varied, appearing in 12.5% of cases in 2022 and 17.7% in 2023, but none in 2024, for an overall rate of 13.0%. There was a significant association between year and outcome (χ^2 = 11.206, p =.024).

Conclusions: DSD for PrEP was effective in improving continuity among clients initiated on PrEP.

EP0320

Long-acting HIV PrEP preferences through pregnancy and the postpartum period among women in Kenya: a latent transition analysis

S. Watoyi[1], T. Concepcion[2], J. Pintye[2,3], A. Wagner[2], G. Stewart[4,2], J. Dettinger[2], E. Akim[1], J. Kinuthia[1], F. Abuna[1], B. Odhiambo[1], N. Ngumbau[1], E. Mukenyi[1], L. Gomez[4], J. Mogaka[2], B.-P Flaherty[5]

[1]Kenyatta National hospital, Medical Research, Nairobi, Kenya, [2]University of Washington, Global Health, Seattle, United States, [3]University of Washington, Nursing, Seattle, United States, [4]University of Washington, Epidemiology, Seattle, United States, [5]University of Washington, Psychology, Seattle, United States

Background: Adherence to daily oral HIV PrEP wanes over pregnancy and postpartum periods and new long-acting injectable HIV PrEP (LAI-PrEP) methods may address barriers to adherence. Understanding changing preferences for LAI-PrEP during the perinatal period could inform the integration of new HIV prevention methods and maternal healthcare.

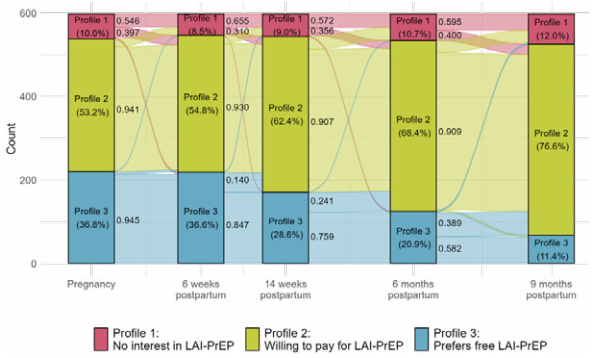
Methods: We used data from a randomized trial of pregnant women initiating oral PrEP in antenatal care followed through 9 months postpartum (NCT04472884) at five public facilities in western Kenya. Participants completed surveys on LAI-PrEP interest and preferences from the third trimester through nine months postpartum. Latent Transition Analysis (LTA) was used to examine the underlying patterns of LAI-PrEP interest throughout pregnancy and postpartum. Predictors of profile transitions between profiles were assessed using univariate logistic regression.

Results: Overall, 598 participants enrolled in pregnancy with a median age of 25 years (IQR: 22–29). Nearly two-thirds (63.2%) had at least secondary education, 21.1% had regular employment, and 70.6% were married.

We identified three profiles of LAI-PrEP preferences: "No interest in LAI-PrEP", "Willing to pay (WTP) for LAI-PrEP", and "Prefers free LAI-PrEP". Approximately 10% comprised the "No interest in LAI-PrEP" at each time point (Figure 1).

In pregnancy, 36.8% belonged to the "Prefers free LAI-PrEP" profile, with participants increasingly transitioning to "WTP for LAI-PrEP" through the postpartum period.

The "WTP for LAI-PrEP" profile grew from 53.2% in the third trimester to 76.6% at nine months postpartum. Women who were primigravida had 5-fold higher odds of transitioning from "WTP for LAI-PrEP" to "Prefers free LAI-PrEP" (95% CI: 5.29 - 5.39, p<0.001).



Conclusions: Most women belonged to a profile interested in LAI-PrEP across pregnancy and postpartum, with the willingness to pay for LAI-PrEP membership growing over time. Expanding PrEP options within MCH systems to include LAI-PrEP, especially for postpartum and primigravida women, could improve PrEP use during this critical period.

EP0321

Long-term retention in facility-based HIV pre-exposure prophylaxis services among female sex workers in Tanga, Tanzania: a prospective cohort study

W.P. Mikomangwa[1], K. Moen[2], E.J. Mmbaga[2], E. Metta[3], M.T. Leshabari[3], S.M. Kibusi[4], C.R. Sudfeld[5], M. Bakari[6], A.A.R. Kamuhabwa[7], G. Kwesigabo[1]
[1]Muhimbili University of Health and Allied Sciences, Epidemiology and Biostatistics, Dar es Salaam, United Republic of Tanzania, [2]University of oslo, Community Medicine and Global Health, Oslo, Norway, [3]Muhimbili University of Health and Allied Sciences, Behavioural Sciences, Dar es Salaam, United Republic of Tanzania, [4]University of Dodoma, Department of Public Health, Dodoma, United Republic of Tanzania, [5]Harvard T.H. Chan School of Public Health, Global Health and Population, Boston, United States, [6]Muhimbili University of Health and Allied Sciences, Internal Medicine, Dar es Salaam, United Republic of Tanzania, [7]Muhimbili University of Health and Allied Sciences, Clinical Pharmacy and Pharmacology, Dar es Salaam, United Republic of Tanzania

Background: To achieve a high level of impact of pre-exposure prophylaxis (PrEP) at the population level, retention in PrEP services among people at high risk of HIV is of paramount importance. Evidence is scarce on long-term retention in PrEP services among female sex workers in Sub-Saharan Africa.
The objective of this study was to determine the long-term retention in facility-based PrEP services and its determinants among female sex workers in Tanzania.
Methods: We conducted a prospective cohort study involving 313 female sex workers (≥18 years) enrolled by respondent-driven sampling in the City of Tanga, Tanzania. We followed each participant attending for PrEP service at Ngamiani Health center for 16 months between 2022 and 2023. Information on PrEP attendance/refill was extracted from PrEP files using case report form at 16th month. Long-term *retention in PrEP care* was defined as the cumulative proportion of participants attending ≥3 PrEP clinical follow-up visits in the first 16 months after PrEP initiation. A multivariable logistic regression model with clustered robust standard error was used to determine factors associated with long-term retention in PrEP services at p<0.05.
Results: Among 313 participants, the median age was 27 (IQR: 23-32) years, 72.2% self-perceived to be at high risk of HIV, 63.9% experienced "moderate" sex work stigma and 80.2% perceived "low" PrEP stigma. More than half (64.6%) had inadequate PrEP knowledge and 99.4% had high PrEP self-efficacy. At baseline, 4.2% had a history of STIs, and three (3) participants had a positive test for hepatitis B virus. Long-term retention in PrEP care was 11.0% (95% CI: 7.67-15.61). The determinants of long-term retention were having self-perceived "high" PrEP stigma (aRR 0.16, 95%CI: 0.03-0.99, p=0.049) and self-perceived "moderate" HIV risk (aRR 5.03, 95%CI: 1.37-18.47, p=0.015).
Conclusions: The long-term retention in facility-based HIV PrEP care was low. Perceived "moderate" HIV risk and "high" PrEP stigma were positively and negatively associated with long-term retention respectively, suggesting. These suggest that female sex workers face challenges to be retained in facility-based PrEP services for a long time. Client-cantered approach is recommended to address PrEP stigma and reinforce self-HIV risk assessment among female sex workers using facility-based PrEP services.

EP0322

Early Infant Diagnosis surveillance system evaluation, Mongu and Ndola District 2024, Zambia

H. Kaoma[1], D. Banda[2], J. Zulu[2], N. Sinyange[2]
[1]Zambia National Public Health Institute, Lusaka, Zambia, [2]Zambia National Public Health Institute, Field Epidemiology, Lusaka, Zambia

Background: The Early Infant Diagnosis (EID) surveillance system is a crucial indicator of how a country is faring in the early diagnosis of HIV in infants and determining how the Elimination of the mother-to-child transmission program is effective and efficient. EID surveillance system has not been evaluated in Zambia. This evaluation aimed to assess the system's performance in two cities with a high burden of HIV infection.
Methods: A qualitative approach was employed, including interviews, document reviews, and site visits to health facilities in Western and Copperbelt provinces. Data collection focused on the operational aspects of the EID surveillance system and its effectiveness in meeting program goals.
The MMWR Guidelines for Evaluating Surveillance Systems were used to evaluate the EID surveillance system. Attributes evaluated included; simplicity, flexibility, acceptability, timeliness, and stability.
Results: The EID surveillance system demonstrated high simplicity and efficiency, with Point-of-Care (POC) testing significantly reducing turnaround times. Flexibility was evident through adaptations such as new data collection tools and minimal training requirements.
The system showed high acceptability among stakeholders and sensitivity in detecting HIV in infants. While the system was operationally stable, it relied heavily on external support. Timeliness was robust, with rapid diagnosis and prompt initiation of care.
However, challenges included reliance on external funding, stock-outs of testing supplies, logistical barriers, and refusal of treatment by some mothers.
Conclusions: The system effectively supports Zambia's efforts to eliminate mother-to-child transmission of HIV by enabling early detection and treatment. Also, the EID surveillance system is a critical tool in Zambia's HIV response. While it has achieved notable successes, addressing operational and sustainability challenges is essential to ensure its continued effectiveness and alignment with national and global elimination targets.

EP0323

Pre-exposure prophylaxis awareness and associated factors among HIV-negative Female Sex Workers in Rwanda, 2023

J.C. Kwizera[1], G. Gatete[1], B. Ikuzo[1], G. Mujawamariya[1], A. Taofeek Tope[2], G. Nshogoza Rwibasira[1]
[1]Rwanda Biomedical Centre, Kigali, Rwanda, [2]University of Rwanda, Kigali, Rwanda

Background: Pre-exposure prophylaxis (PrEP) is an essential HIV prevention tool for female sex workers (FSWs) in Rwanda, a group with high HIV prevalence. While a study in Kigali reported 81% awareness of PrEP among FSWs, this study assessed nationwide awareness and examined factors influencing it.

Methods: A cross-sectional bio-behavioral survey was conducted from May to June 2023 among 2,541 FSWs aged 15 and older across Rwanda. Of these, 1,675 HIV-negative participants were analyzed to assess PrEP awareness, defined as having ever heard of PrEP. Data were adjusted for recruitment biases using Gile's sequential sampling weights, and statistical analyses, including Chi-square tests and multivariate logistic regression, were performed using STATA 17 to identify predictors.

Results: Majority of HIV-negative FSWs were aged 25–34 years (44.4%, 95% CI: 40.1–48.7) and had completed primary education (53.1%, 95% CI: 48.7–57.4). Most were single (77.4%, 95% CI: 74.4–80.5), while only 44.2% (95% CI: 39.9–48.6) were enrolled in key populations (KPs) programs at health facilities.

Awareness of PrEP was 60.2% (95% CI: 55.8–64.5), with 51.5% (95% CI: 46.0–56.9) of those having ever used it in their lifetime and 37.0% (95% CI: 31.9–42.4) having used it in the past six months. Awareness was higher (82.8%, 95% CI: 76.6–87.6) among FSWs enrolled in KP programs at health facilities.

Multivariate analysis identified predictors of being unaware of PrEP as never attending school (aOR: 1.8, 95% CI: 1.2–3.2), being married or cohabiting (aOR: 4.0, 95% CI: 1.4–11.5), and not enrolled at KP programs at health facilities (aOR: 7.6, 95% CI: 4.8–11.9).

Conclusions: PrEP awareness among HIV-negative female sex workers (FSWs) in Rwanda remains below optimal levels, with disparities influenced by factors such as education, marital status, and access to HIV program support.

Although key population-friendly services are increasingly available at health facilities nationwide, addressing stigma and discrimination is essential to improving disclosure and access to HIV prevention services for FSWs.

Expanding the reach of HIV program assistance and implementing targeted interventions for underserved FSW subgroups are critical steps to enhancing PrEP awareness, increasing uptake, and ensuring equitable access to HIV prevention tools.

EP0324

Awareness and acceptability of Doxy-PEP for the prevention of sexually transmitted infections among persons living with HIV in two Nigerian hospitals: a cross-sectional assessment

V. Okonkwo[1,2], C. Agbo[1,2], O. Eze[1], M. Agu[1,2], S. Ejimofor[1], O. Igwebuike[1], K. Ngwu[1], C. Opah[3], F. Agbaeze[1], C. Osuji[1], A. Isah[1,2]
[1]University of Nigeria, Nsukka, Clinical Pharmacy and Pharmacy Management, Enugu, Nigeria, [2]Person-Centered HIV Research Team, Enugu, Nigeria, [3]University of Nigeria Teaching Hospital, Enugu, Nigeria

Background: Sexually transmitted infections (STIs) are becoming more widespread globally and can negatively impact treatment outcomes of antiretroviral therapy (ART). It is essential for Persons Living with HIV (PLHIV) to be aware of preventive measures against STIs such as Doxycycline Post-exposure Prophylaxis (Doxy-PEP) which has shown efficacy in preventing some STIs such as Chlamydia, Gonorrhea and Syphilis.

This study evaluated the level of awareness among PLHIV in two Nigerian hospitals regarding the utilization of Doxy-PEP as a preventive measure against STIs, as well as their willingness to consider its use.

Methods: Employing a cross-sectional study design, we used an 18-item structured and self-administered questionnaire to collect data from PLHIV at two hospitals in southeastern Nigeria: faith-based Bishop Shanahan Hospital (BSH) and the government-owned University of Nigeria Teaching Hospital (UNTH). Data was collected from 334 participants (152 from BSH and 182 from UNTH) from November to December, 2024. Inferential and descriptive analysis were done using IBM SPSS 27.0 where significance was set as $p < 0.05$.

Results: More than half of the respondents were females (n = 242; 72.45%) and were within the age of 35-44 years (n = 114, 34.1%). Of the 334 participants, 294 (88.0%) were unaware of Doxy-PEP, with 150 (44.9%) respondents reporting that they would prefer to receive information about Doxy-PEP at healthcare facilities.

Most respondents (n = 276; 82.6%) were willing to use Doxy-PEP if accessible, citing STI prevention (30.5%) as a key reason. Having a higher educational qualification ($p = 0.001$), engagement in entrepreneurship ($p = 0.038$) and being unmarried were associated with better knowledge of Doxy-PEP.

Conclusions: The level of awareness of Doxy-PEP is low in the two hospitals whereas the willingness to use it is high. Awareness or education on Doxy-PEP as a prophylaxis for STIs should be increased especially in rural communities. Healthcare providers should educate more PLHIV about Doxy-PEP and its role in STI prevention.

EP0325

Experiences of disclosure of oral pre-exposure prophylaxis (PrEP) and dapivirine vaginal ring use among South African women using PrEP: a qualitative study

F.A. Cholo[1], F.M. Musvipwa[1], S. Dada[1], M. Pleaner[1], C.E. Martin[1], S. Mullick[1]
[1]Wits RHI, University of the Witwatersrand, Johannesburg, South Africa

Background: Oral pre-exposure prophylaxis (PrEP), and the dapivirine vaginal ring (DVR) are effective in preventing HIV. However, their success is dependent on effective use. Studies show that disclosing oral PrEP use enhances adherence. While experiences of oral PrEP disclosure are well-documented, little is known about DVR disclosure and how experiences might differ, given its discreet, long-acting nature.
This study explores experiences of oral PrEP and DVR disclosure among South African women.
Methods: This study is nested within an implementation study evaluating the introduction of new PrEP methods in eight primary healthcare and four linked mobile clinics in South Africa. Women ≥18 years, enrolled in a cohort offering an option of PrEP methods, and having used either oral PrEP or DVR, were purposefully invited to participate in focus group discussions (FGDs). Between April and May 2024, 12 FGDs were conducted with 126 women aged 18-57 years across sites in two provinces. FGDs explored, among other themes, experiences with disclosing PrEP use, factors influencing disclosure, and reactions of person to whom they disclosed. FGDs were audio-recorded, transcribed, and analysed thematically.
Results: Women reported greater disclosure of DVR use than oral PrEP, primarily to friends, partners, and family. Disclosure occurred both voluntarily and involuntarily. DVR disclosure to partners was mostly involuntary, occurring when partners felt the DVR or when it was accidentally expelled, while voluntary disclosure to friends was motivated by the belief they may be interested in using the DVR themselves. Voluntary disclosure of oral PrEP was influenced by partners' familiarity with oral PrEP. Both methods elicited supportive reactions, with oral PrEP disclosures leading to daily reminders and praise, and DVR disclosure resulting in support with insertion and pick-up reminders. However, oral PrEP disclosure sometimes led to mistrust and HIV-related stigma, while DVR disclosure led to mistrust, requests for removal, myths, and efficacy concerns.
Conclusions: Our study contributes new findings on PrEP disclosure among women offered an option of oral PrEP or DVR in real-world settings. While most disclosures elicited supportive reactions, negative reactions highlight the need for ongoing counselling and support for PrEP users, and education and engagement with key influencers.

EP0326

Preference for long-acting injectable HIV PrEP among adolescent girls and young women accessing sexual and reproductive health services at retail pharmacies in Kenya

F. Mogaka[1], B. Rono[1], B. Nyerere[1], G. Rota[1], H. Lagat[2], J. Odoyo[1], K. Ortblad F.[3], M. Lenn[2], M. Mugambi[2], M. Sharma[2], A. Omolara[2], V. Omollo[1], Z. Kwena[1], E. Bukusi[1], J. Pintye[2], C. Otachi[1]
[1]Kenya Medical Research Institute, Centre for Microbiology Research, Kisumu, Kenya, [2]University of Washington, Seattle, United States, [3]Fred Hutchinson Cancer Research Centre, Seattle, United States

Background: Adolescent girls and young women (AGYW) frequently access sexual and reproductive health services at retail pharmacies in Kenya and HIV PrEP delivery is being studied in this setting. Yet, discontinuation is common among AGYW who initiate either daily oral HIV PrEP or the dapivirine vaginal ring (DPV-VR) within pharmacies. We assessed the preferences for long-acting injectable HIV PrEP (LAI-PrEP) among AGYW accessing contraception and HIV PrEP at retail pharmacies in Western Kenya.
Methods: We analyzed data from AGYW participating in an ongoing cluster randomized controlled trial (NCT05467306) investigating pharmacy-based HIV PrEP delivery models at 20 retail pharmacies in Kisumu, Kenya. PrEP-eligible AGYW (ages 15–24) purchasing contraception were offered daily oral HIV PrEP or the monthly DPV-VR per national guidelines. Preferences for LAI-PrEP was ascertained at one-month follow-up visits, analyzed and presented descriptively.
Results: From May 2023 to January 2024, 1511 AGYW enrolled in the trial and were eligible for one-month follow-up visits. Among the 1241(82%) AGYW who completed month one follow-up, the median age was 21 years (IQR 19–23), most (83%, 1030/1241) were unmarried, and roughly half reported casual sexual partners (59%, 732/1241) and a prior pregnancy (54%, 670/1241).
Oral PrEP or DPV-VR uptake among AGYW at enrollment was 82% (1017/1241). If LAI-PrEP became available, two-thirds (66%, 819/1241) of AGYW reported that they would prefer this over oral PrEP or DPV-VR.
Preference for LAI-PrEP varied among AGYW who accepted oral PrEP (67%, 539/810), DPV-VR (71%, 156/220), or declined both (59%, 125/211) (p<0.001). Primary reasons for preferring LAI-PrEP included longer action duration (84%, 687/820) and pill burden elimination (84%, 691/820).
Primary concerns about LAI-PrEP included injection site pain (69%, 276/403) and potential side effects (51%, 207/403). Retail pharmacies were identified as the most preferred location for LAI-PrEP access (78%, 641/820) followed by healthcare clinics (16%, 130/820) and family planning clinics (5%, 40/820).
Conclusions: LAI-PrEP was preferred among AGYW seeking sexual and reproductive health services at retail pharmacies in Kenya. Scaling up LAI-PrEP within pharmacies could reach AGYW at high risk for HIV acquisition in this setting.

EP0327

Circumcision for HIV prevention in men who have sex with men: a 2024 update on evidence

S. Davis[1], D. Philpott[1], G. Mansergh[1], R. Bain[1], R. Bhatia[1], P. Bastani[1], A. Hakim[1], C. Toledo[1]

[1]US Centers for Disease Control and Prevention, Atlanta, United States

Background: Voluntary medical male circumcision (VMMC) is recommended for HIV prevention for men who have sex with women in sub-Saharan Africa. However, consensus on its effectiveness for men who have sex with men (MSM) is lacking, partly due to inconsistencies between studies. A 2024 randomized trial conducted in China showed protection among primarily-insertive MSM. We conducted an updated review of observational data to clarify the total weight of the evidence.

Methods: We conducted a systematic global observational literature search through mid-October 2024 on the association of HIV with circumcision in MSM, adding published biobehavioral survey (BBS) reports in our possession and studies available only as abstracted data in prior meta-analyses (e.g., inaccessible dissertations).

We excluded studies from VMMC-implementing countries, where self-selection of MSM with HIV out of VMMC creates bias toward protection. We analyzed all results, and the subgroup stratifying by sexual positioning, as VMMC is expected only to benefit MSM with predominantly-insertive roles.

We accepted all measures of association, normalizing their coefficients (CoAs) so values <1 reflect protection. We categorized findings as "lower-risk, significant" (LRS; CoA < 0.94, p<.05), "not significant" (LRNS; p≥.05), "neutral" (CoA 0.94-1.06), "higher-risk, not significant" (HRNS; CoA>1.06), and "significant" (HRS).

For studies stratifying by sexual positioning, we also compared findings among all participants with those in the predominantly-insertive subgroup.

Results: We identified 49 observational studies and BBS reports - 12 not in prior meta-analyses - in five global regions. 8 were LRS, 23 LRNS, 10 neutral, 7 HRNS, and 1 HRS. The median CoA was odds ratio (OR)=0.79; among studies with significant results, it was OR=0.46. Among 12 studies reporting on predominantly-insertive men, nine had 400 or fewer predominantly-insertive participants.

Nine assessed significance: 1 LRS, 4 LRNS, 2 neutral or mixed LRNS/HRNS (stratified by race), 2 HRNS. The median CoA was OR=0.61.

Ten provided CoA estimates for both predominantly-insertive men and all participants (11 total estimates); estimates were lower-risk for predominantly-insertive men than for the full participant pool in 7/11. Confidence intervals overlapped.

Conclusions: In addition to recent trial evidence, and consistent with prior meta-analyses, observational data suggest circumcision may be somewhat protective for predominantly-insertive MSM.

EP0328

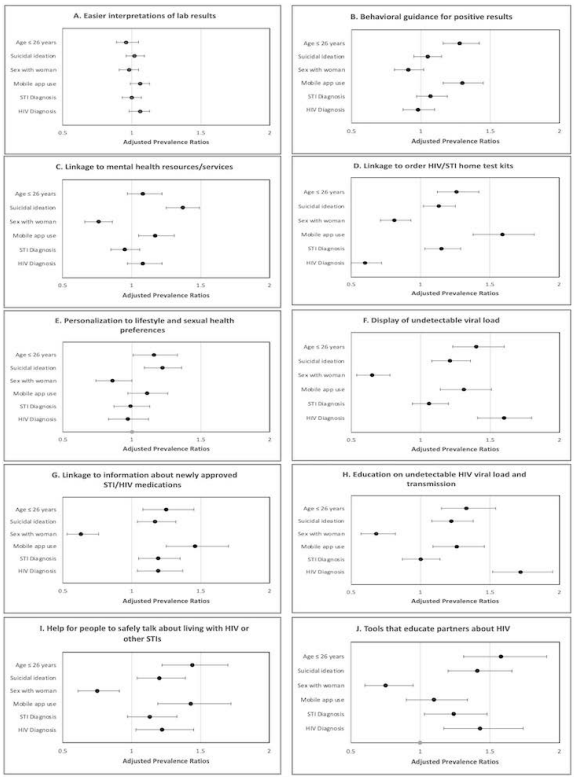
Differences in the desired sexually transmitted infection prevention features for patient portals among men who have sex with men in the United States

K.-M. Jackman[1], T. Carpino[2], M. Trent[2], T. Sanchez[3], S. Baral[2]

[1]Johns Hopkins University School of Medicine, Pediatrics, Baltimore, United States, [2]Johns Hopkins University, Baltimore, United States, [3]Emory University, Atlanta, United States

Background: Gay, bisexual and other men who have sex with men (MSM) are more likely to acquire sexually transmitted infections (STIs), including HIV. The development of digital health tools that leverage the patient portal to improve STI prevention and care outcomes are a burgeoning area of research. To inform priorities for designing novel tools, this study explores interest in incoporating 10 specific STI prevention features into patient portals among MSM in the United States.

Methods: Data come from the 2022-2023 American Men's Internet Survey. Participants were asked to indicate which of 10 STI prevention features were desired for incorporation into patient portals. Multivariable Poisson regression analyses with robust error variance were conducted to compare prevalence ratios (PR) for each feature by factors including, (a) age category, (b) suicidal ideation, (c) any type of sex with a woman, (d) mobile app use to meet men, (e) bacterial STI diagnosis in the prior 12 months, and (f) living with HIV.



Results: The final analytic sample included 3,495 participants. The most desired features were: [A] Easier interpretations of lab results (64.2%); [B] Behavioral guidance for positive results (43.1%); and [C] Linkage to mental health

resources/services (40.5%). 'Younger' versus 'older' MSM were more interested, whereas, 'bisexual' versus 'gay' MSM were less interested in all features except [A] and [B]. MSM reporting suicidal ideation had the highest PRs for [B] and [E]. MSM reporting mobile app use to meet men reported the highest PRs for [D] and [G]. MSM living with HIV reported the highest PRs for [F] and [H], while having the lowest interest in [G].

Conclusions: The integration of person-centric STI prevention features into patient portals represent transformational opportunities for increasing patient engagement and improving health outcomes.

Culturally-congruent strategies are required to make the health information in patient portals easier for its users to understand.

EP0329

The influence of self-efficacy, knowledge, and attitudes on PrEP adherence among women engaged in sex work in Southwestern Uganda

A. Kabarambi[1,2], J. Kiyinji[3], J. Samiri[1,2], P. Namatovu[1,2], M. Naseh[2,1], P. Nabunya[2,1]
[1]International Center for Child Health and Development, Masaka, Uganda, [2]Washington University in St.Louis, St. Louis, United States, [3]University of California in San Franscisco, San Franscisco, United States

Background: We examined the role of self-efficacy and attitudes on PrEP adherence among women engaged in sex work (WESW) in Southwestern Uganda.

Methods: We conducted a cross-sectional sub-study within the Kyaterekera study (2018–2023), which recruited women engaged in sex work (WESW) aged 18 years and older from HIV hotspots in Southwestern Uganda. This sub-study focused on HIV-negative women who had been on oral PrEP during the final wave of the Kyaterekera study. Participants were surveyed using a validated, interviewer-administered questionnaire in Luganda, capturing socio-demographic information such as age, marital status, education level, and alcohol use.

Attitudes toward PrEP use were assessed through five questions about participants' willingness to use PrEP, with higher scores indicating more favorable attitudes. PrEP knowledge was measured using a 10-item knowledge scale, and self-efficacy was assessed using an 8-item scale, with higher scores indicating greater confidence in using PrEP. Adherence was self-reported based on participants' use of PrEP in the past 30 days.

Descriptive statistics were calculated for all variables. A multivariate logistic regression model was employed, adjusting for potential confounders and clustering at the study site level. Adjusted odds ratios, 95% confidence intervals, and statistical significance were reported.

Results: The study participants had a mean age of 30.77 years, with most being divorced or separated (54.21%) and over half having post-primary education (57%). 40.19% reported good adherence.

Higher odds of good PrEP adherence were significantly associated with higher levels of PrEP self-efficacy (AOR = 1.54, 95% CI: 1.26–1.87, $p < 0.001$) and more favorable attitudes toward PrEP use (AOR = 1.32, 95% CI: 1.03–1.68, $p = 0.029$). PrEP knowledge (AOR = 1.05, 95% CI: 0.52–2.12, $p = 0.897$) was not significantly associated with PrEP adherence.

Conclusions: Fostering positive attitudes toward PrEP use and enhancing self-efficacy is crucial for improving PrEP adherence among women engaged in sex work. Interventions targeting this population should focus on building confidence in PrEP use through tailored support programs rather than solely emphasizing knowledge dissemination.

EP0330

An integrated approach to customary male initiation practices improves access to male circumcision services in Eastern Cape, South Africa

N. Igaba[1], M. Phohole[1], K. Moyo[1], S. Hlongwane[1], E. Majaya[1], S. Grove[1], C. Wose Kinge[1], C. Chasela[1]
[1]Right to Care, VMMC, Pretoria, South Africa

Background: Male circumcision (MC) is part of the customary male initiation (CMI) activities of AmaXhosa males in the Eastern Cape (EC) Province as part of the rite of passage from boy to manhood. We assessed the effect of an integrated model of CMI support to offer high quality, safe MC services to males in five districts supported by Right to Care (RTC) and Population Service International (PSI) in EC.

Description: The integrated model of CMI support involved community entry processes, community advocacy campaigns on Safe MC, screening of prospective initiates for chronic illnesses, MC procedure, follow-up, and adverse events management.

Routine program data were collected using standardized tools. The data were captured and stored in a cloud data storage system and later analyzed using descriptive analysis.

Program indicators' data from Financial Year (FY) 2016-2018 (before implementation) and FY2019-2022 (after implementation) were compared.

Lessons learned: In the period of this study, a cumulative number of 280,483 MMCs were performed in the five EC districts with 237,864 (85%) MMCs performed after the implementation of this model. Only 26,079 males aged 15-24 (12%) were circumcised before the implementation of this model, compared to 198,876 (88%) circumcised after the implementation.

The circumcision rate for the 15-24 years age group increased dramatically from 1.8% before implementation to 11.4% after the introduction. Equally, 87% of males had at least one follow-up after MMC after implementation compared to 13% before implementation.

The uptake of HIV testing service was improved from 76.94% before implementation to 94,65% after implementation. There was a reduction of 64, 888 (13%) in the population of 15-24-year-old males in these five districts over the period of this study.

Conclusions/Next steps: The results demonstrated that the implementation of the integrated model of CMI support in the EC contributed to a shift towards reaching the 15-24 years age group for circumcision services including

total number of males circumcised, proportion of males tested for HIV and follow-up after circumcision procedure. This model is a viable option to implement on CMI practicing communities to scale up MMC services in SA.

EP0331

Factors associated with awareness and utilization of pre-exposure prophylaxis for human immunodeficiency virus (HIV) prevention among MSM in Rwanda

G. Twagirimana[1], C. Kayitesi[1], Z. Nzeyimana[2], C. Ndinda[1], G. Gatete[1], B. Ikuzo[1], V. Umubyeyi Mupenzi[3], G. Nshogoza Rwibasira[4]

[1]Rwanda Biomedical Center, HIV Epidemiology Surveillance and Research Unit, Kigali, Rwanda, [2]Rwanda Biomedical Center, HIV Prevention Unit, Kigali, Rwanda, [3]Rwanda Biomedical Center, Director of HIV Epidemiology, Surveillance and Research Unit, Kigali, Rwanda, [4]Rwanda Biomedical Center, HIV Division Manager HIV, STIs and Hepatitis Programs in Rwanda, Rwanda Biomedical Centre, Kigali, Rwanda

Background: Pre-exposure prophylaxis (PrEP) is an essential biomedical intervention to prevent HIV among men who have sex with men (MSM). Despite its availability, the uptake and awareness levels among MSM in Rwanda remain suboptimal.

This study investigated the factors associated with PrEP awareness and utilization among MSM in Rwanda.

Methods: A secondary analysis of data from the Bio-Behavioral Surveillance (BBS) survey was conducted in 2024 using respondent-driven sampling.

Multivariate logistic regression models were used to identify determinants of PrEP awareness and utilization, focusing on demographic, social, and behavioral factors. Adjusted odds ratios (AORs) and 95% confidence intervals (CIs) were reported.

Results: We analyzed data of 3757 MSM and nearly a half (48.1%) aged 18 to 24 years PrEP awareness among MSM was 48.57% (95% CI: 45.76–51.39), while utilization was 22.42% (95% CI: 19.27–25.92).

Awareness was significantly associated with residing in the North (AOR: 2.66; 95% CI: 1.80–3.94) and South (AOR: 1.45; 95% CI: 1.07–1.97), being a merchant (AOR: 2.87; 95% CI: 1.47–5.60), self-employed (AOR: 3.37; 95% CI: 1.53–7.42), or a sex worker (AOR: 29.29; 95% CI: 6.25–137.29), and exposure to HIV-related messages (AOR: 2.75; 95% CI: 2.12–3.57). PrEP utilization was higher among individuals who traveled outside the country for sex (AOR: 7.60; 95% CI: 1.81–31.60), those using male condoms during sex (AOR: 1.34; 95% CI: 1.04–1.72), and self-employed individuals (AOR: 11.63; 95% CI: 1.89–71.53).

Conversely, losing respect in the community (AOR: 0.63; 95% CI: 0.45–0.87) and avoiding illicit drug use (AOR: 0.38; 95% CI: 0.16–0.89) were negatively associated with utilization.

Conclusions: PrEP awareness and utilization among MSM in Rwanda are influenced by regional, occupational, and behavioral factors. Targeted interventions addressing awareness gaps, regional disparities, and stigma are critical for improving PrEP uptake. These findings emphasize the need for personalized strategies to promote PrEP accessibility and usage within this high-risk population.

EP0332

HIV pre-exposure prophylaxis uptake and continuation among adolescent girls and young women enrolled in the DREAMS Urban Model Program in Masaka-Wakiso, Uganda, 2023-2024

M. Nagawa[1], B. Kisubika[1], G. Nakabugo[1], E. Nasuuna[1], M. Ssuuna[1], P. Kavuma[1]

[1]Infectious Diseases Institute, Health System Strengthening, Kampala, Uganda

Background: Adolescent girls and young women aged 15-24 years have the highest HIV incidence in Uganda. The Determined Resilient Empowered AIDS-free Mentored Safe (DREAMS) is an HIV prevention program aimed at reducing HIV infections among AGYW.

We present experiences, lessons learned from providing Pre- Exposure prophylaxis, an HIV prevention strategy to AGYW most at risk of acquiring HIV in Masaka-Wakiso region of Uganda.

Methods: The program was implemented from October 2023 to September 2024 in 11 districts. We screened AGYW 15-24 years for HIV, STIs, PrEP eligibility using Ministry of Health recommended screening tools if they fulfilled criteria for being most at risk of HIV acquisition like irregular condom use, multiple sexual partners, transactional sex, recurrent sexually transmitted diseases, early pregnancy. Eligible AGYW were offered Prep and were initiated at the health facility, safe spaces or outreaches.

Interventions to improve uptake and adherence included: peer-to-peer support and reminders, use of PrEP ambassadors, health educations, home delivery, male partner engagement, keeping PrEP drugs at the safe spaces.

Follow up for continuity was done through phone calls and home visits. Data was entered in the Uganda DREAMS Tracking system, we analysed PrEP uptake as proportion of AGYW enrolled and retained on PrEP through PrEP registers and Ms Excel.

Results: A total of 21,938 AGYW were enrolled 15-19years, of which 14,253 (65%) were screened and all tested HIV negative. A total of 1,414 (9.6%) were eligible for PrEP with more than one risk; 521 (36%) were engaged in transactional sex, 242 (17.1%) had multiple sexual partners, 446 (31.5%) had an STI, 181 (12.8%) irregular condom use, and 603 (42.6%) had history of pregnancy. Of AGYW eligible for PrEP, 989 (69.9%) were initiated on PrEP.

However, 591 (59.7%) continued with PrEP while 398 (40.2%) discontinued PrEP due to perception of reduced HIV risks (108, 27.1%), behavioural change (203,51%), fear of daily pill burden (87,21%).

Conclusions: The tried interventions were effective for Prep uptake, there is need to intensify engagement of Prep champions to conduct adherence counselling, improve the drug package and consider Roll out of Injectable Cabotegravir for all AGYW in the DREAMS program.

EP0333

Community priorities for PrEP research and delivery: insights from the People's Research Agenda

G. Kumwenda[1], N. Jain[2], C. Kasanda[3], I. Mulala[3], J. Limo[4], U. Mtamba[5], S. Hannah[6], M. Warren[2]
[1]AVAC, Research Engagement, Blantyre, Malawi, [2]AVAC, New York, United States, [3]Treatment Advocacy and Literacy Campaign (TALC), Lusaka, Zambia, [4]Ambassador For Youth and Adolescent Reproductive Health Program (AYARHEP), Nairobi, Kenya, [5]GEM, Blantyre, Malawi, [6]AVAC, Atlanta, United States

Background: Daily oral tenofovir-based Pre-exposure Prophylaxis (PrEP) has become the most widely used ARV-based prevention method since its 2015 approval, with over 7 million people initiating globally. Over time, additional prevention products have entered the research pipeline, with some approved and others under investigation.
Innovations like injectable options, including cabotegravir (CAB) and lenacapavir (LEN), have transformed HIV prevention by offering diverse delivery mechanisms, protection durations, and adding choice.
Despite advancements, barriers such as stigma, limited access, costs, and inequitable rollout hinder uptake, sustained use, and impact. Meaningful community engagement remains vital to ensure product development translates into impact.
Description: The Coalition to Accelerate & Support Prevention Research (CASPR) developed the People's Research Agenda (PRA) to identify community priorities for the HIV prevention R&D pipeline. The PRA employed a mixed-method approach, engaging over 130 advocates from 23 countries. Data collection took place between March and August 2024 through surveys, focus groups, and convenings.
The collected data was synthesized, analyzed, and validated, culminating in the launch of the PRA in October 2024. The PRA provides key recommendations for advancing the pipeline; here, we present targeted recommendations for PrEP research and delivery.
Lessons learned: The PRA highlighted that PrEP R&D require people-centered approaches, emphasizing:

- Implementation science should prioritize understanding user preferences, adherence patterns, product switching in the context of choice, and challenges with PrEP continuation and reinitiation.
- Future product modifications, such as self-administered ARV-based methods or alternative dosing schedules have the potential to expand prevention services and increase user choice.
- Equitable access requires early action to address systemic barriers, including costs, licensing, and supply chain challenges, alongside investments in provider training and community engagement.
- Social and behavioral science integration, along with early engagement with policymakers and regulators during the research phase, is essential to mitigate potential bottlenecks in the rollout and scaling of new technologies.

Conclusions/Next steps: Communities play an important role in shaping HIV prevention R&D and delivery. The PRA provides a clear roadmap for aligning innovations with community-defined needs and preferences. In 2025, the PRA will focus on developing a framework for advocacy, decision-making and accountability to address critical gaps in HIV prevention research and delivery.

EP0334

Factors influencing PrEP adherence among female sex workers (FSWs) in Kinshasa, Democratic Republic of Congo: a longitudinal, mixed-methods cohort study

B. Bepouka[1,2], A. Okolo[3], A. Demule[3], M. Sikando[3]
[1]University of Kinshasa, Internal Medicine, Kinshasa, Congo, the Democratic Republic of the, [2]Kinshasa University Hospital, Kinshasa, Congo, the Democratic Republic of the, [3]University of Kinshasa, Ecology of Infectious Diseases, Kinshasa, Congo, the Democratic Republic of the

Background: The Democratic Republic of Congo (DRC) has low HIV prevalence in the general population, with much higher prevalence and incidence among female sex workers (FSWs) than other key populations. PrEP adherence is one of the strategies to reduce HIV prevalence and incidence among FSWs.
The aim of the study was to identify factors influencing PrEP adherence among FSWs in Kinshasa, DRC as well as determine the retention rate of FSWs at the PrEP site during follow-up.
Methods: We used both quantitative and qualitative approaches. The quantitative part was a 6-month longitudinal cohort follow-up of 120 FSWs in 4 user-friendly centers in Kinshasa in 2024. We also conducted 12 in-depth interviews with purposively selected FSWs. Pill count and self-reported missing doses in the past 7 days were used to measure adherence. Multivariate logistic regression was used to identify factors influencing adherence to PrEP, and thematic analysis was used for the qualitative part.
Results: A total of 120 FSWs on PrEP were included. The median age was 28 years (IQR: 24-37 years). During follow-up, adherence improved in all four sites (80% adherents at Month 1, 93% at Month 3 and 95% at Month 6). In the quantitative part, the independent factor associated with non-adherence was being forced to have sex in the last month (aOR :6.35; CI 95% :1.57-25.65).
Sex as the only source of income (aOR :0.19; CI 95% :0.09-0.42), systematic condom use (aOR: 0.042; CI 95%: 0.002-0.73) and duration of more than 2 years as a PS (aOR 0.04; CI 95%:0.003-0.60) had good adherence. For the qualitative part, the barriers to adherence were stock-outs at the facility, persistence of side effects, mobility and hunger.
There was no seroconversion during follow up, and retention at the sites was 92% at Month 3 and 84% at Month 6 respectively.
Conclusions: Our results highlight obstacles to PrEP adherence among FSWs in the DRC. Future interventions should aim at helping FSWs to improve PrEP uptake and community awareness, and structures to support FSWs to face the challenges related to PrEP uptake.

EP0335

HIV periconception PrEP as an empowerment tool for women in HIV-serodifferent relationships or otherwise exposed to HIV in southwestern Uganda

M. Owembabazi[1], M.C. Pratt[2], W. Muyindike[1], A. Kaida[3], D. R. Bansberg[4], B. B. Mwebesa[5], C. Psaros[6], E. Atukunda[5], L.T. Mathews[2]

[1]Mbarara University of Science and Technology, Research, Mbarara, Uganda, [2]Division of Infectious Diseases UAB Medicine, Medicine, Albama, United States, [3]Simon Fraser University,, Faculty of health sciences, Burnaby, Canada, [4]Oregon Health Sciences University - Portland State University, Portland, United States, [5]Mbarara University of Science and Technology, Mbarara, Uganda, [6]Massachusetts General Hospital,, Boston MA, United States

Background: Uganda has one of the world's highest fertility rates, yet HIV prevention before pregnancy remains under-addressed, despite robust perinatal transmission prevention services for pregnant women with HIV. Women in HIV-affected partnerships often engage in condomless sex to fulfill personal and sociocultural goals of having children, placing them at risk of HIV.

This study explores how women initiate and adhere to PrEP as a peri-conception HIV risk-reduction strategy.

Methods: The study provided safer conception care to HIV-negative women in rural Uganda who reported a partner who is likely to have HIV and plans for pregnancy. Participants (N=37 women and N=7 partners) were followed with adherence counseling and qualitative interviews exploring PrEP adherence experiences, barriers, and facilitators. Women were purposively sampled by adherence levels: ≥80%, <80%, and non-use of PrEP. A thematic analysis of interview data was conducted to identify key patterns and insights.

Here, we present a secondary analysis of the qualitative data focused on the challenges women faced during peri-conception and how PrEP emerged as an empowering tool in their HIV prevention journey.

Results: 34 women and 6 men were included in the analysis with a median age of 33 years, with the majority having less than primary education (62%) and reporting self-employment (51%). Women feared HIV acquisition in their partnerships before safer conception counseling.

Women's lack of decision-making and relationship power limited their ability to negotiate HIV prevention strategy use when trying to conceive. PrEP was accepted as a female-controlled method of HIV prevention that did not require male participation, giving women back some control over their sexual and reproductive health.

Through the use of PrEP, women felt empowered, leading them to adhere well to the medication as it was a "rescue method" that improved their self-worth and relationships and gave them hope for having an HIV-free child.

Conclusions: Women may adhere to periconception PrEP in order to exert control over their sexual and reproductive health while maintaining and strengthening their relationships. Incorporating psychological and relational factors into prevention strategies may help optimize use.

EP0336

Changes in product use perceptions during a crossover study utilising placebo long-acting Pre-exposure Prophylaxis (LA-PrEP) injections and implants for HIV-prevention among South African men

M.H. Diaz[1], C. Hart[1], N. Mangxilana[2], S. Tenza[3], S.K. Zulu[3], T. Palanee-Phillips[3,4], M. Atujuna[2], N. Ndlovu[3], P. Sibiya[3], K. Reddy[3], Z. Njengele-Tetyana[3], K. Gill[2], A. Minnis[1], E.T. Montgomery[1,5], SAMURAI Study Team

[1]Research Triangle Institute (RTI) International, Women's Global Health Imperative, Berkeley, United States, [2]University of Cape Town, Desmond Tutu HIV Centre Institute of Infectious Disease and Molecular Medicine, Faculty of Health Sciences, Cape Town, South Africa, [3]University of the Witwatersrand, Wits RHI, Faculty of Health Sciences, Johannesburg, South Africa, [4]University of Washington, Department of Epidemiology, School of Public Health, Seattle, United States, [5]University of California, San Francisco, Department of Epidemiology and Biostatistics, School of Medicine, San Francisco, United States

Background: Existing barriers to daily oral PrEP use among men may be mitigated through LA-PrEP delivery methods such as intramuscular injections and subdermal implants. There is limited data on how cisgender men in South Africa, the epicentre of the HIV epidemic, perceive these LA platforms.

To explore their perspectives and experiences, we conducted in-depth interviews (IDIs) with participants from the South African Male User Research on Acceptability of Implants and Injections (SAMURAI) study, a crossover trial evaluating placebo LA-PrEP options.

Methods: Between July 2022 and October 2023, SAMURAI enrolled a total of 184 cisgender men-who-have-sex-with-women-only (MSW) and men-who-have-sex-with-men (MSM) in Johannesburg and Cape Town. Participants underwent a 12-month randomized crossover study of two placebo LA-PrEP products, receiving three bimonthly intramuscular injections and a six-month subdermal implant.

After trying both products a subset of 20 purposively-selected participants (10 MSM and 10 MSW) participated in IDIs at study exit, sharing their experiences and perspectives on study products. Interview recordings were transcribed, translated to English, and thematically coded in Dedoose software, with 10% of the transcripts triple-coded.

Results: Prior to beginning product use, participants expressed initial concerns about the pain associated with injection administration or implant insertion, which were eased by their actual experience of receiving both study products. They found the implant insertion process less invasive and injections less painful than expected. As expectations shifted, so did perceptions around masculinity and product use.

Participants who reported their communities viewing these potential PrEP delivery methods, particularly the implant, as "feminine," were able to educate family and friends on the research and use of these products by men. Many participants expressed willingness to use active ver-

sions of these delivery methods for HIV prevention in the future, citing discreetness, convenience, and longer-term duration of protection as perceived benefits.
Conclusions: After experiencing previously unfamiliar LA-PrEP delivery methods through placebo products in the SAMURAI study, men were open to using both products in the future, overcoming barriers including social stigma and fear of pain. These findings suggest opportunities to achieve acceptability of novel implantable and injectable HIV prevention among South African men.

EP0337

Prescription of HIV Pre-Exposure Prophylaxis and HIV incidence in a cohort of women with Severe Mental Illnesses in the U.S.

S. Bunting[1], M. Hyman[2], A. Hazra[3]
[1]University of Chicago, Dept. of Psychiatry & Behavioral Science, Chicago, United States, [2]University of Chicago, Center for Health and the Social Sciences, Chicago, United States, [3]University of Chicago, Section of Infectious Disease, Dept. of Medicine, Chicago, United States

Background: Approximately 20% of HIV diagnoses in the U.S. occur among women. Despite, this pre-exposure prophylaxis (PrEP) use among women has failed to meet the public health need. Women with severe mental illness (SMI) are a priority population for PrEP scale-up and engagement in the PrEP care continuum.
Methods: We utilized data from the Merative MarketScan® Commercial Claims Database to identify women with SMI (schizophrenia, schizoaffective disorder, or bipolar disorder [BD]) between 2010-2022. Enrollees with claims for HIV and those with HepB were excluded. HIV incidence was defined as two outpatient claims (different dates) or an inpatient claim with HIV-associated diagnosis codes. PrEP was defined as prescription for TDF/FTC or TAF/FTC without concurrent prescription for a third antiretroviral. Binomial logistic regressions evaluated associations between demographic and clinical variables and HIV incidence and PrEP use. The PrEP-to-need ratio (PnR) was calculated (PrEP prescription/HIV incidence, per 100,000 people). National PnR data for women (available beginning 2012; publicly-available) was taken from AIDSVu.
Results: Of 225,757 women in the cohort, 206,642 (91.5%) were diagnosed with BD and 19,115 were diagnosed with schizophrenia/schizoaffective disorder. In the BD group, 101 new HIV diagnoses were identified and 281 PrEP prescriptions. In the schizophrenia group, 25 new HIV diagnoses and 22 PrEP prescriptions were identified. Between 2010-2012 the PnR increased from 0.71-3.70 for women with BD and from 1.00-2.50 for women with schizophrenia, the national PnR for women increased from 0.45 to 4.89. HIV incidence was associated with co-morbid stimulant use disorder (aOR=2.76 [1.50-5.09], p<.001), and having encounters for STIs (aOR=2.46 [1.45-4.15], p<.001). Women with SMI in rural areas were less likely to receive PrEP compared to those in urban areas (aOR=0.59 [0.35-0.98], p=.04). Between 2010-2022, the PnR for women with schizophrenia (0.00-2.50) and BD (0.71-3.70) increased, however remained lower than the national PnR (0.45-3.89).
Conclusions: PrEP use relative to HIV incidence among commercially-insured women with SMI is lower than national trends suggesting rates of prescription are not meeting the public health need.
Concerted, specific effort is needed to increase PrEP use among women, especially those living with SMI given disproportionate HIV incidence among this group.

EP0338

The safety and tolerance of PrEP among MSM in China: a prospective cohort study

J. Liu[1], S. Wu[1], Q. Li[2,3], Z. Yin[4], C. Li[5], C. Fan[6], Y. Dai[7], K. Wang[8], I. Jiang[9], H. Huang[8], J. Lio[9], A. Hazra[9], J. Tucker[10], R. Sherer[9], L. Li[2,3], W. Tang[10], K. Liang[1]
[1]Zhongnan Hospital of Wuhan University, Wuhan, China, [2]Guangzhou Eighth People's Hospital, Guangzhou, China, [3]Guangzhou Medical University, Guangzhou, China, [4]University of North Carolina Project-China, Guangzhou, China, [5]The University of Tokyo, Tokyo College, Tokyo, Japan, [6]Nanjing Medical University, Nanjing, China, [7]Dermatology Hospital of South Medical University, Guangzhou, China, [8]Wuhan Tongxing LGBT Center, Wuhan, China, [9]University of Chicago, Chicago, United States, [10]University of North Carolina at Chapel Hill, Chapel Hill, United States

Background: Pre-exposure prophylaxis (PrEP) has been demonstrated as an effective strategy for preventing HIV infection. However, its uptake remains suboptimal in China, because of the continuous concerns about drug safety from both the patients and clinicians.
This study aimed to assess the safety and tolerability of oral TDF/FTC for PrEP in a real-world setting of men who have sex with men (MSM) in China.
Methods: An open-label, prospective cohort study was conducted between September 2021 and September 2024 in Guangzhou and Wuhan, China. MSM at high risk of HIV infection were enrolled in the study. Eligible participants were prescribed TDF/FTC as PrEP and followed up for 12 months.
Adverse events (AEs) were self-reported, and participants underwent regular monitoring for HIV and syphilis infections and liver and kidney function during follow-up.
Results: A total of 1,138 participants were enrolled, with 1,045 completing at least one follow-up visit. 7 participants were diagnosed with HIV, resulting in an HIV incidence rate of 0.80 per 100 person-years (95% CI: 0.21–1.39). 68 participants acquired syphilis, yielding an incidence rate of 7.75 per 100 person-years (95% CI: 5.98–9.51).
A total of 63 participants reported 102 AEs, most of which were related to the use of PrEP. Sixteen participants discontinued PrEP due to AEs, with the majority being mild.
Four participants reported Grade 3 AEs and withdrew from the study, two of whom experienced allergic reactions, manifested as acute facial neuralgia.
Additionally, 144 instances of elevated serum creatinine (SCr) and 839 instances of liver function abnormalities were recorded. One participant withdrew from the study due to increased liver enzymes. ALT elevations were primarily observed during the early follow-up period, while SCr elevations occurred predominantly in the later stages.

Conclusions: PrEP with TDF/FTC is safe and well tolerated for the prevention of HIV among Chinese MSM in a real-world setting. Effective PrEP implementation, accompanied by cost-effective and targeted follow-up, will facilitate the promotion and broader use of this intervention in China.

EP0339

Market size and demand estimations to enable introduction and scale-up of community preferred low dead space syringes and needles

K. Gupta[1], V. Rivas[2], K. Gustafson[3], B. Vu Ngoc[4], K. Ahafonov[5], A. Hegde[6], K. Green[7]
[1]PATH, New Delhi, India, [2]PATH, Washington DC, United States, [3]PATH, Minneapolis, United States, [4]PATH, Hanoi, Viet Nam, [5]PATH, Kyiv, Ukraine, [6]PATH, Mumbai, India, [7]PATH, Geneva, Switzerland

Background: A 2023 systematic review estimated that 2.3 million people who inject drugs (PWID) are living with HIV (15% prevalence) and 5.8 million with hepatitis C virus (HCV) (39% prevalence). Approximately 2.3 million people are co-infected with HIV and HCV, and more than half of them inject drugs.
The practice of sharing of needles and syringes (N&S) among PWID can lead to increased risk of HIV/HCV transmission. Studies have shown that lowering the dead space is associated with reduced survival of HIV/HCV in the remaining blood.
In 2012, WHO recommended that needles and syringe programs (NSPs) offer low dead space syringes/needles (LDSS/N), which may reduce the survival of HIV and HCV and transmission risk.
However, lack of market size and demand estimations for LDSS/N has resulted in limited availability, poor quality and variable prices in low- and middle-income countries (LMICs). We aim to estimate the market size and demand to enable product introduction, accessible pricing and scale up of LDSS/N in LMICs.
Methods: The market size estimation model for LDSS/N was developed based on PWID population, NSP program availability and coverage. Latest available NSP program access data was applied as a proxy for coverage. Number of clients estimated in the base year (2025) was multiplied by WHO target of N&S distribution per PWID to arrive at demand estimates. This was extrapolated cumulatively, informed by industry reports, to provide estimates for 2030.
Results: The potential global market for LDSS/N is estimated at 4.5 billion, with a market value of USD 223 million. Demand for LDSS/N is estimated at 292 million N&S combinations in 2025 (55 LMICs), with a market value of USD 14.6 million.
This estimate is expected to grow to 433 million by 2030. LDSS/N options should be offered in NSPs to reduce the risk of bloodborne virus transmission (including HIV/HCV).
Conclusions: Market size and demand estimates demonstrate a viable market for LDSS/N in LMICs. This is an important step toward introduction and scaling of LDSS/N in LMICs. Further research is needed to understand the market enablers, constraints, acceptability, values and preferences and willingness-to-pay to develop compelling business case for LDSS/N in LMICs.

EP0340

Inadequate HIV prevention services in substance use disorder treatment facilities that do not have HIV-specific care for people with HIV

K.A. Siddiqi[1], S.N. Tuli[2], R. Nath[2], S. Akter[2], G.S. Mohammad Pritom[3], AMK. Islam[4], M.A. Hatch[5], M.G. McDonell[1]
[1]Washington State University Elson S. Floyd College of Medicine, Community and Behavioral Health, Spokane, United States, [2]North South University, Dhaka, Bangladesh, [3]University of South Carolina, Columbia, United States, [4]University of Rochester Medical Center (URMC), Rochester, United States, [5]University of Washington, Seattle, United States

Background: People with substance use disorder (SUD) are at increased risk of HIV acquisition, yet many SUD treatment programs lack HIV-specific preventive and care services, including facilities not having specialized programs for people with HIV (PWH).
This study aims to assess the availability of HIV-related services in SUD treatment facilities in the United States (US) with no HIV-specific programs.
Methods: The 2023 National Substance Use and Mental Health Services Survey (N-SUMHSS) was used to examine the availability of HIV-related services in US SUD treatment facilities that do not have specific programs/groups for clients with HIV or AIDS (PWH-specialized) compared to other facilities. Descriptive statistics and bivariate comparisons using chi-square tests assessed the differences in services across facility types, with statistical significance set at $p < 0.01$: SUD treatment only (n=5,873) and a mix of mental health and SUD treatment services (n=7,655).
Results: PWH-specialized SUD treatment facilities offer more HIV-related services than non-PWH-specialized facilities, both in SUD-only and mixed settings. Compared to PWH-specialized facilities, HIV testing was less prevalent in non-PWH-specialized SUD-only (31.3% vs. 47.3%) and mixed facilities (29.2% vs. 48.8%). HIV counseling and education were less common in non-specialized settings, with 62.4% (vs. 81.50%) in SUD-only settings and 52.1% (vs. 72.53%) in mixed settings than in PWH-specialized settings. Ancillary HIV interventions and Hepatitis C and HIV PrEP medication were also less prevalent in non-specialized facilities.
Additionally, non-PWH-specialized facilities test less for Hepatitis B, C, and STDs and have fewer programs for the LGBTQ+ population.
Conclusions: Non-PWH-specialized SUD treatment offers fewer HIV-related services than specialized settings, representing missed opportunities to identify at-risk clients and engage them in HIV care. Given that people with SUD are equally at risk of HIV, prevention efforts should be directed to both types of SUD facilities to prevent the HIV epidemic in the US.

EP0341

HIV pre-exposure prophylaxis care cascade and risk factors associated with loss to follow-up among key populations in Indonesia: data from a real-world pilot implementation 2021 – 2023

R. Wisaksana[1], N. Hanum[2], M. Handayani[1], M. Pohan[1], T. Putri[1], F. Rakhmat[1], D. Anggiani[3], N. Afriana[3], E. Lukitosari[3], B. Prabowo[4]
[1]Padjajaran University, Research Center for Care and Control of Infectious Disease, Bandung, Indonesia, [2]Bandung Institute of Technology, Pharmacology and Clinical Pharmacy, Bandung, Indonesia, [3]Ministry of Health of Indonesia, HIV and STI Working Group of the Directorate of Disease Prevention and Control, Jakarta, Indonesia, [4]UNAIDS, Jakarta, Indonesia

Background: The pre-exposure prophylaxis (PrEP) care cascade depicting eligibility, initiation, and continuation, as well as loss to follow-up (LTFU) among individuals taking PrEP has not been systematically evaluated in Indonesia. We examined baseline factors associated with PrEP initiation, the PrEP care cascade, and longitudinal risk factors of LTFU in a large-scale implementation program for key populations vulnerable to HIV in Indonesia.
Methods: Numbers of HIV-negative individuals screened for eligibility, eligible for, initiated, continued to use PrEP from month-one until month-12, and loss to follow-up (LTFU; defined as not returning for PrEP refill for 100 days) were retrieved from the Indonesia PrEP Pilot Program database, a longitudinal oral PrEP implementation rolled out in 21 districts in 10 provinces between Dec-2021 and Dec-2023 among men who have sex with men (MSM), female sex workers (FSW), people who inject drugs (PWID), transgender women (TGW), and serodiscordant partners of people living with HIV (SD-PLHIV). We used logistic regression models to assess factors associated with PrEP initiation and time-varying Cox's models to determine risk factors of LTFU.
Results: Of the 16,469 eligible individuals, 9,124 (55.4%) initiated PrEP up to December 2023 (mean age 29.8 [SD 16.3], 85% men, 75% MSM, 92% from Java-Bali). PrEP initiations were significantly higher among older people, women, FSW and TGW (versus MSM), and those reporting higher-risk sexual behaviours, while significantly lower among PWID and SD-PLHIV, and those living in provinces not covered by the program (all $p<0.001$). PrEP continuations at months one and three were very low among FSW (37% and 34%, respectively). The cumulative LTFU rate at 12 months was 40% (95% confidence interval [CI] 38%-42%). In age-adjusted models, becoming LTFU while on PrEP was predicted by younger age ($p=0.037$), living in Yogyakarta, West Java or East Java (versus Jakarta, $p<0.001$), no STI diagnoses ($p<0.001$), using event-driven PrEP ($p=0.023$), and reporting higher risk behaviours ($p<0.001$).
Conclusions: Our findings revealed gaps in PrEP initiation, continuation, and LTFU among key populations taking PrEP in Indonesia. Targeted interventions are needed to address engagement among those likely to LTFU and populations underserved by the program to improve initiation and continuation.

EP0342

People who use drugs and human immunodeficiency virus (HIV) in Rwanda

J.M. Murerwa[1], C. Ndinda[1], B. Ikuzo[1], J.C. Kwizera[1], G.N. Rwibasira[1]
[1]Rwanda Biomedical Centre, HIV/AIDS Disease Prevention and Control, Kigali, Rwanda

Background: Injecting drug use is a growing contributor to HIV transmission in numerous countries globally. Due to limited epidemiological data on people who use drugs (PWUD). Rwanda has not been able to develop targeted interventions. This study aimed at determining HIV prevalence among PWUD in Rwanda to inform public health interventions.
Methods: A cross-sectional biological and behavioral survey was conducted to assess HIV knowledge among PWUD. Respondent-driven sampling was used to recruit participants aged 18 and above who injected drugs 12 months prior to the interview date; sample size was 1113. Consenting participants were interviewed using a structured questionnaire. With the use Python programming, the analysis focuses on HIV prevalence among male and female PWUD, across different age categories, and provinces in Rwanda.
Results: The overall HIV prevalence among PWUD was 12% (95% CI: 10.8–13.1), with a significantly higher prevalence among female PWUD at 47% (95% CI: 42.6–51.6), compared to 6.2% (95% CI: 5.3–7.1) among male PWUD. The prevalence was also higher among PWUD aged 35 years and above, at 25.2% (95% CI: 22.1–28.4), compared to 10.9% (95% CI: 9.4–12.5) among those aged 25–34 years and 3.6% (95% CI: 2.4–4.8) among those aged 18–25 years.
Geographically, the highest prevalence was observed in the Southern Province at 20.2% (95% CI: 16.4–23.9), followed by the Western Province at 17.4% (95% CI: 14.7–20.0), the Northern Province at 9.5% (95% CI: 6.1–12.8), the City of Kigali at 9% (95% CI: 7.5–10.4), and the Eastern Province at 5% (95% CI: 2.9–7.2).
Conclusions: Our study identified disparities in HIV prevalence among PWUD with a high prevalence among women particularly in the Southern province. We suggest development of strategic targeted interventions that are gender-sensitive, and district-specific.
Other mitigation approaches are but not limited to harm reduction programs such as needle exchange, opioid substitution therapy, and enhanced access to HIV care are necessary. Addressing these disparities are key to improving health outcomes and reducing the HIV burden with PWUD in Rwanda.

EP0343

Evaluating the implementation, services gap and cost of six and twelve months antiretroviral therapy dispensation among HIV-positive migrant clients in Gaza Province, Mozambique (January-April 2024)

A. Chissaque[1], N. Herrera[2], M. Songane[1], H. Inguane[1], C. Chambe[3], A. Louvado[4], S. Chilundo[4], A. Muteerwa[5], C. Alons[6], M. Bonou[7], N. Bhatt[2]

[1]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Research, Maputo, Mozambique, [2]Elizabeth Glaser Pediatric AIDS Foundation, Research, Washington D.C., USA, United States, [3]Assucênio Chissaque, Technical, Maputo, Mozambique, [4]Division of Global HIV/AIDS and TB, U.S. Centers For Disease Control and Prevention, Maputo, Mozambique, Division of Global HIV/AIDS and TB, Maputo, Mozambique, [5]Division of Science, U.S. Centers For Disease Control and Prevention, Maputo, Mozambique, Division of Science, Maputo, Mozambique, [6]Elizabeth Glaser Pediatric AIDS Foundation, Technical Leadership and Program Optimization, Washington D.C., USA, United States, [7]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Technical, Maputo, Mozambique

Background: Retention in HIV care and viral load suppression (VLS) remain significant challenges in Mozambique, including in Gaza Province, where 24.4% of people aged 15–49 years are living with HIV. Migrant populations, particularly face barriers to consistent, comprehensive care. To address this, Mozambique introduced multi-month dispensing (MMD), providing antiretroviral therapy for six (6MMD) or twelve (12MMD) months.

This study evaluates the outcomes, costs, and service gap of 6MMD and 12MMD among migrant clients.

Methods: A cross-sectional study was conducted January-April 2024 in 14 health facilities across seven districts of Gaza Province. Migrant clients ≥18 years on 6MMD or 12MMD models were enrolled in the study. Data were collected using structured surveys and data abstraction from medical records and were analyzed using descriptive statistics. The main indicators included healthcare system, client self-reported incurred costs, family planning services, and viral load suppression (VLS). We estimated healthcare system and client self-reported incurred costs and classified incurred costs as catastrophic if they exceeded 10% of the client's income.

Results: Among 201 clients enrolled, 160 (79.6%) were on 6MMD and 41 (20.4%) on 12MMD. Half (51.0%) were 35–50 years and 96.0% reported spending most of the year outside Gaza, with 71.2% returning annually. Among the 104 female clients, 65.4% were neither asked about nor referred for family planning during their last visit, and 60.6% reported not using a family planning method.

Additionally, 62.5% of females were never screened for cervical cancer, including 55.7% on 6MMD and 84.0% on 12MMD. Viral load were collected for 70.6% of clients, among whom 99.3% achieved VLS.

In both models, <15% of clients reported transportation costs and/or income loss exceeding 10% of their income. The annual healthcare system costs per client were US$201 (6MMD) and US$190 (12MMD).

Conclusions: The study identified challenges in the provision of family planning, cervical cancer screening and viral load coverage to migrant clients enrolled in 6MMD or 12MMD. High VLS rates were achieved, but a small subset of clients faced catastrophic financial burdens. Addressing service delivery gaps and integration could be essential to ensuring comprehensive care and improving viral load testing for migrant clients on MMD.

EP0344

Male circumcision, sexual positioning, and HIV status among men who have sex with men in Namibia and Zimbabwe, 2019

O. de León[1], C. Dide-Agossou[1], S. Davis[1], T. Maharadze[2], C. Samba[3], T. Nakanyala[4], F. Tjituka[5], D. Philpott[1], A.J. Hakim[1]

[1]US Centers for Disease Control and Prevention, Division for Global HIV and Tuberculosis, Atlanta, United States, [2]US Centers for Disease Control and Prevention, Division for Global HIV and Tuberculosis, Harare, Zimbabwe, [3]Association of LGBTI People in Zimbabwe, Harare, Zimbabwe, [4]US Centers for Disease Control and Prevention, Division for Global HIV and Tuberculosis, Windhoek, Namibia, [5]Ministry of Health and Social Services, Health and Social Welfare Policy, Health Sector Response, Windhoek, Namibia

Background: Men who have sex with men (MSM) have 23 times the risk of acquiring HIV compared to the general population. Male circumcision is effective at preventing HIV acquisition among men who have sex with women but its effectiveness among MSM is unknown.

We analyzed data from biobehavioral surveys (BBSs) of MSM in Namibia and Zimbabwe to better understand the interaction between sexual positioning, circumcision, and HIV status.

Methods: We searched for BBSs in sub-Saharan Africa since 2017 with available data about circumcision and sexual positioning. We analyzed data from 511 MSM in Namibia and 1,124 in Zimbabwe who participated in respondent-driven sampling surveys in 2019.

Participants were aged ≥18 years and had had oral or anal sex with another man in the last 6 months (Namibia) or 12 months (Zimbabwe). We analyzed data by circumcision status and sexual positioning with the most recent male anal sex partners in the last 6 months.

We used logistic regression to evaluate the association between HIV test results and circumcision status, sexual positioning, and their interaction, with a random effect for country.

Results: We found that compared to uncircumcised MSM who only engaged in insertive anal sex, circumcised MSM who only engaged in insertive anal sex in the last six months were less likely to have HIV (OR: 0.29, 95% CI: 0.19 to 0.44), controlling for reported number of partners.

Circumcised MSM who engaged in both insertive and receptive anal sex likely had a protective benefit from circumcision (OR: 0.60, 95% CI: 0.35 to 1.04). Circumcised MSM who engaged in only receptive anal sex had no protective benefit from circumcision (OR: 0.67, 95% CI: 0.36 to 1.28).

Conclusions: Our analysis indicates that circumcision may be protective against HIV for MSM, specifically those who engage exclusively in insertive anal sex. It is plausible that MSM who engage in both insertive and receptive anal sex may benefit too.
These results add to findings from a recent circumcision trial that also showed protection for predominantly-insertive MSM. Consideration could be given to reviewing guidance and messaging on voluntary male medical circumcision for MSM in light of these results.

EP0345

Self-concept as a predictor for HIV prevention attitudes among adolescents orphaned by HIV/AIDS in Uganda

P. Nartey[1], A.Z. Girma[1], P. Nabunya[1], A. Kabarambi[1], M. Naseh[1], F.M. Ssewamala[1]
[1]Washington University in St. Louis, Brown School, St. Louis, United States

Background: Adolescents orphaned by HIV/AIDS in Uganda face heightened vulnerability to HIV due to psychosocial and economic challenges. Self-concept, an underexplored yet critical factor, influences adolescents' confidence and ability to adopt health-promoting behaviors. A positive self-concept empowers adolescents to embrace protective strategies, such as condom use, HIV testing, and open communication about sexual health.
This study investigates the role of self-concept in predicting HIV prevention attitudes among school-going adolescents orphaned by HIV/AIDS.
Methods: We utilized baseline data from the Suubi-Maka study, a two-arm NIMH-funded cluster-randomized trial for orphaned adolescents (2008-2012). A total of 346 adolescents-caregivers (dyads) from 10 rural public primary schools were randomly assigned to either the control group (n = 167 dyads) receiving usual care for school-going orphaned children (such as lunch and learning materials) or the treatment group (n = 179 dyads) receiving a family economic empowerment intervention (focused on a matched savings account), financial planning and management workshops. Data were collected at baseline, at 12-month and 24-month follow-ups.
Adolescents were aged 12-17 years and were recruited from the Masaka and Rakai political districts of Uganda, two areas severely impacted by HIV/AIDS and poverty. This study conducted a Poisson regression analysis using baseline data to examine the relationship between self-concept and HIV prevention attitudes.
Results: Adolescents' mean age was 13.38 years and females constituted 65% of the sample. The Poisson regression results showed that self-concept (β = 0.005, p<0.01; exp(β) =1.005) is a significant positive predictor of HIV prevention attitudes indicating that participants with more positive self-concept were more likely to exhibit stronger HIV prevention attitudes. Females had significantly lower HIV prevention attitudes, compared to males (β = -0.091, p<0.05; exp(β) =0.913) and participants who identified as Christians (β = -0.047, p<0.05; exp(β) =0.954) also demonstrated lower HIV prevention attitudes.
Conclusions: These findings highlight the importance of self-concept in promoting HIV prevention behaviors among orphaned adolescents in Uganda. Interventions focusing on improving self-concept may be critical in reducing HIV risk among this vulnerable group.
By addressing psychosocial factors, such interventions could enhance the adoption of protective health behaviors, contributing to broader efforts to combat the HIV epidemic in Uganda.

EP0346

Oral PrEP persistence among key populations in a center from Buenos Aires, Argentina: survival analysis of the program's first three years

C. Cesar[1], D. Salusso[1], G. Mernies[1], M. Sandoval[1], J. Garcia[1], C. Petriglieri[1], F. Bilbao[1], D. Parera[1], C. Perez[1], A. Duran[2], M.I. Figueroa[1], P. Cahn[1]
[1]Fundacion Huesped, Research Department, Ciudad Autonoma de Buenos Aires, Argentina, [2]Ministry of Health, Buenos Aires, Argentina, Coordinación Salud Sexual, VIH e Infecciones de Transmisión Sexual (ITS), Ciudad Autonoma de Buenos Aires, Argentina

Background: PrEP with TDF/FTC was implemented in a non-governmental organization in Buenos Aires in 2021. We aimed to analyze PrEP persistence in key populations and explore its correlates in real life.
Methods: Oral PrEP was offered at no cost to men who have sex with men (MSM), transgender women (TGW), and cisgender female sex workers (cFSW) at increased HIV risk. PrEP persistence was defined as the time to first PrEP discontinuation (TFD): user report or calculated as the date the last pill supply would run out if taken daily. TFD was assessed using survival analysis. Cox proportional hazard models examined associations between TFD and sociodemographic and behavioral factors.
Results: Between September-2021/December-2024, 958 participants initiated PrEP: median age 31 years (IQR:26-36); 670 (69.9%) MSM, 227 (23.7%) TGW, and 61 (6.3%) cFSW. Median follow-up time: 18 months (IQR:9-29). Reasons for discontinuation: loss to follow-up (44%), decreased risk (23%), user decision (23%) and adverse events (11%). PrEP discontinuation probabilities were 6.3% (CI95%:4.7-7.8), 14.1% (11.8-16.3), 23.9% (21.1-26.6), 36.7% (33.3-40.0), and 57.4% (51.7-62.4) by months 1, 6, 12, 24, and 36 respectively. In bivariate analysis older age reduced the risk of PrEP TFD [HR:0.98 (CI95%:0.97-0.99), p=0.004]; cFSW [HR:8.81 (6.24-12.45), p<0.001] and TGW [HR:2.51 (2.02-3.12), p<0.001] faced higher risks compared to MSM, as well as living in the suburbs [HR:1.35 (1.07-1.70), p=0.01], lower education [OR:2.04 (1.61-2.58), p<0.001], sex work [OR:2.34 (1.91-2.86), p<0.001], and cocaine use in last month [OR:2.14 (1.66-2.76), p<0.001]. Multivariable analysis controlling for demographics and behavioral factors showed that age, key population, and cocaine use remained associated with PrEP TFD (Figure 1).
Conclusions: PrEP discontinuation was higher among cFSW, TGW, younger users, and those with recent cocaine use. Targeted interventions addressing structural and behavioral barriers are essential to improve persistence in these populations.

EP0347

Can it protect my baby and me from HIV? A mixed-methods evaluation of intention to discuss, accept and use lenacapavir by pregnant women in polygamous relationships in a Nigerian community

A. Isah[1,2], G. Ezenri[2], E.J. Ugochukwu[1,2], J.C. Onyehalu[2], C.E. Agbo[2], A. Ngige[2], M.M. Abubakar[3,2], C. Idabor[2], B.O. Ukoha-Kalu[4,2]

[1]University of Nigeria, Clinical Pharmacy and Pharmacy Management, Nsukka, Nigeria, [2]University of Nigeria, Person-Centred HIV Research Group, Nsukka, Nigeria, [3]Nigerian Air Force, Directorate of Therapeutic Services, Medical Services Branch, Kaduna, Nigeria, [4]University of Nottingham, School of Medicine, Nottingham, United Kingdom

Background: With the success of the PURPOSE 1 and 2 trials, Lenacapavir, a novel long-acting injectable antiretroviral agent, is a promising therapy for the prevention of HIV in people at acquisition risk. The twice-yearly Lenacapavir could protect both the pregnant woman and child in polygamous relationships who are at risk of HIV acquisition. Unaware of possible facilitators and barriers to its use, we evaluated the intention to discuss, accept, and use Lenacapavir by these women.

Methods: We conducted a mixed-methods study from December 2024 to January 2025 where 350 randomly selected cisgender pregnant women responded to structured 22-item validated questionnaires (quantitative phase) while 15 provided insights through in-depth interviews.

The study was conducted across 10 primary healthcare centres in Ankpa, northcentral Nigeria to measure their knowledge, perceptions and intention to discuss, accept, and use. Descriptive and inferential statistical analyses were conducted on the quantitative data while thematic analysis was used for the qualitative data.

Results: Of 294 total respondents, the mean age was 29.7 ± 5.3 years, and 48% (n =141) had attained secondary education. Out of the participants, 68% (n=200) expressed an intention to discuss the use of Lenacapavir, and 59% (n=174) showed willingness to use it.

Prior knowledge of pre-exposure prophylaxis (PrEP) (aOR: 3.6; 95% CI: 2.1–5.9) and supportive partner attitudes (aOR: 2.8; 95% CI: 1.6–4.8) were predictors of having the intention to discuss Lenacapavir. The respondents reported fear of side effects (n = 112, 38.1%) and misconceptions about safety during pregnancy (n = 79, 26.9%) as the key barriers to the use of Lenacapavir. From in-depth interviews conducted, cultural barrier was the major theme. Other synthesized themes that would affect their choices were "protection of my child", "fear of divorce", and "disruption of genealogy".

Conclusions: There was a substantial level of intention to discuss, accept, and use Lenacapavir among cisgender pregnant women in polygamous relationships in the Nigerian community**,** showing potential acceptability of the drug as a novel HIV prevention strategy among this population. A culturally tailored counseling is essential to address safety concerns and enhance the acceptance of Lenacapavir among pregnant women in polygamous relationships.

EP0348

The use of Post-exposure prophylaxis (PEP) in a national sample of 14-22 year old gay and bisexual boys and young men in the United States

M. Ybarra[1], A. White[1], S. Bull[2], R. Garofalo[3], D. Feaster[4]

[1]Center for Innovative Public Health Research, San Clemente, United States, [2]Clinic Chat, Aurora, United States, [3]Lurie Children's Hospital, Chicago, United States, [4]University of Miami, Miami, United States

Background: Although data suggest that Post-exposure prophylaxis (PEP) is associated with an 80% reduction in HIV risk for those exposed,[my1] little is known about adolescents' knowledge and usage of it.

Methods: Data were collected at baseline as part of a randomized controlled trial of a text messaging-based HIV prevention program for 14-20 year old boys and young men who identified as cisgender gay, bisexual, or with another sexual minority identity living across the United States. 463 youth were recruited via social media, consented/assented online or over the telephone, and surveyed online. In addition to age, sex assigned at birth, gender and sexual identity, eligible youth had to have had anal sex in the past 12 months.

Results: Almost three in four (73%, n=338) participants had heard of PEP and one in five (22%, n=104) had talked with a healthcare professional about it. One in 14 (7%, n=33) had ever used PEP; 3% (n=14) have used it 3 or more times. By comparison, 90% (n=417) reported knowing about PrEP (pre-exposure prophylaxis; PrEP).

Significant overlap was observed: 79% (n=26) of PEP users also were PrEP users. PEP use was also associated with condom use: 57% (n=247) of people who never used PEP vs. 70% (n=23) of people who ever used PEP reported non-condom insertive anal sex in the past 12 months (p=0.17); 65% (n=279) of people who never used PEP vs. 76% (n=25) of people who ever used PEP reported non-condom receptive anal sex in the past 12 months (p=0.21).

Among those who reported transactional sex, more (28%, n=9) reported ever using PEP compared to those who reported never using PEP (11%, n=49; p=.005).

Conclusions: Despite the dearth of research about adolescent PEP use, most gay and bisexual adolescent boys and young men in our cohort have heard of it and many have had a conversation with a healthcare provider

about it. Given the strong correlations between behaviors that are associated with HIV risk and PEP use in this sample, covering the gap of knowledge so that the 27% of youth unfamiliar with PEP are aware of it could have important public health impact.

EP0349

HIV pre-exposure prophylaxis continuum and reasons for never using pre-exposure prophylaxis among transfeminine persons in the United States: results from the Transgender Women's Internet Survey and Testing (TWIST)

D. Islek[1], T. Sanchez[1], S. Baral[2], J.A. Caldwell[1], J.L. Glick[3], J. Jones[1], I. Lucas[1], S. Sarkar[4], L. Ragone[4], A. de Ruiter[5], P.S. Sullivan[1], M. Valentine-Graves[1], S. Winter[1], V. Vannappagari[4]
[1]Emory University, Rollins School of Public Health, Atlanta, United States, [2]Johns Hopkins University, Johns Hopkins School of Public Health, Baltimore, United States, [3]Louisiana State University Health Sciences Center, Community Health Science & Policy, New Orleans, United States, [4]ViiV Healthcare, Durham, United States, [5]ViiV Healthcare, London, United Kingdom

Background: The estimated HIV incidence is 5.5 per 1000 person-years in the eastern and southern US among transfeminine persons (TFP), yet information about pre-exposure prophylaxis (PrEP) utilization among TFP remains scarce.
We examined current PrEP use, adherence, persistence and reasons for never using PrEP among a US nationwide sample of TFP.
Methods: Sexually active TFP age 15+ were recruited between April 2023-June 2024 through an online survey. TFP were asked about PrEP use, dose, duration, and reasons for never using PrEP (stratified by age).
Results: Of 1625 TFP not living with HIV (median age:24), 76% (1236/1625) were non-Hispanic White, 11% (185/1625) were Hispanic/Latino, 65% (1058/1625) resided in large central/fringe metro counties, 9% (147/1625) used PrEP in the past 12 months, 4% (61/1625) had ever used PrEP, 87% (1417/1625) had never used PrEP and 6% (96/1625) were currently using PrEP.
Among TFP currently using PrEP, 94% (90/96) used daily oral PrEP, 6% (6/96) used long-acting injectable (LA) PrEP. Among oral PrEP users, 64% (58/90) used 30 pills in the last 30 days and 28% (25/90) persisted taking PrEP more than 24 consecutive months.
Among those who didn't use PrEP daily, 25% (8/32) were taking PrEP when they had sex. Among those who never used PrEP, 67% (947/1417) were aware of PrEP. Among those 15-24 years (n=770), common reasons for never using PrEP were privacy concerns related to health insurance and living arrangements.
Among those 25+ years (n=647), common reasons for never using PrEP were no insurance and concerns about side-effects *(Table)*.

Table. Reasons for never using PrEP among transfeminine persons, stratified by age group, The Transgender Women's Internet Survey and Testing (TWIST) project, United States, 2023-2024 (n=1417)

	Age 15-24 years (n=770) (n, %)*	Age 25 years and over (n=647) (n, %)*
I'm worried about my privacy on my parent's health insurance plan	**112 (91.1)**	11 (8.9)
I'm worried about my privacy with someone that I live with	**69 (76.7)**	21 (23.3)
Having no reliable transportation	**52 (74.3)**	18 (25.7)
I'm worried that people will think that I have HIV	**39 (69.6)**	17 (30.4)
I don't know which doctor to see about starting PrEP	**142 (68.6)**	65 (31.4)
I'm worried people will think I am very sexually active	**46 (67.6)**	22 (32.4)
Not knowing enough about PrEP to make a decision	**222 (67.1)**	109 (32.9)
Worried that doctor will treat me poorly if I ask them about starting PrEP	**65 (67.0)**	32 (33.0)
Not sexually active	**160 (65.3)**	85 (34.7)
Not sure I can remember to take the PrEP as prescribed	**71 (64.5)**	39 (35.5)
Too expensive	**81 (58.3)**	58 (41.7)
Prefer to use other methods to protect myself from HIV	**113 (55.9)**	89 (44.1)
In a monogamous relationship with an HIV-negative partner	**360 (49.0)**	375 (51.0)
Concerns about side-effects of PrEP	**73 (47.1)**	**82 (52.9)**
Having no insurance	**37 (46.8)**	**42 (53.2)**
Another reason	**59 (44.0)**	**75 (56.0)**

*Participants were allowed to choose more than one option. Bold text indicates the top three reasons for never using PrEP

Conclusions: PrEP use among TFP remains low even though PrEP has been available for more than a decade in the US. Strategies to increase PrEP use among TFP could be tailored to address needs of specific age groups. LA PrEP may address some privacy concerns, particularly among young TFP.

EP0350

Knowledge and attitude toward HIV pre-exposure prophylaxis among reproductive age women 15-49 years in Ghana: a multilevel model analysis of the 2022 Demographic and Health Survey

F.G. Wongnaah[1], R.G. Aboagye[2,3], B.O. Ahinkorah[4,5], E.V. Mahatara[6]
[1]Ghana Health Service, Disease control and prevention, Kukurantumi, Ghana, [2]University of New South Wales, School of Population Health, Sydney, Australia, [3]University of Health, and Allied Sciences, Department of Family and Community Health, Fred N. Binka School of Public Health, Hohoe, Ghana, [4]The University of Adelaide, Faculty of Health and Medical Sciences, Adelaide, Australia, [5]REMS Consultancy Services Limited, Secondi-Takoradi, Ghana, [6]Kilimanjaro Christian Medical University, Moshi, Tanzania, the United Republic of

Background: HIV remains a significant public health concern in sub-Saharan Africa, with women bearing a disproportionate burden of the disease. Pre-exposure prophylaxis (PrEP) has been proven effective in reducing HIV transmission, yet, knowledge, attitudes, and access influence its adoption.
The study examines the predictors of knowledge and attitudes toward PrEP among reproductive-age women 15-49 years in Ghana.
Methods: We analyzed a cross-sectional dataset from the 2022 Ghana Demographic and Health Survey (GDHS), with a weighted sample of 13,980 women. Data analysis was conducted using Stata 18, employing a multilevel logistic regression model to examine PrEP knowledge and attitudes predictors.
Results were reported as adjusted odds ratios (AOR) with 95% confidence intervals (CI). Statistical significance was set at $p < 0.05$.

Results: Overall, 12.13% (95% CI: 11.1–13.3) of women had positive knowledge and attitudes toward HIV PrEP. The Ashanti region had the highest proportion 20.25% (95% CI: 18.67–21.93), and the lowest in the Northern region 1.68% (95% CI: 1.46–1.93). Women with two or more sexual partners (AOR = 0.51, 95% CI: 0.28–0.96) were less likely to have positive PrEP knowledge and attitudes than those with one partner.

Women aged 25–29 (AOR = 1.75, 95% CI: 1.28–2.40), 30–34 (AOR = 1.61, 95% CI: 1.14–2.27), 35–39 (AOR = 1.69, 95% CI: 1.22–2.32), 40–44 years (AOR = 1.48, 95% CI: 1.03–2.12), having higher education (AOR = 3.27, 95% CI: 2.35–4.55), listening to radio (AOR = 1.20, 95% CI: 1.01–1.43), living in Ahafo (AOR = 5.02, 95% CI: 2.54–9.91), Oti (AOR = 5.64, 95% CI: 3.06–10.40), and Upper East (AOR = 4.17, 95% CI: 2.05–8.50) regions increased the odds of PrEP knowledge and attitude among women in Ghana.

Conclusions: Approximately 1 in 10 women aged 15–49 in Ghana have positive HIV PrEP knowledge and attitudes, highlighting a gap in knowledge and attitudes toward PrEP among women. Policymakers should focus on targeted education and equitable access to HIV prevention services to strengthen efforts in reducing HIV transmission.

EP0351

Group by time analysis of decision making and working together for prevention and pleasure: outcomes from a digital HIV serostatus neutral intervention trial with adult, cisgender male couples

J. Mitchell[1], A. Sophus[1], C. Rodriguez[1], Z. Bursac[1]
[1]Florida International University, Stempel College of Public Health and Social Work, Miami, United States

Background: Few HIV serostatus neutral interventions exist in the US that are efficacious, couples-based, and delivered digitally for adult, sexual minority male couples. LuvHub, a couples-based, digital HIV serostatus neutral intervention (DHI), seeks to address this problem and is currently being evaluated via a nation-wide, digital randomized controlled trial (RCT).

LuvHub teaches couples skills to help manage and align their HIV/STI vulnerabilities with their sexual pleasure needs via a sexual agreement.

Methods: We enrolled 389 eligible and consented adult, cisgender sexual minority male couples across the US to participate in a 16-month, digital RCT to assess the efficacy of LuvHub over time. Upon completion of the baseline assessment, couples were randomized to one of two trial conditions: immediate intervention condition to use LuvHub for 16 months or 8-month delayed control condition in which access and use of LuvHub began after the 8-month assessment.

Assessments occurred every 4 months post baseline. Present analyses examined differences between couple trial conditions (immediate vs. delayed) from baseline to month 4 on individual perceptions of how well he and his partner make decisions and work together to have a detailed sexual agreement and use HIV prevention and care strategies in their relationship. Both items were captured using a Likert-type response range of 0=not at all to 4=a great deal. Linear mixed models were conducted to test for group, time, and group by time interaction effects.

Results: A significant group by time interaction effect was detected for making decisions (p=.03). Couples in the immediate intervention condition, compared to those in the delayed condition, had greater improvements in making decisions together over time (b=0.24, SE=0.06, p<.001 vs. b=0.04, SE=0.06, p=0.47).

A significant group by time intervention effect was detected for working together (p=.02). Couples in the immediate intervention condition, compared to those in the delayed condition, had greater improvements in working together over time (b=0.29, SE=0.06, p<.001 vs. b=0.09, SE=0.06, p=0.16).

Conclusions: Findings show promise of LuvHub regarding couples' decision-making and working together about agreements and using HIV/STI prevention and care strategies in their relationship. Analyses of remaining assessment data, once available, are needed to reveal longitudinal trends in these outcomes.

EP0352

Safety and immunogenicity of an HIV vaccine with chimpanzee adenovirus vector

M.V. Villaran[1], Z. Euler[2], S.L. Hendricks[1], A. Takalani[3,2], F. Laher[4], P.-C. Yu[1], Y. Fong[1], T. Hermanus[5], E. Swann[6], N. Naicker[7], R. Dassaye[8], Z. Xiang[9], H. Ertl[9], S.C. De Rosa[1], P.L. Moore[5,10], N. Mkhize[5,10], E. Andersen-Nissen[2], A. Goga[8], V. Naicker[8]
[1]HIV Vaccine Trials Network (HVTN), Seattle, United States, [2]Cape Town HVTN Immunology Laboratory, Hutchinson Centre Research Institute of South Africa, Cape Town, South Africa, [3]University of the Witwatersrand, Department of Family Medicine and Primary Care, Faculty of Health Sciences, Johannesburg, South Africa, [4]Wits Health Consortium, Perinatal HIV Research Unit, Johannesburg, South Africa, [5]National Institute of Communicable Diseases, Johannesburg, South Africa, [6]National Institutes of Health, Division of AIDS, Vaccine Clinical Research Branch, Washington DC, United States, [7]University of KwaZulu-Natal, Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [8]South African Medical Research Council, HIV and other Infectious Diseases Research Unit, Durban, South Africa, [9]The Wistar Institute, Vaccine Center, Philadelphia, United States, [10]University of the Witwatersrand, SAMRC Antibody Immunity Research Unit, Johannesburg, South Africa

Background: Adenovirus (Ad) vectors offer tolerability, thermal stability and large genetic cargo capacity. However, trials using human Ad5 as HIV vaccine vectors showed increased likelihood of acquiring HIV and impaired immunogenicity in Ad5-seropositive men. Chimpanzee adenovirus (AdC6 and AdC7) vectors could overcome these issues.

We evaluated safety and immunogenicity of AdC6 and AdC7 vectors expressing HIV gp140.

Methods: HVTN 139, a phase 1 double-blinded placebo-controlled trial at six South African sites, enrolled adults without HIV. Participants were randomized into six groups across low or high doses (Table).
Data on reactogenicity, adverse events (AEs), and immune responses were collected. To measure Ad neutralizing antibodies (nAbs), viral particles of GFP-expressing AdC6/AdC7 were mixed with diluted sera, incubated, fixed, stained, and quantified under epifluorescence microscopy. NAbs against HIV-1 were measured using the TZM-bl neutralizing assay. Vaccine-specific T-cell responses were assessed using intracellular cytokine staining.

	Study groups	N	AdC dose (vp)	M0	M3	M6
Part A: Low Dose (LD)	Group 1 (G1)	5	1x 10^{10}	AdC6-HIVgp140	-	-
	Group 2 (G2)	5	1x 10^{10}	AdC7-HIVgp140	-	-
	Group 3 (G3)	2	0	Placebo	-	-
Part B: High Dose (HD)	Group 4 (G4)	10	5 x 10^{10}	AdC6-HIVgp140	AdC7-HIVgp140	400 mcg CH505TF gp120/GLA-SE
	Group 5 (G5)	10	5 x 10^{10}	AdC7-HIVgp140	AdC6-HIVgp140	400 mcg CH505TF gp120/GLA-SE
	Group 6 (G6)	2	0	Placebo	Placebo	Placebo

Table: Schema.

Results: Thirty-four participants (median age 26, 65% male) were enrolled. Low-dose groups (n=12) reported mild solicited AEs and mild to moderate unsolicited AEs, unrelated. High-dose groups (n=22) reported mild to moderate solicited and unsolicited AEs, one unrelated fatal stabbing and two HIV acquisitions in product-receiving groups. Ad nAb response rates at months 0, 1, and 4, were 50%, 80% and 90% respectively for AdC6, and 27%, 65% and 75% for AdC7.
Most participants developed tier 1 HIV nAb responses after the third vaccination with no significant differences in the response rate between high-dose regimens (G4 and G5); nAb responses to the vaccine-matched HIV viruses were rare.
Higher Env-specific CD4+ T-cell response rates were seen with AdC7 compared to AdC6 (88% versus 33%, p=0.026 after one high dose), but CD8+ T-cell response rates were similar (63% and 56%).
Conclusions: Chimpanzee Ad vectors were well tolerated but two people acquired HIV in high-dose groups. This vaccine induced robust cellular but limited tier 2 nAb responses against HIV.

EP0353

A scoping review of the impact of vaccine characteristics on the acceptability of HIV vaccines: current global trajectory of evidence

U.-K. Blessing[1], U. Chima[1], A. Isah[1], Z. Tang'an[1], J. Onyehalu[1], S. Anierobi[1], A. Ngige[1], N. Lawal[1], C. Amoke[1], G. Ezenri[1], C. Nwachuya[1]
[1]Person-Centered HIV Research Team, Department of Clinical Pharmacy and Pharmacy Management, University of Nigeria, Nsukka, Nigeria

Background: Developing safe and effective preventive HIV vaccines is the best long-term solution for controlling the HIV/AIDS pandemic. Nonetheless, characteristics of future HIV vaccines may influence their acceptability.
The aim of this scoping review was to determine the impact of vaccine characteristics on the acceptability of future HIV vaccines.
Methods: Using the Arksey & O'Malley's (2005) guidelines, we searched Scopus, Web of Science, PubMed, and Google Scholar databases for peer-reviewed articles published from Jan 1996 – Dec 2024 using the terms *HIV, HIV Vaccines, Vaccine Characteristics, Acceptability, and Impact*. Title/abstract and full-text screening were independently conducted by 2 authors. Data from the included articles were charted and summarized.
Results: Of the 1,228 studies screened, only 11 met the inclusion criteria. Most were quantitative (9/11, 81.8%), conducted in the USA (9/11, 81.8%), and utilized conjoint analysis (7/11, 63.6%) with impact scores rated on a 0–100 scale. Few studies included key populations like men who have sex with men (3/11, 27.2%) and adolescents (4/11, 36.4%). Various vaccine characteristics were identified: efficacy had the highest influence on HIV vaccine acceptability in 8 studies (72.7%), with impact scores ranging from 15.9 to 51.4%.
Side effects/safety ranked second in 5 studies (45.4%), with scores between 8.56 and 13.9%. Cost was the third most influential factor, reported in 5 studies (45.4%) with impact scores from 7.57 to 19.4%.
Protection duration ranked fourth in 4 studies (36.4%), with scores from 5.2 to 8.3%. The type of vaccine (e.g., killed, live attenuated, synthetic) was the second most impactful in 2 studies (18.2%), with scores ranging from 22.9 to 24.3%, while mode of delivery had no impact in 2 studies (18.2%). Vaccines with the highest acceptability shared key features: high efficacy (80–99%), long protection duration (10 years), a single dose, low cost ($0–$50), and minimal or no side effects.
Conclusions: Efficacy was the most impactful characteristic influencing HIV vaccine acceptability, followed by side effects/safety and cost. Educational programs emphasizing the benefits of partially efficacious HIV vaccines, along with transparent communication about side effects and cost subsidies, may boost HIV vaccine uptake.

EP0354

Factors associated with oral HIV pre-exposure prophylaxis (PrEP) continuation in the Indonesian pilot program, 2022-2023

G.B.S. Wirawan[1,2], B.D.K. Wardhani[2], E. Lukitosari[3], N. Afriana[3], D.S. Anggiani[3], R. Wisaksana[4], A. Grulich[1], P.P. Januraga[2], B. Bavinton[1]

[1]UNSW Sydney, Kirby Instiute, Sydney, Australia, [2]Udayana University, Center for Public Health Innovation, Denpasar, Indonesia, [3]Indonesian Ministry of Health, HIV and STI Working Group of the Directorate of Disease Prevention and Control, Jakarta, Indonesia, [4]Padjadjaran University, Research Center for Care and Control of Infectious Disease, Bandung, Indonesia

Background: Despite high HIV incidence among key populations, Indonesia did not roll out PrEP until a pilot program was introduced in 2022 to 2023. Using pilot program data, this study aimed to determine PrEP continuation over one year and identify factors associated with discontinuation.

Methods: We analyzed the pilot program data from 1 February 2022 to 31 December 2023. Participants with complete demographic data (visit date, age, sex, key populations [KPs]) were included.

Time-varying independent variables included PrEP regimen (daily/event-driven), province, and facility type (government-run public health centres [PHCs], hospitals, and private KP-friendly clinics) where visits were conducted.

Discontinuation events for PrEP users were determined at the last recorded visit for voluntary discontinuations or 90 days after the last visit for those lost-to-follow-up.

Otherwise, observations were censored at seroconversion, one year after initiation, or on 31 December 2023. A Kaplan-Meier estimator estimated the PrEP continuation rate. Predictors of discontinuation were identified using bivariable and multivariable Cox regression.

Results: The program recorded 19,014 visits for 9,488 individuals during the observation period. At baseline, the median age was 27 (IQR 23-32) years, 85.5% were male, 75.2% were men who have sex with men (MSM), 66.4% initiated PrEP on a daily regimen, 39.7% lived in Jakarta, and 85.7% initiated PrEP at PHCs. 12.7% of participants had a break and recontinued PrEP.

The continuation rates at 3, 6, 9, and 12 months were 69.8% (95%CI=68.9-70.7%), 57.7% (95%CI=56.6-58.9%), 44.8% (95%CI=43.4-46.1%), and 5.7% (95%CI=4.4-7.2%). Female sex worker (aHR=1.55, 95%CI=1.28-1.92) compared to MSM; living in West Java (aHR=1.32, 95%CI=1.18-1.48) and South Sulawesi provinces (aHR=1.32, 95%CI=1.11-1.55) compared to Jakarta; and last visit at a PHC (aHR=1.14, 95%CI=1.01-1.28) or hospital (aHR=1.20, 95%CI=1.01-1.43) compared to private KP-friendly clinics were associated with PrEP discontinuation.

Conclusions: A very high proportion of participants in Indonesia's first pilot PrEP program discontinued PrEP, with higher discontinuation observed in specific geographic regions, among sex workers, and among those attending PHCs and hospitals. Lower discontinuation at private KP-friendly services suggests that PrEP at these sites or other similar KP-friendly settings should be scaled up. Barriers to PrEP continuation by key populations must be urgently addressed.

EP0355

Preferences for future HIV vaccines among key populations in India: findings from the DigiTaPP Choice Experiment Study

V. Chakrapani[1], M. Shunmugam[1], R. Nelson[1], B.R. Mohan[1], A. Jaya[2], K. Kaavya[3], M. Sundaramoorthy[4], M. Awasthy[5], S. Sayyed[6], M. Sivasubramanian[7], R. Chhetri[8], M. Devi[9], K. Ondeng'e[10], Y.W. Machira[10], P. Saha[11], S.u. Hadi[11], J. Mukherjee[11]

[1]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [2]Sahodaran, Chennai, India, [3]Thozhi, Chennai, India, [4]Bro. Siga Social Service Guild (BSSSG), Chennai, India, [5]Tweet Foundation, Mumbai, India, [6]Aastha Parivaar, Mumbai, India, [7]The Humsafar Trust, Mumbai, India, [8]Mitr Trust, New Delhi, India, [9]Arth Charitable Trust, New Delhi, India, [10]IAVI, Nairobi, Kenya, [11]IAVI, New Delhi, India

Background: The DigiTaPP study aimed to assess preferences for future HIV vaccines among key populations in India, specifically transgender women (TGW), men who have sex with men (MSM), and female sex workers (FSWs). This research is critical given the high HIV burden among these groups and high prevalence of condomless anal sex, which significantly increases transmission risk.

Understanding vaccine preferences is crucial for developing acceptable and effective HIV prevention strategies, particularly as new tools like vaccines emerge.

Methods: A quantitative choice experiment was conducted in Chennai, Mumbai, and New Delhi between September and December 2024. The study included 150 TGW, 36 MSM, and 36 FSWs. Participants were presented with various vaccine scenarios, varying in immunization schedule, degree and duration of protection, delivery modality, and potential side effects. Preferences were analyzed using a threshold technique for trade-offs.

Results: Among TGW (n=150), over half were young (18-27 years), 78% single and 14% lived with male partners. MSM (n=36) participants were predominantly young (69% aged 18-27 years), and 86% never married. FSWs (n=36) were relatively older (two-thirds aged 36-48 years) and 50% were currently married.

Digital platform usage was high among participants, with over 80% using smartphones daily and a significant proportion using dating apps to seek sexual partners.

A majority of participants across all groups accepted high vaccination burdens (6-8 shots over 2.5 years) even for lower degrees of protection. TGW (90%), MSM (91.7%), and FSWs (77.8%) showed high acceptance of intensive schedules. Preferences for vaccine access points varied, with 65.3% of TGW, 77.7% of MSM, and 69.4% of FSWs preferring availability for priority/key populations only.

Side effect tolerance significantly influenced preferences, with those accepting severe side effects more likely to prefer combined interventions (vaccine plus other prevention methods).

Conclusions: The study demonstrates high acceptance of future HIV vaccines among key populations in India, even with intensive schedules. Preferences varied based on factors like side effects and delivery modality. These findings suggest that tailored approaches considering diverse preferences are crucial for maximizing vaccine uptake and effectiveness. Future HIV prevention programs should consider combining vaccines with other methods and leveraging digital platforms for outreach

EP0356

Exploring barriers to inclusive care: knowledge gaps and training needs of Sri Lankan government doctors in LGBTIQ health – a cross-sectional study

A. Manathunge[1], N. Kulathunge[2]
[1]National STD/AIDS Control Programme, Ministry of Health, Maradana, Sri Lanka, [2]National STD/AIDS Control Programme, Health, Colombo, Sri Lanka

Background: Despite increasing recognition of the health disparities faced by LGBTIQ individuals, medical curricula and in-service training often inadequately address LGBTIQ health needs. This gap contributes to healthcare providers' limited knowledge, skills, and cultural competence in delivering appropriate care to LGBTIQ populations. The lack of targeted education on topics such as gender identity, sexual orientation, and related health issues results in insufficient support for these patients, potentially exacerbating health inequalities.
Methods: A descriptive cross-sectional study was carried out using a randomly selected sample of medical officers working in the Ministry of Health - Sri Lanka regarding their understanding about homophobia and the challenges they face in providing care to LGBTQIA+ patients. The tool consisted of seven close ended questions and two open ended questions.
Results: Of the 212 respondents (50.1% response rate), 74.1% were comfortable to treat LGBTIQ patients, while 10.9% found it uncomfortable. One doctor has expressed it as "very difficult" to treat LGBTIQ individuals. Though no respondent refused to treat LGBTIQ patients, 3.3% preferred not to be involved. On the other hand, a majority (64.3%) were willing to treat LGBTIQ patients. However, over a quarter (29.1%) were unsure or lacked confidence in treating them, with only 41.7% reporting confidence in treating.
Regarding further knowledge, psychological issues and safe sex education were the most requested topics, with over 50% of respondents expressing interest in these areas. The least interest was medical knowledge related to gender reconstruction.
Regarding perceived barriers, 68.6% either did not know of any barriers or provided no response. Among those who identified barriers (18.5%), stigma and discrimination were most commonly cited, with one respondent mentioning sexual advances from patients as a barrier.
Conclusions: Similar to many Western medical curricula, Sri Lanka should incorporate LGBTIQ-related health education into its medical training, alongside strong advocacy efforts to reduce stigma and discrimination. The presence of homosexual panic and homophobia among medical professionals likely reflects both a lack of understanding and persistent discriminatory attitudes toward the LGBTIQ community.

EP0357

Introducing long-acting cabotegravir in Zambia: lessons learned from early implementation

C. Phiri[1], K. Zyambo[1], D. Kampamba[1], S. Sivile[1], M. Musukuma[1], L. Mulenga[1], T. Mwamba[2], M. Silondwa[2], D. Resar[3], M. Mulenga[2], A.J. Mwamelo[2], B. Longwe[2], P. Haimbe[2]
[1]Ministry of Health, Department of Public Health, Directorate of Infectious Diseases, Lusaka, Zambia, [2]Clinton Health Access Initiative, Lusaka, Zambia, [3]Clinton Health Access Initiative, Boston, United States

Background: Zambia achieved significant progress scaling oral pre-exposure prophylaxis (PrEP), with 184,256 people receiving PrEP in 2023. However, 23,000 new HIV acquisitions in 2023 highlight persistent unmet need. Oral PrEP alone will not meet the needs of populations at risk of HIV acquisition. In 2024, Zambia became the first low- and middle-income country to introduce long-acting cabotegravir (CAB-LA), a significant global milestone in HIV prevention programming.
Description: CAB-LA was introduced through a Ministry-led, phased approach following an announcement by PEPFAR in March 2023 that Zambia would receive PEPFAR-donated CAB-LA. To prepare, the Ministry-led PrEP Task Force updated PrEP guidelines and developed a CAB-LA implementation plan, M&E tools, and communication materials. These processes were informed by a Value Chain Situation Analysis conducted in 2022, and leveraged lessons learned from oral PrEP introduction.
9 sites were selected across 4 provinces for early rollout based on epidemic burden and to build experience across diverse implementation settings. Vial allocations were determined based on historic PrEP uptake and use. Provider training was rolled out in 2023 and CAB-LA was launched in February 2024.
Lessons learned: Strong Ministry leadership and coordination across technical partners has driven successful early introduction in Zambia. An agile, Ministry-led PrEP Task Force has been essential to support health systems changes required for introduction. By the end of 2024, 2,436 clients were initiated on CAB-LA across 26 sites and 8 provinces with 8.5% reported to have discontinued (Figure 1).

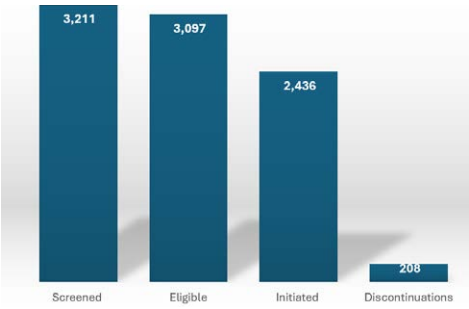

Figure 1. CAB-LA Cascade, 2024.

In November 2024, eligibility criteria were revised to allow pregnant and breastfeeding women to initiate, based on new clinical data from HPTN 084.

Conclusions/Next steps: Based on early success with CAB-LA, Zambia will continue to scale injectable PrEP to address unmet need and curb HIV transmission. This early success positions Zambia to lead the way in choice-drive prevention programming and will inform the introduction of next-generation products, like lenacapavir.

EP0358

Factors associated with PrEP acceptance among people seeking care in resource-limited and security-challenged settings: the case of Borno State

M.M. Shallangwa[1], E. Emmanuel[2], U. Adamu[2], A. Babatunde[2], J. Shaibu[3], A. Olaitan[4], M. Abubakar[2], N. Watsamanda[5], M. Luke[6], U. Omo-Emmanuel[7], C. Ukanwa[8], S. Saidu Musa[9]

[1]Achieving Health Nigeria Initiative (AHNI), Monitoring and Evaluation, Maiduguri, Nigeria, [2]Achieving Health Nigeria Initiative (AHNI), Yola, Nigeria, [3]FHI360, Yola, Nigeria, [4]FHI 360, Maiduguri, Nigeria, [5]Achieving Health Nigeria Initiative (AHNI), Jalingo, Nigeria, [6]FHI 360, Yola, Nigeria, [7]USAID, Abuja, Nigeria, [8]NASCAP, Abuja, Nigeria, [9]Chulalongkorn University, Clinical Sciences, Bangkokth, Thailand

Background: Nigeria has the largest HIV burden in Sub-Saharan Africa, with over 1.9 million people currently living with HIV. Despite the proven effectiveness of pre-exposure prophylaxis (PrEP) in preventing HIV transmission, particularly in high-risk populations, the uptake of PrEP remains low in many regions. This is especially true in resource-limited and conflict-affected settings, where structural and socio-demographic factors, including widespread stigma and discrimination, can influence acceptance of PrEP.

This study explores factors influencing PrEP acceptance among individuals assessing health care services at health facilities providing comprehensive Antiretroviral Therapy (ART) in Borno State, Nigeria. Learnings will guide strategies for improving uptake in similar contexts.

Methods: From November 2023 to April 2024, a cross-sectional, clinic-based survey was conducted among individuals aged 18 years and above accessing healthcare services at nine PEPFAR-supported facilities in Borno State. They were offered HIV testing services, and individuals identified as HIV-negative and had high-risk factors based on risk screening were offered PrEP, along with counseling on usage and adherence.

Socio-demographic characteristics, HIV test results, and PrEP acceptance were collected and analyzed to identify factors influencing acceptance.

Results: Males constitute 57% (n=1805) of the study participants. The median age was 30 (male 30, female 29). Of the participants, 61.5% (n=1948) accepted PrEP services. PrEP acceptance was highest among individuals with primary education (AOR: 5.67, 95% CI: 3.87–8.37), followed by those with secondary education (AOR: 4.39, 95% CI: 3.56–5.43) and tertiary education (AOR: 3.09, 95% CI: 2.59–3.71). Being unmarried (AOR: 2.11, 95% CI: 1.82–2.44) and employed (AOR: 1.65, 95% CI: 1.38–1.96) were also associated with a higher likelihood of PrEP acceptance compared to being married and unemployed, respectively. Conversely, females were significantly less likely to accept PrEP compared to males (AOR: 0.26, 95% CI: 0.22–0.30).

Conclusions: The likelihood of PrEP acceptance was higher among individuals with primary education, unmarried status, and employment but lower among females, highlighting key sociodemographic disparities. Addressing these barriers through targeted, inclusive interventions is crucial to improving PrEP acceptance and strengthening HIV prevention efforts.

EP0359

Preferences and concerns for using long-acting injectable HIV pre-exposure prophylaxis (PrEP) among female barmaids in Dar es Salaam, Tanzania

W. Akyoo[1], I. Mosha[2], H. Goymann[3], R. Mpembeni[4], A. Jahn[5]

[1]Muhimbili University of Health and Allied Sciences, School of Public Health and Social Sciences, Behavioural Sciences, Dar es Salaam, United Republic of Tanzania, [2]Muhimbili University of Health and Allied Sciences, School of Public Health and Social Sciences, Dar es Salaam, United Republic of Tanzania, [3]Heidelberg University, Global Health, Heidelberg, Germany, [4]Muhimbili University of Health and Allied Sciences, Department of Epidemiology and Biostatistics, Dar es Salaam, United Republic of Tanzania, [5]Heidelberg University, Institute of Global Health, Heidelberg, Germany

Background: Oral HIV pre-exposure prophylaxis (PrEP) has been introduced globally and, if taken accordingly, can lower the risk of HIV acquisition. However, women in sub-Saharan Africa frequently experience challenges in its uptake and adherence. Long-acting injectable PrEP has the potential to overcome pills challenges and improve HIV prevention. Female bar workers (FBWs) frequently engage in transactional sex and are particularly vulnerable to HIV.

In this study we explored FBWs perspectives on preferences and concerns about long-acting injectable HIV PrEP use.

Methods: This qualitative study was embedded in a randomized trial to asses workplace-based PrEP provision for FBWs in Dar es Salaam. We conducted in-depth-interviews with 17 purposefully selected FBWs, oral PrEP-users and non-users, in 2024. Interviews were conducted in Kiswahili using semi-structured questions. We analysed the data using an inductive approach.

Results: The majority of PrEP non-users expressed no preference for any form of PrEP while oral PrEP-users expressed high interest in long-acting PrEP. Most participants favoured long-acting over oral PrEP, being concerned about the pill size and the daily regime. Participants highlighted the advantages of long-acting PrEP including more discretion, less side effects, prolonged prevention and no daily pill fatigue

Most participants indicated preference for a three-month PrEP injection while some preferred PrEP injection on a monthly basis to better monitor and control potential side effects.
The participants preferred health facilities as service providers because of the timely service, their resources to manage complications and more privacy, reducing stigma. Some participants mentioned community spots as a preferred provider model due to its convenience, no contempt related to facility visit and friendly services given by community providers.
Many participants had no concerns about the use of long-acting PrEP. However, some feared it being in a trial phase, causing cancer and side effects, including fatigue, nausea, dizziness, increased hunger, and risky sexual behaviour.
Conclusions: The majority of the participants showed strong interest in long-acting injectable PrEP, highlighting its convenience and discretion. Our findings suggest that it can overcome challenges in PrEP pills and adherence while addressing the need for a more tailored approach for FBWs and other vulnerable groups in Tanzania.

EP0360

How willing are sexual and gender minorities to use pre-exposure prophylaxis modalities? An online survey from Brazil, Mexico and Peru

J. Qquellon[1], K.A. Konda[1,2], H. Vega-Ramirez[3], T.S. Torres[4], C.F. Caceres[1], R. Robles-Garcia[3], P.M. Luz[4], B. Hoagland[4], C. Pimenta[4], M. Benedetti[4], V. Veloso[4], B. Grinsztejn[4]
[1]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, Sida y Sociedad, Lima, Peru, [2]USC Keck School of Medicine, Division Disease Prevention, Policy and Global Health, Department of Population and Public Health Sciences, Los Angeles, California, United States, [3]Instituto Nacional de Psiquiatría Ramon de la Fuente Muñiz, Mexico City, Mexico, [4]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz), Rio de Janeiro, Brazil

Background: Pre-exposure prophylaxis (PrEP) urgently needs to be scaled up among sexual and gender minorities (SGM) in Latin America. New PrEP modalities have been developed and may address daily oral PrEP adherence challenges. We assessed factors associated with willingness to use daily oral, event-driven oral (ED-PrEP) and bimonthly injectable PrEP among SGM from Brazil, Mexico and Peru.
Methods: Cross-sectional survey was conducted online from August to November 2024 among SGM aged 18+ years, excluding people living with HIV (PLWH). Willingness to use PrEP modalities was evaluated using a 4-point Likert scale, and we considered "Very likely" as "Willing". Multivariate Poisson regression models were used to estimate prevalence ratios for willingness to use each PrEP modality, adjusting for age, country, race, income, sex with PLWH, depression (PHQ-9), homonegativity, perceived HIV risk (PHR), and HIV knowledge (HIV-KN). We assessed these four latter variables with validated scales accordingly.
Results: We had 9257 participants (Brazil: 65.5%; Mexico: 24.6%; Peru: 9.9%) with a median age of 38 years (IQR:31–46), and 20.2% reported earning minimum wage or less. Most respondents were willing to use bimonthly injectable PrEP (68.7%), then daily oral PrEP (58.5%), and ED-PrEP (45.3%). Across the three PrEP modalities, willingness increased as PHR rose and decreased with higher homonegativity. Willingness to use ED-PrEP and bimonthly injectable PrEP was higher with increased HIV-KN.
Compared to Brazilians, Mexicans and Peruvians were more willing to use daily oral PrEP, but less willing to use ED-PrEP and bimonthly injectable. Participants who reported sex with PLWH were less willing to use ED-PrEP, but more willing to use the bimonthly injectable (see table below).

Characteristics	Daily oral aPR* [95% CI]	Event-driven oral aPR* [95% CI]	Bimonthly injectable aPR* [95% CI]
Country (Ref: Brazil)			
Mexico	1.15 [1.05 - 1.26]	0.86 [0.78 - 0.94]	0.74 [0.69 - 0.80]
Peru	1.16 [1.02 - 1.31]	0.72 [0.62 - 0.83]	0.84 [0.75 - 0.93]
Race (Ref: White)			
Mixed	1.10 [1.02 - 1.20]	1.01 [0.93 - 1.09]	1.05 [0.99 - 1.12]
Black/Asian/Indigenous/Other	1.08 [0.96 - 1.22]	1.01 [0.90 - 1.12]	1.00 [0.91 - 1.09]
Monthly income (Ref: ≤ minimum wage)			
> 1 to 2 minimum wage	1.01 [0.91 - 1.12]	0.94 [0.84 - 1.04]	1.03 [0.94 - 1.13]
> 2 to 6 minimum wage	0.94 [0.85 -1.03]	0.91 [0.83 - 1.00]	1.02 [0.94 - 1.11]
> 6 minimum wage	0.88 [0.78 - 0.99]	0.88 [0.79 - 0.99]	1.03 [0.94 - 1.13]
Depression (Ref: No)			
Yes	1.14 [1.06 - 1.23]	1.10 [1.03 - 1.18]	1.05 [0.99 - 1.11]
Homonegativity	0.99 [0.98 - 0.99]	0.99 [0.99 - 1.00]	0.99 [0.99 - 1.00]
Perceived HIV risk	1.03 [1.02 - 1.04]	1.03 [1.02 - 1.04]	1.01 [1.01 - 1.02]
HIV knowledge	1.00 [0.98 - 1.02]	1.04 [1.01 - 1.06]	1.06 [1.03 - 1.08]
Sex with PLWH (Ref: No)			
Yes	1.02 [0.91 - 1.15]	0.83 [0.75 - 0.92]	1.09 [1.01 - 1.17]
I don't know	1.00 [0.92 - 1.09]	0.91 [0.84 - 0.99]	1.06 [0.99 - 1.13]

**Adjusted also for age. PLWH: People living with HIV, bold font indicates a p-value of less than 0.05*

Conclusions: Bimonthly injectable PrEP was the preferred modality overall and in Brazil, while daily oral PrEP was preferred in Mexico and Peru, possibly reflecting diverse PrEP availability. Willingness to use ED-PrEP and bimonthly injectable PrEP increased with HIV knowledge.

EP0361

Condom use among young people aged 15-24 years receiving HIV pre-exposure prophylaxis at MARPI Clinic Mulago, Kampala district, Uganda

J. Nampiima[1], P. Awor[1], S. Nabukeera[1], J.K. Matovu[1], A. Kisakye[1], D.M. Byonanebye[1]
[1]Makerere University School of Public Health, Kampala, Uganda

Background: The World Health Organization recommends PrEP to be used with other existing HIV prevention measures, such as condoms. Consistent condom use prevents one from acquiring other sexually transmitted infections and unwanted pregnancies. Although there is data on condom use among PrEP users in the key populations, there is limited data among young people, especially in resource-limited settings.
This study therefore seeks to determine the prevalence, factors associated with condom use at the last sexual encounter among young people (15-24 years) on PrEP at the Most At Risk Populations Initiative (MARPI) clinic.

Methods: This was a cross-sectional study carried out in Uganda among young people receiving pre-exposure prophylaxis at Most At Risk Population Initiative Uganda. The participants were systematically sampled from the clinic registers. Quantitative data on condom use and associated factors was collected using a questionnaire and analyzed using Stata version 15. Modified Poisson regression with robust errors was used to assess associated factors at bivariable and multivariable stages.

Results: In this study 356 young people on PrEP were recruited; 58.7%of them were males, median age was 22 (3) years, 41.9% were married/cohabiting and 40.4% had been on PrEP for a duration of (6-12months). Of the 356 young people enrolled, 46.1% (95% CI: 0.41-0.51) had used condoms at the last sexual encounter.

Nearly half (45.8%) of young people were not using condoms because they felt that they were not at risk of acquiring HIV. In the adjusted analysis: the prevalence of condom use at the last sexual encounter among young people was found to be associated with the level of education, confidence in using condoms and the type of sexual partner at the last sexual encounter; (APR: 1.24, 95% C.I: 1.03-1.50, p=0.027), (APR: 4.56, 95% C.I: 2.80-7.43, p= <0.001) and (APR: 2.31,95% C.I: 1.69-3.17, p= <0.001) respectively.

Conclusions: The study findings highlight low (46.1%) condom use among this population because more than half of the participants relied solely on PrEP for HIV prevention. Therefore, this puts young people at a high risk of acquiring other sexually transmitted diseases and unwanted pregnancies and hence the need for immediate interventions.

EP0362

Designing a safety monitoring system for BRILLIANT consortium-led HIV vaccine trials in Africa

S. Hendricks[1], A. Takalani[1], B. Mabilane[1], Y. Brown[2], I. Seocharan[3], A. Joubert[4], T. Reddy[3], N. Yende-Zuma[3], K. Woeber[3], N. Garrett[5], L.-G. Bekker[5,6], G. Gray[7]

[1]Hutchinson Centre Research Institute of South Africa, HIV Vaccine Trial Network Leadership Operations Centre South Africa, Johannesburg, South Africa, [2]Hutchinson Centre Research Institute of South Africa, HIV Vaccine Trial Network Laboratory Operations Centre South Africa, Johannesburg, South Africa, [3]South African Medical Research Council, Durban, South Africa, [4]BioInformatiCo, Johannesburg, South Africa, [5]University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa, [6]University of Cape Town, Department of Medicine, Cape Town, South Africa, [7]South African Medical Research Council, Cape Town, South Africa

Background: The BRILLIANT (Bringing Innovation to clinical and Laboratory research to end HIV in Africa through New vaccine Technology) Consortium aims to lead HIV vaccine development in Africa by integrating novel immunogen designs and innovative safety monitoring systems (SMS).

Description: The SMS will span across eight African countries and coordinate input from multidisciplinary partners, with the first pilot trial being BRILLIANT-001. The design was developed over a period of six months, with the majority of this time dedicated to mitigating safety risks associated with novel immunogens. Enhanced components include additional tailored fields within Clinical Data Acquisition Standards Harmonization (CDASH)-compliant case report forms (CRFs), near real-time detection of adverse events (AEs) of concern through database-triggered email alerts, clinician access to a 24/7 safety hotline, extra safety oversight provided by local expertise within both internal and independent safety monitoring committees, and continuous safety refresher training to ensure that quality management standards are upheld.

Lessons learned: Designing a robust SMS required contextual adaptation specific to Africa. The development the clinical database incorporated rigorous safety reviews of protocol-specific aspects with stakeholder involvement. A safety database was extensively tailored for the BRILLIANT Consortium Discovery Medicine trials to include the requirements of multiple regulatory authorities in serious AE reporting. An adaptive integrative system will support safety reporting across both the clinical and safety databases. Multiple reporting mechanisms were established, including paper, web, and app-based CRFs, to account for power disruptions. Early-career investigators are incorporated and mentored within safety monitoring committees to enhance safety oversight expertise within the BRILLIANT Consortium. Increased training efforts were required for site clinicians to bridge the gap between traditional Phase 1 safety reporting and the specialized requirements of Discovery Medicine trials.

Conclusions/Next steps: SMSs are essential for global HIV vaccine development. As CRSs begin activation, the BRILLIANT Consortium will apply lessons learned to improve drug safety, strengthen clinical trials, and guide regulatory decisions in Africa. Plans include creating an integrative safety database dashboard to monitor safety report submissions between sponsors, country-specific regulatory authorities, and immunogen developers.

EP0363

Knowledge about and attitudes towards PrEP and PEP use among transgender girls and non-binary youth in the United States

M. Ybarra[1], C. LaBranche[1], L.Z. DuBois[2], R. Garofalo[3]

[1]Center for Innovative Public Health Research, San Clemente, United States, [2]University of Oregon, Eugene, United States, [3]Ann & Robert H. Lurie Children's Hospital of Chicago, Adolescent and Young Adult Medicine, Chicago, United States

Background: Although transgender girls and non-binary (TNB) youth assigned male at birth face HIV risks similar, if not greater than, cisgender sexual minority boys, there is a significant dearth of research about their knowledge and attitudes towards pre- and post-exposure prophylaxis (PrEP and PEP, respectively).

Methods: Seven online focus groups with 67 youth were conducted between December 2021 and February 2022. Youth were recruited across the US on social media and assented over the telephone. Groups were stratified by

sexual experience (ever/never). Eligible youth were 14-18 years of age, assigned male at birth and identified as transgender or non-binary.

Results: Almost none of the youth, both sexually experienced and inexperienced, had heard of PrEP, and even fewer had heard of PEP. Almost all said they would be open to taking it however, especially if they were able to learn more about the drugs' side effects and drug interactions, risks, and efficacy. They also wanted to know about delivery options (e.g., mail order).

There was mixed feedback about how comfortable youth would feel about talking to a healthcare provider. For example, one girl said: "I would not feel very comfortable with talking to my primary health provider about it because I still go to a pediatrician. However, I would be comfortable with talking to someone who specializes in that area of medicine."

The biggest access barriers articulated were cost and parents. As one non-binary youth shared: "No longer interested [if my parents found out]. The health is much more in danger by my parents than by HIV to be honest. We don't have health insurance though soooo.."

Another non-binary youth similarly said: "If my parents could see it, I would not be able to get or use it [PrEP/PEP]. They are a largely prohibiting factor, as they are transphobic, conservative, and incredibly Christian."

Conclusions: To impact HIV acquisition rates among TNB youth in the US, increasing knowledge about PrEP and PEP is a public health imperative. Equally important is addressing key access barriers, particularly the drugs' cost, and alternatively, disclosure to one's parents about the prescription when one's health insurance coverage is used.

EP0364

Awareness and factors associated with acceptability of HIV pre-exposure prophylaxis among female university students aged 18 to 24 years in Rwanda

C. Murebwayire[1], A. Kidane[2], Z. Nzeyimana[3]
[1]Rwanda Biomedical Centre, National Reference Laboratory, Kigali, Rwanda, [2]Mount Kenya University, MPH, Kigali, Rwanda, [3]Rwanda Biomedical Centre, HIV, Viral Hepatitis, and STIs Division, Kigali, Rwanda

Background: HIV epidemic remains a global health threat especially among young people. In 2019, Young women represented around twenty-five percent of all world's new infections. Although pre-exposure prophylaxis (PrEP) can help protect people at high risk of HIV, especially young women, from getting the epidemic, there is still limited literature on PrEP awareness and acceptability level especially among young women (YW) aged 15 to 24 years.

This study was conducted to identify the prevalence and factors associated with PrEP acceptability among YW in Rwanda.

Methods: This cross-sectional study collected quantitative data from young women students at selected universities across Rwanda between August 8 and November 8, 2024. A structured questionnaire captured socio-demographic details and information on PrEP awareness and acceptability. Data analysis was conducted using STATA 17, with descriptive methods and logistic regression to identify factors influencing PrEP acceptability. Statistical significance was set at $p<0.05$.

Results: We interviewed 455 YW university students aged 18 to 24 years with mean age 21 years, 98.9% single, 63.3% were from rural areas, and 45.1% in Year 1 of their university education. Out of the 455 YW, 87.5% had ever heard about PrEP and 87.9% willing to start PrEP once identified eligible for it.

Although, majority of the students would accept to use PrEP once identified eligible for PrEP, significantly higher likelihoods of acceptability were observed among students who had never heard about PrEP before [aOR: 13.8 with 95% C.I: 1.0-185.4], certain that PrEP can be taken as an injection [aOR:20.4 with 95% C.I: 3.3-124.8] or daily taken oral PrEP as pills [aOR:15.8 with 95% C.I: 2.5-99.6], lack of hindrance to use PrEP [aOR:4.5 with 95% C.I: 1.0-19.5], and among those who would recommend it to others [aOR: 153 with 95% C.I: 3.5 -66.3].

Conclusions: The study reveals high awareness and acceptability of PrEP among young women university students but notes that the pill burden of oral PrEP may reduce its acceptability. It underscores the importance of campaigns to dispel myths and promote evidence-based messaging about PrEP. Additionally, introducing injectable PrEP options could enhance uptake in Rwanda.

Integration of HIV services with other services, including sexual and reproductive health services

EP0365

Community-centered approaches: insights from Toronto's sex workers' and former prisoners' HPV self-testing

S. Shumba[1,2]
[1]Great Zimbabwe University, Sociology and Anthropology, Masvingo, Zimbabwe, [2]Prisoners with AIDS Support Action Network, Women Living With HIV, Toronto, Canada

Background: In order to overcome stigma and limited access to healthcare, this pilot project investigated the acceptability of HPV self-sampling kits among marginalized women, such as sex workers and ex-prisoners. Providing stigma-free HPV testing in community settings, showcasing the ability to include HPV testing into larger HIV prevention initiatives, and proving how successful peer mobilizers are at reaching these populations were among the goals.

Description: Through two community organizations that serve marginalized women, this three-month study involved 80 women in Toronto from February to April 2024. Because of stigma and structural barriers to healthcare, PASAN mobilized 40 ex-prisoners and Maggie's mobilized 40 sex workers, both of whom were at high risk for HPV-re-

lated health problems. HPV self-testing kits were made available to participants in comfortable drop-in center environments.

Women between the ages of 25 and 69 who were not pregnant or breastfeeding and had not had a Pap smear or HPV testing within five years were recruited by peer mobilizers. Nurses trained them on how to use the kit, and later mobilizers would go with participants who had abnormal test results to hospitals for pap smears. Data collection highlighted the acceptability and convenience of self-testing, demonstrating the success of community-led approaches in reducing barriers to cervical cancer prevention and providing stigma-free care. This project emphasized the importance of tailored strategies to improve health equity.

Lessons learned: Through strong community engagement and peer mobilization 80 participants were mobilized in 3 months. By making HPV self-testing kits available in community-based settings, accessibility was guaranteed, and prejudice issues were allayed. On-site nurses offer direction, which boosts participants' self-esteem and contentment. To meet the special requirements of sex workers and ex-prisoners, flexibility and cultural awareness reduced resistance and increased inclusion. Peer-led involvement, decentralized testing, integrated care, and on-site assistance were among the best approaches. More than 90% of participants said they were satisfied, and the majority suggested the kits because they were convenient.

Conclusions/Next steps: The pilot study combined HIV treatment and HPV screening, demonstrating the value of community-based, peer-led healthcare for marginalized populations. By offering services in safe spaces, it was able to overcome barriers like stigma.

EP0366

Urgent need for syphilis micro-elimination among MSM living with HIV in Georgia

M. Karchava[1,2], O. Chokoshvili[2,3], N. Dvali[2], L. Gatserelia[2], L. Dzigua[2], N. Rukhadze[2], R. Mechurchlishvili[2], M. Todua[4], M. Jamutashvili[2,5], N. Kifiani[6], A. Abutidze[2,4], L. Sharvadze[2,4]

[1]Tbilisi Medical Academy, Tbilisi, Georgia, [2]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia, [3]Georgian National University, Tbilisi, Georgia, [4]Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia, [5]European University, Tbilisi, Georgia, [6]Tbilisi State Medical University, Tbilisi, Georgia

Background: A systemic review and meta-analysis of syphilis among Men who have sex with men (MSM) report, that global prevalence of syphilis among MSM is 15 times higher than that of men in the general population (7.5% compared to 0.5%). These finding highlights the urgent need to assess and address syphilis burden in Georgian MSM living with HIV.

In this study we are reporting the trend of syphilis prevalence and incidence in Georgian MSM living with HIV over the period of 20 years in order to address syphilis epidemic for the purpose of micro elimination action plan proposal.

Methods: We have retrospectively analyzed syphilis laboratory testing data among MSM and non-MSM population living with HIV. RPR and/or TPHA laboratory results were extracted from national HIV health information system since 2004.

The prevalence of syphilis was calculated at using test result conducted at registration visits at AIDS Centers throughout the country. HIV cumulative incidence was calculated by person month using R packages "tidycmprsk". Maximum follow-up period was 15 months.

Results: Laboratory testing data for syphilis were available for 87% MSM (1283 from 1476) compared to 68% of the non-MSM group (6399 from 9324). Among tested MSM cohort, 37.7% (484/1283) had positive syphilis results, whereas only 11.4% (731/6399) of the non-MSM group. This difference was statistically significant (X-squared = 553.24, 95% CI 0.23–0.29, $p < 0.001$). Interestingly, since 2016 there has been a notable and sustained increase in the prevalence with rates rising to 51% among MSM and 25% among non-MSM population. We suspect that the observed doubling of syphilis prevalence among the non-MSM group may be attributable to the presence of a hidden MSM population within non-MSM cohort.

A total of 484 new syphilis cases were diagnosed during the study period, yielding an observed incidence rate of 11.3 per 100 person-years (95% CI: 10.3 – 12.3).

Conclusions: Our study identifies a significant increase in syphilis prevalence and incidence over time, particularly among MSM, underscoring the critical need for continued surveillance and targeted interventions, such as the implementation of DozyPEP, to mitigate transmission and facilitate micro-elimination within this population.

EP0367

Enhancing HIV/STI services accessibility through ProtectNow Linktree: a digital initiative in Malaysia

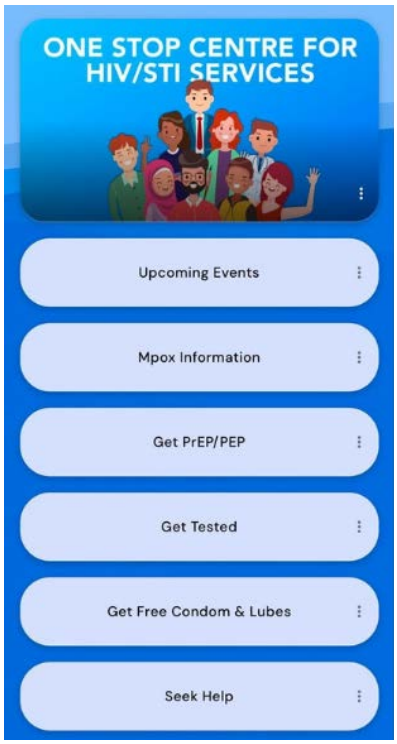
W.M. Ikhtiaruddin[1], Y. Yusoff[1]

[1]Malaysian AIDS Council, Program Department, Kuala Lumpur, Malaysia

Background: In response to the growing need for accessible HIV and STI services in Malaysia, ProtectNow Linktree was launched as a digital platform designed to centralize and streamline access to a variety of services. The platform provides a user-friendly directory of HIV/STI-related services, including HIV testing, PrEP/PEP, chemsex tools, addiction clinics, and support networks.

Aimed at improving service accessibility, ProtectNow also acts as an online learning hub for community health workers (CHWs), creating a supportive environment for at-risk populations.

Description: Since its launch, ProtectNow has gained significant traction, with over 54,000 views, a 72% click rate, and a growing subscriber base. The platform's most popular services are HIV testing and PrEP/PEP, demonstrating a clear demand for HIV/STI prevention tools. A key feature of ProtectNow is its ability to connect users directly with CHWs via WhatsApp, facilitating immediate support and service delivery.



Service	Clicks
Get PrEP	12.54k
PrEP at klinik kesihatan	10.13k
PrEP at private clinic and pharmacies	5.43k
Get tested	11.8k
Test at NGO	5.07k
Order free HIV self-test kit	3.17k
Chemsex Tools	2.15k

Lessons learned: This digital initiative aligns with global trends emphasizing digital tools in improving healthcare access, as seen in studies like Lee et al. (2018). The success of ProtectNow highlights the potential of digital platforms to bridge healthcare gaps, especially for hard-to-reach populations.

Conclusions/Next steps: The impact of ProtectNow on HIV/STI prevention and testing is substantial, offering a seamless pathway for users to connect with essential services. The platform's future expansion promises further reach and integration of specialized services, strengthening Malaysia's overall HIV/STI response strategy.

By continuing to enhance digital tools like ProtectNow, Malaysia can improve the accessibility and effectiveness of HIV/STI services, driving progress in the nation's public health efforts.

EP0368

Provision of HIV pre-exposure prophylaxis to migrants who self-identify as priority populations along their migratory route in Guatemala and Colombia offered an effective additional prevention tool

C. Casalini[1], J.R.G. Cañizares[2], J.F.R. Correa[2], C. Valdes[3], A. Diaz[4], A. Gottlib[1], A. Richardson[1], C. Akolo[1]
[1]FHI360, HIV, Washington, DC, United States, [2]Corporación Red Somos, HIV, Bogota, Colombia, [3]Asociación Lambda, HIV, Guatemala city, Guatemala, [4]USAID, Bogota, Colombia

Background: UNAIDS target for HIV prevention is for 95% of people at risk of HIV acquisition, to use pre-exposure prophylaxis (PrEP) and condoms. Reports around PrEP uptake among migrants are understudied, despite the socioeconomic vulnerabilities which put them at increased HIV risk, particularly among priority populations (PP).

The PEPFAR/USAID-funded Meeting Targets and Maintaining Epidemic Control (EpiC) project offers PrEP to close equity gaps among PP migrants transiting through Colombia and Guatemala.

Methods: Condoms, lubricants, HIV testing services, and oral PrEP were provided through Corporación Red Somos and Asociación Lambda in six cities (Bogotá-Soacha, Barranquilla in Colombia; Guatemala City, San Marco, Chiquimula, Izabal in Guatemala). Clients were reached through peer networks and offered HTS at hot spots (defined as areas of high HIV vulnerability where migrants transit), at Red Somos-supported clinics and Lambda-supported migrant shelters; Red Somos initiated PrEP directly, while Lambda navigated clients to another organization for PrEP initiation.

Clients were counseled about PrEP initiation and refill in other countries along their migratory route. We present aggregated project data from June through September 2024 for HIV negative clients offered and started PrEP, disaggregated by PP type (men who have sex with men [MSM], female sex workers [FSWs], trans [trans] people, and "other PP" [bisexual, lesbian, intersex, queer]). For the Red Somos subset of PrEP clients, we present syphilis test (non-treponemal followed by treponemal test) and treat data.

Results: Among 166 PP migrants testing HIV negative, 100% were offered PrEP, 69% (115) of whom started with a 90-day supply. Of these, 62% (71) were MSM, 15% (17) FSWs, 13% (15) trans, and 10% (12) other PP. Among 109 PrEP clients, 20% (22) tested syphilis positive: 24% among MSM, 12% among FSW, 20% among trans, 8% among other PP; 100% were treated.

Conclusions: EpiC effectively provided PrEP services to PP migrants moving along the migratory route in Colombia and Guatemala. However, optimizing service delivery and PrEP use requires understanding PP migrants' barriers and facilitators to PrEP initiation.

The high syphilis prevalence highlights the critical role of PrEP and the need for integrated sexual health services that address HIV prevention and STI management among PP migrants.

EP0378

Prevalence and risk factors of renal dysfunction among HIV patients: findings from a nested study in the CHAO cross-sectional cohort in Meru County, Kenya

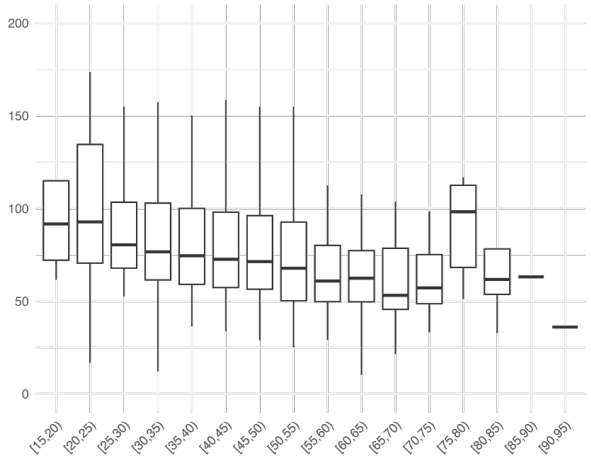
C. De Santo1[1], M. Cicala[1], B. Welu[2], H. Ndoi[2], C. Mosconi[1], M. Carestia[1], A.M. Doro Altan[3], J. Mugugni[4], K. Muthuri[5], G. Guidotti[6], S. Orlando[1], F. Ciccacci[1]

[1]University of Rome Torvergata, Biomedicine and Prevention, Rome, Italy, [2]DREAM Program, Community of Sant'Egidio, Meru, Kenya, [3]Link Campus University, Rome, Italy, [4]County AIDS&STI Coordination, Meru, Kenya, [5]County Direction of Health Services, Meru, Kenya, [6]ASL Roma 1, Rome, Italy

Background: Renal dysfunction is a growing concern among HIV-positive populations, particularly in sub-Saharan Africa. Previous studies have identified general risk factors, such as advanced age, reduced CD4 counts, and elevated viral loads.

This study aims to assess the prevalence and determinants of renal dysfunction among HIV-positive individuals receiving ART in Meru County, Kenya.

Methods: This study is a nested sub-analysis within the broader CHAO cross-sectional cohort. Eligible participants included adult people living with HIV (PLWH). Renal function was classified in: normal (>90 mL/min), mild (60-90 mL/min), moderate (30-60 mL/min), and severe impairment (<30 mL/min). Logistic regression models were employed to determine the risk factors associated with eGFR levels below 60 mL/min. Data collection encompassed demographic variables, ART regimen details, and the presence of comorbidities.



Results: Among the 1,042 participants included in the analysis, 33.4% demonstrated evidence of renal dysfunction, characterized by an eGFR below 60 mL/min. The findings indicate that advancing age is a significant predictor of renal impairment, with the odds of reduced eGFR increasing by 24% for each additional five-year increment (OR: 1.24; 95% CI: 1.16–1.33; p<0.001).

Female participants exhibited a nearly fivefold increased likelihood of renal dysfunction compared to their male counterparts (aOR: 4.76; 95% CI: 3.13–7.69; p<0.001). The presence of dyslipidemia was linked to an increased risk, with the odds of reduced eGFR rising by 12% for every 10-unit increase in cholesterol levels (aOR: 1.12; 95% CI: 1.08–1.15; p<0.001).

Other comorbidities, including hypertension and obesity, were more prevalent among patients with impaired renal function.

Conclusions: This study highlights the prevalence of renal dysfunction in PLWH, especially older women and those with metabolic comorbidities. It emphasizes the need for targeted renal monitoring and management, integrating HIV and non-communicable disease care to address renal impairment, particularly in resource-limited settings.

EP0379

Low bacterial load is associated with asymptomatic gonorrhea and chlamydia in key populations

L. Spadaccini[1], M. Vacchino[2], M. Ceschel[1], M.I. Figueroa[1], C. Perez[1], P. Galarza[2], P. Cahn[1]

[1]Fundacion Huesped, Research department, City of Buenos Aires, Argentina, [2]ANLIS Malbran Institute, STI Laboratory, City of Buenos Aires, Argentina

Background: Asymptomatic gonorrhea and chlamydia (NG/CT) are the source of ongoing transmission. We aimed to evaluate the association between NG/CT bacterial load (inversely estimated by Cycle threshold value) in positive samples and the presence of symptoms in key population.

Methods: We included samples with NG/CT diagnosis from asymptomatic (AP) and symptomatic participants (SP) attending an STI center in Buenos Aires, Argentina from February to October 2022.

AP samples included NG/CT screening in first void of urine, rectal and pharyngeal swabs in men who have sex with men (MSM).

SP samples included urethral and/or rectal swabs in MSM and transgender women (TGW).

No participant presented with pharyngeal symptoms so all pharyngeal samples were from AP. Diagnosis of NG/CT was performed by real-time PCR, allowing the determination of the Cycle threshold value (Ctv). Ctv is inversely related to bacterial load (BL) being Ct ≤ 28 considered high BL and Ct ≥40 considered negative.

We compared Ctv among SP and AP in different locations using the Wilcoxon rank sum test.

Results: Of 66 NG/CT positive samples from 49 participants, 46 were from AP and 20 from SP. In rectum, SP had lower Ctv than AP for NG and CT ($p < 0.05$). In urethra, gonorrhea showed lower Ctv in SP vs AP (23.5 vs. 38; $p = 0.004$), while for chlamydia there were no differences.

In pharynx, Ctv in AP were high (gonorrhea: 35.8; chlamydia: 37.6). Median global Ctv in AP was higher than SP ($p < 0.001$), indicating low BL. (Table 1, below.)

Conclusions: Asymptomatic NG/CT in key populations was associated with low BL (most Ctv near the cut-off limit of detection), which might have implications in spontaneous clearance and potential transmission.

Positive samples	Ct median value (IQR)/overall	Asymptomatic participants Ct median value (IQR)/ n	Symptomatic participants Ct median value (IQR)/ n	p-value
Gonorrhea in rectum	33.8 (29.8, 35.9) n: 17	34.6 (32.0, 36.0) n: 14	25.9 (25.5, 29.8) n: 3	0.047
Chlamydia in rectum	30.1 (28.3, 33.7) n= 15	33.7 (30.1, 37.4) n= 8	28.6 (27.0, 30.5) n = 7	0.021
Gonorrhea in urethra	31.7 (25.1, 38.0) n= 11	38.0 (35.6, 39.3) n= 6	23.5 (21.6, 26.8) n= 5	0.004
Chlamydia in urethra	29.45 (25.73, 30.77) n: 6	32.15 (32.15, 32.15) n: 1	29.26 (24.55, 29.64) n: 5	0.3
Gonorrhea in pharynx	35.8 (34-38.5) n: 10	35.8 (34-38.5) n: 10	- n:0	
Chlamydia in pharynx	37.6 (35.7-37.8) n: 7	37.6 (35.7-37.8) n:7	- n:0	
Global gonorrhea	35.4 (33.4, 37.8) n:38	35.4 (33.4, 37.8) n:30	25.5 (23.0, 26.9) n:8	<0.001
Global Chlamydia	31.2 (29.1, 36.6) n:28	35.8 (31.9, 37.7) n: 16	28.9 (26.0, 30.0) n:12	<0.001

Table 1. Comparison of NG/CT Ct values between asymptomatic and symptomatic participants.

EP0380

Findings from integrating COVID-19 vaccination into HIV clinics: programmatic outcomes and reasons for vaccine hesitancy among people living with HIV in 2023 in the littoral, Cameroon

P. Tchendjou[1], B. Tchounga[1], A.F. Nkodo[1], E. Lyonga[2], G. Nyemb[1], R. Kana[1], C. Moki[1], L. Simo[1], E. Shu[1], T. Djikeussi[1], R. Ajeh[3,4], L. Esso[5,6], Y. Moussa Fadil[2], E. Takem[2], S. Lekeumo[1], E. Moma[1], J. Ditekemena[7], A. Tiam[8,9], J. Fokam[10,4], A. Berhan[8], K.A. Bosh[2], M.F. Jalloh[2]

[1]Elizabeth Glaser Pediatric AIDS Foundation, Yaoundé, Cameroon, [2]Division of Global HIV and TB, U.S. Centers for Disease Control and Prevention, Yaoundé, Cameroon, [3]Global Funds and Partners' subvention unit, Ministry of Public Health, Yaoundé, Cameroon, [4]Faculty of Health Sciences, University of Buea, Buea, Cameroon, [5]Directorate of the Fight Against Diseases, Epidemics, and Pandemics, Cameroon Ministry of Public Health, Yaoundé, Cameroon, [6]Faculty of Medicine and Biomedical Sciences, University of Yaounde I, Yaoundé, Cameroon, [7]Elizabeth Glaser Pediatric AIDS Foundation, Kinshasa, Kinshasa, Congo, the Democratic Republic of the, [8]Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States, [9]George Washington University Milken Institute School of Public Health, Washington, United States, [10]National AIDS Control Council, Ministry of Public Health, Yaoundé, Cameroon

Background: People living with HIV (PLHIV) have an increased risk of developing severe COVID-19 disease. Integrating COVID-19 immunization within health facilities was identified as a promising strategy to prevent COVID-19 among PLHIV. The infodemic surrounding the introduction of COVID-19 vaccines affected vaccine uptake among vulnerable populations such as PLHIV.

We assessed COVID-19 vaccination uptake among PLHIV and identified potential reasons for hesitancy among PLHIV in the Littoral region of Cameroon

Methods: Routine data collected on PLHIV who accessed care between June and September 2023 in 14 health facilities implementing the Global VAX project in the Littoral region were retrospectively analyzed. In May 2023, a package of COVID-19 services was integrated into selected HIV clinics, including SARS-CoV-2 symptoms screening, rapid antigen testing and vaccination for those eligible. The integration strategy relied on existing personnel and two additional nurses and data clerks.

We performed descriptive analysis to show uptake of at least one dose of the COVID-19 vaccine among the eligible population of PLHIV, completion of the vaccination regimen among those who started the regimen, and reasons for vaccine hesitancy. Vaccine refusal was the primary measure of vaccine hesitancy (vaccination delay and only accepting one dose were other measures).

Results: Overall, 9,769 HIV clinic attendees (73.5% female, 67.1% aged 18-49 years) were included. We excluded 3,078 (31.5%) declared not eligible for COVID-19 vaccine based on Cameroon COVID-19 guidelines. Of the 6,691 (68.5%) eligible clients, only 702 (10.5%) received at least one dose of vaccine. Among those who started the COVID-19 vaccination regimen, 517/702 (73.6%) completed the regimen and were deemed fully vaccinated. Among the

5,989/6,691 (89.5%) ART clients not vaccinated, the most frequent reasons for vaccine hesitancy were mistrust of any type of vaccine (20.2%), mistrust of COVID-19 vaccine specifically (20.1%), not concerned about getting COVID-19 (13.8%), fear of side effects (12.9%), and not being sure that COVID-19 exists (12.5%).

Conclusions: COVID-19 vaccine was successfully integrated into HIV clinics in Littoral, but with low uptake. Suboptimal uptake was likely driven by vaccine hesitancy.

Understanding the drivers of vaccine hesitancy among PLHIV can inform enhanced communication around health seeking behaviours and improve future vaccination uptake among PLHIV

EP0381

Human papillomavirus (HPV) vaccination uptake among adolescent girls living with HIV (AGLHIV) in Cote d'Ivoire: a national multi-center study

S. Boni[1,2], J. Jesson[3], E. Akotangni[1], V. Leroy[3], M. Folquet-Amorissani[4,5], A. Jaquet[6], on behalf leDEA West Africa - COVADOCI Study

[1]Programme PAC-CI, Research, Abidjan, Côte d'Ivoire, [2]National Cancer Control Program, Abidjan, Côte d'Ivoire, [3]Université Paul Sabatier Toulouse 3, Centre d'Epidémiologie et Recherche en Santé des POPulations (CERPOP) , UMR 1295, Inserm, Toulouse, France, [4]Centre Hospitalier Universitaire (CHU) de Cocody, Pédiatrie, Abidjan, Côte d'Ivoire, [5]Université Felix Houphouet Boigny, Mère-Enfant, Abidjan, Côte d'Ivoire, [6]University of Bordeaux, INSERM U1219, GHiGS – Global Health in the Global South, Bordeaux Population Health Research, ISPED, Bordeaux, France

Background: To eliminate cervical cancer as a public health threat, WHO has set the goal of reaching 90% of HPV vaccination coverage. In Côte d'Ivoire, national HPV vaccination has been scaled-up since 2019, targeting girls aged 9-14, free-of-charge. However, vaccination uptake in adolescent girls living with HIV (AGLHIV), still requiring a three-dose schedule are lacking. We estimated the HPV vaccination uptake and associated factors among AGLHIV in Cote d'Ivoire.

Methods: A cross-sectional study was conducted within HIV pediatric care facilities at a national level. Participating facilities were selected through a hybrid sampling combining a convenience approach by including the largest HIV pediatric facilities including those contributing to the leDEA West Africa pediatric cohort; and a random sample of integrated facilities based on the national HIV registry.

A standardized questionnaire assessing vaccine uptake and related factors was administered to actively followed AGLHIV aged 9-19 (and/or their parent/legal guardian), separately. A logistic regression analysis was used to identify factors associated with HPV vaccination uptake.

Results: Between July and November 2024, a total of 476 AGLHIV were included: median age of 15 years [Interquartile range (IQR): 12 - 17)], living in Abidjan for 47.9%, and in HIV-care since nine (IQR: 5 -12) years. Among participants, 65 (13.7%) had received at least one dose of HPV vaccine: 53 (11.1%) one dose; nine (1.9%) two doses and three (0.6%) three doses. HPV vaccine uptake was higher in facilities from outside Abidjan (19.4%) than Abidjan (7.5%), p<0.001. AGLHIV followed up outside Abidjan (aOR = 3.28 [Confidence Interval at 95% (CI95%): (1.69 – 5.74)], and identifying HPV as a sexually transmitted infection (aOR = 3.64 [CI95%: (1.66 – 7.99)] were more likely to get vaccinated compared to others. Main reported barriers to HPV vaccination were a lack of information about vaccine (84.7%) and the fear of adverse effects (4.4%).

Conclusions: HPV vaccine uptake is worryingly low among AGLHIV in Cote d'Ivoire despite decentralization and affordability of the immunization program. A sensitization program is needed targeting AGLHIV, their parents and caregivers. HPV vaccination initiatives through HIV facilities are also required to achieving the WHO 90% HPV vaccination coverage in AGLHIV.

EP0382

Hypertension cascade of care among adults living with HIV in Zambia and Zimbabwe: a cohort analysis

A. Mandiriri Ndanga[1,2,3], B.V. Chihota[4], V. Whitesell Skrivankova[2], T. Shamu[1,2,3], G. Muula[4], C. Bolton-Moore[4,5], C. Chimbetete[1], G. Wandeler[2,6]

[1]Newlands Clinic, Harare, Zimbabwe, [2]University of Bern, Institute of Social and Preventative Medicine, Bern, Switzerland, [3]Graduate School of Health Sciences, Bern, Switzerland, [4]Centre for Infectious Disease Research, Lusaka, Zambia, [5]University of Alabama, Medicine, Brmingham, United States, [6]Bern University Hospital, Infectious Diseases, Bern, Switzerland

Background: Arterial hypertension is a major risk factor for premature death and disability, with the African region having the world's highest prevalence. With HIV endemic in Africa, integrated care services manage comorbidities like hypertension among peopleliving with HIV (PLWH). Little is known about service outcomes.

We describe the hypertension care cascade among PLWH in Zambia and Zimbabwe.

Methods: We analysed data from adults aged 30+ seen between 2019 and 2024. Participants were hypertensive if they had elevated blood pressure (systolic BP ≥ 140 mmHg and/or diastolic BP ≥ 90 mmHg) at two consecutive visits, or reported antihypertension therapy use. The cascade evaluated hypertension screening, confirmation, treatment, and control(systolic BP < 140 mmHg and diastolic BP < 90 mmHg on treatment). Multilevel logistic regression evaluated associations between age, sex and hypertension treatment/control.

Results: 541 PLWH were included; median age was 42 years (IQR 36-48), and 50.2% (n=272) were males. Median time in care was 2 years (IQR 1-3), and 87 (16%) had recent HIV viral load >1000 copies/ml. Hypertension prevalence was 26% in females (95% CI 21-32) and 25% in males (95% CI 20-30%). Among 139 persons with hypertension, 65% (n=91) reported treatment at latest follow-up, and 54% (n=49) were controlled (Figure). Men were less likely than women to be treated (aOR 0.34, 95% CI 0.14-0.83). Every

5-year age increase raised treatment likelihood by 40% (aOR 1.40, 95% CI 1.10-1.76). Evidence of sex- and age-based differences in hypertension control was weak; male odds were (OR 1.56, 95% CI 0.69-3.64), and 5-year age increase had odds (OR 0.82, 95% CI 0.66-1.05).

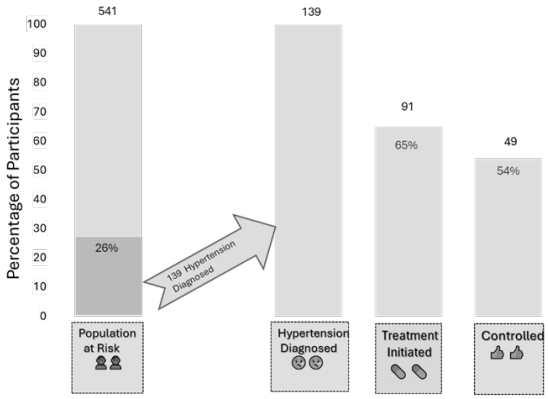


Figure: Hypertension care cascade among PLWH (2019-2024, n=541)

Conclusions: One in four PLWH has hypertension in our cohort. Males were less liekly to receive treatment. Evaluating current hypertenion control strategies including medication effectiveness and adherence support is essential for improved outcoomes within intergrated HIV services.

EP0383

Perceptions of concurrent use of injectable PrEP and injectable contraceptives among young women in Durban, South Africa

A.R. Khumalo[1], P.-G. Zwane[1], S. Govere[2], S. Shezi[1], L.M. Ngcobo[1], J. Jarolimova[3,4,5], D. Zionts[6], L.S. Johnson[6], C. Psaros[7], I.V. Basset[8,9,10]

[1]Adrenergy Research Innovations, Research, Durban, South Africa, [2]AIDS Healthcare Foundation, Research, Durban, South Africa, [3]Massachusetts General Hospital, Boston, United States, [4]Medical Practice Evaluation Center, Boston, United States, [5]Harvard Medical School, Boston, United States, [6]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States, [7]Massachusetts General Hospital, Psychiatry, Boston, United States, [8]Massachusetts General Hospital, Division of Infectious Disease, Boston, United States, [9]Harvard University, AIDS Research, Boston, United States, [10]Africa Health Research Institute, Research, Durban, South Africa

Background: Young women in South Africa (SA) are at high risk of unintended pregnancy and HIV. Injectable contraceptives are popular and highly effective.
However, adherence to oral HIV pre-exposure prophylaxis (PrEP) remains challenging due to daily dosing. Injectable PrEP offers a promising alternative, potentially improving adherence and providing highly effective prevention. Perceptions around taking both injectable contraception and PrEP simultaneously to address the concomitant need to prevent pregnancy and HIV are unexplored. We investigated young women's perceptions of the concurrent use of injectable contraception and PrEP.

Methods: We conducted in-depth interviews with a subset of Black African women (≥18y) receiving oral PrEP and/or other reproductive and sexual health services in hair salons in urban SA through a randomized control trial. Participants were followed for 12 months. Interviews were conducted privately in a salon by trained interviewers in isiZulu, recorded with participant consent, and transcribed into English. Two research assistants performed a thematic analysis assessing participants' perceptions of the simultaneous use of injectable contraception and PrEP.
Results: We interviewed 51 participants who completed at least six months of study visits. Positive reactions to concurrent injection included convenience as a major benefit, describing how concurrent injections will save time by reducing the need for multiple clinic visits. This also contributed to ease of adherence, simplifying their prevention regimens.
Many women preferred injections because of their durability and reliability, suggesting they could be widely accepted. Participants largely expressed confidence in receiving dual injections, trusting their effectiveness and emphasizing the need to cater to individual preferences. Simultaneous injection was perceived as safe, enhancing participants' sense of security and trust in their effectiveness.
Despite these positives, some participants raised concerns about potential side effects and physical reactions to the two injections, as well as concerns about additional visits if the PrEP injection and contraception injection schedules didn't align.
Conclusions: Concurrent contraception and PrEP injections are perceived as a convenient, effective, and preferred option that can simplify adherence. However, addressing concerns about potential side effects, uncertainty about safety, and timing of simultaneous injections will be crucial as injectable PrEP becomes more readily available in South Africa.

EP0384

Burden of human papillomavirus (HPV) infection and precancerous lesions among women living with HIV in AIDS Healthcare Foundation (AHF) supported health facilities in rural and urban Rwanda

S. Tuyisenge[1], E. Nkubito Mirimo[1], G. Mbaraga[1], F. Ndayisaba[1], C. Karangwa[1], D. Sebuhoro[2], L. Rangira[3], L. Buzaalirwa[4], N. Dube[5], C. Baribwira[6]

[1]AIDS Healthcare Foundation-Rwanda, Medical Department, Kigali City, Rwanda, [2]AIDS Healthcare Foundation-Rwanda, Monitoring & Evaluation Department, Kigali City, Rwanda, [3]AIDS Healthcare Foundation-Rwanda, Administrative Department/ Country Program Manager, Kigali City, Rwanda, [4]AIDS Healthcare Foundation, Quality improvement and Medical logistics/Africa bureau, Kampala, Uganda, [5]AIDS Healthcare Foundation, Quality Management and Clinical operations/Africa bureau, Manzini, South Africa, [6]Georgetown University, Independent Contractor, Kigali City, Rwanda

Background: Women living with HIV (WLHIV) are about 6 times more likely to develop Cervical cancer from a persistent HPV infection compared to HIV-negative ones. In Rwanda despite high HPV vaccination coverage, cervical cancer screening and its integration into HIV clinics face challenges.

This study describes an initiative by AHF Rwanda to enhance cervical cancer screening and treatment among WLHIV across 38 supported sites.

Methods: In collaboration with the Rwanda Biomedical Center (RBC), a 3-month cervical cancer screening campaign was launched in 2023 focusing but not limited to women aged 25–65 years, with a focus on WLHIV in this cross-sectional study. The initiative included community mobilization, training of 76 HIV clinic healthcare providers, self-sampling molecular HPV-DNA testing kits, and reagent provision.

Eligible women following a molecular HPV-DNA positive test underwent Visual Inspection with Acetic Acid (VIA) for triage, followed by treatment using thermal ablation or Loop Electrosurgical Excision Procedure (LEEP) depending on lesion severity. Data was recorded in an electronic cervical cancer screening registry (mUzima/openMRS) and analyzed.

Results: Out of 17,174 eligible women, 7,320 (42.6%) were screened. The HPV positivity rate among WLHIV was 26.9% compared to 6.5% in HIV-negative women. Age-specific positivity rates were highest in women under 25 years (37.1%) and progressively decreased with age: 28.2% for 25–49 years, 23.7% for 50–65 years, and 23.3% for those over 65 years. The 25–49 age group represented the majority (68%) of participants. Among HPV-positive women, 1,396 underwent VIA triage (70.8%) with a VIA positivity rate of 16.8% in WLHIV, and 1,275 (91.3%) received thermal ablation. Additionally, 34 cases required referral for further management, including LEEP and biopsy.

Conclusions: This study proved that cervical cancer screening coverage in urban and rural Rwanda was still very low, yet the prevalence of HPV and precancerous lesions in WLHIV is significant. The age group most affected was those under 25, meaning we need to focus on younger age groups.

Integrating cervical cancer services into HIV clinics, along with ongoing community engagement, campaigns, and capacity building, is essential for improving coverage and meeting WHO's 2030 cervical cancer elimination targets.

EP0385

Impact of integrating music workshops, peer-peer education and scorecard sessions in reducing stigma and promoting access to HIV/SRHR services among AGYWs in institutions of higher learning in Malawi Pamodzi project

E. Kayimba[1]

[1]University of Malawi, Public Health, Lilongwe, Malawi

Background: Adolescent Girls and Young Women (AGYWs) in higher learning institutions often face significant barriers to accessing HIV and Sexual and Reproductive Health and Rights (SRHR) services. Despite the availability of such services, challenges like limited awareness, stigma, unfriendly service provision, and inadequate support systems often prevent AGYWs from seeking essential healthcare. Additionally, there is a lack of accountability from service providers and policymakers to ensure accessible, quality services for AGYWs.

To address these challenges, MANASO is implementing an integrated approach of using MUSIC workshops, peer-to-peer education, and scorecards with support from USAID Pamodzi project since 2021. This approach has effectively improved knowledge, service uptake, and coordination.

Description: In 2021, 309 students from four colleges (MUBAS, UNIMA, LUANAR, and MCHC) were trained to conduct MUSIC workshops, peer-to-peer education, and scorecard sessions to raise awareness on HIV prevention, treatment, and SRHR. The MUSIC workshops uses music as a tool to promote HIV prevention, reduce stigma, and encourage students to take proactive steps in HIV care. Students create original songs on HIV-related issues, which are performed on campuses, sparking discussions and raising awareness.

In addition, the students serve as ambassadors to conduct peer-to-peer HIV/SRHR education, distribute condoms, and refer peers for other HIV/SRHR services. They also facilitate scorecard sessions to identify issues in health clinics that require attention from duty bearers.

Lessons learned: Results from 2022 to 2024 showed an 85% increase in students' knowledge of HIV and SRHR after the peer-to-peer education sessions. The songs reached almost all students on campuses, sparking dialogue.

Over 90% of participants in the music activities reported increased confidence in discussing HIV/SRHR issues. Ambassadors distributed over 532,741 condoms across four institutions over four years, with demand increasing from 13,948 condoms per institution in 2021 to 40,445 in 2024.

The scorecard sessions contributed to improved youth-friendly services and increased availability of HIV/SRHR commodities.

Conclusions/Next steps: The integrated approach has proven effective in raising awareness, reducing stigma, and improving service accessibility and quality for AGYWs. However, institutionalizing this approach is necessary for sustainability.

EP0386

Optimizing STI prevention: barriers, behaviors, and broader impacts of doxycycline post-exposure prophylaxis (DoxyPEP)

N. Eynon[1], K. Prasad[1], H. Bassett[1], J. Johnson[1], R. Smith[1], A. Johnson[2], S. Doblecki-Lewis[3]
[1]University of Miami Miller School of Medicine, Department of Medical Education, Miami, United States, [2]University of Miami Miller School of Medicine, Department of Public Health Sciences, Miami, United States, [3]University of Miami Miller School of Medicine, Division of Infectious Diseases, Department of Medicine, Miami, United States

Background: Doxycycline post-exposure prophylaxis (DoxyPEP) offers a novel approach to preventing sexually transmitted infections (STIs). While its clinical effectiveness is well-documented, gaps remain regarding its practical implementation, particularly regarding accessibility and behavioral adaptations.
This study explores these concerns at the University of Miami Rapid Access Wellness (RAW) clinic—a sexual health clinic that provides PrEP, nPEP, HIV care, and, as of May 2023, DoxyPEP—with the goal of optimizing DoxyPEP as a comprehensive tool for STI prevention.
Methods: Clients attending the University of Miami Rapid Access Wellness (RAW) Clinic from February to November, 2024 were approached and offered electronic surveys assessing DoxyPEP awareness, barriers, behavioral patterns, and satisfaction. Survey respondents completed informed consent including permission for linkage to medical records for further analysis.
Results: Participants (n=135) had a mean age of 36. 104 (77%) participants identified as male, 6 (4%) as female, and 21 (16%) as on the transgender spectrum. 93 participants (69%) identified as Hispanic/Latino and 18 (13%) identified as Black/African American. Mean number of sexual partners reported at participants' initial visit was 12. Overall, participants demonstrated high awareness of DoxyPEP (89%), with 77% actively using it. Most felt comfortable discussing DoxyPEP with doctors (92%), friends (60%), and sexual partners (55%). Cost was not a reported barrier for the majority of respondents (68%).
Nearly half (46%) of participants report some change in their sexual behavior as a direct result of taking DoxyPEP, with increased number of sexual partners (20%) as the largest behavioral change, followed by reduced condom use (17%), more frequent anal sex (15%), and oral sex (14%). Over half (55%) reported feeling less concerned about STI exposure. A majority (84%) have recommended DoxyPEP to others, primarily friends (67%), and 94% planned to continue use.
Conclusions: DoxyPEP was highly acceptable, well-utilized, and was perceived to be affordable by most. Many clients reported recommending DoxyPEP to others in their social / friendship networks, indicating a potential mechanism for broadening awareness of DoxyPEP among priority populations. Additional work to explore the extent and impact of risk compensation behavior may be warranted.

EP0387

Syphilis and hepatitis B among clients seeking injectable HIV pre-exposure prophylaxis from Western, Eastern, and Southern Province, Zambia in 2024

K. Watala[1], M. Sakala[1], M. Mwansa[2], A. Olufunso[2], O. Chilyabanyama[2], B. Kaliki[3], O. Chituwo[3], N. Soko[4], K. Musokotwane[4], C. Baumhart[5,6], T. Simwanza[7], M. Luhanga[8], J. Muhone[9], E. Silomba[10], B. Chimbala[10], W. Mbokile[10], J. Mwanza[10], L.K. Mwango[10], C.W. Claassen[2,5,6], L. Hachaambwa[5,6,10]
[1]Ministry of Health, Southern Provincial Health Office, Choma, Zambia, [2]Maryland Global Initiatives Corporation Zambia, Lusaka, Zambia, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Lusaka, Zambia, [4]National AIDS Council, Lusaka, Zambia, [5]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [6]Center for International Health, Education, and Biosecurity, Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [7]Ministry of Health, Lusaka, Zambia, [8]Ministry of Health, Provincial Health Office, Eastern Province, Chipata, Zambia, [9]Ministry of Health, Provincial Health Office, Western Province, Mongu, Zambia, [10]Ciheb Zambia, Lusaka, Zambia

Background: Syphilis and Hepatitis B Virus (HBV) are sexually transmitted infections (STIs) of significant public health concerns in Zambia, particularly among populations at high risk for HIV. Both STIs share transmission pathways with HIV (sexual and blood-borne). HBV is endemic with chronic prevalence of 5.6% among those aged 15-59 years. National prevalence of ever infected with syphilis is at 6.8% among those aged 15-59 years, while 3.4% of women in this age group have active syphilis infection. Among clients seeking injectable HIV pre-exposure prophylaxis (PrEP), STI co-infections pose additional risks. We screened clients initiating injectable PrEP for syphilis and HBV to inform integrated prevention strategies.
Methods: From February to October 2024, clients initiating injectable PrEP with cabotegravir long acting (CAB-LA) in Western, Eastern, and Southern Provinces of Zambia were screened for syphilis and HBV. Syphilis screening involved both rapid treponemal and non-treponemal assays; rapid positive tests were confirmed using rapid plasma reagin test (RPR). HBV testing included Hepatitis B surface antigen rapid tests. Data on sociodemographic characteristics, sexual risk behaviors, and prior history of STIs or HBV infection were collected. Deidentified and aggregated data were analyzed to assess the prevalence of co-infections.
Results: A total of 442 clients initiated on injectable PrEP across the three provinces were screened for syphilis and HBV. Clients ages ranged from 16 to 51 years (median, 25; interquartile range, 20-32). Of these, 418 were screened

for syphilis with 18 testing positive, resulting in positivity of 4.3% (18/418). Southern Province highest proportional contribution of syphilis, accounting for 78% (14/18) of cases, with equal sex distribution and a notable proportion (33%) among young adults. HBV screening showed 2/375 (0.5%) clients tested positive. Co-infection with both syphilis and HBV was observed in one female client from Southern Province, representing 0.2% (1/418).

Conclusions: Among CAB-LA users in Zambia, we found rates of syphilis similar to national estimates while HBV was lower than national prevalence. HIV prevention programs represent an opportunity to identify and offer treatment for co-transmitted infections; programs may consider supporting WHO CAB guidance encouraging testing CAB users for HBV. Variations in syphilis positivity yield indicate a need for targeted, region-specific interventions.

EP0388

Fragmentation of health systems as a threat to continuity of care for people living with HIV in Mexico

P. Alarcón-Murra[1], A. Piñeirua-Menéndez[2], N. Caballero-Suárez[3], E. Gutiérrez-Velilla[3], J. Mejía-Castrejón[1], O. Ocampo-Valdez[1], J. Sierra-Madero[1], A. López-Iñiguez[1]

[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán (INCMNSZ), Department of Infectious Diseases, Mexico City, Mexico, [2]Consorcio de Investigación sobre VIH SIDA TB (CISIDAT), Mexico City, Mexico, [3]Instituto Nacional de Enfermedades Respiratorias (INER), Centro de Investigación en Enfermedades Infecciosas (CIENI), Mexico City, Mexico

Background: Public healthcare in Mexico is fragmented and based on employment status. People living with HIV (PLWH) face challenges when transitioning between health systems, potentially leading to loss in engagement in care and interruptions in antiretroviral treatment (ART) with individual and public health negative consequences. We aimed to describe the clinical outcomes and experiences of PLWH undergoing migration between different public health systems.

Methods: A cross-sectional study was conducted among PLWH aged ≥18 who had recently migrated between the main health systems in Mexico City (Health ministry, IMSS and ISSSTE) due to changes in employment status. Participants were required to have continuous HIV care in one system for at least 6 months and 3 months at the new site. Data was collected through an online REDCap questionnaire that included sociodemographic information, HIV diagnosis, and experiences related to health system migration.

We assessed: the time between referral and first consultation, interruptions in ART after referal to the new system, and the reasons reported, perceived quality of care in the new system, and user's experiences.

Results: Between June 2023 and October 2024, 162 participants answered the questionnaire. 136 (84%) were male, with mean age 43.7 years. 92 (57%) reported to have a steady job. Before migration 104 (64%) were receiving INSTI, and 131 (81%) were undetectable. After migration, 135 (89%) were enrolled in the new site within three months, and 17(11%) were engaged after 3 months or not engaged at all. 120(74%) reported ART adherence over 95%. Most participants 107 (66%) reported that migration was easy; 42 (26%) interrupted ART because: ART was not dispensed in the new site 23 (55%), not specified 10 (24%), not engaged in care in the new site 4 (10%) and personal decision 4 (10%). 34 (21%) reported an overall bad experience at the new site.

Conclusions: This study highlights that migration between healthcare systems for PLWH in Mexico is a significant obstacle for maintaining the continuity of care and retention required in successful ART programs. These results should prompt authorities to devise novel legal and administrative tools to protect the well-being of this vulnerable population.

EP0389

Incorporating point-of-care early infant diagnosis of HIV into routine postnatal care services in Nigeria: assessing mothers and caregivers' perspectives using the RE-AIM framework

A. Isah[1,2], G. Ezenri[2], E.J. Ugochukwu[1,2], J.C. Onyehalu[2], C. Nwachuya[2], C.E. Agbo[2], A. Ngige[2], M.M. Abubakar[3,2], C. Idabor[2], B.O. Ukoha-Kalu[4,2], E. Ezea[5]

[1]University of Nigeria, Clinical Pharmacy and Pharmacy Management, Nsukka, Nigeria, [2]University of Nigeria, Person-Centred HIV Research Group, Nsukka, Nigeria, [3]Nigerian Air Force, Directorate of Therapeutic Services, Medical Services Branch, Kaduna, Nigeria, [4]University of Nottingham, School of Medicine, Nottingham, United Kingdom, [5]Healthy Neighborhood Rural Assist Foundation, Abuja, Nigeria

Background: Early infant diagnosis (EID) of HIV is crucial for timely management, reducing morbidity and mortality among exposed infants. However, access to point-of-care (POC) EID in Nigeria is very limited, leading to delays in diagnosis and management. Also, sociocultural and systemic barriers such as stigma, inadequate postnatal services and poor awareness in both the mothers and caregivers can significantly influence the provision and the incorporation of these services.

In this study we aimed to explore the perceptions of mothers and caregivers towards incorporating POC EID into routine postnatal care services in a Nigerian hospital.

Methods: We conducted a mixed-methods study among mothers and caregivers visiting the 10 primary health care centres in Ankpa, northcentral Nigeria in December 2024. The quantitative phase was conducted among 500 mothers/caregivers using a structured questionnaire, while 30 mothers and caregivers were interviewed for the qualitative phase. The RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) framework guided the interview and interpretation of results.

Results: Among 420 mothers and caregivers who participated in the quantitative phase, the mean age was 28.6±6.1 years. The majority [62% (n=254)], resided in rural

areas, and 55% (n=225) had attained secondary education. Willingness to use POC EID services was reported by 357 (85%) participants. Identified barriers to use included cost (n=164; 40%), fear of stigma (n=90; 22%), and lack of support from healthcare workers (n=74; 18%).
Higher maternal education (aOR: 2.7; 95% CI: 1.8–4.2), urban residence (aOR: 1.9; 95% CI: 1.2–2.8), and prior antenatal counseling (aOR: 3.1; 95% CI: 2.0–4.8) were predictors of the willingness to use POC EID services.
Strong preference for community-based health intervention was the major theme raised during the focused group discussion held.
Conclusions: Mothers and caregivers in the Nigerian community are receptive to POC EID, although certain challenges would have to be overcome. Expanding antenatal counselling, community-based awareness and involvement of communities in cocreating and implementing supportive strategies will improve the uptake of POC EID among the mothers and caregivers.

EP0390

Awareness of drug supply changes and uptake of fentanyl testing services among people who use drugs enrolled in a PrEP program in Kampala, Uganda

M. Figgatt[1], J. Kibuuka[2], P. Smith[3], T. Wood[3], T. Muwonge[2], P. Mudiope[4], L. Komuhangi[2], M. Nakitende[2], F. Nambi[2], H. Kadama[4], L. Nakabugo[2], R. Kansiime[5], D. Donnell[6], S. Glick[6], B. Lambdin[7], R. Heffron[3], A. Mujugira[2]
[1]Brown University Health, Providence, United States, [2]Makerere University, Infectious Disease Institute, Kampala, Uganda, [3]University of Alabama at Birmingham, Birmingham, United States, [4]Ministry of Health, Kampala, Uganda, [5]Most-At-Risk Populations Initiative, Kampala, Uganda, [6]University of Washington, Seattle, United States, [7]Research Triangle Institute, San Francisco, United States

Background: Fentanyl is a synthetic opioid that can be added to the drug supply, emerging as a cheaper yet more potent alternative to heroin. We evaluated the implementation of a drug checking service (lateral flow test strips) to test for the presence of fentanyl among drug samples obtained from people who use drugs (PWUD) engaged in harm reduction programs in Uganda.
Methods: From November 2023 through December 2024, we embedded questions about drug supply characteristics into our existing cohort of PWUD in Kampala, Uganda, whose access to PrEP was integrated into a community-based syringe access program or facility-based opioid treatment program. Fentanyl testing was offered to participants returning for clinic visits, which included obtaining drug samples or residue for analysis on-site with Dance Safe test strips. We used modified Poisson regression models to calculate prevalence ratios (PR) and their 95% confidence intervals (CI) to examine factors associated with the uptake of fentanyl testing strips.
Results: This nested study of 110 PWUD had a median age of 29 (interquartile range of 25-35) and were largely (85%) assigned male sex at birth. The majority had injected drugs (88%) or used heroin/street opioids (74%) in their lifetime. Twenty-six percent had previously heard of fentanyl and 8% had ever knowingly used fentanyl. Among 78 PWUD offered fentanyl testing, 63 (81%) people provided samples, 46% of samples were believed to be cocaine, 40% were heroin/street opioids, and 99% of tests were negative. Among the 63 people returning for fentanyl, concurrent services they accessed included obtaining PrEP (89%), HIV testing (83%), drug use equipment (44%), and condoms (41%). Clients of the syringe access program compared to those in the opioid treatment program (PR=1.96, CI=1.35-2.84) and those with better transportation access (PR=1.41, CI=1.08-1.85) were more likely to uptake fentanyl testing services.
Conclusions: Fentanyl was largely absent from the drugs tested in this sample. However, given the high interest in this testing and uptake alongside other key harm reduction services, the expansion of drug checking services for PWUD in Uganda could be considered an overdose prevention strategy, particularly if testing is accessible and comprehensive for other emerging substances.

EP0391

Evaluating the potential of Lenacapavir and Doxy-PEP as a game-changer in HIV and Sexually Transmitted Infections prevention for female sex workers in Abuja, Nigeria

G. Ezenri[1,2], J. Onyehalu[1,2], A. Ngige[1,2], C. Idabor[1,2], C. Nwachuya[1,2], D. Attama[3], A. Isah[1,2]
[1]Person-Centred HIV Research Team (PeCHIVReT), Nsukka, Nigeria, [2]University of Nigeria, Clinical Pharmacy & Pharmacy Management, Nsukka, Nigeria, [3]University of Nigeria, Nsukka, Nigeria

Background: High-risk populations like female sex workers in Nigeria face a dual burden of HIV and sexually transmitted infections (STI), necessitating innovative prevention strategies. Lenacapavir, a long-acting HIV pre-exposure prophylaxis, and Doxycycline Post-Exposure Prophylaxis (Doxy-PEP) hold promise as transformative tools in reducing transmission in high risk populations.
This study assessed the knowledge, attitudes, perceptions, preferences for service delivery, barriers to use on the co-administration of Doxy-PEP and lenacapavir intervention among female sex workers.
Methods: This study adopted a cross-sectional design to obtain responses from 122 randomly sampled female sex workers in Abuja, Nigeria using a validated 29-item questionnaire in January 2025. Their knowledge, attitudes, perceptions, preferences for service delivery, barriers to use were assessed.
Descriptive and inferential analysis were used to summarize the study's findings. Ethical approval was obtained from the Institutional Review Board.
Results: A total of 114 female sex workers responded to the questionnaire (93% response rate) with 51(44.7%), being unmarried and 56(49.1%), have been sex workers for 1-5 years. Also, 72(63.2%) and 78 (68.4%) have not heard of lenacapavir and Doxy-PEP respectively. Among the 42 participants that they had earlier heard of lenacapavir,

32 (76.2%) were willing to use it ($p < 0.001$). Just over half, 58(50.9%) are willing to use lenacapavir if available. The majority, 87(76.3%) do not believe these medications can improve HIV and STI prevention outcomes with 86(75.4%) concerned about potential side effects. A total of 75(65.8%) prefer long-acting injectables for prevention with 60(52.6%) citing effectiveness as the most important factor when deciding to use a new prevention method.

Conclusions: There is a huge gap in awareness of Lenacapavir and Doxy-PEP among high-risk populations, particularly female sex workers. Despite concerns over side effects, there is a clear preference for long-acting injectable methods emphasizing the need for more research to be conducted in this population and tailored educational and outreach programs to address misconceptions and increase knowledge of these innovative prevention options.

EP0392

Community-pharmacy HIV prevention research among adolescent girls and young women in Uganda: recruitment challenges, lessons learned, and strategies applied

A. Nalumansi[1], T.R. Muwonge[1], E. Laker[1], R. Nsubuga[1], B. Kamusiime[1], V. Kasiita[1], K. Beima- Sofie[2], M. Nakitende[1], A. Nakyanzi[1], A. Mujugira[1,2], R. Heffron[2,3]

[1]Infectious Diseases Institute, Makerere University, Research Department, Kampala, Uganda, [2]University of Washington, Global Health, Seattle, United States, [3]University of Alabama, Department of Medicine, Birmingham, United States

Background: Adolescent girls and young women (AGYW) in sub-Saharan Africa have a high incidence of unintended pregnancies, HIV, and other sexually transmitted infections. Although pre-exposure prophylaxis (PrEP) and HIV self-testing (HIVST) are available, there remains an underutilized opportunity to expand HIV prevention delivery through community pharmacies where AGYW readily access emergency contraception (EC).

By leveraging the existing reach of community-pharmacies, we highlight recruitment challenges faced and lessons learned.

Methods: From May to December 2022, we mapped community pharmacies within 45 km of our research clinic in Kasangati, a peri-urban area in Kampala to assess the willingness, readiness, and feasibility of integrating PrEP delivery with EC services. Pharmacy providers were encouraged to identify and refer AGYW to our research clinic for study screening when they sought EC services.

Additionally, we documented challenges faced during the recruitment of AGYW at these community pharmacies for HIV prevention research.

Results: Ten of 15 community pharmacies participated, referring 162 AGYW for screening; 130 were enrolled. Reasons for ineligibility (N=32) were exceeding age limit (10), uninterested (9), not using EC (7), and lacking time (6).

Recruitment challenges included (a) obtaining contact information from AGYW who obtained EC without further interaction; (b) provider reluctance to disclose AGYW use of EC; (c) research assistants facing difficulties in physically reaching certain pharmacies, which limited outreach efforts; (d) incorrect contact information for AGYW that hindered follow-up activities; (e) cultural barriers that inhibited provider-AGYW discussions about sexual behaviors; (f) disinterest or lack of time to participate; and (g) exceeding age limit.

To tackle these challenges, we implemented several strategies: strengthening communication and building rapport with pharmacy providers to improve comfort and accuracy in referrals; focusing weekend outreach efforts to better accommodate AGYW, who often face difficulties during weekdays; and developing targeted communication approaches to alleviate the cultural discomfort and hesitancy expressed by AGYW when discussing sexual health.

Conclusions: Tailored engagement strategies and adaptability are key to addressing AGYW recruitment barriers at community pharmacies. Lessons learned highlight the need for holistic, culturally sensitive, and collaborative approaches to maximize participation and effectiveness in similar settings.

EP0393

Prevalence and risk factors of rifampicin resistance among TB-HIV patients in Rwanda: estimates from programmatic surveillance data (2019-2024)

Y. Habimana Mucyo[1], J. Ndayisenga[2], K. Nshimiyimana[3], J.D. Hagenimana[4], C. Karimba[4], F. Byukusenge[5], A. Kilibazayire[6], A. Ngeneye[6], C. Ndayishimiye[6], V. Mupenzi[7], G. Mujawamariya[7], T.T. Adegboyega[8], E. Remera[2], J.C. Semuto Ngabonziza[2], F. Kitema Rubuga[4], P. Rukundo[5], P. Migambi[3]

[1]Rwanda Biomedical Centre (RBC), Tuberculosis and Other Respiratory Communicable Diseases (TB&ORD) Division, Kigali, Rwanda, [2]Rwanda Biomedical Centre (RBC), Research, Innovation and Data Science (RIDS) Division, Kigali, Rwanda, [3]Rwanda Biomedical Centre (RBC), Tuberculosis and other Respiratory Communicable Diseases (TB&ORD) Division., Kigali, Rwanda, [4]Centre for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition (CIIC-HIN), Kigali, Rwanda, [5]Rwanda Biomedical Centre (RBC), Tuberculosis and other Respiratory Communicable Diseases (TB&ORD) Division, Kigali, Rwanda, [6]Kabutare District Hospital, MDR-TB Treatment Centre, Huye, Rwanda, [7]Rwanda Biomedical Centre (RBC), HIV, STI, Viral Hepatitis and other Viral Diseases Control Division, Kigali, Rwanda, [8]University of Rwanda, College of Medicine and Health Sciences (CMHS), Huye, Rwanda

Background: Tuberculosis (TB) is the major cause of death among people living with human immunodeficiency virus (PLHIV). Rwanda's integration of HIV and TB services through one-stop clinics allowed enhanced treatment delivery as well as accurate diagnostics like Xpert MTB/RIF for early TB detection including its susceptibility to rifampicin, the core first-line anti-TB drug. However, the epidemiology and determinants of rifampicin-resistant TB

(RR-TB) among PLHIV remain insufficiently studied. Understanding these patterns and associated risk factors is essential for policy development and improving TB control strategies, ultimately enabling targeted interventions to reduce drug-resistant TB burden in this vulnerable population.

Methods: A retrospective analysis was conducted on routine surveillance data from pulmonary bacteriologically confirmed TB patients co-infected with HIV notified into TB case surveillance system from July 2019 to June 2024. It included demographic and clinical variables, utilizing descriptive statistics and logistic regression to evaluate factors associated with RR-TB among TB patients co-infected with HIV.

Results: Among 3,610 pulmonary TB patients co-infected with HIV who underwent rifampicin susceptibility testing, 60 (1.66%) were found to have RR-TB. The RR-TB prevalence was at 1.21% among new and 4.19% in previously treated TB cases. From 2019 to 2024, the proportion of RR-TB cases remained relatively stable, ranging from 1.0% to 1.4% and 3.4% to 4.1% among new cases and previously treated patients respectively.

Patients with a previously known HIV history at the time of TB diagnosis had a significantly higher risk of RR-TB compared to those newly tested positive for HIV (aOR 2.05, 95% CI [1.03-4.09], P=0.04).

Contacts of individuals with multidrug-resistant TB (MDR-TB) had a substantially elevated risk of developing RR-TB (aOR 117.22, 95% CI [15.82-868.64], P<0.001) compared to those without such history. Working in the mining sector exhibiting a higher likelihood of having RR-TB (aOR 4.31, 95% CI [1.22-15.28], P=0.023) compared to those in other occupations.

Conclusions: The prevalence of RR-TB among HIV coinfected pulmonary TB patients had been constant and relatively remained low over time. Known HIV status, MDR-TB contacts, and working in mining sector were the significant risk factors. These underscore the need for targeted prevention and management strategies for such vulnerable populations.

EP0394

Early NCD screening and diagnosis at Marindi SCH-Homabay County among people living with HIV at Marindi Sub County Hospital in Homabay County, Kenya

O. William[1]
[1]*Kenya Medical Training College, Health, Kendubay, Kenya*

Background: Non Communicable Diseases (NCDs) are of increasing concern globally due to their high mortality rates. Globally NCDs account for 41 million deaths annually; this is equivalent to 74% of deaths globally according to WHO 2018 statistics, 86% of these mortalities are due to late diagnosis of the diseases. At marindi sch, the whole of 2021 we were able to diagnose a total of 206 clients with NCD; 38 were PLHIV diagnosed within the CCC. The 94 clients were cases who presented with obvious symptoms of the mentioned NCDs. This occasioned screening order to reduce mortalities associated with late diagnosis.

Methods: Following the performance NCDs performance review meeting, the following gaps we identified ;Lack of a standardized tool for screening of the five key NCDs prioritized; Inadequate knowledge for clinicians to screen and diagnose the NCDs early

The facility together with the supporting partner developed an NCD screening tool for use in all service delivery points. The clients who screened positive were referred for further evaluation and or diagnostic investigations. The clinical team was also capacity built through CMEs and OJT to screen and diagnose NCDs.

Results: From 2019 to 2023, Marindi Sub-County Hospital maintained a stable annual workload of 12,900 individuals. NCD screening increased from 112 in 2019 to 6,201 in 2023. Similarly, diagnoses with NCDs and initiation of treatment rose from none in 2019 to 105 in 2023, peaking at 212 in 2021. NCD-related mortalities declined significantly from 12 in 2019 to zero in both 2022 and 2023, indicating improved care and outcomes. NCD and HIV co-diagnoses also increased, with no cases in 2019 or 2020, 12 cases annually in 2021 and 2022, and 26 in 2023.

Conclusions: A standardized screening tool for NCDS needs to be used in all facilities to ensure early diagnosis. This tool can also be incorporated in the Kenya EMR for routine screening of all PLHIVs of common NCDs like hypertension and diabetes; NCDs management should be integrated into CCC for better and improved outcomes.

EP0395

Introducing the screen, triage and treat with HPV DNA Testing for cervical cancer screening among women living with HIV: lessons learned from Zimbabwe, 2024

T.P. Sibanda[1], T. Chimwaza[1], M. Ndlovu[1], J. Muguse[1], M. Muzondo[1], G. Choga[1], K. Nyathi[1], N. Ganje[1], T. Apollo[2], L. Gondongwe[2], M. Muchekeza[2], M. Mukuzunga[2], T. Tafuma[1], S. Mukungunurwa[3], M. Mhangara[3], E. Tachiwenyika[1], T. Nyamundaya[1]
[1]*Zimbabwe Health Interventions, Harare, Zimbabwe,* [2]*Ministry of Health and Child Care, Harare, Zimbabwe,* [3]*United States Agency for International Development, Harare, Zimbabwe*

Background: In Zimbabwe cervical cancer remains a leading cause of cancer-related morbidity and mortality, and women living with HIV (WLHIV) have a sixfold higher risk than their negative counterparts. The primary screening method in Zimbabwe has been Visual Inspection with Acetic Acid and Cervicography (VIAC), which allows for immediate treatment in a single visit and is referred to as "screen and treat". In 2021, the world health organization (WHO) recommended a "screen, triage, and treat" approach, using HPV DNA PCR as the primary test, followed by colposcopy, VIA, or cytology as triage procedures for those who test HPV positive. This method is more sensitive, requires less manpower, and allows for longer intervals between screenings.

Description: Since April 2024, Zimbabwe Health Interventions (ZHI) through the Accelerated and Comprehensive HIV Care for epidemic Control (ACCE) program has sup-

ported roll-out of HPV DNA PCR test as a new screening strategy in the country in 4/9 project supported districts This paper reviews the lessons learned from implementation between June and December 2024. The assessment was covered by the Medical Research Council of Zimbabwe-approved non-research determination protocol (MRCZ/E/159).

Lessons learned: Data for 5169 women on antiretroviral therapy (ART) with HPV DNA specimens collected were analyzed. About 84% (4,321/5169) received their results, of these 19% (840/4321) screened HPV DNA positive. Approximately only 65% (540/840) of clients testing HPV-DNA positive were triaged with VIAC of these 7.6% (41/540) tested VIAC positive, and 80% (33/41) received treatment for precancerous lesions. The overall positivity for VIAC in the "screen, triage, and treat" supported districts i.e., in the four districts was 7.6% against 2% (263/1498) in the five districts screen and treat with VIAC only.

Conclusions/Next steps: Scaling up HPV screening has the potential to lessen health worker workload if the leakages across the screening cascade are comprehensively addressed.

We recommend wider scale up of the HPV screening with improved support from the laboratory and community to track women who test positive for HPV, so they complete the treatment cascade.

EP0396

Factors influencing family planning discontinuation and switch among Women Living with HIV in Kenya

N.M. Ngumbau[1], J.A. Unger[2], C. Atieno[1], K. Beima-Sofie[3], E. Nzove[1], A.K. Karume[1], E. Wetzler[3], J. Kibugi[1], A. Seth[3], J. Udren[3], J. Kinuthia[1], A. Drake[3,4]

[1]Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, [2]Warren Alpert Medical School, Brown University, Women and Infants Hospital, Obstetrics and Gynecology, Providence, United States, [3]University of Washington, Global Health, Seattle, United States, [4]University of Washington, Epidemiology, Seattle, United States

Background: Women living with HIV (WLHIV) experience higher rates of unmet need for contraception, contraceptive failure and unintended/unplanned pregnancies. Understanding factors influencing family planning (FP) discontinuation and switch among WLHIV is required to optimize FP use.

Methods: We utilized baseline data from the Mobile Solutions to Empower Reproductive Life Planning for WLHIV trial In Kenya (NCT05285670). WLHIV included in this analysis were using a non-permanent modern FP method, and were not pregnant. We compared women who switched, or discontinued FP (for reasons other than pregnancy/desired pregnancy), FP within the last year to women who continued FP.

Results: Among 1962 WLHIV, the median age was 34years, median HIV duration was 8years, 89% were on Dolutegravir, 14% reported moderate-high internalized HIV-related stigma and 75% had a regular partner. The majority(89%) reported partner support of FP and 41% discussed FP with a healthcare worker(HCW). Less than half of WLHIV (41%) used long-acting, reversible FP (37% and 4% on implants and intrauterine devices respectively), 35% used injectables, 16% used condoms and 7% oral contraceptive pills (OCPs).

Overall, 2% discontinued and 7% switched FP, with 42% switching from injectables, 38% from implants, and 12% from OCPs. WLWH who switched from injectables, chose implants (54%), OCPs (20%), and condoms (19%); those that switched from implants chose injectables (61%) and OCPs (20%) and those that switched from OCPs chose implants (47%) and injectables (40%).

Compared to women who continued FP, WLHIV who jointly decided on FP with their spouse were less likely (OR:0.42; 95%CI:0.20-0.85) to discontinue FP while women in polygamous marriages were more likely (OR:2.76; 95%CI:1.24-6.11) to discontinue FP.

Women ≤24years (OR:2.47; 95%CI:1.43-4.27), with moderate-to-severe internalised HIV-related stigma (OR:1.75; 95%CI:1.09-2.80), using OCPs (OR:3.20; 95%CI:1.81-5.66), whose spouse chose their FP (OR:3.69; 95%CI:1.27-10.74) and discussed FP with a HCW (OR:2.82; 95%CI:1.86-4.27) were more likely to switch FP methods. WLHIV were less likely to switch their FP method if they initiated FP after age 23(OR:0.58; 95%CI:0.39-0.85).

Conclusions: Tailored FP strategies for adolescent girls and young WLWH, and those with high internalized stigma may promote FP method continuation and appropriate FP switch, mitigating risks for unintended/unplanned pregnancies. Involving partners in FP counseling, and continually offering FP during routine care may reduce FP discontinuation and support optimal FP method switch among WLHIV.

EP0397

Prevalence of sexually-transmitted infections and linkage-to-care rates in a Southeast Asian transgender cohort study

T. Payuha[1], R. Janamnuaysook[1,2], N. Phanuphak[1,2], P. Pumphosuwan[1], S. Suriwong[1], W. Tasomboon[1], S. Saiwaew[3], R. Pagtakhan[4], T.M. Le[5], T. Sangpasert[3], P. Boonyawan[3], J.D.B. Ruanto[4], Z. Black[4], M.T. Tran[5], T.T. Lu[5], K. Samitpol[1,2], T. Amatsombat[1], R.A. Ramautarsing[1], J. Ross[6], SEATrans Study Team

[1]Institute of HIV Research and Innovation, Bangkok, Thailand, [2]Chulalongkorn University, Center for Excellence in Transgender Health, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]LoveYourself Inc., Mandaluyong, Philippines, the, [5]Glink Vietnam Social Enterprise Company Limited, Ho Chi Minh City, Viet Nam, [6]The Foundation for AIDS Research, amfAR's TREAT Asia, Bangkok, Thailand

Background: Transgender persons in Asia experience a disproportionate burden of HIV and sexually-transmitted infections (STIs), and their access to related healthcare services are limited. We established Asia's first prospective observational transgender cohort study to assess HIV, STI and other health risks and impacts.

Methods: Between December 2022 to October 2024, transgender persons aged ≥18 years were enrolled as they attended the Rainbow Sky Association of Thailand and Tangerine Clinic in Thailand, Glink in Vietnam, and Victoria by LoveYourself in the Philippines. Six-monthly study visits were conducted, which included HIV testing and STI screening.
Multi-compartment chlamydia (CT) and gonorrhea (NG) testing were performed using self-collected pooled specimens, and syphilis and viral hepatitis C (HCV) testing conducted using blood specimens collected at each study visit. STI treatments were documented according to each setting's standard of care. Data were analyzed using Stata.
Results: Of 415 transgender persons enrolled by October 2024, median (interquartile range, IQR) age was 28 (23-33) years, 92% (n=381) were transgender women, 7% (n=31) transgender men, and 1% (n=3) non-binary.
Overall, 29% (n=121) were living with HIV, 35% (n=145) were on PrEP, and 36% (n=149) did not use PrEP. The prevalence of any baseline STI among these was 39% (n=47), 22% (n=32), and 14% (n=21) respectively. At baseline visit, 100 (24%) had at least one STI. Prevalence of CT was 15% (n=61) NG 8% (n=33), syphilis 9% (n=36), and HCV 1% (n=3).
Linkage-to-care rate for CT was 64% (39/61), NG 52% (17/33), syphilis 50% (18/36), and HCV 67% (2/3). Median (IQR) days to treatment initiation was 0 (0-4) for CT, 3 (0-7) for NG, 2 (0-6) for syphilis, and 50.5 (29-72) for HCV.
Conclusions: STIs were prevalent among our transgender cohort, with CT most prevalent, and the prevalence of any STI highest among those with HIV. We identified gaps in STI diagnosis, linkage and treatment initiation across all settings.
Our findings highlight the need to explore and address barriers to STI diagnosis, linkage, and care for transgender communities in Southeast Asia.

EP0398

Impact of the dual HIV/syphilis rapid diagnostic tests in improving maternal syphilis testing coverage in antenatal care

A.T. Bashorun[1], O. Fasawe[2], O.A. Ijaodola[1], M. Mobolaji-Bello[1], C. Nwafor[2], L. Bwala[2], E. Neenwi[2], A. Storey[3]
[1]National AIDS, STI and Viral Hepatitis Control Programme, Abuja, Nigeria, [2]Clinton Health Access Initiative, Abuja, Nigeria, [3]Clinton Health Access Initiative, Boston, United States

Background: Mother-to-child transmission of HIV and syphilis is a significant public health concern in sub-Saharan Africa. Evidence suggests that HIV incidence increases about two-times with syphilis exposure. Without adequate treatment, an estimated 15% of infants will acquire congenital syphilis from syphilis-exposed mothers. In Nigeria, HIV and syphilis prevalence in ANC is 1.4% and 0.7% respectively, while testing coverage for both diseases was 67% and 16% as at 2019. The very low syphilis testing rates lead to adverse pregnancy outcomes in 60% of the over 77,000 annual congenital syphilis cases.
Description: The Federal Ministry of Health is scaling up dual HIV/syphilis Rapid Diagnostic Test use following an initial pilot supported by CHAI. Across 31 health facilities in three states, a total of 1,678 healthcare workers were trained through CHAI and Ministry of Health facilitated trainings. Backed by a donation of 55,000 tests, training focused on dual RDT use, counseling, treatment, demand generation and data management.
Lessons learned: 45,413 pregnant women were tested for HIV and syphilis during the pilot. HIV and syphilis positivity rates were 2.0% and 0.2% respectively. Subsequent Dual RDT scale up between 2019 and 2022 resulted in over 10 million pregnant women being tested for HIV and syphilis cumulatively. ANC syphilis testing coverage increased from 16% in 2019 to 36% in 2022. Maternal syphilis treatment coverage is 89%.
Conclusions/Next steps: Syphilis screening has significantly and sustainably increased following dual RDT introduction in 2019. While substantial investments are still required to improve data management, the continued opportunity to leverage existing HIV delivery platforms holds promise for congenital syphilis and mother-to-child transmission of HIV elimination.

EP0399

36-months post treatment High-risk Human Papillomavirus (hr-HPV) infection and predictors, and cervical precancerous lesions prevalence among women living with HIV in West Africa

S. Boni[1,2], P. Debeaudrap[3], F. Kaboré[4], E. Kasilé-Pooda[5], B. Doukouré[6], A. Poda[7], E. Messou[8], A. Jaquet[9], A. Horo[5,10], on behalf leDEA West Africa - IPHOTHER Study
[1]National Cancer Control Program, Abidjan, Côte d'Ivoire, [2]Programme PAC-CI, Research, Abidjan, Côte d'Ivoire, [3]Institut de Recherche pour le Développement (IRD)/ Centre Population et Développement (CEPED) UMR 196, Paris, France, [4]Centre Muraz, National Institute of Public Health, Bobo-Dioulasso, Burkina Faso, [5]University Hospital of Yopougon, Department of Gynecology and Obstetrics, Abidjan, Côte d'Ivoire, [6]Centre Hospitalier Universitaire (CHU) de Cocody, Anatomo-Cytopathologie, Abidjan, Côte d'Ivoire, [7]Sourou Sanou University Hospital, Hopital du Jour, Bobo-Dioulasso, Burkina Faso, [8]Centre de Prise en Charge, de Recherche et de Formation (CePReF), Yopougon, Abidjan, Côte d'Ivoire, [9]University of Bordeaux, INSERM U 1219, GHiGS – Global Health in the Global South, Bordeaux Population Health Research, ISPED, Bordeaux, France, [10]Université Felix Houphouet Boigny, Mère-Enfant, Abidjan, Côte d'Ivoire

Background: Although mounting evidence of the good performance of HPV-based screen and treat approach to identify women with cervical lesion and treatment with thermal ablation approach exist, more data is required on the long-term outcomes especially among women living with HIV (WLHIV) who are at increased risk of recurrence. We aimed to estimate the high-risk human Papillomaviruses (hr-HPV) infection and predictors among WLHIV; as well as precancerous lesions prevalence at 36-months following a treatment in West Africa.

Methods: From October 2019 to October 2024, a cohort study was conducted among WLHIV in specialized clinics in Bobo-Dioulasso (Burkina Faso) and Abidjan (Cote d'Ivoire).
All WLHIV with a positive HPV test who received thermal ablation were followed up at 12 and 36-months. During the follow-up visits, gynecological examination, including DNA HPV testing, visual inspection and biopsy were done. Hr-HPV persistence/recurrence was defined as having at least one hr-HPV type (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66 and 68), while precancerous lesions prevalence was defined as having had a cervical intraepithelial neoplasia grade 2 or higher (CIN2+) result after a colposcopy-directed biopsy at 36-months.
Results: A total of 200 WLHIV, aged 42 years [Interquartile range (IQR): 38–45], with a Nadir CD4 of 214 [IQR: 109 – 325] cell/mm3 were treated with thermal ablation and followed up. Positive hr-HPV was retrieved for 55.2%, 39.5% at 12 and 36-months post treatment, respectively. WLHIV who had a CD4 count<200 cell/mm^3 around treatment (aOR= 3.48 [CI 95%: 1.28–9.46]) or having no or a primary school level (aOR= 1.93 [IC95%: 1.03 – 3.63]) were more likely to present at 36-months with HR-HPV persistent infection, compared to others.
At 36-months post-treatment, the precancerous lesions prevalence was 3.8% (n=6) among the 176 WLHIV assessed, and 8.7% (n=2) among those treated for CIN2+ at baseline, were CIN2+, respectively.
Conclusions: Post therapeutic hr-HPV infection remains high over three years in WLHIV highlighting the need of a long-term follow-up, particularly in WLHIV with advanced HIV disease. The association between education and hr-HPV deserves further studies to understand how social determinants of health mediate the risk of persisting post therapeutic hr-HPV.

EP0400

Persistently high syphilis seroprevalence among pregnant women in southern Uganda: a longitudinal population-based study

D. Tantry[1], X. Feng[1], R. Ssekubugu[2], G. Nakigozi[2], M. Nakalanzi[2], T. Quinn[1,3], F. Nalugoda[2], G. Kigozi[2], S. Reynolds[1,3,2], C. Kennedy[4], L. Chang[1,2], Y. Manabe[1], M. Hamill[1], G. Kigozi[2], D. Serwadda[2], A. Tobian[1], K. Grabowski[1], R. Galiwango[2]
[1]Johns Hopkins University School of Medicine, Baltimore, United States, [2]Rakai Health Sciences Program, Kalisizo, Uganda, [3]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: In the Lake Victoria basin of East Africa, where many pregnant women deliver outside of health facilities and HIV prevalence is high, longitudinal population-level data on syphilis seropositivity are rare, especially in the era of widespread HIV treatment. These data are essential for identifying care gaps, guiding targeted interventions, and improving maternal and neonatal health outcomes.

Methods: We analyzed data from the Rakai Community Cohort Study collected over four survey rounds (2016–2022) in Uganda. The study included adults aged 15–49 years from 37 inland agrarian and trading communities (HIV prevalence ~12%) and 4 Lake Victoria fishing communities (HIV prevalence ~40%).
The primary outcome was individual syphilis seropositivity, determined using the SD Bioline Syphilis 3.0 test. Syphilis seroprevalence was calculated as the proportion of individuals testing seropositive.
Analyses were stratified by HIV serostatus, community type (inland vs. fishing), age, and calendar time. Adjusted prevalence ratios (adjPR) were estimated using multivariable Poisson regression, adjusting for age, community type, education, marital status, life time and past year sexual partners, and HIV serostatus. Syphilis treatment was provided free to study participants.
Results: Among 3,491 pregnant women, 3,265 (93.5%) had syphilis test results across 3,592 visits. Overall seroprevalence was 10.0% (95% CI: 9.0%-11.1%), with higher prevalence in fishing communities compared to inland communities (22.3% vs. 6.7%; adjusted PR = 2.18, 95% CI:1.75–2.03) and in those with prevalent HIV infection compared to those without (24.7 vs. 7.1%;PR = 1.94, 95% CI:1.55–2.43).
Prevalence remained stable over calendar time across community types. Among girls aged 15–19 and young women aged 20–24, seroprevalence was 14.3% (95% CI:7.8%-23.2%) and 16.7% (95% CI: 11.7%-22.7%) in fishing communities, respectively, and 3.4% (95% CI: 1.8%-5.9%) and 5.4% (95% CI: 3.9%-7.3%) in inland communities, respectively. Higher syphilis burden was also significantly associated with lower education levels and more lifetime sexual partners.
Conclusions: Syphilis seropositivity remains high among pregnant women in southern Uganda, particularly in Lake Victoria fishing communities. The concurrent burden of syphilis and HIV highlights the importance of integrating syphilis testing and treatment into HIV programs and expanding targeted interventions to high-risk populations.

EP0401

Enhancing cervical cancer screening among women living with HIV through collaboration with community healthcare workers in Ncamagoro District, Kavango West Region, Namibia

L. Hauwanga[1], T. Haufiku[2], H. Simon[3], P. Johannes[1], T. Kamati[1], G. O'Bryan[4], L. Muzingwani[1], A. Ensminger[4], B. Zemburuka[5], N. Foster[1]
[1]International Training and Education Center for Health (I-TECH), Windhoek, Namibia, [2]Ministry of Health and Social Services, Rundu, Namibia, [3]Development Aid from People to People (DAPP), Rundu, Namibia, [4]International Training and Education Center for Health (I-TECH), Department of Global Health, University of Washington, Seattle, United States, [5]Division of Global HIV and Tuberculosis, Global Health Center, U.S. Centers for Disease Control and Prevention, Windhoek, Namibia

Background: Cervical cancer is a public health concern in Namibia impacted by limited access and low uptake of screening and high prevalence of HIV and Human Papillomavirus (HPV). Human Resources for Health (HRH) is crucial in addressing these issues. Engaging community healthcare workers (CHW) can increase demand for facility-based cervical cancer services through community-based education and improving screening access by reducing structural barriers.
An outreach program was conducted, employing a series of activities and engaging CHW to increase screening access and uptake among WLHIV.
Description: The Ncamagoro District in Namibia's Kavango West Region aimed to screen 425 WLHIV between October 2023 and September 2024. At baseline, in January 2024, only 10% (43) of the target had been achieved. To improve screening uptake, a series of programmatic activities were conducted between February and April 2024 in 10 health facilities, engaging both facility staff and CHWs. Activities included an orientation on cervical cancer demand creation strategies. The CHWs subsequently identified unscreened WLHIV usually served by respective health facilities.
Every facility was assigned screening targets, and mobilization of WLHIV was undertaken by the CHWs through telephonic calls and physical tracing in the community. Health education sessions were conducted, and information, education and communication (IEC) materials were distributed in the vernacular language. The cumulative number of
WLHIV screened and percentage of screening target achieved were calculated monthly using routine programmatic data and analyzed descriptively to determine improvements.
Lessons learned: Achievement of screening targets in Ncamagoro District increased from 10% (43) at baseline in January 2024 to 98% (416) in April 2024. Community mobilization ensured the WLHIV were reached and came to the facilities for screening.
While the activities led to rapid improvement, challenges were noted, including unavailability of transport and staff shortage resulting in fewer screening days undertaken.
Conclusions/Next steps: Working collaboratively and fostering teamwork with CHWs accelerated the achievement of screening targets among WLHIV in Ncamagoro District in Namibia. Scaling up community-based education campaigns and the collaborative efforts of facility teams and CHWs to align ART care services with cervical cancer screening can increase access and uptake.

EP0402

Childhood immunization uptake in children of female sex workers: a Nairobi, Kenya study

E. Wanjiku[1], J. Kimani[2], V. Ojiambo[3], M. Akolo[4], F. Kiogora[5], A. Kamau[4], B. Mbilu[5], E. Machogu[6], M. Kungu[7]
[1]Partners for Health and Development in Africa, Management, Nairobi, Kenya, [2]Partners for Health and Development in Africa, Director, Nairobi, Kenya, [3]Jomo Kenyatta University, Research, Nairobi, Kenya, [4]Partners for Health and Development in Africa, Clinical, Nairobi, Kenya, [5]Partners for Health and Development in Africa, Monitoring and Evalutation, Nairobi, Kenya, [6]Kenyatta University Teaching, Referral and Research Hospital, MCH, Nairobi, Kenya, [7]Partners for Health and Development in Africa, Research, Nairobi, Kenya

Background: Access to immunizations is critical for achieving Sustainable Development Goal 3.8. Partners for Health and Development in Africa (PHDA) operates ten Sex Workers Outreach Program (SWOP) clinics in low-income areas of Nairobi, focusing on HIV prevention. Although SWOP clinics do not provide maternal and child health (MCH) services, clients are referred to government health centres.
This study evaluated immunization uptake among children of female sex workers (FSWs) registered at SWOP clinics. FSWs face unique challenges in accessing healthcare for their children, including routine vaccinations, conflicting with the Universal Health Coverage principle of leaving no one behind.
Methods: This eleven-month retrospective observational study combined quantitative and qualitative data sources. Interviews with participants and clinical data from MCH handbooks informed the analysis. The sample size was 378 FSWs, determined using the Cochran formula. Data was collected using Kobo Toolbox and analyzed using STATA and MS Excel, with descriptive statistics summarizing key findings.
Results: The study reported high overall immunization coverage (94.0%) among children of female sex workers (FSWs), with slight disparities noted in the Maternal Child Health (MCH) Handbook (92.48%).
Awareness of immunization importance was high (92.6%), and nearly all respondents (99.4%) acknowledged its benefits. Key enablers included proximity to health facilities (36.2%), friendlier health workers (48.2%), and home-based vaccinations (43.2%).
However, specific vaccines, such as Yellow Fever at nine months (9.1%) and MR at six months (15.0%), exhibited low uptake, alongside a general decline in adherence over time. Barriers to full immunization included sex work-related challenges (28.4%), stigma related to HIV (19.57%),

alcohol and substance use (25.4%), and operational issues; limited service hours, long queues, and insufficient staffing. Additional challenges included inconsistent vaccine availability, lack of transport, and inadequate reminders. Factors supporting uptake included widespread belief in vaccine safety (99.2%).

Conclusions: Barriers to achieving full immunization reflect a complex interplay of systemic and situational factors, including constraints related to sex work, HIV status, substance use, healthcare discrimination, and logistical challenges. Addressing these barriers requires a comprehensive, integrated approach that incorporates vaccination services within SWOP Clinics, alongside HIV prevention and care, and sexual reproductive health to create a convenient, one-stop solution for FSWs.

EP0403

Hepatitis C self-testing to expand screening, diagnosis and treatment of HCV among key populations and people living with HIV in Cameroon

K. Hatzold[1], B. Kerschberger[2], H. Plessy Mboussam[3], I. Tchamy[3]

[1]Population Services International, HIV/TB/Hepatitis, Cape Town, South Africa, [2]Population Services International, HIV/TB/Hepatitis, Mbabane, Eswatini, [3]ACMS, Yaounde, Cameroon

Background: Hepatitis C virus (HCV) is a significant global public health issue, with care coverage particularly low in resource-limited settings. In Africa, only 13% of people with HCV knew their status in 2022, primarily due to limited access and low awareness. HCV self-testing (HCVST) provides a pathway for individuals to learn their status, facilitating access to treatment and prevention.

This study assessed the acceptability and feasibility of HCVST among key populations in Cameroon.

Methods: From June 2023 to March 2024, consenting adults (≥21 years) were recruited through four service delivery models:

1. People living with HIV (PLHIV) at antiretroviral therapy clinics (ARTC),

2 Men who have sex with men (MSM),

3 People who inject drugs (PWID) at drop-in centers (DIC), and;

4 Individuals ≥45 years at chronic disease clinics (CDC).

Participants were randomly assigned blood-based or oral-fluid HCV self-test kits, with the option for on-site or off-site self-testing. Participants reported results and were linked to confirmatory testing and treatment with direct-acting antivirals (DAAs). Feasibility, acceptability, HCV prevalence, and linkage to care were analyzed using descriptive statistics

Results: Of 2,653 clients offered HCVST, 99.7% (n=2,644) accepted. Among those completing self-testing (ARTC: 596; CDC: 648; MSM-DIC: 702; PWID-DIC: 698), 2.3% chose off-site testing, highest at ARTC (5.0%, p<0.001). Most (91.7%) found the test easy to use, citing rapid results (60.4%), simplicity (45.8%), and confidentiality (23.1%). Nearly all (98.7%) recommended HCVST, with 45.9% favoring unassisted home testing. Overall HCV seroprevalence was 4.4%, higher at PWID-DIC (12.2%) than ARTC (3.0%, p<0.001). Of 117 positive screenings, 93.2% (n=109) were linked to confirmatory testing. At ARTC, linkage was 88.9% (n=16/18), with 76.9% (n=10/13) viremic cases initiating therapy. At three months, all tested (n=9) achieved undetectable viral loads.

Conclusions: HCVST is highly acceptable, feasible, and user-friendly among diverse populations in Cameroon, increasing HCV testing uptake and care engagement. These findings support the integration of HCVST into broader HCV strategies, particularly in high-burden, resource-limited settings

EP0404

Syphilis reinfection in Argentina: a new challenge for Argentine public health in the context of U=U

M. Pedrola[1], F. Bagilet[1], N. Haag[1], P. Trinidad[1], G. Bassi[2], F. Biasutti[2], D. Gimenez[1], G. Perafan[2], J.C. Cisneros[1]

[1]AIDS Healthcare Foundation, Buenos Aires, Argentina, [2]AIDS Healthcare Foundation, Rosario, Argentina

Background: In order to ascertain the frequency of syphilis reinfection in a context of increasing incidence of syphilis in Argentina, we conducted this study in two community-led clinics that focus on sexual health.

Methods: All syphilis diagnoses were obtained from January 1, 2023, to December 31, 2024, from a Community Sexual Health Center in the city of Rosario and from a Community Sexual Health Center in the city of Buenos Aires.

All patients had a positive result to the Bioline® HIV/Syphilis DUO or Determine® Syphilis TP test at the point of care (PoC), and their diagnosis was confirmed by VDRL

Results: The following results were obtained in 2023, there were 125 syphilis diagnoses, with 5 (4%) cases involving individuals who had been re-infected and all of them were people living with HIV. In 2024, there were 508 syphilis diagnoses, with 64 (13%) cases involving individuals who had been re-infected and 57% of them were people living with HIV.

The majority of affected individuals were between the ages of 30 and 39 (60% in 2023 compared to 38% in 2024), and the male-to-female ratio was 100% in 2023 and 89% in 2024.

Conclusions: The increase in new syphilis diagnoses is a public health concern in Argentina, and re-infection is also a significant public health issue. As evidenced by the data, there is a high prevalence of HIV/syphilis co-infection, which, within the framework of the Undetectable=Untransmissible (U=U) concept, serves to compound the challenges confronting healthcare providers.

This study underscores the necessity for augmented efforts in the primary and secondary prevention of syphilis to effectively manage this pandemic.

Population-specific interventions for HIV prevention

EP0405

Utility of pre-exposure prophylaxis in averting postnatal seroconversion among infants born from breastfeeding mothers testing HIV negative at delivery in four facilities of Eastern province of Zambia

L. Nyau[1], J. Nkaama[1], M. Luhana[1], J. Tembo[1], M. Ng'ambi[1]
[1]Eastern Provincial Health Office, Ministry of Health, Chipata, Zambia

Background: In Zambia, HIV negative pregnant and breastfeeding women require routine HIV retesting as part of elimination of mother-to-child transmission (EMTCT). Pregnant women attending antenatal are re-tested during these visits. After delivery, however, postnatal mothers often elude HIV retesting. In such settings, maternal postpartum HIV acquisition contributes to a significant proportion of infants with HIV. Pre-exposure prophylaxis (PrEP) is a safe and effective prevention strategy to reduce women's risk of HIV in pregnancy and postpartum. We will describe and assess the utility of PrEP in averting seroconversion among infants born from breastfeeding mothers testing HIV negative at delivery in Eastern Province, Zambia.
Methods: This retrospective review utilized 2021 program data from SmartCare. The data included counts of HIV negative breastfeeding women (BFW) which we categorized into two subgroups: those receiving PrEP and those not receiving PrEP.
Descriptive statistics were used to summarize the demographic characteristics of the BFW and the mother-infant HIV status outcomes at 24 months postnatal. Chi-square test was employed to assess differences in the mother-infant HIV status outcomes between the two subgroups. Statistical significance was set at p<0.05.
Results: In December 2021, 261 (27%) BFW were receiving PrEP, while 704 (73%) were not. Among the PrEP cohort, 95% had status outcomes, of which 98.8% were negative. All children (100%) from the 2 BFW who seroconverted remained HIV negative. From the no PrEP cohort, 86% had documented outcomes. 4% (24) had a seropositive outcome, of whom 21% had a concordant maternal-infant serostatus. Maternal seroconversion was significantly lower among the PrEP cohort at 0.8%, compared to those not on PrEP (4%) (p< 0.001).
Similarly, infant seroconversion was not observed in the infants of seroconverted mothers from the PrEP cohort, but was significant (21%) among infants from mothers who seroconverted and not receiving PrEP (p< 0.001).
Conclusions: Though only 27% of PBW during the review period were receiving PrEP, this analysis shows low postnatal maternal incident HIV and vertical transmission outcomes. In contrast, unfavourable HIV serostatus outcomes persisted among BFW not receiving PrEP and their infants. These findings underscore the critical role of PrEP services in complementing other interventions to optimize EMTCT efforts.

EP0406

Improving engagement in HIV prevention services among immigrant communities in the U.S.

K. Pillinger[1], L. Molloy[1], L. Simone[1], J. Carter[1], C. Napolitan[1], J. Ross[2]
[1]PRIME Education, New York, United States, [2]Montefiore Einstein, Bronx, United States

Background: Immigrants in the United States are disproportionately impacted by HIV yet are less likely to use pre-exposure prophylaxis (PrEP). We conducted a series of focused educational initiatives aimed at increasing awareness of and interest in HIV prevention resources among immigrants.
Methods: We designed an evidence-based workshop on culturally competent HIV prevention care, which was delivered to healthcare professionals (HCPs) at 4 federally-qualified health centers (FQHCs) and staff at 2 community-based organizations (CBOs) from March-September 2024. Staff from the FQHCs and CBOs then delivered 3 community education sessions (CES) and 3 micro-learning engagements (MLEs; e.g., pamphlet distribution and short discussions about sexual wellness and HIV within health fairs) on HIV awareness and prevention for local immigrant communities, in both English and Spanish. Participants completed pre/post-activity surveys which were analyzed using descriptive statistics.
Results: 129 people participated in the CES (N=46) or MLEs (N=83) (85% Hispanic/Latinx; 31% Mexican; 60% non-U.S. born), including 22 reporting a prior HIV diagnosis. The proportion of CES participants with negative HIV status who felt they were very likely to be exposed to HIV in the next 6 months increased from 8% to 53% (p = .001) and those reporting they were very likely to get tested for HIV in the next 30 days increased from 49% to 88% (p = .006). When asked about barriers to HIV testing, fear of judgement by medical staff was most commonly selected by community members (48%) but was perceived as a barrier by only 17% of HCPs and CBO leaders.
Community members' interest in taking PrEP increased from 63% to 94% (p = 0.038) following the CES. In surveys from the MLE, 79% agreed that they knew where to go for testing and 58% felt informed/very informed about local resources, such as legal aid and English classes.
Conclusions: Community-focused, brief education sessions effectively reached immigrant communities, improving perception of risk, likelihood of future HIV testing, and interest in PrEP, while also uncovering discordant views on HCP stigma as a barrier to HIV testing.

EP0407

Perceptions on HIV related services among male overseas employment seekers at state-run pre-departure training centres in Colombo, Sri Lanka

H.M.A.H. Karunaratne[1], A.K.A. Manathunge[2]
[1]Sexual Health clinic, Hambantota, District General Hospital Hambantota, Hambantota, Sri Lanka, [2]National STD/AIDS Control Programme, Coolombo, Sri Lanka

Background: Even though Sri Lanka has low-level HIV epidemic, a notable proportion of People Living with HIV (PLHIV) report external migration with male preponderance. The majority of external migrant workers from the country have been male since 2015. To address STI/HIV related vulnerabilities, a sexual health / HIV module has been introduced into their pre-departure training program carried out by SrLanka Bureau of Foreign Employment (SLBFE) .
This study aimed to explore the perceptions on pre-departure services related to HIV among male overseas employment seekers at pre-departure training centres in Colombo.
Methods: This descriptive cross-sectional study was conducted among 432 male foreign employment seekers at the main SLBFE training center, Sri Lanka using an interviewer-administered questionnaire assessing their perceptions regarding HIV related pre- departure services Including the training on sexual health/HIIV . Data were analysed for measures of central tendency and dispersion associations were calculated using chi-squared testing.
Results: The majority were never-married young men (mean age 27.86, SD-7.38) heading for Middle Eastern countries (70.0%).
All had attended the module on HIV and 24.1% expressed that their main source of HIV information was the pre-employment training.
Only 83(19.2%) had undergone HIV testing and only 201 (46.6%) claimed that they were aware of a HIV test service provider in their locality. The majority strongly felt the importance of carrying out the HIV training module in training programme (64.5%) and arranging free Pre-departure HIV-screening (59.4%).
Attendees strongly agreed that the session on sexual health increased their knowledge of HIV (n=210, 53.0%) and STDs (n=200, 50.5%).
Participants' suggestions for improving the sexual health module included increasing the content (n=40), allocating more time (n=20) and having more audio-visual content.
Conclusions: The participants trusted the conventional methods of STD /HIV knowledge to be the best source of information.
Most of the attendees of the HIV/sexual health module in the training programme felt that it increased their knowledge of HIV (53.0%) and STD (50.5%) and they requested more time and content with better multimedia content.
It is recommended to strengthen the sexual health module in the pre-departure training and develop free access to HIV and STI testing.

EP0409

Improving the uptake of antiretroviral prophylaxis for HIV exposed infants in Kubwa General Hospital, Nigeria: a continuous quality improvement project

G. Alozie-Chijioke[1], J. Ekere[2]
[1]Federal Capital Territory Ministry of Health, Public Health Department, Abuja, Nigeria, [2]Federal Ministry of Health, National AIDS and STI Control Programme, Abuja, Nigeria

Background: The Nigerian National HIV/AIDS Treatment Guidelines recommends Antiretroviral Prophylaxis for HIV Exposed Infants(HEI) using Nevirapine and/or Zidovudine commenced within 72 hours after birth, a critical way of eliminating Mother-to-Child Transmission of HIV. Despite the high burden of HIV in Africa, gaps exist in paediatric HIV case-finding, whose primary mode of acquisition is through vertical transmission from mother-to-child.
A quality improvement (QI) collaborative was initiated to improve the percentage of HEIs initiated on ARV prophylaxis within 72 hours from 93% to 100% in Kubwa General Hospital from January to June 2024.
This study aims to investigate the impact of targeted QI interventions on HEI ARV prophylaxis initiation rates.
Methods: In January 2024, maternal cohort data were analyzed for HIV testing rates, HEI ARV prophylaxis commencement and positivity rates and root causes identified such as, Mentor Mothers were unaware the women had given birth, occasional stockout of HIV test kits in the labour ward, and unavailability of Nevirapine and Zidovudine in the labour and postnatal wards were analyzed using a fishbone diagram. Site-specific interventions were developed and prioritized through a counter-measures matrix and implemented using Plan-Do-Study-Act cycle. Interventions included weekly calls by the mentor mothers to the registered Antenatal women Living with HIV from 36 weeks gestation to delivery, ensuring availability of HIV test kits in the labour ward, and a bottle of Nevirapine and Zidovudine in the labour/postnatal wards.
Results: Pre-CQI intervention data from the maternal cohort register showed 93% of ARV prophylaxis uptake within 72 hours from July-December 2023, which increased to 100% at June 2024. All 17(100%) women in antenatal care were called weekly till they gave birth. No stockout of HIV test kits, Nevirapine, and Zidovudine were recorded in the labour and postnatal wards. A total of 32(100%) HIV exposed infants were born during this period and received timely ARV prophylaxis.
Conclusions: The QIC interventions addressing maternal follow-up and ARV accessibility yielded promising results in HEI ARV prophylaxis management, highlighting the importance of addressing facility specific challenges using a CQI approach.

EP0410

"Do people who inject drugs exist in Malawi?": a study to inform the National AIDS Commission's response

D. Chilongozi[1,1], N. Madidi[2], D. Gondwe[3], W. Ozitingotsauka[4], C. Mabulekisi[3], C. Akolo[5], A. Gotlieb[5], R. Luhanga[1], M. Ruberintwari[6], M. Kiriuki[7], T. Kamanga[8], N. Mack[5], T. Lillie[5], A. Mwansambo[3], B. Afirima[3], G. Phombeya[1], N. Madidi[1], T. Chatepa[1], B. Magomero[1]

[1]FHI360, EpiC Project, Lilongwe, Malawi, [2]FHI360, EpiC Project, City Center, Lilongwe, Malawi, Malawi, [3]Government of Malawi, National AIDS Commission, Lilongwe, Malawi, [4]Ministry of Health, Department of HIV/AIDS, Lilongwe, Malawi, [5]FHI360, Global Health Programs, Washington, DC, United States, [6]FHI360, EpiC Project, Bamako, Mali, [7]FHI360, EpiC Project, Nairobi, Kenya, [8]FHI360, EpiC, Lilongwe, Malawi

Background: The government of Malawi has continued implementation of programs to address the HIV epidemic among at-risk populations and their social networks. However, data on injecting drug use in Malawi are limited, making it challenging for the National AIDS Commission (NAC) to incorporate people who inject drugs (PWID) into its HIV strategies.

As the NAC considered the potential inclusion of PWID, and with funding through the Meeting Targets and Maintaining Epidemic Control (EpiC) project, the NAC commissioned a study aimed at investigating the presence of PWID and their social networks in the districts of Lilongwe, Blantyre, Mangochi, Machinga, Zomba, Phalombe, Balaka, and Mzuzu.

Methods: From May through August 2021, EpiC conducted an exploratory qualitative assessment and characterized PWID congregation, type of drugs used, and nature and extent of drug use. The seed study participants were identified by a PWID representative from Centre for KP Rights serving PWID, with additional participants identified through snowballing.

The study team purposively selected and obtained views on drug injecting practices from individuals of different KP typologies, uniformed officers, health care workers, university students, youth, and religious leaders.

We conducted 18 focus group discussions and 72 in-depth interviews with PWID who consented to participate and corroborated their responses on various themes with gatekeepers. NVivo12 was used to analyze the data thematically.

Results: The assessment registered 11,120 PWID reported in the seven districts and revealed a growing culture of injecting drug use across all strata of society, with a decrease in initiation age of drug use. Drug use was reported as prevalent among girls and school-going youths.

Needle sharing was common among people reporting illicit drug injection, a practice increasing risk of HIV acquisition. Opioids were the most frequently reported injecting drug used. Home practices such as improvisation of drugs to feed an addiction were also reported.

Conclusions: Our findings informed government policy on including PWID in the HIV response and establishing the PWID National Steering Committee to oversee the introduction of the PWID program in Malawi. Findings were also used for planning a PWID national size estimation exercise in Malawi.

EP0411

Awareness of pre-exposure prophylaxis for HIV prevention among men who have sex with men (MSM) in Rwanda

G. Twagirimana[1], C. Kayitesi[2], Z. Nzeyimana[3], C. Ndinda[2], G. Gatete[2], B. Ikuzo[4], V. Umubyeyi Mupenzi[5], G. N Rwibasira[6]

[1]Rwanda Biomedical Center, HIV Epidemiology Surveillance and Research Unit, Kigali, Rwanda, [2]Rwanda Biomedical Center, Kigali, Rwanda, [3]Rwanda Biomedical Center, HIV Prevention Unit, Kigali, Rwanda, [4]Rwanda Biomedical Center, Director of HIV Prevention Unit, Kigali, Rwanda, [5]Rwanda Biomedical Center, Director of HIV Epidemiology, Surveillance and Research Unit, Kigali, Rwanda, [6]Rwanda Biomedical Center, Division Mager of HIV Head of HIV, STIs, and Hepatitis Programs in Rwanda, Kigali, Rwanda

Background: HIV remains a global public health concern, and pre-exposure prophylaxis (PrEP) is an effective prevention strategy for populations at high risk, including men who have sex with men (MSM). Rwanda incorporated PrEP into its national HIV prevention guidelines in 2018. However, data on PrEP awareness among MSM in Rwanda remain scarce.

This study examined factors associated with PrEP awareness among MSM in Rwanda.

Methods: This study involved secondary data analysis from a cross-sectional Bio-Behavioral Surveillance (BBS) survey conducted in 2024 using respondent-driven sampling (RDS). Descriptive statistics assessed PrEP awareness proportions.

Logistic regression models were used for bivariate and multivariate analysis to identify predictors. Adjusted odds ratios (AOR) with 95% confidence intervals (CI) were calculated, and statistical significance was set at $p<0.05$

Results: We analyzed data of 3757 MSM and of them with nearly a half (48.1%) aged 18 to 24 years ,the proportion of MSM aware of PrEP was 48.57% (95% CI: 45.76–51.39). Regional disparities revealed significantly higher awareness in the North (aOR: 2.66; 95% CI: 1.80 – 3.94) and South (aOR: 1.45; 95% CI: 1.07–1.97) compared to the East.

Sex workers (aOR: 29.29; 95% CI: 6.25–137.29) and self-employed individuals (aOR: 3.37; 95% CI: 1.53–7.42) demonstrated the highest likelihood of awareness compared to agro-farmers and other occupations, such as merchants (aOR: 2.87; 95% CI: 1.47 - 5.60) and carpenters (aOR: 2.42; 95% CI:1.06 - 5.50), were also significantly associated. Of the behavioral factors included only condom use during sex (aOR: 1.34; 95% CI: 1.04 – 1.72)

Similarly, as social factors, higher likely likelihood was also among those who heard or received messages about HIV/AIDS in the last six months (aOR: 2.75; 95% CI: 2.12–3.57). Interestingly, loss of respect in the community did not affect participants' awareness on PrEP, instead it was associated with higher likelihood (aOR: 1.59; 95% CI: 1.15–2.18).

Conclusions: Nearly half of MSM in Rwanda are aware of PrEP, with awareness influenced by regional behavioral, and social factors. Targeted interventions addressing regional disparities are essential for improving PrEP awareness and utilization among MSM. Strengthened outreach and educational campaigns can enhance HIV prevention efforts.

EP0412

"Hello! I'm Your Personal Health Guide!" Results of a randomized controlled trial demonstrating efficacy of a talking relational agent-based mobile phone application on ART adherence

M. Dworkin[1], K. Herrera[1], S. Upton[1], C. Luc[1], J. Jones[2], P. Burns[3], L. Liu[1], A. Jimenez[1], R. Ren[1], M. Woody[2], R. Garofalo[4], S. Lee[5]

[1]University of Illinois at Chicago School of Public Health, Division of Epidemiology and Biostatistics, Chicago, United States, [2]Emory University, Rollins School of Public Health, Atlanta, United States, [3]University of Mississippi Medical Center, School of Population Health, Jackson, United States, [4]Ann & Robert H. Lurie Children's Hospital of Chicago, Adolescent and Young Adult Medicine, Chicago, United States, [5]Connecticut College, Computer Science, New London, United States

Background: We iteratively developed My Personal Health Guide, an innovative, theory-driven mobile phone application, featuring a relational agent designed to motivate and facilitate adherence-related behavioral skills among young African American men who have sex with men (AAMSM). The talking realistic avatar also educates to improve health literacy.

We performed a randomized controlled trial to determine 6-month efficacy on improving antiretroviral therapy (ART) adherence among AAMSM living with HIV. We hypothesized that those randomized to My Personal Health Guide would have greater odds of achieving ≥80% adherence compared to the controls.

Methods: AAMSM ages 18-34 years with non-optimal ART adherence were recruited throughout the United States and randomized 1:1 (intervention: control). ART adherence was measured at baseline and monthly for 6 months by self-report.

Generalized estimating equations using backward model selection were used to evaluate the efficacy of My Personal Health Guide on achieving ≥80% ART adherence over time, after adjusting for demographic characteristics. Interactions between time and group were assessed. An α of 0.05 was used for all analyses.

Results: Between February 2020 and September 2023, 253 AAMSM were randomized (124 intervention: 129 control). Three-quarters (73.5%) completed the 6-month follow-up (99 intervention: 87 control). The odds of achieving ≥80% adherence was greatest at months 1 (OR 2.14; 95%CI 1.17-3.89) and 4 (OR 2.19; 95%CI 1.10-4.35) post-randomization. The interaction between time and group effect was not significant, indicating the group difference in the probability of achieving ≥80% adherence did not change over time.

However, a significant group effect (p-value=0.014) indicated that those randomized to My Personal Health Guide were 1.54 (95%CI 1.25-12.50) times more likely to achieve ≥80% adherence throughout the study duration. Residing in the South, Hispanic ethnicity, and higher HIV treatment adherence self-efficacy were also associated with increased odds of achieving ≥80% adherence.

Conclusions: This is the first study to demonstrate that a relational agent-based behavioral intervention can improve medication adherence, providing evidence of long-term efficacy among young AAMSM.

We recommend further research of this approach to medication adherence, especially among populations with poor health literacy.

EP0413

PrEP persistence among a cohort of female sex workers in Argentina

M.V. Iannantuono[1], G. Miernes[1], M.M. Sandoval[1], M. Loutfy[2], C.M. Romanelli[1], C. Cesar[1], A. Nava[1], M. Ceschel[1], M.E. Esandi[1], J. García[1], D. Salusso[1], M. Romero[3], G. Orellano[4], V. Salazar[1], I. Arístegui[1], M.I. Figueroa[1], Z. Ortiz[1], P. Cahn[1], A. Durán[5], S. Walmsley[6], V. Fink[1]

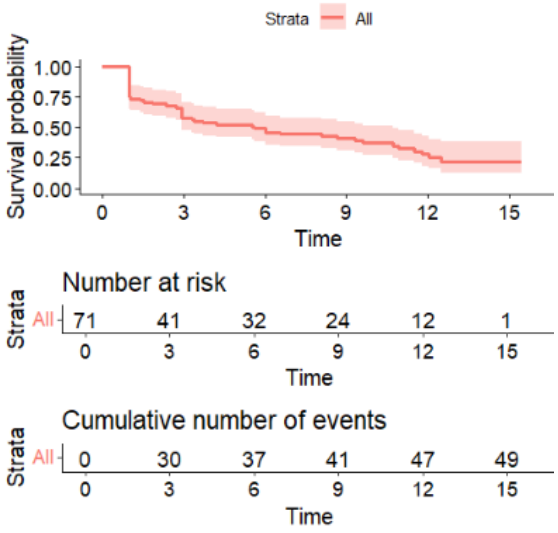
[1]Fundación Huésped, Research Department, Buenos Aires, Argentina, [2]Women's College Hospital, University of Toronto, Toronto, Canada, [3]Asociación de Travestis, Transexuales y Transgénero de Argentina, Buenos Aires, Argentina, [4]Sindicato de Trabajadorxs Sexuales de Argentina, Buenos Aires, Argentina, [5]Coordination of Sexual Health, HIV and Sexually Transmitted Infections of the Ministry of Health of Buenos Aires, Buenos Aires, Argentina, [6]University Health Network, Toronto, Canada

Background: Oral PrEP was implemented in Argentina in 2021. Female sex workers (FSW) face substantial barriers to accessing HIV prevention services, including PrEP. We aimed to assess the PrEP persistence and associated factors among FSW.

Methods: "MAS por Nosotras" is a prospective cohort of FSW, conducted at an NGO in Argentina where PrEP was offered. PrEP persistence was defined as the time to first-PrEP-discontinuation. Persistence probabilities were estimated through Kaplan-Meier curves for participants starting PrEP at-or-after study enrolment.

Factors associated with PrEP discontinuation were analyzed using logistic regression models (covariates: gender, age, education, residence, nationality, drug use during last year, prior sexually transmitted infections (STIs), knowledge and prior use of PEP and PrEP).

Results: Between June 2023-March 2024, the cohort enrolled 200 FSWs: 101 cisgender women (CGW), 99 transgender women (TGW), 37 with HIV (34 TGW/ 3 CGW). Of the 163 without HIV, 19 were already on PrEP. Of 71 who initiated PrEP (42 CGW, 29 TGW); median age was 35 (IQR: 27-43); 37% had prior STIs; 68% had used substances in previous year; 23% knew about post-exposure prophylaxis (PEP) and 6% had previously used it, while for PrEP it was 34% and 4%, respectively. Median follow-up time was 4.3 months (IQR:1-10.5); 22 (31%) persisted on PrEP (Figure 1).



In the bivariate analysis, CGW had higher risk of PrEP discontinuation than TGW [HR=1.26 (1.02-1.57, p=0.04)]. When controlled for covariates, probability of PrEP discontinuation was higher among those who used substances (OR: 1.59, p=0.01) and those who knew about PEP (OR:1.49, p=0.03).

Conclusions: Persistence on PrEP was low among FSWs. Substance use and previous knowledge of PEP were associated with PrEP discontinuation. Further research to improve PrEP persistence among FSWs, with a gender-focus-approach, as part of a comprehensive HIV prevention package is warranted.

EP0414

Acceptability and willingness to pay for different HIV pre-exposure prophylaxis strategies, among women attending antenatal clinic in a University Medical Center in Zaria, Kaduna State Nigeria

B.B. Wadalla[1], A. Isah[2]

[1]Ahmadu Bello University Zaria, Faculty of Pharmaceutical Sciences, Zaria, Nigeria, [2]University of Nigeria, Clinical Pharmacy and Pharmacy Management, Nsukka, Nigeria

Background: Despite global efforts to reduce HIV transmission, women, especially pregnant women, are at a higher risk of HIV acquisition due to both biological and behavioral changes during pregnancy. Pre-exposure prophylaxis (PrEP) strategies, such as Oral PrEP (Truvada), Dapivirine Vaginal Ring [DPV-VR], and Long-acting Cabotegravir Injection (CAB-LA), have been identified as effective measures in preventing HIV transmission.

Methods: This study adopted a cross-sectional, non-interventional design to obtain responses from 105 pregnant women at a University Medical Center in Zaria Nigeria in 2024. A validated questionnaire was adopted and distributed to participants, assessing demographic characteristics, HIV testing status, willingness to use PrEP, and WTP for three PrEP options, namely Oral PrEP (Truveda), DPV-VR and CAB-LA. Data were summarized using descriptive statistics, while relationships between socio-demographic factors and WTP were assessed using chi-square tests. P< 0.05 was considered statistically significant. Ethical approval was obtained from the Institutional Review Board of the University Research and Ethics Committee.

Results: A total of 105 responses were obtained for the study. Majority of respondents were aged between 18 and 29 years (n=82, 78%) with (n=32, 30.5%) having Post-graduate education.

More than half of the respondents (n=73, 69.5%) knew their HIV status. In addition, 44(41.9%) were willing to pay for Oral PrEP, 19(18.1%) for the DPV-VR, and37 (35.2%) for the CAB-LA.

The maximum WTP was N30,000 for Oral PrEP and the DPV-VR, and up to N5,500,000 for CAB-LA. A significant portion 101 (96.2%) preferred government provision of PrEP, indicating limited personal financial commitment.

The most common reasons for PrEP choice included its convenience 19.4%, perceived effectiveness, ease of use (14.2%), and cost (7.7%).

The highest WTP association was observed among those with postgraduate qualifications (P=0.004) and marital status (P=0.015).

Conclusions: The study reveals a low-moderate acceptance of PrEP options among pregnant women, with a preference for cost-effective government-provided PrEP services. Those that were willing to pay indicated price below the market prices for the commodities. Educating the public especially women on the benefit of PrEP, alongside subsidized government provision, may enhance uptake and adherence, ultimately reducing HIV transmission among high-risk groups.

EP0415

Community-based pre-exposure prophylaxis (PrEP) delivery accelerates PrEP uptake among priority populations in Cambodia

V. Ouk[1], S. Samreth[1], B. Ngauv[1], S. Tep[1], V. Keo[2], R. Tep[2], C. Rin[2], M. Ngo[2], V. Virak[2], S. Seng[3], K. So[2], V. Kem[4], P. Dork[5], A. Chhorn[6], S. Sem[7], W. Steve[2]

[1]National Center for HIV/AIDS, Dermatology and STD (NCHADS), Phnom Penh, Cambodia, [2]EpiC, FHI 360, Phnom Penh, Cambodia, [3]EpiC, FH I360, Phnom Penh, Cambodia, [4]Men's Health Cambodia (MHC), Phnom Penh, Cambodia, [5]Men's Health Social Service (MHSS), Phnom Penh, Cambodia, [6]Cambodian Women for Peace and Development (CWPD), Phnom Penh, Cambodia, [7]Friends-International (FI), Phnom Penh, Cambodia

Background: Cambodia is committed to eliminating new HIV infections and achieving the 95-95-95 targets by 2025. HIV infection remains concentrated among priority populations (PPs), accounting for 70% of new HIV infections in 2023. Given the recognized effectiveness of pre-exposure prophylaxis (PrEP) in reducing new infections among PPs, the National Center for HIV/AIDS, Dermatology and Sexually Transmitted Diseases (NCHADS), supported by EpiC project, introduced PrEP at health facilities in 2019 and community-based drop-in-centers (DICs) in 2022. DIC-based PrEP delivery offers a safe, non-judgmental environment, convenient hours of operation, peer support, and confidentiality, all appealing to PPs.

Description: National PrEP guidelines and standard operating procedures were modified to include community-based PrEP delivery. Over the last three years, PrEP delivery has expanded to 44 sites (30 facilities and 14 DICs) in 16 provinces with the largest number of PP residents (Figure 1).

Figure 1. Clients initiating PrEP at community-based and facility sites by month.

Lessons learned: In total, 27,167 individuals initiated PrEP between July 2022 and September 2024: at-risk men 68%, at-risk women 15%, HIV negative partners 3%, others 14%. PrEP clients were young: ages 15–24 (47%) and 25–35 (39%). Although DICs accounted for only 30% of the total PrEP sites from January to September 2024, they enrolled 66% of new clients and retained 62% (vs. 32% at facility sites) as of September 2024

Conclusions/Next steps: PrEP delivery at DICs, supported remotely by facility-based providers, is an effective option for increasing PP client enrollment and retention, where peer delivery and client-tailored hours of operation promote client uptake and retention. More DIC PrEP sites should be established to help Cambodia reach its ambitious HIV elimination target by 2025

EP0416

Virtual mapping of MSM in Nigeria: enhancing HIV intervention strategies

J. Egwu[1], P. Onoja[2], A. Andrew[3], E. Omaga[3], O. Oshagbami[3]
[1]National Agency for the Control of AIDS, Research, Monitoring and Evaluation, Abuja, Nigeria, [2]National Agency for the Control of AIDS NACA, Special Duties, Abuja, Nigeria, [3]National Agency for the Control of AIDS NACA, Research, Monitoring and Evaluation, Abuja, Nigeria

Background: Men who have Sex with Men (MSM), comprising less than 1% of Nigeria's population, face a disproportionately high HIV burden. The 2014 Integrated Biological and Behavioural Surveillance Survey (IBBSS) reported a 22.9% HIV prevalence among MSM, highlighting the critical need for targeted interventions. Traditional mapping methods often underestimate MSM populations, limiting effective service provision.
This study utilized virtual mapping to better understand MSM distribution and online engagement across Nigeria.
Methods: Data from existing programmatic mapping and size estimation studies were analyzed across 20 Nigerian states. A two-stage virtual mapping approach were employed: sequential listing of virtual sites frequented by MSM, followed by profiling and size estimation. Online surveys and interviews with MSM recruited from virtual platforms were conducted to gather data.
Results: The study identified approximately 73,925 MSM engaging on virtual platforms in the 20 states. Plateau State had the highest number of MSM accessing these platforms (12,898), followed by Kogi (8,926), while Kebbi recorded the lowest (87).
Notably, 82% of MSM on virtual platforms had visited a physical hotspot in the past month. Popular online platforms included LGBT-specific websites and apps, Facebook, WhatsApp, Instagram, and Messenger.
Conclusions: Virtual mapping offers critical insights for designing tailored HIV/AIDS interventions for MSM in Nigeria. The overlap between virtual and physical hotspots presents opportunities for integrated service delivery, enabling comprehensive outreach and improved health outcomes. These findings emphasize the need to leverage digital platforms to expand access to HIV prevention, care, and support services for MSM.

EP0417

Utility of social support and social networks theory in the PrEP continuum of care for adolescents: a review of the literature

E.N. Essam Nkodo[1,2], M. Rosen[2], S.S. Rajaram[2], M. Tibbits[2]
[1]University of Nebraska Medical Center, College of Medicine, Omaha, United States, [2]University of Nebraska Medical Center, College of Public Health, Omaha, United States

Background: In 2020, approximately 410,000 new HIV cases were reported among adolescents aged 10-24 years globally, with nine out of ten infections occurring in sub-Saharan Africa. To ensure adolescents receive the necessary support to prevent HIV/AIDS, social support and social network theories are important frameworks that can help optimize the PrEP continuum of care.
This literature review explores the potential of social support and social network theories in improving enrollment and retention in HIV pre-exposure prophylaxis (PrEP) care for at-risk adolescents aged 10-24.
Methods: This literature review involved searches across various databases. Inclusion criteria for articles were publication in English from January 2012 to December 2023, with a focus on adolescents aged 10 to 24, PrEP, social networks, social support, and any aspect of the PrEP Continuum of Care.
Results: The study encompasses eight peer-reviewed articles, each differing in study type, focus, and geographical context. The theories of social support and social networks were examined within various facets of the PrEP Continuum of Care, yet no study assessed the effects of interventions rooted on these theories. Key support figures were listed, particularly family members, showing interest in adolescents' PrEP usage, with a readiness to provide active support.
However, some parents' support was contingent upon the adolescent's request for it, while others' support hinged on their prior knowledge of PrEP. Frequent and

quality discussions between parents and children about sexual health and HIV/AIDS correlated with provision of support, increased awareness of PrEP and a greater likelihood of its use among adolescents. The studies also recognized the role of friends' networks in encouraging PrEP adoption, notably among adolescents who are sexual and gender minorities.

Conclusions: Social support and networks have the potential to improve the PrEP continuum of care for adolescents at risk of HIV. Future studies should investigate the application of interventions based on these theories.

EP0418

Leveraging data-driven mapping to optimize HIV prevention and care services for key populations in Bauchi state, Nigeria

I.J. Obiajulu[1]
[1]African Network of Adolescents and Young Persons Development, NGO, Kaduna, Nigeria

Background: Key populations (KPs)—female sex workers (FSW), men who have sex with men (MSM), people who inject drugs (PWID), and transgender individuals (TG)—face significant HIV risks and barriers to care.

This study aimed to accurately map and estimate the size of KPs using Multiple Source Capture-Recapture (MS-CRC) methods to inform targeted interventions.

Methods: A cross-sectional study was conducted across Bauchi State over six months. Three rounds of venue-based surveys identified 2,019 active hotspots, including brothels, street locations, and informal spaces. Bayesian latent class modeling provided size estimates for each KP group. Accessibility to healthcare facilities was analyzed, and service gaps were highlighted to guide interventions.

Results: The study estimated 5,100 FSW, 3,600 MSM, 7,600 PWID, and 1,000 TG individuals. Notably, only 39.4% of hotspots were within 1 km of healthcare facilities, limiting access to HIV prevention and care services. Mobile health clinics and decentralized service models increased HIV testing by 45% and linkage to antiretroviral therapy (ART) by 30%.

Conclusions: The findings demonstrate the utility of MS-CRC methods for precise KP size estimation and hotspot mapping. Targeted interventions, including mobile clinics and community engagement, significantly improved service accessibility and HIV outcomes.

Scaling these data-driven approaches will accelerate progress toward UNAIDS 95-95-95 goals in Bauchi State and similar settings.

EP0419

Determinants of Daily Oral Pre-exposure Prophylaxis (PrEP) among adolescent girls and young women (AGYW): insights from the Namibia DREAMS Program

E. Melese[1], E. Moyo[2], S. Takawira[3], H. Mangwana[3], B. Harases[3], F. Frans[3], M. Moongo[4], A. Kuthedze[4], M. Shilomboleni[4], L.N. Nambambi[4], N. Ekandjo[4], L. Muzart[5]
[1]Project HOPE- The People-to-People Health Foundation, Inc, Windhoek, Namibia, [2]University of Kwa-Zulu Natal, College of Health Sciences, School of Nursing & Public Health, Durban, South Africa, [3]Project HOPE Namibia, Windhoek, Namibia, [4]IntraHealth Namibia, Windhoek, Namibia, [5]United States Agency for International Development (USAID) Namibia, Windhoek, Namibia

Background: Adolescent girls and young women (AGYW) aged 15-24 years in sub-Saharan Africa continue to face a significant risk of HIV acquisition. Oral pre-exposure prophylaxis (PrEP) can reduce the likelihood of HIV acquisition by more than 90% with optimal adherence. A DREAMS (Determined, Resilient, Empowered, AIDS-Free, Mentored, and Safe) program, implemented by the Project HOPE Namibia (PHN)-led consortium, provided PrEP services in the Khomas, Oshikoto, Zambezi, and Oshana regions.

This secondary analysis of DREAMS program data aimed to assess the rate of daily oral PrEP initiation among AGYW aged 15-24 and identify key characteristics and HIV risk factors associated with PrEP initiation.

Description: DREAMS delivered nurse-led, comprehensive PrEP services through a hybrid model, combining health facility-based delivery via adolescent and youth-friendly corners and community-based service delivery through a facility-linked outreach approach. AGYW were informed in advance about the schedule for community-based PrEP services through interpersonal communication. The DREAMS curriculum, flipcharts, pamphlets, posters, social media posts, and radio spots were utilized to generate demand.

Lessons learned: Among the 29,828 AGYW eligible for PrEP, 24,182 (81.1%) were newly initiated on PrEP. AGYW from Windhoek and Oshakati, those with 1-2 biological children, and those who perceived themselves at risk of HIV were more likely to initiate PrEP. In contrast, a lower likelihood of PrEP initiation was associated with AGYW from Omuthiya and Tsumeb, those unaware of their partners' HIV status, those with HIV-positive partners during pregnancy or breastfeeding, individuals with recent or recurrent sexually transmitted infections, those engaging in sexual activity while under the influence of alcohol or drugs, and those with multiple or concurrent sexual partners.

Conclusions/Next steps: These findings highlight the need for targeted HIV education in smaller urban and rural communities to address stigma and discrimination associated with PrEP use. Enhancing HIV education to improve risk perception among AGYW and dispelling misconceptions about PrEP side effects is critical. Additionally, providing user-friendly PrEP services can encourage greater uptake and adherence.

EP0420

Prevalence and factors associated with the diagnosis of sexually transmitted Infections among adolescentgGirls and young women (AGYW) in Namibia: insights from the DREAMS Program

E. Melese[1], E. Moyo[2], S. Takawira[3], H. Mangwana[3], B. Harases[3], F. Frans[3], M. Moongo[4], A. Kuthedze[4], M. Shilomboleni[4], L.N. Nambambi[4], N. Ekandjo[4], L. Muzart[5]
[1]Project HOPE- The People-to-People Health Foundation, Inc, Windhoek, Namibia, [2]University of Kwa-Zulu Natal, College of Health Sciences, School of Nursing & Public Health, Durban, South Africa, [3]Project HOPE Namibia, Windhoek, Namibia, [4]IntraHealth Namibia, Windhoek, Namibia, [5]United States Agency for International Development (USAID) Namibia, Windhoek, Namibia

Background: Approximately one million curable sexually transmitted infections (STIs) are contracted daily by individuals aged 15-49 years worldwide, with adolescent girls and young women (AGYW) experiencing disproportionately higher incidence rates, particularly in sub-Saharan Africa.
This study assessed the prevalence of STIs and associated factors among AGYW enrolled in the DREAMS (Determined, resilient, empowered, AIDS-free, mentored, and safe) program implemented by Project HOPE Namibia.
Description: The DREAMS program's support for the prevention and control of STIs included revising and updating the national guidelines, conducting staff training on the management of STIs, increasing literacy about STIs among AGYW and their sexual partners, implementing routine STI screening at all entry points, and providing diagnosis and treatment of STIs using the syndromic management approach.
Lessons learned: Among 27,992 AGYW in this analysis, 3,184 (11.4%) were diagnosed with an STI (95% CI: 11.0% – 11.8%). AGYW aged 15-19 years (AOR = 0.74, 95% CI: 0.68–0.81), those enrolled between 2022 and 2023, programs participants for over 13 months, those who were pregnant or breastfeeding (COR = 0.12, 95% CI: 0.02–0.87), those using family planning (AOR = 0.25, 95% CI: 0.23–0.29), or those perceiving themselves to be at risk of HIV (AOR = 0.81, 95% CI: 0.75–0.88) were less likely to have an STI diagnosis. Conversely, higher STI diagnoses were observed among recurrent post-exposure prophylaxis PrEP) users (COR = 2.71, 95% CI: 1.21–6.07), individuals with a history of sexual violence (AOR = 3.96, 95% CI: 2.23–7.02), participants from all DREAMS districts except Katima Mulilo and AGYW engaging in sex under the influence of alcohol or drugs (AOR = 1.93, 95% CI: 1.2–2.95). A subgroup analysis of PrEP users who returned for a one-month follow-up showed no significant change in STI prevalence compared to enrolment.
Conclusions/Next steps: The findings underscore the need to intensify education on safe sexual practices and promote the consistent use of condoms to prevent STIs among high-risk AGYW while continuing to strengthen syndromic management. Additionally, leveraging existing laboratory and point-of-care systems for the molecular diagnosis of asymptomatic STIs is crucial to improving prevention and treatment efforts among high-risk AGYW.

EP0421

Survey focused promotion of injectable PrEP to enhance uptake of the service among adolescent girls and young women in a prospective cohort study in Lusaka, Zambia

S. Itwi[1], C. Kabengele[1], M. Muwowo[2], H. Lumano[3], C. Chanda[1], K. Malama[3], M. Price[4], S. Francis[5], P. Maenetje[6], M. Kuteesa[5], W. Kilembe[7]
[1]Center for Family Health Research in Zambia, Medical, Lusaka, Zambia, [2]Center for Family Health Research in Zambia, Laboratory, Lusaka, Zambia, [3]Center for Family Health Research in Zambia, Data, Lusaka, Zambia, [4]UCSF, Epidemiology, San Francisco, United States, [5]IAVI, Nairobi, Kenya, [6]Aurum Institute, Johannesburg, South Africa, [7]Center for Family Health Research in Zambia, Lusaka, Zambia

Background: Adolescent girls and young women (AGYW) in Zambia face disproportionate HIV risk, making them key candidates for HIV prevention trials. For both future trial participation and personal well-being, PrEP is essential, yet uptake remains low.
We assessed PrEP awareness and knowledge among Zambian AGYW in the Multisite Study with Adolescent girls and Young women (MAGY) to develop a tailored intervention to promote uptake.
Methods: We administered a survey, between June and December 2024 among AGYW in Lusaka and Ndola Zambia. Eligible participants were aged 15-24 years and sexually active. We collected data on social demographics, the participant's current HIV prevention and awareness of and attitudes towards PrEP (oral, injectable and vaginal ring). Participants who were not using PrEP were invited to a tailored PrEP-focused HIV prevention education session that utilized information, education and communication tools developed by the *Maximizing Options to Advance Informed Choice* for HIV Prevention (MOSAIC). When available, participants who were already on PrEP and satisfied with the method, were asked to share their experience using PrEP to an audience of non-users i.e. "Happy client" model. Data were analyzed to describe awareness of long-acting Cabotegravir (CAB-LA) and impact of the survey on its uptake.
Results: Among 159 AGYW surveyed (mean age 20.5±2.3 years, 95 (60%) >20 years), only 9 (6%) were on PrEP, including 5 (3%) on CAB-LA. Of those not using CAB-LA but aware of it (n=87, 56%), 54 (62%) believed it was effective, and 58 (67%) were comfortable receiving it. Among 24 participants expressing discomfort, primary concerns were side effects (9/24, 37%) and fear of needles (5/24, 21%). Post-intervention, 72/154 (47%) initiated CAB-LA and 9 (6%) chose oral PrEP. CAB-LA uptake was higher among participants >20 years (49/93, 53%) compared to those <20 years (23/61, 37%) (p<0.001).
Conclusions: Awareness of CAB-LA was high among AGYW given its recent rollout in Zambia in early 2024. Despite delivery of information on PrEP during our study and through ongoing AGYW HIV programs, uptake of PrEP remained low. The survey facilitated tailored messaging and improved uptake of Oral/injectable PrEP among AGYW.

EP0422

Attitudes towards HIV pre-exposure prophylaxis in middle-aged and older adults: a qualitative study in rural South Africa

M. Marcus[1], J. Hove[2], A. Berner-Rodoreda[3], J. Rohr[3], S. Tollman[2], B. Maughan-Brown[4], T. Bärnighausen[3], K. Kahn[2], J. Manne-Goehler[1]
[1]Brigham and Women's Hospital, Department of Infectious Diseases, Boston, United States, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Heidelberg Institute of Global Health, Heidelberg, Germany, [4]University of Cape Town, Cape Town, South Africa

Background: Pre-exposure prophylaxis (PrEP) is one of the most significant breakthroughs in HIV prevention; however, its uptake in South Africa is limited and more than 150,000 people acquire HIV every year – a significant proportion of which is occurring in middle-aged adults. In the "Health and Aging in Africa: Longitudinal Studies in South Africa (HAALSA)" cohort study, 45% of individuals with a negative HIV status and aged 40 or higher qualify for PrEP counselling based on South African PrEP guidelines.
The objective of this study was to explore attitudes towards and barriers of PrEP use in this population.
Methods: The study was conducted in Agincourt, Mpumalanga, South Africa in 2024. We recruited a subset of participants from the 2022 HAALSA study. We randomly selected 30 participants that tested negative for HIV.
The sample selection was stratified by age with 50% of respondents being 50-59 years old and 50% being 60 years or older.
We conducted one-time, in-depth interviews in Shangaan. Audio recordings of the interviews were transcribed and translated into English. Rapid Analysis was used for analyzing the data.
Results: We interviewed 21 female and 9 male respondents. Our preliminary analysis revealed that PrEP awareness is very low.
Some participants expressed positive attitudes towards taking PrEP in the context of i) new partners, ii) their existing partner having multiple partners, or iii) their existing partner living with HIV.
Barriers to PrEP use included i) low perceived need due to old age or low sexual activity, ii) confusion about the distinction between PrEP and antiretroviral therapy, and iii) concerns about acceptance of PrEP in their partnership.
Participants preferences varied between oral and injectable PrEP; and between distribution via the clinic or community health workers, depending on privacy concerns and past experiences with the healthcare system.
Conclusions: Many middle-aged and older adults in South Africa are not aware of PrEP and when it should be used. If this awareness can be addressed, diverse PrEP modality preferences, partnership dynamics, and privacy concerns should be considered.

EP0423

Double dividend: PrEP uptake among pregnant and breastfeeding women in USAID/ PEPFAR-supported programs

J. Rodrigues[1], A. Amzel[2], T. Okegbe[3], K. Abuelgasim[4], N. McDavid[5], T. Mukherjee[5], A. Wate[6], S. Mukungunugwa[7], A. Muchara[7], M. Musonda[8], D. Mwamba[8]
[1]Independent Consultant, New Jersey, United States, [2]Independent Consultant, Florida, United States, [3]Independent Consultant, Maryland, United States, [4]Independent Consultant, Virginia, United States, [5]Independent Consultant, New York, United States, [6]Independent Consultant, Maputo, Mozambique, [7]Independent Consultant, Harare, Zimbabwe, [8]Independent Consultant, Lusaka, Zambia

Background: Pregnant and breastfeeding women (PBFW) are at heightened risk of HIV acquisition, accounting for 24% of new pediatric infections globally (UNAIDS 2024). Oral and injectable pre-exposure prophylaxis (PrEP) options have the potential to reduce HIV incidence among PBFW and stagnating vertical transmission rates – a double dividend.
Description: We conducted a descriptive analysis of USAID/PEPFAR-supported PrEP uptake across 17 countries reporting PrEP initiations (PrEP_NEW) and PrEP return visits (PrEP_CT) among PBFW in fiscal year (FY) FY24 (October 2023 - September 2024).
Lessons learned: PrEP initiations among PBFW increased 35% from 11,305 in FY24Q1 to 15,296 in FY24Q4 for a total of 57,628 initiations in FY24. Zambia, Mozambique, and Zimbabwe reported the highest number of initiations in FY24, accounting for 71% of all initiations among PBFW.
Fourteen countries reported more than 50% of initiations among PBFW during pregnancy and seven countries reported more than 70% of initiations during pregnancy.
Three countries-- Nigeria (59%), Tanzania (60%) and Rwanda (93%)-- reported a higher proportion of PBFW initiations among breastfeeding women.
During FY24, the number of PBFW who returned for PrEP at least once in a quarter (PrEP_CT) increased from 4,851 in Q1 to 7,270 in Q4.
Among all PBFW returning for PrEP, pregnant women represented 53% (median percentage) of women across 15 countries.
Eswatini (63%), Burundi (62%) and Malawi (60%) reported the highest proportion of breastfeeding women returning for PrEP per quarter.
Early lessons show that embedding PrEP in maternal and child health services, including post-partum care, well-child clinics, and child health days is critical to improving PrEP uptake and continuation among PBFW.
Provider training and counseling to address biases in recommending PrEP to PBFW, sensitization of community leadership and PBFW partners on PrEP availability, and training of community cadres on demand generation also contributed to increases in PrEP initiations.
Conclusions/Next steps: USAID/PEPFAR-supported PrEP initiations among PBFW are slowly increasing, driven by significant expansion in three countries. Given high HIV incidence in pregnancy and breastfeeding, longer-acting

PrEP options, if approved and prioritized for PBFW, could promote continuation and reduce new infections among PBFW and children.

EP0424

Pre-exposure prophylaxis uptake among pregnant and breastfeeding women in Midlands Province, Zimbabwe, 2024

G. Choga[1], O. Sibanda[1], J.P. Mafara[1], T.P. Sibanda[1], E. Jange[1], C. Sibanda[1], R. Magutshwa[1], S. Ndlovu[1], E. Tachiwenyika[1], T. Tafuma[1], K. Nyathi[1], P. Baloyi[1], M. Muzondo[1], B.N. Chindove[1], T. Apollo[2], A. Mushavi[2], M. Muchekeza[2], S. Mukungunugwa[3], M. Mhangara[3], T. Nyamundaya[1]

[1]Zimbabwe Health Interventions, Harare, Zimbabwe, [2]Ministry of Health and Child Care, Harare, Zimbabwe, [3]United States Agency for International Development, Harare, Zimbabwe

Background: HIV acquisition during pregnancy and breastfeeding remain as one of the greatest contributors of mother-to-child transmission (MTCT) of HIV. Zimbabwe adopted Pre-Exposure Prophylaxis (PrEP) as part of HIV combination prevention strategies for pregnant and breastfeeding women (PBW) to attain the World Health Organization's target of an MTCT rate of less than five percent. The Midlands Province's MTCT for the year 2023 was 9.6% which was higher than the national MTCT rate of 7.4 %. We determined the uptake of PrEP and factors associated with PrEP uptake among PBW in the Midlands Province.

Methods: We conducted an analytical cross-sectional study among 802 women testing HIV negative in antenatal and postnatal care in four districts of Midlands Province in October 2024. Ten facilities were randomly selected from each district. Data was abstracted from HIV testing registers in antenatal and postnatal clinics using a tool designed in the Kobo toolbox. Data was analyzed using Stata version 12 to generate frequencies, proportions and measures of association. We performed logistic regression analysis at 5% significance level to determine independent factors for PrEP uptake.

The study was covered by the Medical Research Council of Zimbabwe (MRCZ) approved non-research determination protocol (MRCZ/E/159).

Results: Of the 802 women, 68.8% were pregnant whilst 31.2% were breastfeeding. About 57.7% of PBW were aged less than 25 years and 68.7% were from rural areas. The PrEP uptake was 21.9%. There were five PBW with serodiscordant partners and all enrolled for PrEP. Among 172 PBW classified as high risk after assessment using an HIV screening tool, 70.9% enrolled for PrEP. The independent predictors of PrEP uptake were being a contact of an HIV index case [AOR 37.78; p=0.002] and high-risk classification during HIV risk assessment [AOR 25.84; p<0.001].

Conclusions: The overall PrEP uptake among PBW was low. The greatest contributor to PrEP uptake among PBW was a perception of high HIV risk. We recommend improved counseling on PrEP services in ANC and PNC departments and investing in community awareness to enhance PrEP uptake among PBW.

EP0425

Comparing PrEP uptake across DREAMS-supported versus non-DREAMS-supported districts in USAID programs

N. Petrovic[1], J. Rodrigues[2], A. Limb[1], M. Musonda[3], M. Manyando[4]

[1]Independent Consultant, Washington, DC, United States, [2]Independent Consultant, New Jersey, United States, [3]Independent Consultant, Lusaka, Zambia, [4]Independent Consultant, Windhoek, Namibia

Background: Pre-exposure prophylaxis (PrEP) is a key intervention offered as part of the secondary package of DREAMS (Determined, Resilient, Empowered, AIDS-free, Mentored and Safe) – a combination HIV prevention program aimed at reducing adolescent girls and young women's (AGYW) HIV incidence. Multiple studies demonstrate that providing wrap-around services such as HIV education, peer support, and access to adolescent-responsive health services can empower AGYW to effectively initiate and use PrEP. The DREAMS platform has served as a catalyst for the roll-out of PrEP in sub-Saharan Africa among AGYW. We sought to compare PrEP uptake in districts with and without DREAMS.

Description: A descriptive analysis was conducted using USAID data for AGYW 15-24 years old from fiscal year (FY)19 to FY23, comparing PrEP uptake reported by USAID in DREAMS and non-DREAMS districts within and across 14 countries. The districts were categorized into three groups, using the first year DREAMS services were reported: 1) districts that never implemented DREAMS; 2) districts that have implemented DREAMS in or before FY19 and; 3) districts that have implemented DREAMS since FY21.

Lessons learned: Districts that never implemented DREAMS reported lower yearly PrEP initiations among AGYW and lower yearly target achievement compared to districts that started implementing DREAMS in FY19 or earlier. Districts implementing the DREAMS program by FY19 initiated a total of 279,167 AGYW on PrEP from FY19 to FY23, nearly twice as many AGYW in that same five-year period as districts that have never implemented DREAMS (143,043). Similarly, districts that started DREAMS in FY21 reported increases in PrEP initiations from FY21 to FY23 and exceeded targets for PrEP initiations.

Conclusions/Next steps: Districts implementing DREAMS show higher PrEP uptake compared to districts that have not implemented DREAMS. While PrEP expansion also occurred outside DREAMS-supported districts, DREAMS infrastructure may have accelerated scale-up.

Existing evidence underscores that strategies such as peer support, community acceptance, and community-based platforms for PrEP delivery support PrEP use, especially for AGYW.

As longer-acting PrEP options are introduced, it will be critical to quantify the contribution of structural and behavioral components of DREAMS to biomedical prevention uptake in order to inform broader programming.

EP0426

Identifying the most-at-risk sub-populations for low HIV testing uptake among adolescent boys and young men: results from a nationally representative survey in Zambia

K. Malama[1,2], T. Nyoni[3]
[1]Center for Family Health Research in Zambia, Lusaka, Zambia, [2]McGill University, Ingram School of Nursing, Montreal, Canada, [3]Dalhousie University, School of Social Work, Halifax, Canada

Background: Adolescent boys and young men (ABYM) have low HIV testing uptake, which is detrimental to HIV prevention and care efforts. However, limited research has identified the sub-populations among ABYM who are less likely to uptake HIV testing and are most-at-risk for HIV acquisition. This targeted approach could inform effective interventions to enhance testing uptake among ABYM. We therefore analysed correlates of HIV testing uptake among ABYM in Zambia.

Methods: This cross-sectional study used the most recent Demographic Health Survey (2018) from Zambia. The survey collected participant socio-demographic information, HIV testing history and HIV risk behaviours.

Our analysis was restricted to ABYM, aged 15-24. We performed logistic regression modelling with odds ratios (ORs) and 95% confidence intervals (CIs) to determine the exposure variables (demographics and sexual behaviours) associated with the study outcome (ever testing for HIV).

Results: Of the total sample of 4846 participants, 59% (n=2852) were adolescent boys aged 15-19, while 41% (n=1994) were young men aged 20-24. The prevalence of lifetime HIV testing was 60% (n=2896).

Adolescent boys were 77% less likely to report ever testing for HIV (OR: 0.27, 95% CI: 0.22-0.32) compared to young men. ABYM who reported paying for sex in the last 12 months were 41% less likely to report a lifetime HIV test (OR: 0.59, 95% CI: 0.45-0.76) than ABYM who did not report paying for sex in the last 12 months.

Lastly, ABYM did not use condoms with their most recent sexual partner had 53% lower likelihood of reporting a lifetime HIV test (OR: 0.47, 95% CI: 0.39-0.57) compared to ABYM who used condoms with their most recent sexual partner.

Conclusions: Our findings identified two key sub-populations among ABYM who have low HIV testing uptake:

1. ABYM who reported high-risk sexual behaviours were less likely to test for HIV than ABYM who reported lower risk sexual behaviours;
2. Adolescent boys were less likely to test for HIV than young men.

These findings highlight a critical gap in HIV prevention and care services targeting these sub-populations. Interventions that reduce barriers to testing and promote safer sexual practices among these sub-populations are required.

EP0427

Leaving no one behind: integrating LGBTIQ+ into key population HIV/SRH programming in Homabay County, Kenya

E.C.O. Okal[1], D. Pinye[2], B. Kadiam[3]
[1]Edward Corneleous Odhiambo Okal, Health, Homabay, Kenya, [2]Ministry of Health, Health, Homabay, Kenya, [3]Centre for Study for Adolescence, Health, Homabay, Kenya

Background: Lesbian, Gay, Bisexual, Transgender, Intersex and queer people (LGBTIQ+) often encounter stigma from healthcare providers and communities due to their nonconforming sexual orientation and gender identity. Stigma poses a significant barrier to accessing HIV prevention services. Kenya's Key Population program focusing on sex workers, Men having sex with men (MSM), and transgender individuals, *other LGBTQ+ communities are excluded.*

Homabay County reported 7,463 Female Sex Workers (FSWs) and 2,432 MSM on follow-up in the Key Population (KP) program in 2024. This abstract highlights a success story of enhanced HIV prevention access for the LGBTQ+ community achieved through integration into the existing key population program in two sub counties.

Description: To improve accessibility to HIV prevention services for LGBTQ+ communities, Ministry of health (MOH) and Centre of Study for adolescence (CSA), under the Equal Rights, Equal Access program, trained 52 healthcare providers from two sub counties in Homabay County in delivering non-discriminatory and stigma-free HIV prevention services. The trained providers then disseminated the acquired knowledge at the facility and community level using the 'Leave No One Behind' curriculum. Communities through support of CSA identified peers for each LGBTIQ+ typology, fostering peer-led empowerment sessions. These peers facilitated referrals and ensured linkage to healthcare facilities and existing KP drop in centers. Furthermore, CSA developed gender-inclusive tools for monitoring SRH/HIV indicators and conducts monthly performance reviews with all stakeholders.

Lessons learned: Peers have effectively reached at least 1,258 LGBTIQ+ persons, with HIV risk reduction information and linkage to health facilities. A total of 778 were referred for PREP and SRH services, encompassing 26 Gender Fluid, 110 Gender Non-conforming, 418 Men, 4 Transgender, and 220 Women. Within the referred group, gay men constituted 40%, Lesbians comprised 28%, bisexual individuals 25%, and 7% identified as queer.

This initiative marks a significant stride towards inclusivity for sexual and gender minorities, ensuring that every individual has equal rights and equal access to HIV Prevention services.

Conclusions/Next steps: Integration of LGBTIQ+ risk reduction within the Key population program is achievable. Integration can help reduce cost due to shared safe space. Sensitization of healthcare providers on provision of non-judgmental care is key to program success

EP0428

Low uptake of oral daily PrEP among men who have sex with men in Thai Nguyen, Vietnam, 2022: identifying barriers and opportunities to enhance access

T. Pham[1], M. Nguyen[2], H. Nguyen[1], K.-A. Le[3], C. Pham[3], L. Do[3], Q. Nguyen[2], T. Duong[2], M. Shah[2], P. Nguyen[1], H. Hoang[1], H. Ngo[1], N. Hoang[1], D. Bui[4]

[1]National Institute of Hygiene and Epidemiology, Ha Noi, Viet Nam, [2]U.S. Centers for Disease Control and Prevention, Ha Noi, Viet Nam, [3]Provincial Center for Disease Control and Prevention of Thai Nguyen, Thai Nguyen, Viet Nam, [4]Vietnam Administration of HIV/AIDS Control, Ministry of Health, Ha Noi, Viet Nam

Background: HIV prevalence among men who have sex with men (MSM) in Vietnam has increased significantly in recent years. While oral daily pre-exposure prophylaxis (PrEP) effectively reduces HIV risk, the factors influencing its use among MSM in Vietnam remain unclear.

This study examined the prevalence of, and factors associated with, daily oral PrEP use among MSM to inform targeted prevention strategies.

Methods: A cross-sectional bio-behavioral survey was conducted from October-November 2022 in Thai Nguyen, using respondent-driven sampling (RDS). Eligible participants were individuals assigned male at birth, aged ≥16, who had engaged in anal intercourse with another man in the past 12 months.

Data on demographics, sexual behaviors, substance use, and HIV service utilization were collected via interview administered questionnaires. Daily oral PrEP use was defined as either currently using, or having ever used, daily PrEP within the past 12 months. Multivariate logistic regression, adjusted for RDS weighting, was performed using R software to identify potential associations.

Results: Among 286 HIV-negative MSM participating in the survey, 9.9% (95%CI: 6.0%-13.7%) reported using daily PrEP within the past 12 months. In multivariate logistic regression models, MSM aged 25 years or older had higher odds of PrEP use than those aged 18-24 years (adjusted odds ratio [aOR]: 4.13; 95%CI: 1.08-15.75).

Those with a college/university education or higher were less likely to use daily PrEP than those with a high school education or lower (aOR: 0.26; 95% CI: 0.07-0.96).

Married individuals had higher odds of using PrEP compared to singles (aOR: 6.64; 95% CI: 1.38-32.08). Being recently screened/tested for sexually transmitted infection (STI) (for symptoms, screening or any reason) (aOR: 16.67; 95%CI: 5.55-56.27) and history of drug use (aOR: 6.60; 95% CI: 1.72-25.35) were positively associated with PrEP use.

Conclusions: This study indicates a low level of daily PrEP uptake within the past 12 months among MSM in Thai Nguyen. Individuals recently screened for STIs, or with a history of drug use, were more likely to use PrEP, suggesting opportunities to leverage these services to enhance access.

Further research could provide valuable insights into barriers to PrEP uptake, focusing on MSM subgroups with higher-risk behaviors.

EP0429

The role of PEPFAR's DREAMS (determined, resilient, empowered, AIDS-free, mentored, and safe) program in pre-exposure prophylaxis (PrEP) rollout and scale-up among adolescent girls and young women

K. Mills[1,2], N. Naqvi[1], M. Davis[1], N. Wadhwa[1], E.K. Dokubo[1]

[1]U.S. Department of State, Bureau of Global Health Security and Diplomacy, Washington, DC, United States, [2]U.S. Agency for International Development, Global Health Bureau, Washington, DC, United States

Background: Despite substantial declines in new HIV acquisitions globally, the HIV pandemic continues to disproportionately impact adolescent girls and young women (AGYW) in many countries.

To address this disproportionate risk for HIV acquisition, there is a need for effective HIV prevention and service delivery options to facilitate PrEP uptake and continuation among AGYW.

Description: PEPFAR implements the DREAMS program in the highest HIV burden districts in 15 countries. DREAMS provides a comprehensive package of core interventions to address key factors that make AGYW particularly vulnerable to HIV.

PrEP is a critical component of a multi-pronged approach to HIV prevention; however, AGYW face multiple barriers to accessing PrEP, including fear of disclosing PrEP-use to partners, difficulty accessing healthcare services, limited social support, and gender-based violence (GBV).

To address these issues, a key component of the DREAMS program involves PrEP education, service delivery, and peer support to provide an effective platform for PrEP uptake.

Lessons learned: DREAMS is implemented in 133 of a total 861 PEPFAR-supported subnational units that provide PrEP. DREAMS strategies to support access and effective uptake of PrEP include provision of integrated and youth-responsive health services in facilities and community outreach models, offering HIV and GBV services, and support through peer-to-peer mentorship for DREAMS participants.

Using FY21-24 PEPFAR Monitoring, Evaluation, and Reporting (MER) data, we assessed PrEP initiations among AGYW. Across PEPFAR-supported countries, AGYW in DREAMS districts accounted for a higher amount of PrEP initiations compared to those in non-DREAMS districts (*Figure 1*).

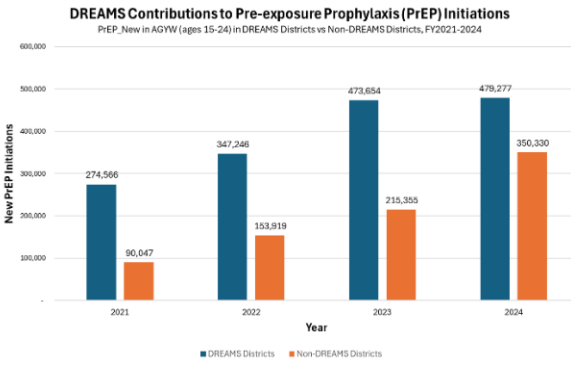


Figure 1.

Conclusions/Next steps: PEPFAR's DREAMS program provides an effective platform and approach for PrEP scale-up.

With promising new biomedical prevention options such as Lenacapavir on the horizon, it's critical that HIV programs build off the lessons learned and utilize structures in place, such as those implemented via DREAMS, to increase uptake and continuation of PrEP and other HIV prevention options among AGYW.

EP0430

Correlates of non-adherence among current HIV PrEP users in Brazil, Mexico and Peru: results from a 2024 on-line survey

C.F. Caceres[1], H. Vega-Ramirez[2], K.A. Konda[1,3], T.S. Torres[4], J. Qquellón[1], R. Robles-García[2], P. Luz[4], B. Hoagland[4], C. Pimenta[4], M. Benedetti[4], V. Veloso[4], B. Grinstejn[4], ImPrEP Study Collaborative Group

[1]Universidad Peruana Cayetano Heredia, Center for Interdisciplinary Studies in Sexuality, AIDS and Society, Lima, Peru, [2]Instituto Nacional de Psiquiatría Ramon de la Fuente Muñiz, Division of Epidemiology and Psychosocial Research, Mexico City, Mexico, [3]University of Southern California Keck School of Medicine, Division of Disease Prevention, Policy and Global Health, Department of Population and Public Health Sciences, Los Angeles, United States, [4]Fundação Oswaldo Cruz (INI-Fiocruz), Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil

Background: While oral HIV PrEP is now being scaled-up in Latin America, suboptimal adherence continues to reduce program effectiveness and should be addressed. We assessed frequency, distribution and correlates of PrEP non-adherence among sexual and gender minorities (SGM) in Brazil, Mexico and Peru.

Methods: We conducted an online, cross-sectional survey (August-November 2024) among SGM aged 18+ years. Individuals not living with HIV were asked about current PrEP use, and current users were asked to estimate their adherence to PrEP.

To explore factors associated with non-adherence (adherence <95%) we included age, country, education, income, race/ethnicity, depression (PHQ-9 score), homonegativity, number of sex partners, recent chemsex, and sex with partners living with HIV in a multivariate Poisson regression model.

Results: Among 9257 subjects not living with HIV (Brazil: 65.5%; Mexico: 24.6%; Peru: 9.9%), 2380 (25.7%, 95%IC 24.8-26.6%) were currently using PrEP. PrEP non-adherence was reported by 704 (30.3%) and varied considerably by country (Brazil: 25.0%; México: 54.2%; Perú: 28.5%).

PrEP non-adherence was significantly associated with being from Mexico, having secondary education or less, lower income, higher self-perceived HIV risk, and recent chemsex (all adjPRs and 95%CIs in Table).

Characteristics	PrEP non-adherence adjPR [95% CI]*
Country (Ref Brazil)	
Mexico	1.90 [1.55-2.35]
Peru	0.99 [0.71-1.38]
Education (Ref: secondary or less)	
More than secondary	0.76 [0.59-0.98]
Monthly income (Ref: <1 minimum wage)	
> 1 to 2 minimum wages	0.89 [0.68-1.17]
> 2 to 6 minimum wages	0.76 [0.59-0.97]
> 6 minimum wages	0.81 [0.62-1.17]
Perceived HIV risk	1.05 [1.03-1.06]
Recent Chemsex	1.16 [1.07-1.49]

*Multivariate prevalence ratios were also adjusted for age, race, depression, homonegativity, number of sex partners, and sex with people living with HIV

Table: Sociodemographic and behavioral factors associated with PrEP non-adherence among SGM currently using PrEP in Brazil, Mexico and Peru, 2024.

Conclusions: PrEP non-adherence was reported by nearly 1/3 of current users in Brazil, Mexico and Peru. Highly prevalent non-adherence fundamentally affects the effectiveness and efficiency of PrEP implementation and should be addressed. Hence, PrEP scale-up should monitor the frequency of non-adherence and consider implementing activities to support users maintain/improve adherence. Users facing context-specific barriers, and members of more marginalized groups such as those with lower income and/or education, or involved in chemsex, may require additional intervention.

EP0431

Higher levels of alcohol use are associated with increased HIV risk among persons at alcohol-serving venues in the OPAL trial in Kenya and Uganda

B. Beesiga[1], J. Litunya[2], J. Z. Nakato[3], J. A. Agola[2], K. Marson[4], E. W. Mugoma[2], P. Agaba[1], J. Temple[4], J. Schwab[4], C. S. Camlin[4], S. B. Shade[4], J. Hahn[4], E. Kakande[1], J. Kabami[1], M. L. Petersen[3], D. V. Havlir[4], L. B. Balzer[3], J. Ayieko[2], M. R. Kamya[1], G. Chamie[4], OPAL-East Africa Trial Team

[1]Infectious Diseases Research Collaboration, Health, Kampala, Uganda, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]University of California, Berkeley, Berkeley, United States, [4]University of California, San Francisco, California, United States

Background: Alcohol-serving venues represent sites of high HIV transmission risk due to unhealthy alcohol use and co-location of persons with increased risk of HIV and untreated HIV. We examined how HIV risk, sexual risk behaviors and untreated HIV varied by levels of alcohol use among persons recruited from alcohol-serving venues in rural East Africa.

Methods: We conducted a cross-sectional analysis at baseline (2023-2024) of a cluster-randomized trial (NCT05862857) of strategies to promote biomedical HIV prevention uptake among adults from alcohol-serving venues in eight communities (~10,000 persons/community) in Kenya and Uganda. Using recruitment cards, we invited patrons and workers (≥18 years) for free HIV

screening at nearby health facilities with referral to HIV prevention (PrEP/PEP) or antiretroviral therapy (ART). We evaluated associations between levels of alcohol use by past-3-month Alcohol Use Disorders Identification Test-Consumption (AUDIT-C) score (no/low-alcohol:0-2 women/0-3 men; medium:3-5 women/4-5 men; high:6-7; very-high:8-12) and self-reported HIV risk among persons without HIV or untreated HIV among persons with HIV (PWH), adjusting for age, sex, and country and accounting for clustering by venue.

Results: At 480 venues, we distributed 9375 recruitment cards: 7744 (83%) participants linked for screening (Kenya:4042; Uganda:3702). Median age 34 years, 2970 (38%) women, 91% patrons, and 4107 (53%) reported unhealthy alcohol use: 26% medium, 11% high, and 16% very high. 6124 (79%) tested HIV-negative of whom 2285 (37%) reported increased HIV risk. Increasing alcohol use was associated with significantly higher odds of HIV risk and sexual risk behavior *(Table)*.

Of persons screened, 1620 (21%) were PWH, of whom 14% had untreated HIV [141 (9%) newly diagnosed and 78 (5%) previously diagnosed PWH not on ART]. Levels of alcohol use were not associated with untreated HIV among PWH.

	Adjusted odds ratio (95%CI) by unhealthy alcohol use level, relative to no/low use		
	Medium	High	Very high
Self-reported HIV risk	1.36 (1.19-1.55)	2.07 (1.73-2.47)	2.12 (1.81-2.49)
Partner unknown status	1.28 (1.11-1.46)	1.93 (1.61-2.32)	2.17 (1.85-2.55)
Multiple partners	1.49 (1.21-1.83)	2.91 (2.26-3.74)	3.10 (2.47-3.89)
Transactional sex	1.35 (1.03-1.77)	2.89 (2.17-3.86)	3.70 (2.84-4.82)
Sexually transmitted infection	1.24 (0.86-1.80)	2.89 (1.95-4.26)	4.90 (3.47-6.92)
Untreated HIV (among PWH)	1.12 (0.77-1.62)	1.18 (0.74-1.89)	0.89 (0.57-1.38)

Conclusions: Increasing levels of alcohol use are associated with self-reported HIV risk and risk behaviours. Our findings highlight the need for interventions to reach, engage and reduce alcohol use among adults at alcohol-serving venues.

EP0432

Reaching the unreached: a gender-sensitive approach to HIV prevention and care for spouses of PWID in Pakistan

U.EA. Mir[1], Y. Akhtar[1], S. Qureshi[2], M. Zafar[2]
[1]*Nai Zindagi, Program Department, Islamabad, Pakistan,*
[2]*Nai Zindagi, Islamabad, Pakistan*

Background: The HIV epidemic in Pakistan remains concentrated among key populations, necessitating targeted programmatic efforts for people who inject drugs (PWID), transgender individuals, and sex workers. Spouses and partners of PWID, identified in 2008 as a leading "bridge population," require focused interventions due to their increased vulnerability to HIV. However, engaging this dispersed and socially integrated group within communities has been challenging.

Description: To address the unique needs and vulnerabilities of the spouses of PWID, Nai Zindagi (NZ) implements a gender-sensitive *Spouses Prevention Program.* With the written consent of HIV-positive PWID, female outreach workers provide services in the privacy and safety of the spouses' homes. This includes counseling, condom distribution, HIV and HCV rapid testing, and quarterly nutritional support for eligible families. For spouses diagnosed with HIV, the program offers critical interventions, such as facilitating the testing of their children—a vital step in a country with low antenatal HIV testing coverage.

Female outreach workers also provide comprehensive case management, support for treatment initiation and adherence at public HIV clinics, and accompaniment services. For spouses who test negative, the program promotes biannual HIV retesting to ensure continued prevention.

Lessons learned: Since its inception in 2012, the program has enrolled 12,630 female spouses, 70% of whom were between the ages of 18 and 35. Of those enrolled, 77% were tested and informed of their HIV status, with an HIV prevalence rate of 10% observed among this group.

Additionally, the program tested 1,777 children (ages 0–18) of HIV-positive mothers, identifying 102 children as HIV-positive during initial testing. In 2024 alone, the program reached 6,457 spouses, including 3,899 tested for HIV, providing a comprehensive suite of prevention, testing, treatment, and care services across 62 districts in Pakistan.

Conclusions/Next steps: This program has demonstrated an effective and innovative approach to engage a previously underserved population, fostering safer practices, and ensuring timely linkage to care.

To further enhance the impact, the addition of pre-exposure prophylaxis (PrEP) to the existing service package is strongly recommended. Such measures would strengthen HIV prevention efforts and support the broader health and well-being of this vulnerable group.

EP0433

Engaging male sexual partners: the MASTER approach to reducing HIV among young women

M.E.A. Kouassi[1], M. Kouadio[1], A. Dalie[1]
[1]*OGRADIE, Abidjan, Côte d'Ivoire*

Background: Côte d'Ivoire faces a significant HIV burden, with 8,978 new cases reported in 2022, 62.8% of which were among women. Adolescent Girls and Young Women (AGYW) are particularly vulnerable, and men, with a 1.1% prevalence rate, play a critical role in transmission. The DREAMS SOUNGOUROU FARIMA project, through its MASTER (Men for AGYW Support, Trust, Engagement and Resilience) approach, aims to involve male sexual partners (MSPs) of AGYW in HIV prevention efforts. By raising awareness, reducing risk behaviors, and improving access to healthcare, the project targets in Abidjan.

Description: The MASTER approach is a strategy that integrates male sexual partners of AGYW to strengthen HIV prevention efforts. It begins by enrolling AGYW aged 20 to 24, followed by the identification and enrollment of their MSPs with their consent. These partners then participate in weekly sessions organized by age group, focusing on topics such as HIV prevention, sexual health, and risk

behaviors. The approach is grounded in the SASA (Start, Awareness, Support, Action), which aims to raise awareness, shift behaviors, and provide biomedical support, including referrals to specialized healthcare facilities. Safe spaces are established to maintain confidentiality and encourage active engagement.

Lessons learned: The approach has exceeded expectations, with the number of MSPs enrolled increasing from 5,424 to 8,124. This outcome highlights the positive impact of involving men in HIV prevention efforts, benefiting AGYW directly. Engaging MSPs helps reduce risky behaviors, providing greater protection for AGYW. By encouraging sustainable behavior change in men, the approach fosters a safer environment for AGYW and accelerates progress in the fight against HIV.

Conclusions/Next steps: Involving MSPs is crucial for effective HIV prevention. The MASTER approach, which combines biomedical, behavioral, and structural interventions tailored to local contexts, has proven successful. The next steps include strengthening SASA sessions and guiding men toward specialized healthcare. This initiative underscores the importance of male involvement in accelerating the fight against HIV/AIDS.

EP0434

Demographic and clinical outcomes of pregnant women living with HIV, and associated STBBI co-infections, and their infants in Saskatchewan, Canada – A Mother-Child Dyad mixed-method study

C. Spence[1,2,3], M. Zettl[1], Z. Ali[1], T. Lee[3], K. Gartner[2,1], A. McConnell[4,1]

[1]University of Saskatchewan, Medicine, Saskatoon, Canada, [2]Westside Community Clinic, Saskatoon, Canada, [3]CIHR Canadian HIV Trials Network, Vancouver, Canada, [4]Saskatchewan Health Authority, Saskatoon, Canada

Background: Saskatchewan (SK) continues to record the highest HIV incidence rates in Canada. Since 2020, epidemiological trends have shifted from intravenous drug use (IVDU) to heterosexual transmission as a primary HIV risk factor. In 2023, women of childbearing years represented 62% of new diagnoses. Between 2020-2023, 7 infants were born with HIV in SK.

This study reports the rates of HIV, syphilis and HCV co-infections and associated health outcomes among women living with HIV (WLWH) and their infant dyads in central and northern SK, Canada.

Methods: A retrospective chart review of 184 pregnant WLWH and 180 live infant dyads was conducted from January 1, 2018, to December 31, 2023. Descriptive variables, testing, treatment, and laboratory trends across periods were extracted. Three time periods were analyzed and compared: T1=Jan.1, 2018–Dec. 31, 2019; T2=Jan.1, 2020–Dec. 31, 2021; T3=Jan.1, 2022–Dec. 31, 2023. Qualitative data were collected through sharing circles and semi-structured interviews. Data was analyzed and coded using NVivo 14, providing insights into WLWH's experiences during pregnancy and seeking and accessing prenatal care and perinatal follow-up within the health system.

Results: Data demonstrates a sharp increase in HIV/syphilis co-infection (T1=0%; T3=26%) and the rise of women with IVDU (T1=55%; T3=64%), with a corresponding reduction of opiate substitution therapy (T1=76%; T3=57%). Infant clinical outcomes and retention in care were correlated with WLWH social and clinical outcomes, with 33% lost to follow-up. Qualitative data identified barriers and facilitators to accessing care, including reasons for disengaging from follow-up care. Barriers included ongoing experiences of stigma, breaches of confidentiality, and restrictive policies. Trusted community spaces, such as harm reduction drop-in centres and culturally responsive wrap-around care approaches, provide critical linkage to care and ongoing support for many WLWH in pregnancy and after birth.

Conclusions: The increasing rates of HIV and co-infections among women of childbearing age in SK underscores the necessity for targeted strategies to reduce infections and vertical transmission risk for infants. Preventing vertical transmission and receiving treatment for addictions and co-infection(s) are critical for maternal and infant clinical outcomes.

EP0435

Prevalence and factors associated with viral load suppression among adolescents living with HIV in Rwanda, 2019-2021

H.V. Mucunguzi[1], A. Ndagijimana[2], J. Ntaganira[2], H.A. Mugisha[1], M.V. Umubyeyi[1], G. Mujawamariya[1], G. Gatete[1], G. Rwibasira[1], S. Nsanzimana[3]

[1]Rwanda Biomedical Centre, HIV/AIDS Disease Prevention and Control, Kigali, Rwanda, [2]University of Rwanda, Kigali, Rwanda, [3]Ministry of Health, Kigali, Rwanda

Background: The goal of antiretroviral therapy is to achieve sustained human immune deficiency virus (HIV) viral suppression. However, research on the prevalence and factors associated with viral load suppression among adolescents in low and middle-income countries is limited.

The objectives of this study were to determine the prevalence and factors associated with viral load suppression among adolescents living with HIV in Rwanda.

Methods: A retrospective study used data from all public health facilities in Rwanda providing services to Adolescents Living with HIV (ALHIV) and who are regularly reporting in Viral Load Sample Management System (VLSMS) from January 2019 to December 2021. Binary logistic regression was used to determine factors that influence viral load suppression among participants, then Odds Ratios (ORs) and 95% C.I were reported. Results were significant at 95% confidence level. Data were analysed using STATA software version 16.

Results: Out of 10,615 participants, 86.9% had achieved HIV viral suppression (<1,000 copies of viral RNA/mL of blood). After adjusting for other covariates, adolescents with good adherence to ART (AOR=4.5, 95% C.I: 3.6-5.7), receiving care and treatment at hospital level (AOR=1.3, 95% CI=1.1-1.5), between the age of 15 to 19 (AOR=1.1, 95% CI=1.0-1.3), receiving second or line ART regimen (AOR=0.4, 95%

CI=0.3-0.4), residing in Western province (AOR=0.7;95% CI: [0.5-0.9]; p=0.01), and Eastern province (AOR= 0.7; 95% CI: [0.6-0.9]; p=0.026) were significantly associated with viral load suppression in ALHIV.

Conclusions: The findings indicate that viral suppression among ALHIV on ART was at 86.9% and this proportion is below the UNAIDS 2030 target set at 95%. The findings indicate that having good adherence to ART, receiving care from hospital level, being an adolescent between the age of 15 to 19 contribute in attaining viral load suppression. However, ALHIV on 2nd or 3rd line treatment have a risk of viral load non suppression.

Strengthening adherence and support program, care and treatment programs at health centre level, development of age and location-appropriate interventions and an individualized care support for ALHIV on 2nd or 3rd line ART regimen are the main recommendation of this study

EP0436

Prevalence of STIs among adolescent girls and young women (AGYW) in the DREAMS Program in the Ugandan military

J. Ngabirwe[1], A. Tumusiime[1], G. Arinaitwe[2], E. Asiimwe[2], D. Bwayo[1], T. Rwegyema[1], H. Tibihenda[3]

[1]URC, Kampala, Uganda, [2]Uganda People's Defense Forces, Directorate of HIV, Kampala, Uganda, [3]Uganda US Embassy, Department of Defense, Kampala, Uganda

Background: PEPFAR's Determined, Resilient, Empowered, AIDS-free, Mentored, and Safe (DREAMS) program aims to reduce high HIV transmission rates among adolescent girls and young women (AGYW) aged 10-24 years. In Uganda, young people aged 15-24 years represent 25% of the population, but account for half of all new sexually transmitted infection (STI) cases.

The DREAMS program provides a comprehensive package of evidence-based interventions, addressing factors contributing to AGYW's vulnerability to HIV. This abstract compares the outcomes of AGYW STI screening at program entry and six months into the program.

Description: With funding from the Department of Defence HIV/AIDS Prevention Program (DHAPP), URC implemented DREAMS interventions at two Ugandan military bases. STI screening was conducted using the syndromic approach with standard Ministry of Health tools at pre- and post-service.

Raw data from the Uganda DREAMS and Orphans Tracking System were analyzed descriptively to assess changes in STI positive screen results between baseline data and six months post DREAMS interventions.

Diagnosis required two or more affirmative responses to questions – partner with STI treatment in the last eight weeks; vaginal discharge; pain during intercourse; genital itching; genital ulcers; and lower abnormal pain.

Lessons learned: Over two Fiscal Years (FYs), 1,865 AGYW were screened for STIs, with a prevalence of 42% (780/1,865). STI prevalence decreased significantly from 55% in FY23 to 29% in FY24. The highest prevalence was observed in the 20–24 age group, accounting for 57% (293/513) in FY23 and 63% (169/267) in FY24, with a mean age of 22 years.

Symptom patterns shifted over time, with lower abdominal pain increasing from 61% (313/513) in FY23 to 88% (234/267) in FY24 and self-reported vaginal discharge decreasing from 61% (313/513) to 52% (140/267). Partner STI testing improved slightly, rising from 2.3% (12/513) in FY23 to 6% (16/267) in FY24. Six months post-intervention demonstrated a 0% prevalence across the fiscal years, highlighting the interventions' effectiveness – linkage for treatment; condom promotion on correct and consistent use; and integrated HIV and STI prevention curricular-based messages.

Conclusions/Next steps: STI prevalence among high-risk AGYW is high in these two districts, highlighting the need for comprehensive targeted STI screening, surveillance, and treatment programs.

EP0437

Expanding access to the prevention of vertical transmission services to distant communities in achieving epidemic control of HIV in Southern Nigeria

O. Ibitoye[1], O. Majekodunmi[2], A. Dorayi[1], O. Ogungbade[3], O. Adegbite[2], O. Ebiekura[1], K. Ikopbo[1], C. Efedionye[1], A. Ezeadikwa[2], O. Bartholomew Boniface[2], C. Umeh[2], S. Bello[4], L. Modey[5], T. Usha[6], O. Igboelina[7], D. Ogundehin[7]

[1]Pathfinder International, Maternal and Child Health, Lagos, Nigeria, [2]Heartland Alliance, Technical, Lagos, Nigeria, [3]West Africa Center of Public Health and Development, Research, Lagos, Nigeria, [4]Pathfinder International, Maternal and Child Health, Abuja, Nigeria, [5]University of Liverpool, Data Science, Liverpool, United Kingdom, [6]USAID, PMTCT, Abuja, Nigeria, [7]USAID, Care and Support, Abuja, Nigeria

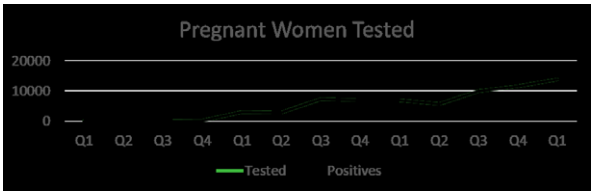
Background: Globally, Nigeria has the highest number of new HIV diagnoses among children, with less than 50% Prevention of Mother to Child Transmission (PMTCT) of HIV coverage, according to National Agency for the Control of AIDS (NACA fact sheet, 2016). Achieving epidemic control of HIV would require PMTCT services to reach the unreachable population in low-resource settings.

This study describes a program's experience in strengthening health systems and addressing inequities in access to PMTCT services in distant communities in three Southern Nigerian states.

Description: A package of interventions on health system strengthening and equity was designed to improve the uptake of these services in the three states: provision of essential products for testing, expanded service delivery through congregational approaches, improved collaboration with religious houses on governance, improved model of reporting on health management information system.

Implementation of the integrated service delivery commenced in January 2023. Analysis of HIV testing data among pregnant women abstracted from DHIS was conducted using Excel and were analyzed on a quarterly trend. A chi-square test was used to compare the proportions across quarters. The review covered January 2022 to December 2025.

Lessons learned: In 2022, 5961 women were tested, 47 positives identified, this increased in 2023, with 29,601 tested, 107 positives diagnosed, upward increase was seen In 2024, with 35,392 tested, and 104 positives identified, at a total of 67,963 screened, 196 women identified with positive results, (80(31%) are previously known clients, 178(69%) are new clients), with a positive screening test of 0.4%. The difference in proportions across the period was statistically significant(p<0.001). The positives were all linked to antiretroviral therapy (ART).



Conclusions/Next steps: There was an increase in testing numbers of pregnant women after the intervention, with increase in positives identified within the same period. This approach is recommended across unreachable communities while optimizing sustainable approaches across all facilities.

EP0438

Trends in maternal HIV testing after first antenatal visit and PrEP uptake among pregnant and breastfeeding women in five PEPFAR-supported countries during fiscal year 2024

M. Zavila[1], E.K. Dokubo[1], T. Bingham[1], M. Chevalier[1]
[1]Bureau of Global Health Security and Diplomacy, Washington, United States

Background: In 2023, 24% of new infant HIV acquisitions resulted from incident maternal HIV transmissions during pregnancy and breastfeeding, and half occurred after the first six weeks of life. Reduction of vertical transmission (VT) relies on rapid identification of new HIV acquisitions in pregnant and breastfeeding women (PBFW) with immediate linkage to antiretroviral therapy or linkage to HIV combination prevention services, including pre-exposure prophylaxis (PrEP) for PBFW who are HIV-negative. The United States President's Emergency Plan for AIDS Relief (PEPFAR) has scaled maternal retesting to achieve UNAIDS targets by accelerating the reduction in VT in countries with the highest burden of HIV in infants.
Methods: Routine PEPFAR programmatic data were analyzed across five PEPFAR-supported countries (Kenya, Mozambique, Tanzania, Uganda and Zambia) in fiscal year 2024 (FY24). Monitoring indicators for HIV retesting include women who tested during pregnancy or labor and delivery (P/L&D), or while breastfeeding (BF) after their first ANC visit (postANC1). Disaggregates were analyzed for individuals newly initiated on PrEP and those re-initiating PrEP to determine PrEP uptake among HIV-negative PBFW.
Results: In FY24, PEPFAR administered 5,748,244 postANC1 HIV tests across the five focus countries, representing 65% of all postANC1 testing in 22 PEPFAR-supported countries with VT programming. From FY24 Q1 to Q4, postANC1 testing volume was highest during P/L&D (3,416,331) compared to BF (2,331,913); however, there was a greater increase in postANC1 during BF (41%) compared to P/L&D (27%) by Q4. Cumulatively, there were 123,040 new PrEP enrollments among PBFW, representing 77% of new enrollments in PEPFAR-supported countries with VT programming in FY24. New PrEP enrollment increased by 26% among PBFW between FY24 Q1 and Q4, while PrEP re-initiation increased by 44%. Of the five countries from Q1 to Q4, Uganda had the largest increase in postANC1 testing (+46% for P/L&D and +59% for BF); Zambia had the highest increase in PrEP re-initiation (+38%).
Conclusions: Maternal HIV retesting scale-up contributed to modest increases in PrEP re-initiation for PBFW at risk of HIV acquisition. Intensified efforts to scale up maternal HIV retesting and linkage to available PrEP options is essential to accelerate progress in reducing VT in areas with high HIV burden.

EP0439

Road to elimination of vertical transmission: optimizing Maternal retesting to identify seroconversion among Women in Southern Nigeria

O. Ibitoye[1], O. Majekodunmi[2], A. Dorayi[1], O. Ogungbade[3], O. Adegbite[2], K. Ikopbo[1], C. Efedionye[2], O. Ebiekura[1], A. Ezeadikwa[2], N. Agboola[2], C. Umeh[2], O. Bartholomew Boniface[2], T. Usha[4], D. Ogundehin[5], L. Modey[6], N. Nsungwara[2], J.P. Mbah[2], D. Zekeri[2], O. Kanu-Orji[2], L. Joram[7], B. Airiagbondu[2]
[1]Pathfinder International, Maternal and Child health, Lagos, Nigeria, [2]Heartland Alliance, Technical, Lagos, Nigeria, [3]West Africa Center of Public Health and Development, Research, Lagos, Nigeria, [4]USAID, PMTCT, Abuja, Nigeria, [5]USAID, Care and Support, Abuja, Nigeria, [6]University of Liverpool, Data Science, Liverpool, United Kingdom, [7]Pathfinder International, Maternal and Child Health, Kenya, Kenya

Background: Maternal retesting for HIV can identify incident maternal HIV diagnosis and prevent vertical transmission. Despite recommendation by WHO and national guideline for management of HIV in Nigeria, implementation is still sub-optimal, at less than 50% PMTCT coverage, with data obtained from the National Agency for the Control of AIDS (NACA fact sheet, 2016).
This study describes the interventions done in strengthening health systems to improve uptake of maternal retesting among pregnant women over three years in three Southern Nigerian states (Lagos, Edo and Bayelsa).
Description: Health system building framework was used to improve the uptake of maternal retesting: Human resources and service delivery through orientation of designated personnel called PMTCT Nurses on the need for retesting; Information through integration of maternal retesting counselling at third trimester, and delivery to antenatal visit health talks; technology through creation of a custom indicator to monitor progress. Implementation of the framework started across all supported sites in

October 2023. Analysis of maternal retesting data among pregnant women in one hundred and seven comprehensive ART site was abstracted from DHIS using Excel from April 2022 to September 2024. A chi-square test was used to assess the significance of the observed trend for those tested and the positives identified.

Lessons learned: A total of 8,333 women were screened within the three years, with a positive screening test of 0.1%. The positives were all linked to antiretroviral therapy. Only 4% of Clients eligible for maternal retesting had testing done. Results showed a statistically significant increasing trend in the number of positives identified over the three years (p<0.01), seroconverted from 1 in 2022 to 2 in 2023 and 4 in 2024, while there was an increase in clients retested within the period from 1120 in 2022 pre-intervention, and this increased to 3400 in 2023, 3813 in 2024 after the intervention.

Conclusions/Next steps: There was an increase in positives identified among women who seroconverted after the initial negative test, with an increasing number of women retested within the same period despite a low coverage of maternal retesting. Maternal retesting needs to be improved while optimizing sustainable approaches across all facilities.

EP0440

Scoping field evaluation of peer-educator-based motivational interviewing on pre-exposure prophylaxis (PrEP) among key populations: a randomized implementation trial in Kisangani, Democratic Republic of the Congo

A. Tagoto-Tepungipame[1], S. Tonen-Wolyec[2], S. Batina Agasa[3], J. Losimba Likwela[1], L. Belec[4]

[1]University of Kisangani, Public Health, Kisangani, Congo, the Democratic Republic of the, [2]University of Bunia, Bunia, Congo, the Democratic Republic of the, [3]University of Kisangani, Kisangani, Congo, the Democratic Republic of the, [4]Laboratoire de Virologie, Hôpital Européen Georges Pompidou and Faculty of Medicine Paris Descartes, University of Paris Cité, Paris, France

Background: Oral pre-exposure prophylaxis (PrEP) is a validated tool for preventing HIV infection. Despite being in full expansion in several sub-Saharan African countries, adherence to PrEP remains mixed in the Democratic Republic of the Congo (DRC).

We herein evaluated in the field whether peer-educator-based motivational interviewing (PEMI) would be an intervention to increase PrEP adherence among users from key populations (female sex workers [FSWs], men who have sex with men [MSMs] and injecting drug users [IDUs]).

Methods: In this randomized non-inferiority trial, eligible participants were offered oral PrEP consisting of emtricitabine/tenofovir disoproxil fumarate (FTC/TDF) and were randomized 1:1 between an intervention group where the PEMI was systematically implemented among PrEP users or a control group with no-PEMI and followed up for 12 months. PrEP adherence was measured by receipt of drug box, self-reported use, observance and compliance with monthly appointments. Observance was based according to standardized observance questionnaire based on the Morisky model.

Results: Among 141 enrolled participants, 126 were eligible and only 113 (intervention [n=62] and control [n=51]) completed the follow-up period. Overall, adherence to PrEP was significantly increased in PrEP users receiving the PEMI (83% *versus* 52%, adjusted RR: 2.3 [95% CI: 1.6-7.8]).

Although there was no difference between the two groups in terms of receipt of the drug box and self-reporting of FTC/TDF use, observance (91% *versus* 62% adjusted RR: 4,3 [95% CI: 1,3-9,9]) and compliance to monthly appointments (88% *versus* 57% adjusted RR: 3,6 [95% CI: 1,7-8,1]) were significantly higher among users of peer-educator-based motivational interviewing.

Regarding inter-group differences in key populations, FSWs were the most adherent to PrEP compared to others, in both intervention and control study groups.

Conclusions: Taken together, these observations highlight for the first time in the cultural context of Central Africa, on the need for psychological support when PrEP is proposed over the long term.

Among the interventions to be implemented, motivational interviewing is a relevant avenue to be explored to facilitate adherence to PrEP in populations with high-risk behaviours, such as key populations.

HIV testing

EP0441

HIV recency testing coverage and partner notification services among newly diagnosed people living with HIV in low- and middle-income countries: a systematic review and meta-analysis

Y.T. Kilumbu[1], T.A. Peter[2], Z.M. Ally[3], H.M. Bakari[4], M.S. Mbwana[5], S.M. Salim[6], H.F. Fussi[7], H.M. Ally[2], I.A. El-Imran[8], T. Lascko[9,10], H.O. Ramadhani[9]

[1]Elizabeth Glaser Pediatric AIDS Foundation, Shinyanga, United Republic of Tanzania, [2]Kilimanjaro Christian Medical Center, Moshi, United Republic of Tanzania, [3]District Hospital, Tanga, United Republic of Tanzania, [4]University of Dar es salaam, Dar es salaam, United Republic of Tanzania, [5]Primary Health Care Institute, Iringa, United Republic of Tanzania, [6]Canada Youth Group, Dar es salaam, United Republic of Tanzania, [7]District Hospital, Dar es salaam, United Republic of Tanzania, [8]University of Maryland School of Medicine, Epidemiology, Baltimore, United States, [9]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [10]Center for International Health Education and Biosecurity, Baltimore, United States

Background: HIV recency testing provides data that can be used to monitor the trend of new HIV infections. The effectiveness of using people identified with recent infection to identify partners with new HIV infection through partner notification services (PNS) is not well document-

ed. We estimated the pooled prevalence of recency testing coverage, recent infection, reclassification (recent to long-term infection) and PNS cascade among newly diagnosed people living with HIV.

Methods: PubMed, Cochrane Library and Embase were searched for articles published between January 2018 and November 2024. Studies were included if they reported recency coverage and/or PNS among people newly diagnosed with HIV and used recent infection testing algorithm (RITA). Recency coverage was defined as proportion of people tested using rapid testing for recent infection (RTRI) among those newly diagnosed with HIV. RITA further classifies RTRI results using viral load results (≥1,000copies/mL vs <1,000 copies/mL) to confirm recency status. For studies with PNS, we evaluated the cascade: number of partners elicited, successfully contacted, eligible for HIV testing, tested and HIV diagnosis.

PNS effectiveness was measured by proportion of new HIV diagnoses from tested partners. Using random effects models, we computed the pooled estimate of recency outcomes and 95% confidence intervals (CIs).

Results: Sixteen studies from 17-low- and middle-income countries (LMICs) were included, of which 11-reported recency coverage only, 4-reported PNS only and 1-reported both coverage and PNS. Of 276,584 newly diagnosed people living with HIV, 80,383 underwent RTRI with an overall pooled recency coverage of 93%(95%CI 71– 99).

Pooled prevalence of RTRI and RITA recency was 9%(95%CI 7–12) and 5%(95%CI 3–8), respectively. Pooled prevalence of RTRI reclassification was 35%(95%CI 19–55). Of the recent cases who agreed to PNS, 253 partners were elicited with an estimated elicitation ratio of 1:1.6.

Among partners elicited, 99% were successfully contacted, 75% were eligible for testing, 68% tested for HIV, and 15% were diagnosed with HIV.

Conclusions: High recency testing coverage among newly diagnosed individuals demonstrates the feasibility of monitoring new HIV infections in LMIC. While PNS yielded a moderate HIV diagnoses, its targeted approach remains a critical strategy for identifying undiagnosed cases.

EP0442

Catalyzing pediatric treatment coverage through the OVC program between October 2022 – September 2024: a strategic pathway to closing the pediatric anti-retroviral treatment gap in Nigeria

O. Oke[1], A. Oluwatosin[2], J. Fagbamigbe[2], O. Ogbanufe[1], E. Folorunsho[1], J. Orjih[1], A. Fagbemi[3], J. Swanson[4], B. Alvarez[4], N. Flowers[4], D. Onotu[1], T. Efuntoye[2], J. Gwamna[5]

[1]Division of Global HIV and Tuberculosis, Global Health Center, Centers for Disease Control and Prevention, Continuum of Care and Treatment, Abuja, Nigeria, [2]Division of Global HIV and Tuberculosis, Global Health Center, Centers for Disease Control and Prevention, Prevention, Abuja, Nigeria, [3]Division of Global HIV and Tuberculosis, Global Health Center, Centers for Disease Control and Prevention, Monitoring and Evaluation, Data Analytics and Science, Abuja, Nigeria, [4]Division of Global HIV and Tuberculosis, Global Health Center, Centers for Disease Control and Prevention, DGHT, Atlanta, United States, [5]Division of Global HIV and Tuberculosis, Global Health Center, Centers for Disease Control and Prevention, Program, Abuja, Nigeria

Background: In Nigeria, the prevalence of HIV among children aged 0–14 years is 0.2%, representing an estimated 130,000–140,000 children living with HIV (CLHIV) in Nigeria. Of these, 34% know their HIV status, resulting in a huge pediatric treatment gap. In October 2022, the U.S. President's Emergency Plan for AIDS Relief introduced the Accelerating Progress in Pediatrics and Prevention of Mother-to-Child Transmission (AP3) program as a multi-prong approach to reach undiagnosed CLHIV. The Orphans and Vulnerable Children (OVC) program was leveraged to accelerate the identification and linkage to treatment of CLHIV in the community. This abstract evaluates the contribution of the OVC program to finding CLHIV.

Description: The OVC program plays a pivotal role in reaching CLHIV who are unaware of their HIV-positive status by utilizing trained community case managers (CCMs) who provide essential services to vulnerable households. These CCMs are strategically positioned within communities, making them effective in identifying CLHIV. Their capacity has been enhanced through training in HIV testing services (HTS) and innovative community-based strategies. CCMs utilize strategies such as family index testing, targeted outreaches, and AP3 congregational testing, ensuring targeted reach to children requiring HIV testing. These activities are coordinated by community-based organizations, which are integral to the OVC program's community implementation framework. To strengthen data collection and reporting, the program supported the development of the OVC module on Nigeria's National Data Repository Lite, a digital platform for data documentation.

Lessons learned: The capacity-building for the OVC case managers to conduct HTS and the availability of the reporting platform led to the OVC program supporting the testing of 216,035 children ages 0–14 years at the community level from October 1, 2022–September 30, 2024, identifying 844 CLHIV. This accounted for 13.2% overall

contribution to pediatric HIV case findings across all the CDC-supported sites during the same period. The findings underscore the benefit of community engagement, HTS training, and leveraging the OVC program reach in closing the pediatric treatment gap.

Conclusions/Next steps: The OVC program's contribution to pediatric HIV case finding through the AP3 model highlights its potential as a game changer in addressing Nigeria's pediatric HIV treatment gap.

EP0443

Low awareness and uptake of HIV self-testing among key populations in Unguja, Zanzibar, 2023

F. Khalid[1], M.J. Mtoro[2], J. Ndayongeje[2], S. Welty[3], C. Said[3], A. Ussi[1], N.J. Nyagonde[4], A. Kailembo[4], G. Mgomella[4], S.E. Porter[4], M. Khamis[5], A. Khatib[6]

[1]Ministry of Health, Zanzibar, United Republic of Tanzania, [2]Global Programs, Dar es Salaam, United Republic of Tanzania, [3]University of California, San Francisco, California, United States, [4]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Dar es Salaam, United Republic of Tanzania, [5]Zanzibar Integrated HIV, Hepatitis, TB, and Leprosy Programme, Zanzibar, United Republic of Tanzania, [6]Zanzibar AIDS Commission, Zanzibar, Tanzania, the United Republic of

Background: In Unguja Island, Zanzibar, a 2019 biobehavioral survey (BBS) identified that only 47.5%–72.5% of key populations (KPs), including female sex workers (FSW) aged ≥18 years and sexually exploited girls (SEG) (girls aged <18 years given money or products for sex), men who have sex with men (MSM), and people who inject drugs (PWID), living with HIV knew their status.

To address this gap, the Zanzibar Ministry of Health introduced evidence-based strategies including HIV self-testing (HIVST) services in 2021. Using a BBS conducted among KPs in Unguja, Zanzibar in 2023, we determined uptake of HIVST and willingness to use HIVST services.

Methods: We used respondent-driven sampling (RDS) to recruit KPs aged ≥15 years who lived in Unguja for ≥3 months and met inclusion criteria: FSW/SEG (exchanged sexual intercourse for money in the prior month), MSM (had anal sex with men in the past 3 months), and PWID (injected illicit drugs in the past 3 months). Information on HIVST knowledge, usage, and preference for HIV testing in general was collected through interviewer-administered questionnaires. We report weighted estimates and 95% confidence intervals (CI), accounting for RDS design.

Results: A total of 598 FSW/SEG, 485 MSM, and 455 PWID participated. Overall, 46.3% (95%CI: 42.9–49.8) of FSW/SEG, 29.5% (95%CI: 25.1–34.0) of MSM, and 25.4% (95%CI: 21.1–29.7) of PWID had heard of HIVST.

Among those who had heard of HIVST, 31.0% (95%CI: 25.1–36.6) of FSW/SEG, 23.6% (95%CI: 15.3–32.0) of MSM, and 9.6% (95%CI: 2.6–16.3) of PWID had used HIVST.

Among KPs who had never self-tested and excluding those living with HIV, 70.1% (95%CI: 66.2–75.1) of FSW/SEG, 70.4% (95%CI: 65.4–75.3) of MSM, and 68.6% (95%CI: 64.0–73.2) of PWID would use HIVST if offered to them by peers or healthcare workers.

Conclusions: We found low awareness and uptake of HIVST among KPs in Unguja despite broad interest in using HIVST after being given information. This suggests comprehensive promotion and scaling up of HIVST services could be an effective way to reach and diagnose more KPs living with HIV.

EP0444

Estimating the prevalence of reclassification of *recent* to *long-term* acquisition of HIV-1 using recent infection testing algorithm (RITA) – Tanzania, October 2023–September 2024

T.W. John[1], C. Said[2], W. Maokola[3], J. Alawi[2], A. Said[2], A. Wang[1], M. Masudi[2], J. Ndayongeje[2], A. Kailembo[1], U. Kategile[4], M.S. Abushir[5], A. Jahzzumi[5], G. King'ori[1], N. Kamugasha[6], O. Malewo[1], M. Makune[7], N. Moremi[8], S. Porter[1], L. Nicas[9], E. Mihayo[3]

[1]Division of Global HIV and TB, US Centers for Disease Control and Prevention (CDC), Dar es Salaam, United Republic of Tanzania, [2]University of California San Francisco (UCSF), Dar es Salaam, United Republic of Tanzania, [3]National AIDS, STIs and Hepatis Control Programme (NASHCoP), Ministry of Health, Dodoma, United Republic of Tanzania, [4]US Agency for International Development (USAID), Dar es Salaam, United Republic of Tanzania, [5]Zanzibar Integrated HIV, Hepatitis, TB and Leprosy (ZIHHTLP), Zanzibar, United Republic of Tanzania, [6]Management and Development for Health (MDH), Dar es Salaam, United Republic of Tanzania, [7]Walter Reed Army Institute of Research (WRAIR)/Department of Defense (DoD), Dar es Salaam, United Republic of Tanzania, [8]National Public Health Laboratory, Dar es Salaam, United Republic of Tanzania, [9]President's Office, Regional Administration and Local Government, Dodoma, Tanzania, the United Republic of

Background: A recent infection testing algorithm (RITA) uses a rapid test for recent infection (RTRI) and baseline HIV viral load (VL) to differentiate recent acquisition of HIV acquired within prior 12 months from longer-term acquisitions. Tanzania started implementing RITA surveillance in 11 regions in August 2023.

We calculated the proportion of RITA long-term reclassification and associated factors among HIV testing services (HTS) clients with RTRI-recent results in Tanzania.

Methods: We included data from consenting HTS clients from 204 of 275 health facilities in mainland Tanzania and Zanzibar collected between October 1, 2023–September 30, 2024, who also met the following criteria: aged ≥15 years; newly diagnosed with acquisition of HIV; with an RTRI-recent result; and available VL results.

Among clients with RTRI-recent results, those with HIV VL ≥1,000 RNA copies/mL were classified as RITA-recent and those with HIV VL <1,000 RNA copies/mL were reclassified as RITA-long term.

We calculated the proportion of RITA-long term reclassification and used frequency-weighted Poisson regression models to calculate adjusted prevalence ratios (aPR) with 95% confidence intervals (CI).

Results: Of 1,009 clients with RTRI-recent results, mean age was 31.4 years (range: 15–78 years) and 785 (77.8%) were women; of those, 358 (35.5%) were reclassified as RITA-long-term. Results adjusted for age, sex, region and testing point showed that RITA long-term reclassification was significantly higher among participants aged 15–24 (aPR: 1.25; 95% CI: 1.04–1.49) and ≥45 years (aPR: 1.36; 95% CI: 1.10–1.67) compared to participants aged 35–44 years; among women (aPR: 1.28; 95% CI; 1.09–1.50) compared to men; among participants who reported sexual partners living with HIV (aPR: 1.18; 95% CI; 1.03–1.36) compared to those who did not; and among male clients reporting sex with other men (MSM) (aPR: 1.72; 95% CI: 1.06–2.78) compared to those with female partners.
Conclusions: Over one-third of clients with RTRI-recent results were reclassified as RITA long-term. This suggests re-engagement into care for individuals with prior HIV diagnosis and a history of anti-retroviral therapy use. Although recency surveillance results are not returned to clients, thorough pre-test counseling screening might identify individuals re-engaging in care.

EP0445

Optimizing Pediatric Index Case Testing outcomes through Pediatric Accelerated Case Finding Effort's (PACE) family tree card

P. Puleni[1]
[1]*Elizabeth Glaser Pediatric AIDS Foundation, Programs, Lilongwe, Malawi*

Background: Despite the effectiveness of active index testing (AIT) in increasing HIV testing services, AIT uptake remains lower among children than adults in Malawi. To close this gap and to increase pediatric HIV testing, the Pediatric Accelerated Case Finding Effort (PACE) used a family tree card to provide a line listing of all children of mothers with HIV being seen in the HIV antiretroviral therapy (ART) clinic. We evaluated the impact of PACE on HIV testing uptake in children and adolescents in Thyolo District Hospital.
Methods: This rapid evaluation used secondary data from HIV testing registers in high-volume facilities, focusing on children and adolescents aged 0–15 years. Outcomes of access to AIT services and HIV testing were compared between pre-intervention (October 2023–March 2024) and post-intervention (April–September 2024) periods. Data were abstracted into DHIS2, and statistical analysis was conducted to calculate proportions and assess associations. Chi-square tests were used, with p-values <0.005 considered significant.
Results: We compared child index testing among 7,445 mothers with HIV seen in ART clinics in the pre-intervention period and 7,470 in the post-intervention period. The proportion of women offered pediatric index testing increased significantly by 62%, from 23% (1,732/7,445) pre-intervention to 85% (6,321/7,470) post-intervention (p<0.001). The number of child contacts elicited rose dramatically, from 1,463 pre-intervention to 7,253 post-intervention. Among women with HIV with children who were not previously tested, 97.3% (3,589/3,689) in the post-intervention period and 99.4% (1,275/1,283) in the pre-intervention period underwent screening (p<0.001). Absolute numbers indicated a significant improvement in child index testing coverage, with 1,256 contacts tested pre-intervention compared to 3,059 contacts post-intervention. The number of children diagnosed with HIV was similar in the pre-intervention and post-intervention periods (19 and 18, respectively); all children identified as HIV-positive were linked to treatment.
Conclusions: The findings demonstrate that PACE, leveraging the family tree card intervention, is an effective strategy to enhance pediatric HIV testing, significantly increasing HIV testing uptake among children and adolescents of women with HIV on ART. This approach offers a scalable solution to address gaps in pediatric HIV testing, accelerating progress toward the 95-95-95 goals in high-burden settings.

EP0446

Navigating HIV realities for testing insights and trends in Manicaland, eastern Zimbabwe: breaking the barriers for testing

W. Otambo[1,2], P. Mandizvidza[3], M. Inghels[4], L. Moorhouse[5], S. Gregson[5], F. Tanser[1,2], P. Mee[6], R. Maswera[3], C. Nyamukapa[3]
[1]*Stellenbosch University, Centre for Epidemic Response and Innovation, Stellenbosch, South Africa,* [2]*Stellenbosch University, South African Centre of Excellence in Epidemiological Modelling and Analysis, Stellenbosch, South Africa,* [3]*Biomedical Research and Training Institute, Harare, Zimbabwe,* [4]*University of Lincoln, Lincoln Institute for Rural and Coastal Health, College of Health and Science, Lincoln, United Kingdom,* [5]*Imperial College London, London, United Kingdom,* [6]*University of Lincoln, Lincoln, United Kingdom*

Background: HIV testing remains crucial for epidemic control. Despite extensive effort implemented to improve access to testing in Zimbabwe, economic and cultural barriers hinder uptake.
This study aims to examine trends in HIV testing uptake, identify barriers to care, and assess awareness and usage of HIV self-testing (HIVST).
Methods: We conducted community surveys in Eastern Zimbabwe from 2018-2023. Study sites were categorized by socio-economic zones: tea estate, rural/village, forestry area, town, roadside settlement, and urban.
Data on socio-demographic characteristics, HIV testing status, perceived barriers to HIV testing, and HIV self-testing (HIVST) knowledge were collected from 26,925 participants.
Results: Between 2018 and 2023, the percentage of individuals reporting that they had never tested for HIV decreased by 32.4% in males (from 21.9% to 14.8%) and by 39.0% in females (from 15.4% to 9.4%). Never testing was most commonly among under-18-year-olds, (from 33.2% in 2021 to 47.6% to 2023, p<0.001).
When analyzing the data by the type of community, the highest non-testing rates by 2023, were found in urban communities (15.7%), while the lowest were in forestry

estates (5.4%). For each perceived barrier to HIV testing, males were three times more likely to report than females (18.9% versus 6.3%; AOR: 3.62, 95% CI: 3.12-4.22, p<0.001). Main perceived barriers were "lack of privacy" and "judgmental staff" for both genders. During the COVID-19 pandemic, perceived barriers increased from 8.2% in 2018-2019 to 10.7% in 2021, with "judgmental staff" (13.2%) and "travel difficulties" (12.2%) the most reported barriers. By 2023, reporting any of perceived barriers had returned to pre-pandemic levels (8.7%). HIVST usage more than doubled between 2018-2019 and 2022-2023, rising from 0.8% to 3.9% in males and from 0.5% to 5.7% in females. In 2023, usage of HIVST was highest among 18-45-year-olds (7.4%) and lowest in those over 45 (2.2%) (p<0.001). However, higher HIVST knowledge did not correlate with higher usage across gender and study site.

Conclusions: Gender disparities in perceived barriers to accessing HIV care persist, with males perceiving more challenges. Despite increased awareness, HIVST uptake remains low, particularly among men and older individuals. Addressing these barriers among men is critical to improving HIV care access.

EP0447

The role of community-based organizations in Kazakhstan's HIV testing

A. Raushanbek[1], A. Kubatova[2], K. Stankevitz[3], C. Fischer Walker[4], T. Mambetov[5], A. Rsaldinova[1], O. Samoylova[6], S. Kassymbekova[7]

[1]FHI360, EpiC Kazakhstan, Almaty, Kazakhstan, [2]FHI360, EpiC Kyrgyzstan, Bishkek, Kyrgyzstan, [3]FHI360, Durham, United States, [4]FHI 360, Remote, United States, [5]FHI 360, EpiC Kyrgyzstan, Bishkek, Kyrgyzstan, [6]FHI 360, Almaty, Kazakhstan, [7]KSCDID, Almaty, Kazakhstan

Background: HIV case finding and linkage to treatment are key challenges in Kazakhstan's HIV response. Community-based organizations (CBOs) are working closely with local communities to improve detection and support HIV efforts. The Meeting Targets and Maintaining Epidemic Control (EpiC) project in Kazakhstan supports epidemic control through innovative testing approaches. EpiC supports CBOs to provide HIV testing and treatment in a stigma-free environment, critical for serving at-risk populations. We sought to determine whether there are differences in the client populations served by CBOs vs. facilities for HIV testing in the Pavlodar and East Kazakhstan oblasts.

Methods: Using electronic databases of EpiC and the Kazakh Scientific Center for Dermatology and Infectious Diseases, we abstracted sociodemographic data, HIV risk characteristics, and HIV testing location for all adult clients diagnosed with HIV between October 1, 2020, and May 31, 2024. Using descriptive statistics and logistic regression modeling, we characterized clients by HIV testing location, using adjusted odds ratios (aORs) to quantify differences.

Results: In total, 2,971 people were diagnosed with HIV during the analysis period, with 674 clients (22.7%) diagnosed at CBOs. There was no difference in gender distribution between CBOs and facilities. In the multivariate model, we found EpiC CBO sites were more likely to reach people who identified as belonging to at-risk populations (aOR=1.56, 95% CI: 1.13–2.16, p=0.007), reported sexual contact with an HIV-positive person (aOR=1.53, 95% CI: 1.27–1.85, p<0.001), or reported drug use in the last 12 months (aOR=1.49, 95% CI: 1.06–2.08, p=0.02). Clients seeking care at CBOs were less likely to be employed (OR 0.64, 95% CI: 0.53–0.79, p<0.001) and less likely to have tested for HIV in the past (aOR=0.86, 95% CI: 0.74–0.99, p=0.04). After testing positive, CBO-supported clients were more likely to start treatment (aOR=2.99, 95% CI: 1.99–4.49, p<0.001).

Conclusions: CBOs may be able to identify clients with risk profiles different from those identified by health facilities. As countries work toward closing critical HIV testing and treatment gaps, collaboration with local CBOs may be important in reaching those who might not be reached by traditional facilities.

EP0448

Decentralizing the distribution of HIV self-testing kits to improve index testing at Nambale Health Centre III, Iganga District East Central Region

G. Ankunda[1], C. Mbaha[1], C. Laloyo[1], A. Kiyimba[2], F.C. Semitala[3]

[1]Makerere University Joint Aids Program, Clinical Services, Iganga, Uganda, [2]Makerere University Joint Aids Program, Clinical Services, Jinja, Uganda, [3]Makerere University Joint Aids Program, Clinical Services, Kampala, Uganda

Background: Ministry of health in 2022 rolled out new HIV self-testing approaches to enhance HIV testing services. With over 54,000 new HIV cases registered in FY 2021/22, MOH through the Aids control program scaled up assisted & non assisted HIV self-testing approaches to enhance HTS and support finding of the un identified cases but also cut down the continuous chain of transmission.

By the end of December 2023 Nambale HC III was performing sub optimally at 0% of the annual target of HIV index testing/positivity due to self-stigma among elicited partners who were fearing to pick HIV self-testing kits from the facility after being notified of their potential risk, long distances to the facility as they lacked transport.

Methods: We mapped drug shops within our facility's catchment area through Village Health teams and other community resource persons.

Visited all drug shops and ascented to the distribution of HIV self test kits through their facilities and trained staff on usage.

We then Distributed self-testing kits together with improvised registers to all mapped drug shops.

All clients who consented to assisted and provider notification and were unable to access the health facility were directed to the mapped drug shops for HIV self-testing services after which all reactive results were referred to the facility for confirmation using the national HTS algorithm.

Results: Nambale HC III was able to identify 27 HIV positive clients through the index testing modality having implemented the decentralized distribution of self-testing

kits through drug shops with 7 of the cases identified in Quarter two FY 23/24, and 10 each in Quarter three and Quarter four of the same year.

Conclusions: Decentralizing HIV self-testing kits distribution at Nambale HC III demonstrated a significant impact on HIV case identification through index testing modality with 27 positives identified over a period of 9 months. This initiative not only increased access to testing in the community but also empowered individuals to take charge of their own health.

Scaling up this initiative to reach additional communities can potentially increase the number of individuals benefiting from HTS but also close the existing gap to the UNAIDs 1st 95

EP0449

Advancing PMTCT uptake integrating HIV screening into general health systems: evidence from the community led AHANA project supported by GFATM in 13 Indian states

K. Biswas[1], L. Rathore[1], S. Dasgupta[2], R. Rana[2]
[1]Plan International (India Chapter), Monitoring & Evaluation-GF, Delhi, India, [2]Plan International (India Chapter), Programme, Delhi, India

Background: While India has made a significant progress in arresting and reversing the HIV epidemic, testing coverage of pregnant women remained very low in many states during 2015. Evidence suggests access to HIV testing remained very low at 34% in the 13 Plan India project states with an estimated annual pregnancy of 14 million per year. Complementing Govt. of India's NACP, Plan India has been implementing AHANA project supported by The Global Fund towards attaining Elimination of Mother to Child Transmission.

Description: Three-fold approach adopted;

a) investing in the capacities of community health worker,

b) advocacy for procurement of Kits and ensuring a smooth supply of kits- consumables and;

c) capacity strengthening at the general primary health care facilities towards services provisioning and effective reporting.

While at the supply side more than forty thousand periphery level Govt. health workers were trained to carry out Whole Blood Finger Prick Testing (WBFPT); rigorous advocacy with Govt. at the national level as well as at the local level to ensure procurement and uninterrupted supplies of kits and consumables.

Lessons learned: HIV testing among pregnant women in the project states increased from 34% during 2016-17 to 92% during 2023-24. Proportion of peripheral HIV testing carried out at the sub district level has increased from 35% to 80% suggesting increased access of HIV testing among the pregnant women in village and rural areas.

Twenty-five thousand primary health facilities activated with HIV testing compared to 6 thousand before the project initiated. This has resulted in 25% increased identification between the periods of 2016-17 to 2023-24. More than 30 thousand pregnant women were identified as HIV positive, linked to ART services and followed up for care and support during the period 2016-24. A total of 16 thousand babies confirmed as negative after receiving confirmatory tests at 18 months.

Conclusions/Next steps: Capacity infusion among primary health care workers has resulted in HIV testing available at the peripheral health facility taking HIV testing at the doorstep of pregnant women. With HIV positive pregnant women linked to treatment cascade, PMTCT access improved significantly. Plan India's AHANA project shows roadmap towards achieving EMTCT.

EP0450

Empowering young female sex workers: the impact of postnatal clubs in preventing mother-to-child transmission of HIV

N. Dorah[1,2], J. Simwogerere[2]
[1]Makerere University School of Public Health, Mulago, Uganda, [2]Out And Proud Uganda, Entebbe, Uganda

Background: The introduction of ART medication has significantly reduced deaths attributed to AIDS as well as HIV transmission. Despite this progress, non-adherence to ART remains a barrier to achieving the maximum benefits especially that of elimination of mother to child among young female sex workers in Uganda.

Description: Out and Proud implemented a pilot study on the postnatal adherence club model at four drop-in centres in four districts of Kampala,Kabarole,wakiso and Mukono for pregnant and breastfeeding young female sex workers aged 15-24 years.

The primary objective of this model was to prevent the transmission of HIV from mother to child within the sex worker community but also support early infant diagnosis of HIV. Each postnatal adherence club consisted of 8 mother-infant pairs.

Adherence club meetings were facilitated by a midwife, a peer mother, and a counsellor. After each session, the clinician at the DIC provided an integrated comprehensive prevention of mother-to-child transmission (PMTCT) services. These services included maternal ART, cotrimoxazole refills, Nevirapine syrup, immunization, HIV counselling, and laboratory monitoring.

Lessons learned: A retrogressive analysis of the DIC data from January 2022 to December 2023 indicated that 64 young female sex workers were enrolled on the program. An 18-month retention rate of 100% from all the sex workers who gave birth from the DIC and were initiated in the adherence club was registered. Viral loads were monitored for all the mothers after 18 months, with a suppression rate of 100% and were still suppressed by end of December 2023. All the infants in the clubs were declared HIV negative after 18 months.

Conclusions/Next steps: Enrolling young female sex workers in postnatal adherence clubs after giving birth is a promising opportunity to improve post-delivery rates and outcomes for young female sex workers who initiated antiretroviral therapy during pregnancy.

EP0451

Exploring experiences with HIV self-screening among women using PrEP in South Africa: implications for HIV prevention

F.M. Musvipwa[1], F.A. Cholo[1], S. Dada[1], C.E. Martin[1], M. Pleaner[1], A. Kutywayo[1], V. Butler[1], S. Mullick[1]
[1]Wits RHI, University of the Witwatersrand, Johannesburg, South Africa

Background: Women are disproportionately affected by HIV, with young women facing the greatest vulnerability. Despite the availability of prevention and testing services, barriers to HIV testing persist. HIV Self-Screening (HIVSS) has emerged as a pivotal tool in HIV prevention, giving individuals autonomy and confidentiality while addressing barriers to testing such as stigma and clinic avoidance. This paper explores experiences with the integration of HIVSS kit distribution among women using PrEP.

Methods: In April and May 2024, we conducted 12 focus group discussions (FGDs) with 126 women, aged 18–57, past and present pre-exposure prophylaxis (PrEP) users. Participants were recruited from participants enrolled in an implementation study cohort, evaluating the introduction of new PrEP methods within integrated sexual and reproductive health (SRH) services at six primary healthcare facilities in Gauteng and Eastern Cape provinces, South Africa.

As part of routine project activities, HIVSS kits were distributed to clients accessing HIV prevention services at the facility and mobile hotspots, with the intention of secondary distribution to partners and peer networks.

We conducted a thematic sub analysis to explore experiences with HIVSS among women using PrEP. The FGDs were audio recorded, transcribed verbatim, and translated into English for analysis.

Results: Participants highlighted multiple benefits of HIVSS, including convenience, privacy, and its role in encouraging partners to test who might otherwise avoid clinic-based services. HIVSS was regularly shared with partners, allowing joint testing and fostering relationship transparency. Joint testing experiences enabled open communication, as partners often disclosed and compared results.

Some participants noted that self-tests helped ease their partner's anxiety around testing. While self-tests offered convenience, there were concerns about how individuals might react to their results and the potential need for follow-up support.

Conclusions: HIVSS is a transformative addition to HIV prevention strategies, promoting accessibility, shared responsibility, and increased testing uptake. Its success in encouraging testing among reluctant individuals highlights its potential for expanded integration into community-based HIV prevention programs.

Nevertheless, these experiences underscore the importance of including guidance on handling test results, ensuring emotional support, and providing clear guidance to confirmatory testing and care.

EP0452

Who is not testing for HIV and why? Insights among transgender people in India

R.P. Kaptchuk[1], A.M. McFall[1], J. Bell[2], E.U. Patel[1], V. Arumugam[3], A.K. Enugu[2], D.V. Ashok[2], M. Datta[3], A. Singh[2], S.H. Mehta[1], S.S. Solomon[2]
[1]The Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]The Johns Hopkins University School of Medicine, Baltimore, United States, [3]YRG CARE, Chennai, India

Background: Transgender populations in India bear a higher HIV burden (3.8% prevalence) compared to general populations (0.2% prevalence) and face immense discrimination. To consider how HIV prevention services can improve reach to transgender communities, we explored factors associated with prior HIV testing and reasons for never testing among transgender people in three high-HIV burden states.

Methods: Individuals ≥18 years whose gender did not align with the sex assigned at birth were recruited using respondent driven sampling (RDS) for an interview-administered survey in Telangana, Maharashtra, and Uttar Pradesh, India in 2022.

Summary statistics and reasons for never testing incorporated RDS-II weights. We examined associations with prior HIV testing using logistic regression.

Results: Among 1,998 respondents (mean age 29 years); 36% from Telangana, 43% from Maharashtra, 21% from Uttar Pradesh; 65% identified as transgender, 28% as Hijra, 6% as women, and 1% as men. Half (47%) were never tested for HIV.

In a multivariable model including sex behaviors, mental health, network size, and demographics, correlates of HIV testing included Hijra identity (aOR:0.74, 95%CI: 0.59-0.94) versus transgender and Maharashtra state (aOR:0.68, 95%CI: 0.52-0.90) versus Telangana. Those reporting 50-99 (aOR:1.69, 95%CI: 1.05-2.74) or 100+ (aOR:2.03, 95%CI: 1.39-2.96) lifetime sex partners, compared to 1-9, were more likely to test.

Respondents with a little anxiety/depression (aOR:0.63, 95%CI: 0.48-0.82) or a lot (aOR:0.41, 95%CI: 0.28-0.60) versus none were less likely to test. Respondents with a larger network size (50-99 [aOR:2.59, 95%CI: 1.86-3.61] or 100-199 [aOR:2.44, 95%CI: 1.77-3.37]) compared to 0-49 were more likely to test. The most cited reasons for never testing were never hearing of HIV (30%), no/low risk perception (34%), and privacy concerns (35%).

Among those unaware of HIV, 71% were from Uttar Pradesh and 13% reported past stigma in healthcare. Among those with no/low risk perception, 65% were from Maharashtra and 52% had ever sold sex. Among those with privacy concerns, 95% were from Telangana and 68% were limited a lot by anxiety/depression.

Conclusions: Learnings can inform HIV testing services to consider differences by geography and gender identity/community affiliation. Findings also suggest that social networks could be leveraged to promote HIV testing while simultaneously addressing mental health barriers.

EP0453

Served the underserved-improving HIV response among transgender individuals in Kasur, Pakistan

M. Moon[1]
[1]Khawaja Sira Society, Program and Service Delivery, Lahore, Pakistan

Background: HIV remains a significant public health concern in Pakistan, particularly among key populations such as transgender individuals, transgender sex workers, and the Khawaja Sira (indigenous) community. These groups face stigma, exclusion from mainstream healthcare services, and discrimination, exacerbating their vulnerability to HIV.

Description: The Khawaja Sira Society conducted an assessment of HIV prevalence among 1,500 transgender individuals in Kasur city, analyzing data from 2023-2024. Using a mixed-methods approach, the assessment captured socio-demographic factors, sexual practices, HIV awareness, and healthcare access, barriers, experiences, providing a comprehensive understanding of the HIV situation among this vulnerable population and how to improve it.

Lessons learned: HIV Prevalence and Risk Factors: A significant HIV prevalence (14.7%) was found among participants, linked to high-risk behaviors (multiple sexual partners, unprotected sex), limited awareness about STIs (57.4% had never heard of STIs), and inadequate use of preventive measures (condom use was reported by only 27.5% of participants).

Barriers to Healthcare: Discrimination (71.2%), fear of disclosure (56.3%), and stigma (53.1%) were significant barriers to accessing healthcare services. Many participants reported experiencing harassment, denial of services, or substandard care due to their transgender status.

Community-Based Support: The involvement of the Khawaja Sira Society enhanced trust and participation, highlighting the importance of community-driven initiatives. Community-based organizations can play a vital role in promoting HIV awareness, providing stigma-free services, and advocating for the rights of transgender individuals.

Education Gaps: Limited knowledge about HIV transmission (42.1% believed HIV could be transmitted through casual contact) and prevention (35.6% reported never using condoms) underscored the need for well-developed educational programs targeting transgender individuals.

Conclusions/Next steps: Expand Access to Stigma-Free HIV Testing and Treatment: Services should not be limited to community-based organizations.

Implement Differentiated Services Delivery Models: To counter stigma and improve access to healthcare.

Develop Community-Led Awareness Campaigns and Educational Initiatives: To improve knowledge and reduce risky behaviors.

Strengthen Partnerships: Between healthcare providers and organizations like the Khawaja Sira Society to build trust and enhance outreach efforts.

Focused action is essential to improve health outcomes and reduce HIV prevalence among this vulnerable population. By implementing these recommendations, we can better address the HIV response among transgender individuals in Kasur, Pakistan.

EP0454

Disproportionate burden of HIV among women of reproductive age in camps for conflict-affected internally displaced persons in northeast Nigeria

S. Atinge[1], M. Balogun[2], O.Y. Ojo[3], A.K. AbdulMumin[3], C.G. Ackerley[4]
[1]Federal University Wukari, Public Health and Community Medicine, Wukari, Nigeria, [2]College of Medicine, University of Lagos, Department of Community Health & Primary Care, Lagos, Nigeria, [3]Federal Medical Centre Abeokuta, Department of Community Medicine & Primary Care, Abeokuta, Nigeria, [4]Emory University School of Medicine, Division of Infectious Diseases, Atlanta, United States

Background: Armed conflicts, which frequently occur in Nigeria's northeastern region, likely contribute to HIV transmission among affected populations. However, in many African countries, displaced people are often not included in national strategic plans to end the HIV epidemic.

Here, we assessed HIV prevalence, uptake of HIV testing services (HTS), and risk factors associated with HIV testing and acquisition among reproductive-age girls and women residing in camps for internally displaced people (CIDPs) in Northeast Nigeria.

Methods: Female participants aged 15-49 years living in CIDPs were enrolled in this cross-sectional, mixed-methods study. Participants completed a semi-structured, interviewer-administered questionnaire (n=700), were offered free HIV testing, and a subset engaged in 4 focus group discussions (n=34).

Qualitative data from 8 key informant interviews with government officials, community leaders, and health professionals were also obtained. Descriptive statistics were used to determine the uptake of HTS and the prevalence of HIV acquisition.

Predictors of HTS uptake and risk factors associated with HIV acquisition were assessed using multivariable logistic regression. The qualitative data was analysed manually using thematic content analysis.

Results: 600 respondents agreed to receive HTS (85.7%). HIV prevalence was 31/600 (5.2%) compared to 2.7% among the non-displaced population in the surrounding region. Predictors of HTS uptake were higher educational level (aOR=2.44, p_{adj}=0.035), duration in camp ≥ 12 months (aOR=0.57, p_{adj}=0.049), and history of sexual violence (aOR=5.440, p_{adj}=0.029).

Widowed relationship status (aOR=5.58, p_{adj}=0.001) and alcohol intake (aOR=0.361, p_{adj}=0.015) were predictors of HIV acquisition.

Barriers to uptake of HTS identified by respondents were fear of stigma and discrimination, unavailability of testing services in CIDPs, distance to health facilities, and cost of testing and other related healthcare services.

Conclusions: HIV prevalence among displaced females in Northeast Nigeria was higher than the general population. While most girls and women enrolled in this study agreed to HTS, significant barriers prevent access to HIV diagnostic services for reproductive-age females affected by regional conflict and displacement.

These findings support the inclusion of CIDPs in national HIV strategic programs of middle- to low-income countries to reduce the burden of HIV among displaced women and to prevent HIV transmission within conflict-affected communities.

EP0455

Meeting the first "95-95-95" target: adoption of HIV self-testing among at-risk gay, bisexual and other men who have sex with men in Taiwan

S.W.-W. Ku[1], C.-W. Li[2], T.-T. Chuang[3], P. Huang[4], H.-J. Wu[5], T.-H. Wu[1], A. Bourne[6], C. Strong[3]

[1]Taipei City Hospital Renai Branch, Department of Internal Medicine, Taipei City, Taiwan, Province of China, [2]National Cheng Kung University Hospital, Department of Internal Medicine, Tainan City, Taiwan, Province of China, [3]National Cheng Kung University, Department of Public Health, Tainan City, Taiwan, Province of China, [4]National Taiwan University, Institute of Health Behavior and Community Sciences, Taipei City, Taiwan, Province of China, [5]Kirby Institute, University of New South Wales, Sydney, Australia, [6]Australian Research Centre in Sex, Health and Society, La Trobe University, Melbourne, Australia

Background: Taiwan has not yet met the UNAIDS 2030 targets, with a cascade of "91-96-95" in 2023. To increase testing rates, HIV self-tests (HIVST) were introduced by Taiwan Centre for Disease Control in 2016; however whether at-risk gay, bisexual and other men who have sex with men (GBMSM) utilize this novel method remains unclear.

Methods: Between November 28th-December 28th2023, a survey comprising 65 questions was administered online to adult GBMSM using social networking applications in Taiwan. Beyond demographics, HIV serostatus, risk behaviors, diagnosis of STIs, uptake of PrEP and other biomedical preventions, the respondents were asked if they have received any HIV tests and, if yes, HIVST in the past 12 months. Respondents were defined "at-risk" if they reported more than one male sexual partner in the past 12 months, condomless anal intercourse (CAI) in the past 3 months, STIs in the past 12 months, or chemsex in the past 3 months.

Results: In total, 1,110 responses are included in the analysis (mean age =34.0 years, SD 8.2). One-quarter received no HIV test in the past 12 months (non-testers), whereas 40.5% were recent testers without using HIVST (conventional testers) and 34.5% with HIVST (self-testers).

A substantial proportion of non-testers reported risk factors such as having more than six male sexual partners (19.9%), CAI (58.8%), STIs (8%), and chemsex (3.2%), although significantly lower than conventioanl and self-testers.

There was a significantly lower proportion of non-testers taking PrEP (4.3%), had received mpox vaccination (30% for any dose), HPV vaccination (18.4% for any dose), or using doxy-PEP (0.7%), compared to conventional testers (37.1% for PrEP, 67.8% for mpox, 44.7% for HPV, 3.8% for doxy-PEP) and self-testers (34.2% for PrEP, 63.2% for mpox, 42.6% for HPV, 2.9% for doxy-PEP). Multivariable logistic regression showed self-testers were younger (aOR: 0.75, 95% CI 0.56-1.00 for age >35 years) and less likely taking PrEP daily (aOR: 0.40, 95% CI 0.19-0.79) compared to conventional testers.

Conclusions: Although HIVST has been implemented in Taiwan nationwide, its utilization by key populations is far from universal. Modifying strategies to reach at-risk individuals not receiving conventional testing or HIVST is essential.

EP0456

Maximizing multi-modality case finding approaches among children in high HIV prevalence settings: a retrospective programme analysis in 15 USAID-PEPFAR supported districts in South Africa

B. Mugisa[1], K. Kehoe[1], O. Mushakarara[1], C. Trapence[1], N. Khanyile[1], H. Mabasa[1], L. Parmley[1], J. Chehab[1]

[1]U.S. Agency for International Development, Pretoria, South Africa

Background: With the largest pediatric HIV epidemic globally, South Africa utilizes age-tailored multi-modality testing approaches to identify children living with HIV (CLHIV) who remain undiagnosed. Within the framework of provider-initiated testing (PITC), there is a growing emphasis on birth and 6-months testing for exposed infants, universal testing of all children at 18-months, and index testing. We examined the scale of implementation of these approaches.

Description: We conducted a descriptive program analysis of HIV case-finding among CLHIV identified through various modalities between 2017 and 2024. Program data were sourced from health facilities across 15 USAID/PEPFAR-supported districts, and triangulated with NAOMI HIV estimates. Descriptive statistics were produced and data visualized using Tableau version 2023.2.

Year	Annual CLHIV Estimate	CLHIV of known status (%)	No. of children receiving HIV testing via PITC modality §	No. and proportion (%) of CLHIV identified via PITC §	No. of children receiving HIV testing via Index testing §	No. and proportion (%) of CLHIV identified via Index testing §	No. and proportion (%) of children receiving HIV testing at 18 months of age ø	No. and proportion (%) of infants receiving HIV testing at birth ø
2017	122,952	95,863	4,414	167 (3.78)	4	1 (25)	-	-
2018	*	-	270,130	5,044 (1.87)	7,586	510 (6.7)	-	-

2023	67,961	58,428	651,012	1,918 (0.29)	58,058	1,033 (1.8)	791,730 (0.3)	352,827 (0.66)
2024	62,532	53,888	720,011	1,615 (0.22)	53,363	880 (1.6)	-	-

*No district-level HIV Estimates available for year. § PEPFAR annual data (October to September of the following year). ø South Africa National Department of Health annual data (April to March of the following year)

Lessons learned: The number of children tested across all modalities increased annually from 2018 to 2024, with a six-fold increase in index testing (2018: 7,586; 2024: 53,363) and nearly 3-fold increase in PITC (2018: 270,000; 2024: 720,011). HIV positivity rate decreased by 88% in PITC (2018: 1.9%; 2024: 0.2%) for the same period and by 75% in index testing (2017: 7%; 2024: 2%). Universal testing at 18 months of age increased steadily from commencement in 2019 (2019: 755,547; 2024: 791,730), with halving HIV positivity (2019: 0.6%; 2024: 0.3%). Birth testing increased by

48% between 2019 and 2024 (2019: 238,392; 2024: 352,827). Subsequently, the proportion of CLHIV with known status increased from 78% in 2017 to 86% in 2024.

Conclusions/Next steps: The increase in differentiated age-tailored testing approaches resulted in narrowing the gap of CLHIV of unknown status from 22% in 2017 to 14% in 2024. In high prevalence settings, when institutionalized within a strong primary health care system, these approaches can be a key sustainable approach in closing the remaining gap of CLHIV with unknown status. More resources are needed to enhance monitoring of service coverage towards finding all CLHIV.

EP0457

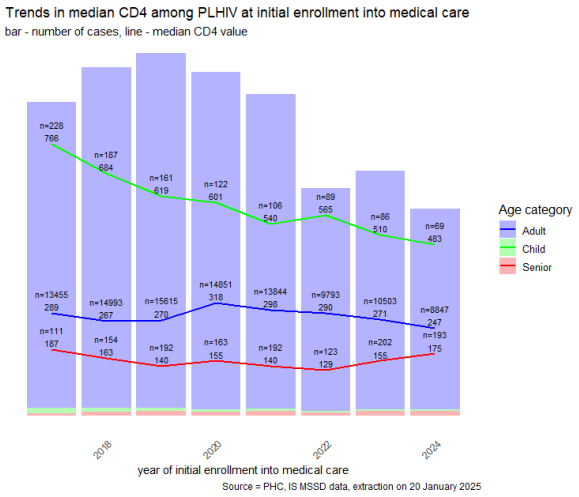
Trends in median CD4 level among PLHIV at initial enrollment into medical care in Ukraine: implications for organizational measures in HIV detection

S. Riabokon[1], O. Samsonova[1], L. Hetman[1]
[1]*Public Health Center of the Ministry of Health of Ukraine, Department of HIV Management and Counteraction, Kyiv, Ukraine*

Background: Timely HIV detection remains a critical challenge for public health systems worldwide. Delayed diagnosis results in the late initiation of ART, leading to poorer health outcomes and increased transmission risks. Late diagnosis is associated with higher morbidity, mortality, and healthcare costs, underscoring the urgent need to enhance testing strategies. The median CD4 level at the time of initial enrollment into medical care serves as an indirect indicator of the effectiveness of current HIV testing interventions.

Description: This study analyzes the trends in median CD4 level across different age groups over the period 2017–2024 and includes CD4 results of all PLHIV registered in Ukraine. PLHIV were categorized based on age at the time of registration into three groups: children (0–17 years), adults (18–64 years), and seniors (65 years and older).

The data were sourced from the national database of PLHIV, managed within the National Information System of Socially Significant Diseases (IS SSD).



Lessons learned: The data reveal a consistent decline in the median CD4 cell level, particularly among adults and children, indicating late HIV diagnosis within these populations. The observed decline in median CD4 level among newly registered PLHIV suggests that a significant proportion of individuals enter care at an advanced stage of immunosuppression. These findings highlight concerning trends that necessitate immediate organizational interventions.

Failure to implement timely interventions presents several critical risks, including:

- Increased incidence of opportunistic infections and AIDS-related complications.
- Greater burden on healthcare systems due to the demand for intensive treatment.
- Social and economic consequences, including loss of productivity and increased disability.

Conclusions/Next steps: The current trends in median CD4 level across different age categories indicate an urgent need to revise existing HIV testing approaches in Ukraine. Implementing comprehensive, patient-centered strategies can improve early detection rates, reduce HIV-related morbidity, and enhance overall public health outcomes.

EP0458

Resilient pediatric and adolescent HIV testing services in conflict settings: strategies and successes from Borno State, Nigeria

O. Achor[1], U. Adamu[2], E. Emmanuel[3], B. Ahmed[4], J. Shaibu[5], M. Shallangwa[6], M. Luke[7], M. Abubakar[4], N. Watsamanda[8], P. Ali[9], H. Satti[10], A. Oduola[11], N. Ezema[12], U. Omo-Emmanuel[13], K. Olatubosun[14], E. James[14], A. Idemudia[15], M. Morka[16]

[1]Family Health International (FHI 360), Total Quality Leadership and Accountability (TQLA), Maiduguri, Nigeria, [2]Achieving Health Nigeria Initiative (AHNi), Program Management, Abuja, Nigeria, [3]Achieving Health Nigeria Initiative (AHNi), Program Management, Yola, Nigeria, [4]Achieving Health Nigeria Initiative (AHNi), Strategic Information, Yola, Nigeria, [5]Family Health International (FHI 360), Total Quality Leadership and Accountability (TQLA), Yola, Nigeria, [6]Achieving Health Nigeria Initiative (AHNi), Strategic Information, Maiduguri, Nigeria, [7]Family Health International (FHI 360), Monitoring and Evaluation, Yola, Nigeria, [8]Achieving Health Nigeria Initiative (AHNi), Strategic Information, Jalingo, Nigeria, [9]Achieving Health Nigeria Initiative (AHNi), Program Management, Maiduguri, Nigeria, [10]Family Health International (FHI 360), Technical, Durham, United States, [11]Family Health International (FHI 360), Monitoring and Evaluation, Abuja, Nigeria, [12]Family Health International (FHI 360), Program Management, Abuja, Nigeria, [13]United State Agency for International Development (USAID), Clinical Laboratory, Abuja, Nigeria, [14]United State Agency for International Development (USAID), Program Management, Abuja, Nigeria, [15]United State Agency for International Development (USAID), Strategic Information, Abuja, Nigeria, [16]National AIDS and STDs Control Programme, Strategic Information, Abuja, Nigeria

Background: Delivering HIV testing services (HTS) in conflict-affected Borno State, Nigeria presents challenges due to insecurity, infrastructure limitations, and stigma. This abstract shares lessons from implementing differentiated HTS (DHTS) under the PEPFAR/USAID-funded Accelerating Control of HIV Epidemic in Nigeria Cluster 1 (ACE-1) project. The project incorporated innovations (cluster model, Incident Command System[ICS], and partnerships with health actors and the government) to expand HTS access and improve care continuity.

Description: ACE-1 implemented DHTS from March 2022 to September 2024 through facility-based (provider-initiated testing and counseling, genealogy testing, early infant diagnosis), community-based (internally displaced people camps, informal health center), and spoke (non-PEPFAR primary health care centers [PHCs], private laboratories) models. Strategies included establishing cluster offices for decentralized service delivery and community trust-building, the ICS for adaptive planning and resource coordination, and partnerships to expand access.

Mobile testing units, pre-stocking supplies, and camp testing addressed security and access challenges, ensuring efficient service delivery. A structured onboarding process for unsupported PHCs expanded service delivery from 12 to 234 sites.

Lessons learned: ACE-1 achieved a 678% increase in year-on-year testing, rising from 25,191 tests in fiscal year (FY) 2021 to 196,040 in FY22. From the inception of ACE-1 project (March 2022) to the end of FY24, 392,079 individuals were tested, of whom 71% were adolescents (ages 10–19 years) and 58% were female.

Among children (ages 1–9) testing HIV positive, 41% were identified through genealogy testing, 25% via community-based testing, and 16% through Outpatient Departments (OPDs).

For adolescents, 37% were identified via community outreach, 28% through OPD, and 15% via index testing. Linkage to antiretroviral therapy remained high at 96.8%, with 98.5% among children.

Key lessons include task-shifting to skilled community counselor testers, flexible testing approaches, and community engagement to reduce stigma. Nongovernment organization partnerships and community structures ensured continuity, while data-driven decisions improved delivery and expanded testing sites.

Conclusions/Next steps: The ACE-1 project demonstrates that DHTS, implemented through collaboration with the Nigerian government, increased HIV testing coverage and care linkage to care among paediatrics and adolescents in Conflict-affected Borno State.

Flexible, community-focused strategies offer a replicable framework for fragile settings, highlighting the role of adaptive programming in overcoming barriers.

EP0459

Improving HIV testing services eligibility rate among youth aged 15-24 years attending outpatient department: a peer-led screening approach from Njombe, Tanzania

E. Lugaila[1,2], O. Kapande[1,2], G. Kavishe[1,2], O. Kileo[1,2], S. Makongwa[3,2], W. Mfwiliye[3,2], G. Mwanakulya[1,2], A. Rehani[1,2], C. Paresso[4,2], A. Mfaume[4,2], B. Christian[4,2], M. Njelekela[3,2], Z. Nensi[3], J. Kalimunda[5]

[1]T-MARC Tanzania, Social and Behavior Change, Njombe Region, United Republic of Tanzania, [2]USAID Afya Yangu Southern Program, Technical staff, Njombe Region, United Republic of Tanzania, [3]Deloitte Consulting, Consulting, Dar es Salaam, Tanzania, United Republic of Tanzania, [4]Management Development for Health, Technical, Dar es Salaam, Tanzania, United Republic of Tanzania, [5]USAID Tanzania, USAID Tanzania, Dar es Salaam, Tanzania, Tanzania, the United Republic of

Background: UNAIDS 2023 reports over 60% of 4,000 new HIV diagnosis among adolescent girls and young women occur in Sub-Saharan Africa. Tanzania HIV Impact Survey (2022/23) showed that 20-37% of 15-24 youth are unaware of their HIV status, while HIV incidence rose from 7% in 2017 to 17% in 2023. Project data in FY23Q1 showed only 23% of youth aged 15-24 visiting the outpatient department (OPD) in Njombe region were eligible for HIV testing. Low eligibility is linked to an intergenerational screening approach that discourages youth from disclosing their vulnerability and risky behaviors. In March 2023, USAID Afya Yangu (My Health) Southern Project introduced peer

led screening at OPD in six health facilities to enhance identification of 15-24 youth eligible for testing and subsequent uptake of HIV testing services among 15-24 youth attending OPD.

Description: The project trained 10 peer champions across 6 health facilities in the Njombe region to implement optimized PITC (o-PITC) HIV screening and prevention services using WHO vulnerability tools. The peer champions screened all youth upon arrival at the Outpatient Department (OPD). Data on OPD attendance, HIV risk screening, and testing were recorded in oPITC and HIV testing registers, then documented in the CTC2 database and exported to the data exchange system. A descriptive statistics analysis was conducted, data was summarized into frequency tables per the o-PITC cascade.

Lessons learned: FY24 data from six facilities (Makambako, Lugarawa, Njombe, Uwemba , Kipengere, and Makete hospitals) showed an increase in eligibility rate from 23% to 59% (3,876 / 6,592) of youth 15-24 screened for HIV. This was a 2.5-fold increase in HIV testing eligibility among 15-24 youths compared to FY23Q1 results (23%). Furthermore, OPD screening rate was at 87% (6,592 / 7,576), all 3876 youth were tested for HIV, among those tested, 22 were HIV-positive (1% positivity rate), and all were linked to care and treatment.

Conclusions/Next steps: Engaging youth peers in o-PITC screening among their fellow 15-24 youths has accelerated the eligibility for HIV testing services and improved access HIV testing services. The approach of using Peer Champions is valuable in reaching youth and will be scaled up to other facilities and regions.

EP0460

Assessing Knowledge, Uptake, and factors associated with cervical cancer screening among women aged 25-49 years receiving HIV Testing services in Wakiso District, Uganda: a population-based Study

R. M Bulamba[1], A.P. Miller[2], W. Byansi[3], A. Daama[1], E. Kyasanku[1], S. Mugamba[1], J.N. Menya[1], G. Kigozi[1], F. Nalugoda[1], A.M. Ekström[4], G. Nakigozi[1]

[1]Africa Medical and Behavioural Sciences Organization (AMBSO), Epidemiology and Behavioral Research, Kampala, Uganda, [2]San Diego State University, Epidemiology and Biostatistics, San Diego, United States, [3]Boston College, Social Sciences, Boston, United States, [4]Karolinska Institutet, Clinical Research, Stockholm, Sweden

Background: Achieving Uganda's national targets for cervical cancer elimination (briefly, 70% of women screened, 90% vaccinated, 70% with precancerous legions treated by 2030) requires scaling targeted high-impact interventions to increase cervical cancer screening uptake. The limited data on women's knowledge and screening uptake at population level in Uganda hampers progress towards achieving these targets. We examined knowledge, uptake, and factors associated with cervical cancer screening among women receiving HIV testing in Wakiso district, Uganda, to inform the design of high-impact targeted community-based prevention interventions.

Methods: A cross-sectional study was conducted in April 2024 among 504 eligible women in Wakiso district, Uganda. Data were collected through face-to-face interviews. Cervical cancer screening uptake was measured dichotomously (past three years, yes/no), while knowledge was assessed using a Likert scale of ten (10) questions adapted from existing literature.

The main predictors investigated included HIV, partner involvement, knowledge of cervical cancer screening and residence, and controlled-for sociodemographic characteristics.

Univariate, bivariate, and multivariable modified Poisson regression models with robust variance were performed using Stata software version 17.

Results: The median age of participants was 30 years (IQR=26-37), with 51.2% living in semi-urban areas. The mean knowledge score for cervical cancer screening was 6.8 (SD=3.2), and 50.8% had high levels of knowledge. One-third (32%) of women had undergone cervical cancer screening, with significantly higher uptake among women living with HIV compared to those without (75.7% vs 28.9%, $p<0.001$). In adjusted models, cervical cancer screening was higher among women living with HIV (aPR= 1.8, 95% CI: 1.3-2.4).

Additional factors associated with higher screening rates included partner involvement (aPR=2.8, 95% CI: 2.2-3.5), high knowledge about cervical cancer screening (aPR=3.6, 95% CI: 2.5-5.0), and residence in an urban area (aPR=1.4, 95% CI: 1.0-1.9).

Conclusions: Women living with HIV are at increased risk of cervical cancer and remain a priority population for routine screening. While this group shows higher screening rates, overall coverage remains inadequate.

Efforts should focus on enhancing cervical cancer screening literacy and integrating screening into community-based HIV testing programs. Strengthening these initiatives can improve screening uptake and contribute to cervical cancer prevention in low-resource settings.

EP0461

Advancing HIV care through quality improvement: a scalable model for frontline healthcare workers in Ekiti State, Nigeria

M. Olotu[1], W. Agbebabu[1], P. David Gbabo[1], C. Anoke[1], O. Ogundare[1], H. Yakubu[1], E. Adelanwa[1], U. Okum[1], E.O. Alalade[1], M.I. Ekeinde[1], T. Ilori[2], A.R. Omolade[2], Y. Olatunji[2], A. Enebeli[1]

[1]Jhpiego, Quality Improvement and Global Health Security, Abuja, Nigeria, [2]National Agency for the Control of AIDS (NACA), Abuja, Nigeria

Background: In Ekiti State, Nigeria, low HIV testing rates (10%; 114 of 1,140 ANC1 attendees) and limited linkage to treatment among pregnant women contributed to missed opportunities for early intervention and elevated the risk of mother-to-child transmission.

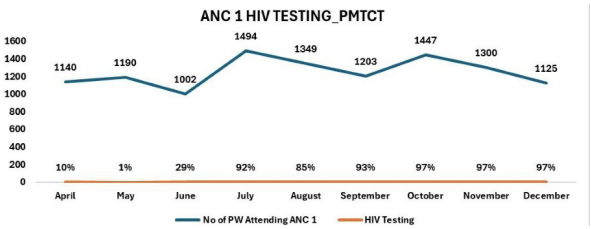
To address these challenges, Jhpiego, funded by the Global Fund, implemented a Quality Improvement (QI) initiative across 120 health facilities in Ekiti, aligned with national and WHO standards, to strengthen health sys-

tem performance in Nigeria. This study evaluates the impact of a PDSA (Plan-Do-Study-Act)-driven QI model on enhancing HIV testing, ART continuity, and maternal health outcomes.

Methods: From March 2024, QI teams, established and supported by Jhpiego and the Ekiti State Health Authority, using a PDSA (Plan-Do-Study-Act)-driven QI model systematically identified service delivery gaps using prioritization matrices and Fishbone analyses, uncovering barriers such as knowledge gap, insufficient HIV test kits, poor documentation, and fragmented care pathways. Targeted change ideas, including service reorganization, improved data tools, and consistent test kit availability, were piloted and refined.

Weekly data reviews and time-series analyses evaluated progress, while competency-based training, continuous mentorship, and peer learning by local and state health authorities to sustain improvements.

Results: By October 2024, HIV testing among pregnant women at first antenatal care (ANC1) visits increased from 10% (114 of 1,140) to 97% (1,116 of 1,151). ART initiation for newly identified HIV-positive cases rose from 9% (6) to 98% (68), and live births among HIV-positive mothers increased from 1 to 10.



Conclusions: These findings demonstrate the transformative potential of a PDSA-driven QI model, rooted in iterative learning, frontline workforce empowerment, and adaptive systems strengthening, for improving HIV outcomes in resource-limited settings.

Scalable and adaptable, this framework offers a replicable model for advancing HIV care and maternal health outcomes in sub-Saharan Africa.

EP0462

Social network strategy testing to improve HIV testing coverage among key populations in Hai Phong City, Vietnam, October 2021-June 2024

H. Nguyen[1], M. Nguyen[1], L. Nguyen[2], T. Hoang[1], B. Nguyen[1], S. Vo[3], T. Nguyen[3], Y. Nguyen[3], H. Le[2], H. Nguyen[2], H. Nguyen[1], M. Shah[1]

[1]Division of Global HIV&TB, U.S. Centers for Disease Control and Prevention, Vietnam, Hanoi, Viet Nam, [2]Hai Phong Center for Disease Control and Prevention, Hai Phong, Viet Nam, [3]Enhancing HIV Program Innovations and Collaboration in Viet Nam (EPIC), Vietnam Ministry of Health/Vietnam Administration for AIDS Control (VAAC) – U.S. CDC Project, Hanoi, Viet Nam

Background: In Vietnam, achieving the target of 95% of people living with HIV (PLHIV) knowing their status remains a significant challenge, particularly among key populations such as men who have sex with men (MSM), people who inject drugs (PWID), and individuals engaged in commercial sex. To bridge this gap, a social network strategy (SNS) testing was implemented alongside other HIV testing modalities from 2021 in five U.S. Centers for Disease Control and Prevention-supported provinces. SNS recruits and trains PLHIV, individuals at risk of HIV to refer their network associates for HIV testing using referral coupons. Based on their HIV status, individuals are linked to appropriate prevention or treatment services. This study evaluated SNS's ability to reach individuals who have never tested for HIV.

Methods: Clients tested through SNS from October 2021 to June 2024 across 10 HIV clinics in Hai Phong were analyzed. We assessed the proportion of clients recruited through SNS who had never been tested for HIV, examining their demographic characteristics, HIV risk exposures, and HIV positivity rates and linkage to treatment or prevention services.

Results: Of 1,770 clients recruited through SNS (28.7% of total tested clients), 1,580 (89.3%) reported never having been tested for HIV. Among these 1,580 individuals, the median age was 37 years, and the majority (1,127; 71.3%) were male. Risk exposure categories included MSM (456; 28.9%), PWID (487; 30.8%), sex partners of PLHIV (345; 21.8%;), women engaged in commercial sex (124; 7.8%), and other risk groups (168; 10.6%). Overall, 6.9% (109/1,580) tested HIV-positive, HIV positivity rates varying by risk group: 14.5% among sex partners of PLHIV, 5.5% among MSM, 3.3% among PWID, 0.8% among women engaged in commercial sex, 10.1% among other groups. Of those who tested positive, 98.2% (107/109) initiated antiretroviral therapy (ART), 24.3% (358/1,471) of those testing negative initiated pre-exposure prophylaxis (PrEP).

Conclusions: SNS can be implemented at health facilities to reach individuals at risk of HIV, particularly those who have not undergone prior HIV testing. SNS also demonstrated its capability to facilitate linking undiagnosed PLHIV to ART and HIV-negative individuals PrEP. Further efforts can be made to improve PrEP use among clients testing negative.

EP0463

HIV self-testing services to hidden key populations through key population led community-based organizations (CBOs) in Yangon, Myanmar

P.P. Phyo[1], T. Soe[1], M.M. Aung[1], L. Htet[1], L.A. Thu[1], Y.W. Soe[1], T. Yamin Pyone[1], K.K. Lay[1], M.M. Kyaw[1], M.K. Kyaw[1], K.P. Naing[1], S.M. Oo[1]
[1]Community Partners International, AIS, Yangon, Myanmar

Background: Myanmar is one of the 35 countries with highest HIV-burdened countries, with an HIV prevalence rate of 0.57% in 2017. HIV testing coverage among key populations was 31% among men who have sex with men (MSM) and transgender (TG), 41% among female sex workers (FSW), and 28% among people who inject drugs (PWID). To increase case detection and improve linkage to care, the HIV/TB Agency, Information and Services (AIS) activity sought and received approval to begin a small demonstration project that introduced an innovative HIV self-testing strategy following the covid-19 and military coup to address the operational challenges related to limited public health facilities and restricted mobility.
Description: AIS implemented the HIV self-testing project to reach the hidden key populations in Yangon, one of the states and regions in Myanmar with the highest burdens of HIV. The project distributed test kits through peers at five CBOs between April 2023 and December 2024 and ensured that testing services were linked with service centers to accelerate care and treatment services through Sate Cha online support.
Lessons learned: From April 2023 to December 2024, the project was able to provide 2503 KPs with access to HIV testing with a result reporting rate (100%). Of these, 139 clients were identified as reactive results, indicating a 5% reactive rate. 119 positive cases were identified, and 105 clients received treatment at ART centers (88% of confirmed tests). 95% of total reactive clients (n=132) were found as first-time testers.
Additionally, the project linked 306 clients among the 2362 non-reactive clients with PrEP services. The results showed that hidden KPs can be reached and linked with ART services through community channels. Challenges included limited-service provision by CBOs, one partner-one township approach, and delays in national-level implementation of HIV self-testing.
Conclusions/Next steps: HIV self-testing distribution can be scaled up through community channels to help the country achieve the global target, the first 95 goals.
Strengthening capacity and continuous monitoring are essential to increase the role of CBOs in service provisions. Strong advocacy and collaboration between CBOs and service centers should be sustained to improve linkage to care.

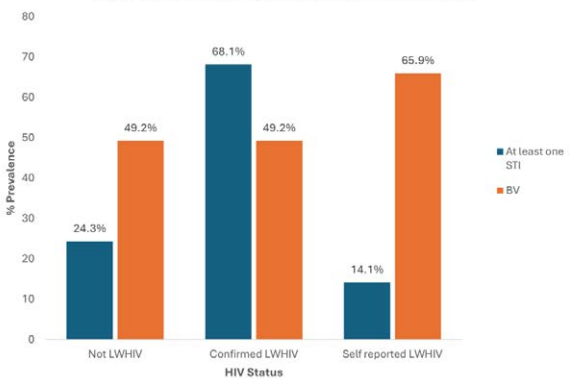
EP0464

Prevalence of sexually transmitted infections and bacterial vaginosis among adolescent girls and young women aged 15 to 24 living with HIV in Lusaka, Zambia

S. Inambwae[1], A. Schaap[1,2], L. Sigande[1], B. Kangololo[1], J. Fitzpatrick[1], M. Cheeba[1], K. Maluzi[1], N. Mwanza[1], F. Chilambe[1], S. Belemu[1], G. Witola[1], V. Cuylaerts[3], I. De Baetselier[3], H. Ayles[1,4], B. Hensen[5], M. Phiri[1]
[1]Zambart, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom, [3]Institute of Tropical Medicine, Clinical Sciences, Antwerp, Belgium, [4]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom, [5]Institute of Tropical Medicine, Sexual Health Unit, Antwerp, Belgium

Background: Adolescent girls and young women (AGYW) living with HIV (LWHIV) may be at increased risk of acquiring other sexually transmitted infections (STIs) and bacterial vaginosis (BV) than those not LWHIV. This study described and compared the prevalence of four curable STIs (chlamydia, gonorrhea, trichomoniasis, and syphilis) and BV among AGYW.
Methods: A cross-sectional survey among adolescents and young people aged 15 to 24 in an urban community (population ~ 200,000) in Lusaka conducted from May-September 2024. Consenting AGYW responded to a questionnaire, provided self-collected vaginal swabs for diagnosis of chlamydia, gonorrhea, and trichomoniasis using GeneXpert, and for BV by Nugent scoring. An HIV/syphilis dual rapid test was offered, reactive syphilis was confirmed by RPR. AGYW were given their results and referred for treatment. This analysis compared the prevalence of STIs and BV among AGYW LWHIV and not LWHIV, and by whether AGYW self-reported their HIV positive status or were diagnosed as LWHIV during the survey.
Results: Among 326 consenting AGYW, 301 (92.3%) tested for HIV or self-reported LWHIV, and provided self-collected samples for STI testing. Overall, 5.0% (15/301) were LWHIV; 60.0% (n=9/15) were diagnosed during the survey. STI prevalence was 24.3% (95%CI 17.2, 31.4) among AGYW not LWHIV compared to 49.8% (95%CI 23.4, 76.1) among AGYW LWHIV (p<0.001); STI prevalence was higher among AGYW diagnosed as LWHIV during the survey compared to those self-reporting LWHIV, with no statistical evidence of a difference (p=0.11; Fig1).

Fig 1: Prevalence of atleast one curable STI (chlamydia, gonorrhea, trichomoniasis, and syphilis) and BV among AGYW by HIV status



Findings were similar for BV; prevalence was lower among AGYW not LWHIV (49.3% 95%CI 42.7, 55.8) than AGYW LWHIV (86.8% 95%CI 69.5, 100; p=0.01)

Conclusions: The burden of STIs and BV was higher among AGYW LWHIV compared to AGYW not LWHIV, with no difference by whether or not AGYW self-reported LWHIV. AGYW LWHIV are an important group for interventions that integrate STI testing and treatment into HIV treatment services.

EP0465

Evaluation of eight HIV rapid test kits: findings from the verification study conducted in Cameroon

J.d.D. Anoubissi[1], R. Onana[1], L. Bissaï[1], F. Tsimene[1], J. Metambou[1], A. Messeh[1], O. Etogo[2], R. Ajeh[3], J. Fokam[4,1]

[1]National AIDS Control Committee, Yaounde, Cameroon, [2]World Health Organization, Country Office, Yaounde, Cameroon, [3]Coordination Unit of the Global Funds and Partners Grants for fight againts Aids,Tuberculosis and Malaria, Yaounde, Cameroon, Yaounde, Cameroon, [4]Chantal BIYA International Reference Centre (CBIRC) for Research on HIV/AIDS Prevention and Management, Yaounde, Cameroon

Background: In 2020, Cameroon started the process of transitioning from a two-test to a three-test HIV diagnostic algorithm, aligning with World Health Organization guidelines. To facilitate this transition, the country conducted a verification study to identify suitable three-test combinations from eight WHO-prequalified HIV rapid diagnostic tests (RDTs).

Methods: Blood samples were collected from consenting clients in four health facilities in Yaoundé and characterized using KHB rapid diagnostic tests and INNO-LIA HIV I/II Ag/Ab assays in parallel to select HIV-negative specimens. Two different lots of each rapid diagnostic test (RDT) were used, and each sample was tested by two different operators on each lot to control for inter-lot and operator variability. In total four tests were conducted for an RDT in each sample.

A sample was considered reactive for an RDT if it was reactive on both lots, negative if non-reactive on both lots and inconclusive otherwise.

Results: A total of 172 samples were collected from four healthcare facilities. Following characterization, 147 samples tested negative, from which a panel of 100 negative samples was randomly selected. False reactivity rates among the eight rapid diagnostic tests (RDTs) were as follows: 0% for First Response® HIV 1-2-0 Card Test, First Response HIV1+2/Syphilis Combo, and STANDARD Q HIV/Syphilis Combo Test; 1% for Determine HIV Early Detect and Bioline HIV/Syphilis Duo; 2% for Alere Determine HIV-1/2; and 4% for Rapid Test for Antibody to HIV (Colloidal Gold Device).

The ONE STEP Anti-HIV (1&2) Test exhibited 0% false reactivity in 99 samples, with one sample yielding inconclusive results. Notably, Bioline HIV/Syphilis Duo and Rapid Test for Antibody to HIV (Colloidal Gold Device) both demonstrated cross-reactivity with a single sample, which also showed reactivity in one lot of the ONE STEP Anti-HIV (1&2) Test. The total false reactivity rate was recorded 1.03% (33/3200).

Conclusions: The study identified instances of false reactivity and shared false reactivity among some of the RDTs. These findings underscore the importance of conducting thorough evaluations of RDTs before their integration into HIV testing algorithms to ensure diagnostic accuracy, minimize the risk of misdiagnosis, and maintain the reliability of HIV testing services.

EP0466

The impact of social network-driven interventions on HIV testing uptake among high-risk populations: a Uganda retrospective cohort analysis

K. Wilson[1], J. Baligobye[2], H. Ssemuwemba[3], L. Buzaalirwa[1], K. Sulaiman[4]

[1]Mbarara University of Science and Technology, Medicine, Masaka, Uganda, [2]Makerere University, Public Health, Kampala, Uganda, [3]Uganda Martyrs University, Public Health, Kampala, Uganda, [4]Makerere University, Medicine, Kampala, Uganda

Background: HIV remains a significant global public health challenge. High risk populations such as People Who Inject Drugs (PWID), Men Who Have Sex with Men (MSM) and Female Sex Workers (FSW) are disproportionately affected by constraints accessing HIV testing services because they are marginalized and stigmatized. Achieving widespread HIV testing coverage, especially among high-risk populations, continues to be a critical component in controlling the epidemic.

The aim of this study is to evaluate the impact of social Network driven interventions on increasing HIV testing rates among high-risk populations.

Methods: This study employed a retrospective cohort analysis from January 2023 to December 2024, focusing on social network-driven strategies to increase HIV testing uptake among high-risk populations. Social networking techniques were applied through peer-driven outreaches, in which individuals from these groups who had already undergone testing encouraged their peers to participate.

Additionally, community leaders within these social networks played an active role in normalizing HIV testing and reducing stigma. Social media platforms were also used to spread awareness, address misconceptions, and provide support. The expected outcome was increased HIV testing rates within these populations. The impact of these strategies was assessed using logistic regression.

Results: The study revealed a significant increase in HIV testing uptake among high-risk populations, from 45% to 72%. Peer-driven outreach contributed to a 50% increase in testing among MSM, while community leaders facilitated a 65% rise among FSW. Social media campaigns and local organizations boosted testing among PWID by 40%. Statistical analysis showed that individuals involved in social network-driven interventions had an adjusted prevalence ratio (aPR) of 1.75 (95% CI: 1.32–2.30, p < 0.001)

for higher testing uptake. The 20-24 age group also exhibited a significant rise in testing, with an aPR of 1.45 (95% CI: 1.10–1.92, p = 0.012). FSW had the highest testing rates among the studied populations, with an aPR of 1.68 (95% CI: 1.25–2.26, p = 0.002), highlighting the success of peer-driven interventions.

Conclusions: Social network-driven interventions significantly enhance HIV testing uptake among high-risk populations and their adoption is key in improving HIV testing service coverage in these marginalized populations.

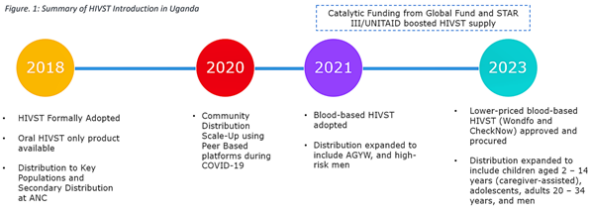
EP0467

Scaling up multiple blood-based HIV self-tests in Uganda: key insights for implementation

M. Lubega[1], P. Nettleton[1], M. Ginivan[1], L. Kabunga[1], J. Kabunga[1], C. Stillson[1], C. Katusiime[2], R. Mutumba[2]
[1]Clinton Health Access Initiative, Kampala, Uganda, [2]Ministry of Health, Kampala, Uganda

Background: HIV self-testing (HIVST) expands access to HIV testing services (HTS) by addressing barriers such as stigma and accessibility. Currently, most countries have implemented only oral HIVST. Uganda adopted HIVST in 2018, but high costs of early kits ($2.00+ EXW) limited use until 2022, when cheaper blood-based (BB) HIVST kits (≤$1.50 EXW) were introduced, enabling increased procurement within constrained budgets. Leveraging lower-priced kits, Uganda initiated an HIVST scale-up program to enhance HTS accessibility. Uganda stands out as one of the first to adopt and scale multiple BB HIVST products, positioning them well to share valuable considerations for BB HIVST implementation.

Description: In 2023, Uganda introduced two lower-priced BB HIVST kits, Wondfo ($1 EXW) and CheckNow ($1.50 EXW). In 2020, only 3% of all HIV tests distributed in Uganda were HIVST. By 2023, distribution increased over four-fold, representing 12% of all rapid HIV tests. This expansion enabled the introduction of more HIVST distribution channels (Fig. 1)



Lessons learned: Implementing multiple HIVST kits in Uganda highlighted several key lessons:

- **Cost savings**: Introducing lower-cost, WHO-prequalified (PQ) BB HIVST kits allowed for more efficient use of available resources, supporting procurement growth from under 500,000 kits in 2018 to nearly 3 million in 2023 while reducing non-PQ products in the private market.
- **Adaptable supply system:** To ensure early adoption at facility level, supply chain used a 'push' system to send kits to facilities based on pre-determined allocations. This then shifted to a 'pull' system where sites place orders for the new BB HIVST. This highlights the need for flexible systems in scaling HIVST services.
- **Demand Generation:** Sensitization of healthcare workers and communities about new products is critical for increasing awareness and uptake.

Conclusions/Next steps: Scale-up of BB HIVST demonstrated the value of diversified HTS options. To sustain progress, efforts will focus on expanding distribution channels and strengthening M&E systems.

EP0468

Machine guided HIV Screening and testing among adolescents girls and young women compared to manual screening and testing outcomes in Kenya

D. Wandina[1], E. Kaunda[2], D. Juma[3], S. Minyatta[1], A. Kahiga[4], M. Kitheka[5], O. Edmond[6]
[1]Gold Star Kenya, HIV Prevention, Nairobi, Kenya, [2]Deloitte & Touché LLP, Health System Developer, Nakuru, Kenya, [3]Deloitte & Touché LLP, Data Manager, Nakuru, Kenya, [4]Deloitte & Touché LLP, Deputy Chief of Party, Nakuru, Kenya, [5]Deloitte & Touché LLP, Chief of Party, Nakuru, Kenya, [6]USAID East Africa, HIV Prevention, Nairobi, Kenya

Background: Kenya has one of the largest HIV epidemics globally, with women constituting 62% of the 1.3 million people (15+ years) living with HIV. In 2023, Kenya achieved 97% of the 1st 95 of the UNAIDS goals. However HIV knowledge among adolescents and young people (AYP) remains low, at 80%. Kenya needs to adopt targeted testing approaches to close the AYP testing Gap. Mutai, C.K.et all 2021estimated with machine learning 11% of females are at high exposure of HIV infection.

The objective was to identify high HIV identification and prevention strategies among Adolescent Girls and Young Women(AGYW).

Methods: A cross-sectional data review was done on outcomes of machine-aided HIV risk stratification in 84 health facilities supported by the USAID Tujenge Jamii project across 4 counties in Kenya. The program trained healthcare workers on the use of machine-aided HIV exposure screening in health facilities using electronic medical records at the HIV testing points in the general population.

The outcomes were compared to facilities using a manual HIV screening guide. All eligible clients were linked for testing with positive client linked to treatment and clients testing HIV negative with ongoing exposure referred for prevention interventions.

Results: Between October 2023 and August 2024 out of 33,697 clients tested for HIV in the 82 facilities 27,413 (62%) were AGYW aged 10-24 years who were screened using machine learning with 421 (22%)were classified as the highest exposure with a 3% positivity, 2803 (17%)were classified as high exposure with a 0.8% positivity, 8,048(48%) as a moderate exposure with a 0.6% positivity and 5,548 (33%)were low exposure with a 0.4% positivity. This was significantly higher than outcomes from manual screening 12% AGYW screened with a manual questionnaire with 10,419 tested a 0.38% positivity among AGYW in non AI health facilities with 55% Very high exposure and 43% high exposure linked to prevention.

Conclusions: The machine-aided HIV exposure classification has higher HIV positivity than manual screening, ML is a useful tool in improving access to HIV identification and and prevention demonstrating the need to scale up ML in facilities with electronic medical records.

EP0469

Bridging pediatric HIV testing gaps in Ghana: a case for client-centered approaches

E.E. Houphouet[1], W. Kwarah[1], E. Sullivan[1], H. Robinson[1], E. Essandoh[1]

[1]United States Agency for International Development (USAID), Accra, Ghana

Background: Despite a variety of testing modalities implemented, UNAIDS estimates 1,200 unidentified children living with HIV in three U.S. President's Emergency Plan for AIDS Relief (PEPFAR)-supported regions of Ghana.
This study assesses pediatric HIV testing outcomes in these regions (Western, Western North, and Ahafo) to inform targeted approaches and close case finding gaps.
Methods: We used Microsoft Excel to analyze routine de-identified PEPFAR program data collected from 2021 to 2022. The primary outcome of interest is HIV detection among children younger than 15 years old, disaggregated by testing modality, geographic region, age group, and sex.
Results: There was an overall yield of 5.3% among the 6,643 children tested. Index testing accounted for a fifth (21%) of all tests and yielded the highest positivity (12.0%). Outpatient testing (OPD) produced the lowest yield (2.7%) but was the most widely used testing modality (60.4% of tests). It accounted for over a third (31.5%) of all detected cases, especially in the regions with fewer children tested, Western North (34.3%) and Ahafo (35.7%) (Table 1).

	Index testing, n=1,396 (21.0%)	Community strategies n=534 (8.0%)	Voluntary counseling and testing, n=703 (10.6%)	Outpatient department testing, n=4,010 (60.4%)	Total n=6,643 (100.0%)
Western, n=3,956 (59.6%)	74 (9.3%)	11 (3.3%)	29 (6.7%)	43 (1.8%)	157 (4.0%)
Western North, n=1,483 (22.3%)	57 (17.5%)	4 (3.5%)	10 (7.9%)	37 (4.0%)	108 (7.3%)
Ahafo, n=1,204 (18.1%)	36 (13.3%)	9 (10.5%)	9 (6.2%)	30 (4.3%)	84 (7.0%)
Total yield	167 (12.0%)	24 (4.5%)	48 (6.8%)	110 (2.7%)	349 (5.3%)

Table 1: Case detection by region and testing modality, n (%)

Positivity was highest among children aged 1-4 (6.7%) and 5-9 (5.9%) and lowest among those aged 10-14. Index testing accounted for the highest yield among all ages, except those 10-14, in which voluntary counseling and testing produced a higher yield (5.2% versus 8.1%, respectively).
Although community testing strategies produced relatively lower yield overall, it proved to be an important modality among children aged younger than five years (Table 2). There were not significant variations by gender (data not shown).

	Index testing, n=1,396 (21.0%)	Community strategies n=534 (8.0%)	Voluntary counseling and testing (VCT), n=703 (10.6%)	Outpatient department (OPD) testing, n=4,010 (60.4%)	Total n=6,643 (100%)
< 5 n= 2,734 (41.2%)	99 (18.3%)	10 (10.4%)	19 (5.4%)	49 (2.8%)	177 (6.5%)
5-9, n=1,837 (27.7%)	52 (9.5%)	9 (5.4%)	17 (8.5%)	30 (3.3%)	108 (5.9%)
10-14, n=2,072 (31.2%)	16 (5.2%)	5 (1.9%)	12 (8.1%)	31 (2.3%)	64 (3.1%)
Total positive	167 (12.0%)	24 (4.5%)	48 (6.8%)	110 (2.7%)	349 (5.3%)

Table 2: Case detection by age group and testing modality.

Conclusions: Each modality proved important among distinct regions and groups to detect pediatric HIV cases. Implementing a mix of high yield and high-volume interventions targeting specific sub populations is crucial for pediatric case finding.

EP0470

Targeted approaches for acute HIV diagnosis in rural Eswatini

I. Ciglenecki[1,2], B. Kerschberger[3], E. Mukooza[3], S. Lekelem[3], N. Ntshalintshali[3], M. Mavimbela[4], S. Dlamini[5], L. Dube[4], N. Mabuza[5], N. Staderini[1], T. Ellman[6], A. Flores[6], L. Toutous Trellu[7], O. Keiser[2], M. Haile[1], S. Matse[4], A. Calmy[2,7]

[1]Médecins Sans Frontières, Geneva, Switzerland, [2]Institute of Global Health, University of Geneva, Geneva, Switzerland, [3]Médecins Sans Frontières, Mbabane, Eswatini, [4]Eswatini National AIDS Programme (ENAP), Ministry of Health, Mbabane, Eswatini, [5]National Reference Laboratory (NRL), Ministry of Health, Mbabane, Eswatini, [6]Médecins Sans Frontières, Cape Town, South Africa, [7]University Hospital of Geneva, Geneva, Switzerland

Background: Acute HIV infection (AHI) is likely contributing to ongoing HIV transmission, but it is rarely diagnosed in high-burden settings due to difficult and resource-intensive diagnosis. Targeted testing of individuals at higher risk of AHI could improve efficiency and AHI yield.
We used data from a cross-sectional study of STI burden to evaluate the performance of different targeting approaches for AHI testing.
Methods: Consenting adults attending routine HIV testing services at six study sites in rural Eswatini from June 2022 to April 2023 underwent HIV viral load testing (VL, Xpert) and completed a questionnaire on demographic, behavioral and clinical characteristics. AHI was defined as a negative or discordant serial HIV rapid diagnostic test (RDT) together with VL ≥10,000 copies/mL.
We used lasso to identify risk factors for AHI. We plotted and cross-tabulated the sensitivity, specificity and proportion needed to test (PNT) estimates to select the optimal cut-off points.
We evaluated the performance of PRS and different simplified targeting approaches ("AHI symptoms": fever, rash, sore throat, aches and pains, lymphadenopathy, mouth sores and/or headache; PrEP initiation AHI screening criteria ("AHI symptoms" and possible exposure in the past 14 days) and young women (18-29 years old) with AHI symptoms).

Results: Among 1064 participants (median age 27 years (IQR 22–33); 651 (61.2%) female), ten (0.9%) were diagnosed with AHI. The PRS included 10 variables: being female, age 18-29 years, visiting facility for family planning or being sick, and reporting headache, vomiting, genital or mouth sores, blood in urine and discordant HIV RDT result. Performance of the PRS at two thresholds (≥10.8 and ≥14.1) and simplified strategies are summarized in the table.

	PRS ≥10.8	PRS ≥14.1	AHI symptoms	AHI screening PrEP initiation	Young women with AHI symptoms
Sensitivity	100% (69-100)	80% (44-98)	100% (69-100)	40% (12-74)	90% (56-100)
Specificity	74.6% (72-77)	89.2% (87-91)	36.2% (33-39)	61.9% (59-65)	72.7% (70-75)
Area under the curve	0.87 (0.86-0.89)	0.85 (0.71-0.98)	0.68 (0.67-0.70)	0.51 (0.35-0.67)	0.81 (0.71-0.91)
Pos predictive value	3.6% (2-7)	6.6% (3-13)	1.5% (0.7-2.7)	1.0% (0.3-3)	3.0% (1-6)
Neg predictive value	100% (99.5-100)	99.8% (99-100)	100% (99-100)	99.1% (98-100)	99.9% (99-100)
Nb (proportion) to test	278 (26.1)	122 (11.5%)	682 (64.1%)	406 (38.1%)	297 (27.9%)
Nb to test for one AHI	28	15	68	101	33

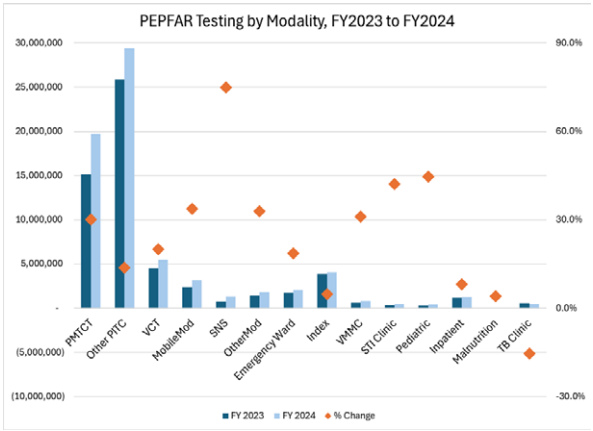
Conclusions: Targeted approaches combining AHI symptoms and locally relevant characteristics may be a way forward to scale-up AHI testing in resource-limited settings. However the current WHO-recommended AHI screening criteria prior PrEP initiation performed poorly.

EP0471

HIV testing scale-up in FY2024 in PEPFAR-supported programs to achieve treatment and prevention goals

A. Jones[1], D. Parrish[1], B. McClure[1], E. Manfredini[2], H. Wolf[1]
[1]U.S. Department of State, Bureau of Global Health Security and Diplomacy/PEPFAR, Washington, United States, [2]United States Agency for International Development, Office of HIV/AIDS, Washington, United States

Background: Beginning in COP22 (FY2023), PEPFAR HIV Testing Services (HTS) guidance evolved to focus on HIV testing for prevention in addition to treatment. Targeted case-finding, including social network strategies (SNS) among priority populations, addresses gaps in the first 95. Testing for prevention facilitates the scale-up of PrEP and supports prevention of mother to child transmission (PMTCT) with repeat testing in pregnant and breastfeeding women (PBFW). This analysis quantifies how PEPFAR's evolving priorities are reflected in testing volume across the program.
Methods: We performed a descriptive analysis of PEPFAR program data for HTS and PrEP reported during FY2023 and FY2024, excluding Nigeria due to ongoing data quality efforts. Total testing volume was summarized by age, sex, modality (method or location of testing), and year. A PrEP use testing proxy was built by adding the number of individuals initiated on PrEP and quarterly disaggregates for HIV testing among individuals continuing on PrEP.
Results: Between FY2023 and FY2024, HIV testing volume increased from 58,696,387 to 70,507,520 (20% increase). Testing volume increased by more than 20% in females under 35 and males under 25 years of age. PMTCT testing volume increased from 15,129,650 to 19,681,113 (30% increase), the largest increase by volume among all modalities, driven in part by retesting of PBFW. SNS testing volume increased from 749,362 to 1,311,299 (75% increase), the largest percentage increase among all modalities. [Figure] PrEP testing proxy volume increased from 3,514,674 to 4,801,982 (37% increase).



Conclusions: Testing increases from FY2023 to FY2024 were greatest in modalities central to PEPFAR's goals of case-finding in priority populations (e.g. SNS), and expanding prevention – particularly PMTCT and PrEP.
Increases were concentrated in pediatrics, youth, and women of reproductive age. As PEPFAR-supported countries work to end HIV as a public health threat, testing strategies must continue to evolve to fit the epidemiologic context.

EP0473

Scaling HIV testing for adolescents and young people: does SNS outperform traditional approaches in Zambia?

C. Musonda[1], N. Mwelwa[1], B. Michelo[1], T. Mwamba[1], P. Haimbe[1], H. Shakwelele[1]
[1]Clinton Health Access Initiative, HIV Testing Services, Lusaka, Zambia

Background: In Zambia, 96% of the general population is aware of their HIV status, 85% of these are adolescents and young people (AYP). In 2024, they accounted for 65% of HIV tests performed. (DHIS2, 2024). In 2019, the World Health Organization recommended Social Network Strategy (SNS) to increase HIV testing among populations at high risk of HIV acquisition such as AYP. Zambia's Ministry of Health (MoH) adopted SNS to increase HIV testing among adolescents and young people. MoH collaborated with the Clinton Health Access Initiative (CHAI) to assess the effectiveness of SNS in reaching AYP testing targets.
Methods: CHAI conducted a desk review of HIV testing data for AYP over 12 months (January- December 2024) from seventy health facilities in two districts of Eastern province. Data was categorized into six testing modalities: community, outpatient department (OPD), social

network strategy testing (SNS) voluntary counseling and testing (VCT), sexually transmitted infection (STI), and index case testing. The review sought to establish whether SNS had a greater reach of AYP than traditional testing modalities and the positivity yield obtained.

Results: A total of 35,027 AYP aged between 15 and 34 years tested for HIV during the period, 10,789 (31%) tested through OPD. 24,221 (69%) were female and 10,806 (31%). 8,822 tested (25%) through the community. 7,868 (22%) through VCT. 3,823 (11%) through SNS 2,331 (7%) through Index and 1,394 (4%) through STI. Index case testing had the highest yield of 42%, followed by OPD with 27%, VCT, and community at 10%, SNS at 7%, and STI at 4%.

Conclusions: The findings of this review suggest that MOH must continue to use a variety of testing modalities to test as many AYP as possible. This will sustain the gains achieved in the first 95 of the UNAIDS targets. SNS though recommended to reach more populations with high risk of HIV acquisition did not reach more AYP testing for HIV in this case. The review determined that in AYP, other testing modalities such as OPD, community, and VCT reached more AYP and yielded higher results.

EP0474

Improving access to HIV testing and prevention services among female sex workers through Social Network Strategy (SNS) at Bar Hostess Empowerment & Support Program (BHESP) mowlem dice Nairobi County, Kenya

M. Brian[1], M. Ken[1], K. Loreen[1], A. Susan[1], R. Marima[1], J. Mecha[1], C.F. Otieno[1], G. Rutto[1], E. Kubo[1], J. Gacheru[2]
[1]University of Nairobi, USAID Fahari ya Jamii Project, Department of Clinical Medicine and Therapeutics, University of Nairobi School of Medicine, Nairobi, Kenya, [2]Bar Hostess Empowerment and Support Program (BHESP), Nairobi, Kenya

Background: The Social Network Strategy (SNS) is an evidence-supported recruitment approach for reaching and providing HIV testing and prevention services to high-risk networked individuals who are unaware of their HIV acquisition. SNS is a cost-effective strategy beneficial for recruiting marginalized and/or hidden persons at risk for HIV, and Key populations are a perfect example due to intertwined reasons such as social stigma, perceived isolation, and legal challenges they face. Despite the advancements in HIV testing and case identification in the general population, Key Populations are still lagging in HIV testing and positive case identification.

Description: Using non-incentivized coupons, existing cohorts referred peers within their social networks—many from previously unserved hotspots—for testing and prevention services. Testing was conducted at these hotspots during outreach events and at the Drop-in Center (DIC) during routine service delivery. Weekly follow-ups by outreach workers enabled tracking and facilitated linkages to additional services.

From October 2023 to July 2024, the project engaged 160 female sex workers, resulting in 875 referrals for HIV testing. Of those referred, 699 (88.4%) were tested, and 53 tested positive, with 100% initiated on ART. Among those testing negative, 93% were linked to prevention services, including PrEP, STI treatment, and Post-Exposure Prophylaxis.

The SNS approach proved twice as effective as standard HIV testing recommendations, contributing to 42% of the total positive cases with an 8% yield. Social network testing has significantly improved HIV testing rates and positive case identification among hard-to-reach key populations by leveraging existing social structures and relationships.

Lessons learned: The Social Network Strategy (SNS) has proven highly effective in identifying HIV-positive cases among Female Sex Workers (FSWs), achieving double the effectiveness of quarterly HIV testing services (HTS) with a higher yield and substantial contribution to total positive cases.

By leveraging social connections, reducing stigma, and improving outreach, SNS successfully reaches hard-to-reach key populations, fostering a supportive environment that encourages testing and links both HIV-positive and HIV-negative individuals to necessary care and prevention resources.

Conclusions/Next steps: Adapt SNS strategies to other public health programs for better engagement and outcomes among marginalized groups

EP0475

Leveraging digital platforms to improve access and utilization of HIV/AIDS services among young people in Uganda

E. Kagguma Kakooza[1], L. Bufumbo[1]
[1]Johns Hopkins University/ Center for Communication Programs, Center for Communication Programs, Kampala, Uganda

Background: Uganda faces challenges in achieving the UNAIDS 95-95-95 targets, with only 81% of adults aged 15 and above aware of their HIV status. Young people (10-30 years), contributing to two-thirds of new HIV acquisition, demonstrate limited comprehensive HIV knowledge (51%, UDHS 2022). To address this gap, USAID's SBCA launched "REAL KOOL is Knowing Your Status," a youth-focused campaign promoting stigma reduction and uptake of HIV prevention, care, and treatment services.

Description: From December 2023 to October 2024, the campaign utilized digital platforms, including social media and interactive tools like "Dr. Ezzy," a virtual character offering support via WhatsApp, SMS, and hotline services. Social media influencers, including people living with HIV, enhanced engagement. Partnerships with private sector companies expanded access to HIV self-test kits and condoms, while TV, radio, and print media complemented outreach efforts.

Lessons learned: Leveraging digital platforms effectively increased awareness and access to HIV services among young people, as evidenced by the distribution of 7,500 HIV self-test kits and 11,250 condoms, with 69% of the kits accessed by individuals aged 20-30 and 52% by females. The campaign's "Dr. Ezzy" platforms recorded 80,000 in-

quiries, with males favoring hotlines and females preferring WhatsApp. Additionally, social media engagement exceeded 1.5 million interactions, while radio and TV reached approximately 4 million individuals, highlighting the impact of tailored, multi-platform approaches.
Conclusions/Next steps: Sustained efforts should prioritize enhancing HIV knowledge, addressing low-risk perception, and expanding access to HIV self-testing kits. Inclusive outreach targeting underrepresented groups, like adolescents aged 10-14, and bridging the digital divide through diverse media platforms are critical for scaling up HIV prevention services.

EP0476

Factors associated with of HIV testing coverage among contacts of HIV index clients in Rwanda: HIV case based surveillance data 2019-2022

V. Masengesho[1], Z. Nzeyimana[2], M. Habtu[3]
[1]Mount Kenya University, Master's of Public Health, Kigali, Rwanda, [2]Rwanda Biomedical Centre, HIV, Viral Hepatitis, and STIs Division, Kigali, Rwanda, [3]Mount Kenya University, MPH, Kigali, Rwanda

Background: HIV/AIDS remains a significant global public health challenge. HIV Case-Based Surveillance (CBS) is a systematic approach to collecting and analyzing data on people living with HIV (PLWH) to inform targeted response efforts based on population and geographic characteristics. Since 2018, the Rwanda Biomedical Centre has implemented CBS and HIV-1 recency testing as part of its epidemic control strategy.
The program involves PLWH aged 18 and above, who provide information on their contacts, including biological children, sexual partners, and social network members. While this data is documented in CBS registers and reported through the District Health Information Software 2 (DHIS-2), not all elicited contacts undergo HIV testing.
This study analyzes HIV CBS data from 2019–2022 to determine the contact-to-index ratio, HIV testing coverage among contacts, and factors associated with non-testing of elicited contacts.
Methods: This study wasa retrospective cross-sectional study analysis HIV CBS data quantitatively. Finally, logistic regression analysis of factors associated with non-testing of elicited contacts was done to determine the strength of the association.
Results: During HIV case-based surveillance (CBS), each index client provided an average of 1.1 contacts. Of the 74,892 contacts elicited, approximately 66% were tested for HIV. The likelihood of being tested was higher among contacts with no history of intimate partner violence involving the index client (aOR: 21.23; 95% CI: 12.32–36.60), those who were married (aOR: 1.37; 95% CI: 1.15–1.60), individuals with 3 to 10 contacts in the past three months (aOR: 1.27; 95% CI: 1.03–1.55), and those currently on antiretroviral therapy (ART) (aOR: 1.5; 95% CI: 1.25–1.79).
Conversely, testing likelihood was lower among married or cohabiting partners compared to other contact-index relationships, such as occasional partners, children, or social network members (aOR: 1.2–1.7). It was also lower among contacts with 21 or more lifetime sexual partners compared to those with 1–2 partners (aOR: 0.52; 95% CI: 0.34–0.79).
Conclusions: This study shows the need to combat HIV related stigma and train HCPs on building trust and safeguarding clients' information confidential especially in countries with low HIV prevalence like Rwanda.

EP0477

Expanding coverage by integrating provider-initiated HIV counselling and testing services at out-patient departments during year 2023 in northeastern India

S. Chawla[1], A. Sekhose[2], J. Ralte[3], N. Jamir[2], S. Zothanzami[3], Y. Yanthan[4], T. Jamir[4], H. Tep[4], A. Chakraborty[4], C. Lalrindiki[4], R. Lalrempuia[4], L. Lalrinawma[4], P. Choudhury[4], R. Singh[4], G.S. Shreenivas[4], R. Sindhu[4], A. Hegde[4], U. Sharma[1], S. Upadhyaya[1], P. Nadol[1]
[1]CDC, Health, New Delhi, India, [2]Nagaland SACS, Kohima, India, [3]Mizoram State AIDS Control Society, Aizawl, India, [4]PATH, New Delhi, India

Background: The states of Mizoram and Nagaland, India have the highest state adult HIV prevalence (2.73% and 1.37%, respectively), relative to the national prevalence (0.20%). Integration of provider-initiated HIV Counseling and Testing (HCTS) into out-patient department (OPD) of hospitals is recommended under national guidelines.
To describe the uptake of the same OPD screening was initiated during April-July 2023 in two high patient load district hospitals of Dimapur and Aizawl, in Nagaland and Mizoram, respectively.
Description: We sensitized OPD medicine, pulmonary, skin and venereal disease department staff and medical officers on the need to scale up provider-initiated HCTS and trained them on providing HCTS aligned with the national guidelines. All patients seeking care at these OPD were routinely offered HIV testing using an opt-out strategy following the national HCTS guidelines, and those that were reactive were referred for confirmatory testing.
Lessons learned: By September 2024, 5,266 people were tested at these two facilities; 57% (2,991/5,266) were males and 69% (3599/5,266) were < 35 years of age. Of those tested, 77% (4,034/5,266) were first-time testers. In total, 4% (232/5266) were found reactive and most (91%, 210/232) were presenting with minor ailments in the Medicine (164) and Dermatology (46) departments, and 91% (212/232) were confirmed HIV-positive, remaining pending. All 212 were first-time testers and linked for treatment initiation, and 89% (189/212) were started on treatment till Sep 2024. Baseline CD4 tests were done for 70% (149/212) and the majority (55%, 82/149) had CD4 counts > 200 cells/mm^3.
Experience from this exercise showed that in high-prevalence areas, it was worthwhile offering testing to everyone presenting in health care setting, despite not having any HIV-specific symptoms.
Conclusions/Next steps: This approach was effective in reaching undiagnosed males and younger people with testing services. Integration of HCTS at OPD can facilitate detection and linkage of asymptomatic people living with

HIV who would have otherwise been missed during routine screening. The success of this initiative underscores the potential value of expanding HCTS to other sectors in the health care system in terms of HIV case-finding and linkage to treatment. The initiative is being scaled up in all the district hospitals of Nagaland and Mizoram.

EP0478

Targeted social network-based testing during the year 2023 among individuals vulnerable to HIV in Mumbai, Maharashtra, India

V. Karanjkar[1], S. Suryavanshi[2], A. Hegde[2], G.S. Shreenivas[2], J. Syed Iqbal[2], S. Sheik[2], R. Singh[2], V. Jondhale[2], P. Jha[2], A. Saxena[2], S. Bhagat[2], S. Dhande[2], S. Mestry[1], A. Shinde[1], S. Chawla[3], U. Sharma[3], S. Upadhyaya[3], P. Nadol[3]

[1]Mumbai District AIDS Control Organization, Mumbai, India, [2]PATH, New Delhi, India, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, New Delhi, India

Background: HIV case identification in Mumbai is a challenge, with approximately 17,000 individuals still unaware of their HIV status. Index testing services (ITS) is a proven approach to test people with known exposure to HIV. Testing of sexual partners of people vulnerable to HIV, known as social network-based testing strategy (SNS), was a related approach adapted in Mumbai with technical assistance from the U.S. President's Emergency Plan for AIDS Relief (PEPFAR)-supported project Sashakt for strengthening case detection. It was implemented at 12 high-load HIV Counselling and testing services (HCTS) sites in Mumbai from January to September 2023.

Description: The project offered SNS testing to all those who were at risk for HIV (as per standardised risk assessment under national guidelines (e.g., people with multiple unprotected sexual partners, people who inject drugs) and recently tested HIV-negative at select HCTS sites. During post-test counselling, counsellors encouraged them through a non-coercive voluntary approach to share their partner's details and refer partners for HIV testing at the same or preferred HCTS site.

Lessons learned: Among the 44,910 individuals tested at 12 high-load HCTS sites in Mumbai, 509 (1%) were diagnosed as HIV-positive, and 44,401 (99%) tested HIV-negative. Out of them, 4% (1,644/44,401) were identified as at risk of getting HIV and provided information about SNS by the counsellors. Among them, 88% (1,450/1,644) were offered partner testing (spouse and other sexual partners), by the project staff, of which 61% (888/1,450) agreed and shared details of 991 (1.1 partner elicitation rate) partners. Of those elicited, 508 (51%) partners were tested till September 2023, with 20 (4%) confirmed positive. All 20 newly-detected people living with HIV (PLHIV) were initiated on treatment.

Conclusions/Next steps: Testing sexual partners of known HIV-negative yet at-risk individuals was effective in identifying and initiating treatment for new PLHIV with a yield of 4%. The initiative was transitioned to the Mumbai District AIDS Control Society after September 2023 and rapidly scaled up to remaining 37 HCTS sites of Mumbai.

Cascades of HIV prevention, treatment and care

Peer navigation improves viral load testing coverage and suppression among at-risk and vulnerable populations in Morogoro, Tanzania

J. Makwandi[1], B. Ogwan'g[1], J. Ng'washemi[1], A. Itaka[1], G. Mwakapinga[1], L. Lutte[1], H. Kiloya[2], E. Herman[1], J. John[2], D. Boyee[1], C. Fischer Walker[3], C. Akolo[3], D. Carpenter[3]

[1]FHI 360, Tanzania, KVP, Dar es Salaam, United Republic of Tanzania, [2]Huruma Aids Concern and Care (HACOCA), Tanzania, KVP, Morogoro, United Republic of Tanzania, [3]FHI 360, Washington DC, HIV, Washington DC, United States

Background: According to the 2022/23 Tanzania HIV Impact Survey (THIS), 98.3% of individuals in Morogoro who are aware of their HIV-positive status are on antiretroviral therapy (ART). However, only 92% have received viral load (VL) testing, highlighting ongoing challenges in reaching at-risk and vulnerable populations (VPs) for consistent HIV care and support for VL suppression (VLS) that are worsened by stigma, socioeconomic constraints, and limited access to health education and care. To address these challenges, peer navigator (PN) approach was introduced to support ART adherence, facilitate VL testing, and improve VLS among KVPs.

Description: In December 2021, the Meeting Targets and Maintaining Epidemic Control (EpiC) project introduced the PN approach in Morogoro, where PNs provided adherence counseling, traced clients with interruption in treatment, and facilitated regular VL testing. PNs leveraged their shared experiences with VPs to build trust and encourage engagement in HIV care. Initially, 22 PNs were engaged in December 2021, with the number increasing to 36 by fiscal year 2024. From December 2021 to September 2024, PNs documented each interaction, including information on patients eligible for tracked VL testing, those who received VL tests, and those who achieved VLS. Chi-square tests were used to compare suppression rates over time.

Lessons learned: The PN approach led to significant improvements in VLS rates among VPs. In the pre-intervention period (July–September 2021), 76% of clients with documented VL results achieved VLS (Table 1).

After this approach was introduced, VLS rates increased annually, reaching 78% in 2022, 96% in 2023, and 97% in 2024 (χ^2=550.53, p <0.001), underscoring the effectiveness of personalized adherence support provided by PNs in enhancing VLS.

Period	Clients eligible for VL testing	Clients tested for VL	Documented VL results	Clients with VLS	VLS rate (%)
July–September 2021	310	239	212	161	76
July–September 2022	952	710	688	539	78
July–September 2023	1697	1596	1544	1488	96
July–September 2024	2306	2057	2028	1963	97

Conclusions/Next steps: The PN approach effectively addressed barriers to HIV care among VPs by reducing stigma and supporting ART adherence and VL testing. This intervention highlights the potential of

EP0480

Uptake and disparities in tuberculosis screening using urine LAM or Sputum Xpert in advanced HIV disease in Africa: a systematic review and meta-analysis

H.M. Ally[1], A.O. David[2], Z.M. Ally[3], H.M. Bakari[4], M.S. Mbwana[5], S.M. Salim[6], H.F. Fussi[7], G.M. Manayon[8], H.O. Ramadhani[9]
[1]Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, [2]Memorial University of Newfoundland, St. John's, Canada, [3]District Hospital, Tanga, United Republic of Tanzania, [4]University of Dar es salaam, Dar es salaam, United Republic of Tanzania, [5]Primary Health Care Institute, Iringa, United Republic of Tanzania, [6]Canada Youth Group, Dar es salaam, United Republic of Tanzania, [7]District Hospital, Dar es salaam, United Republic of Tanzania, [8]San Lazaro Hospital, Manila, Philippines, the, [9]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States

Background: People with advanced HIV disease face unique challenges in tuberculosis (TB) diagnosis due to low bacterial counts and extrapulmonary TB, necessitating the use of sensitive and rapid diagnostic tests such as urine lateral flow lipoarabinomannan (LF-LAM) and sputum Xpert MTB/RIF. Despite WHO recommendations, TB screening uptake remains suboptimal, particularly in resource-limited settings in Africa.
This study aimed to quantify TB testing uptake, prevalence, treatment initiation, and mortality, as well as to identify disparities by age and study setting, addressing critical gaps in the literature.
Methods: We conducted a systematic search of PubMed, Cochrane Library, and Embase for articles published between January 2011 and November 2024. Eligible studies included those reporting on TB testing uptake, prevalence, treatment initiation, or mortality among people with advanced HIV disease (CD4 ≤ 200 cells/mm³ or WHO stage III/IV) in Africa. Pooled estimates of outcome and 95% confidence intervals (CIs) were calculated using random-effects models. Stratified analyses compared TB testing uptake and TB diagnosis by age group (children vs. adults) and study setting (single-site vs. multi-site).
Results: A total of 16 studies encompassing 15,637 participants with advanced HIV disease were analyzed. The pooled TB testing uptake was 67.5% (95% CI: 45.0–84.1), with lower uptake observed among children compared to adults (24.4% vs. 67.6%; p = 0.04) and in multi-site studies compared to single-site studies (61.0% vs. 87.8%; p = 0.13). TB prevalence was 27.5% (95% CI: 19.4–37.4), with similar rates between children and adults (24.2% vs. 28.6%; p = 0.63) and between multi-site and single-site studies (29.5% vs. 21.9%; p = 0.30). TB treatment initiation was 86.6% (95% CI: 73.1–93.9), and mortality among those with TB was 16.1% (95% CI: 5.7–38.2).
Conclusions: Despite WHO recommendations, three in ten people with advanced HIV disease in Africa are not screened for TB, underscoring critical gaps in diagnosis and care. Lower TB testing uptake among children highlights a pressing need to address disparities and improve pediatric screening strategies.
These findings emphasize the importance of targeted interventions to increase TB testing coverage and ensure timely diagnosis in resource-limited.

EP0481

Trends in maternal obesity, gestational weight gain, and birth outcomes among women living with HIV in Kenya: a prospective cohort study (2008–2017)

N. M. Diwan[1], B. Mbithe[2], W. Muema[2], R. Ngomoa[2], C. Kibaara[2], J. Kariuki[3], D. Karanja[2], M. Nderitu[2], A. Nagy Adly[2], M. H. Chung[1,4,5], A. M. Bengtson[1]
[1]Emory University, Epidemiology, Atlanta, United States, [2]Coptic Hope Center, Nairobi, Kenya, [3]Emory University, School of Nursing, Atlanta, United States, [4]Emory University, Global Health Institue, Atlanta, United States, [5]Emory University, School of Medicine, Atlanta, United States

Background: Women Living with HIV (WLWH) may be at increased risk of suboptimal gestational weight gain (GWG) and subsequent adverse birth outcomes. Longitudinal data from sub-Saharan Africa are needed to inform public health interventions.
Methods: Pregnant WLWH in care at the Coptic Hope Center in Kenya from 2008 to 2017 were identified, and trends in pre-pregnancy body mass index (BMI), GWG, and their association with birth outcomes were analyzed. Pre-pregnancy BMI was defined using first-trimester BMI (Kg/m²) and GWG was assessed using average weekly GWG rate in the second and third trimesters per National Academy of Medicine (NAM) guidelines. Associations of GWG z-score with birthweight, low birthweight, high birthweight, and emergency C-section in singleton births were examined. Multivariable Poisson regression with multiple imputation estimated risk ratios, with bootstrap resampling for 95% confidence intervals.
Results: We analyzed 1,190 pregnancies among WLWH, 56% had linked birth outcomes. Most women had normal (45.1%), overweight (34.3%), or obese (18.0%) pre-pregnancy BMI. From 2008 to 2017, overweight BMI prevalence increased by 11.4%, from 35.2% to 39.2%, and obesity more than doubled, from 13.2% to 27.8%. Normal BMI prevalence declined by 16%, from 50.5% to 42.3%. Most WLWH had GWG rate below NAM guidelines, with 45–63% of normal-weight women and nearly all underweight women gaining inadequately in most years. Among overweight and obese women, 25–50% fell below or above recommendations.
Continuous GWG z-scores were associated with higher birthweight (+41.33g, 95% CI: 3.87, 78.79) and a 35% (aRR 1.35, 95% CI: 1.06, 1.65) increased risk of emergency C-section adjusted for socioeconomic factors, CD4 count, ART regimen class and duration. Women in the lower GWG

z-score tertile had lower birthweights (-118.02, 95% CI: -217.18, -18.87) and a reduced risk of emergency C-section (aRR 0.58 95% CI: 0.26, 0.91).

Conclusions: Trends in pre-pregnancy BMI, overweight, and obesity increased among WLWH in Kenya from 2008 to 2017, but GWG rate was below recommended levels. GWG z-score was associated with higher birthweight and emergency C-section. Interventions are needed to support healthy GWG to prevent adverse birth outcomes and long-term cardiometabolic risk for WLWH.

EP0482

Determinants of antiretroviral therapy retention among people living with HIV: a retrospective cohort follow-up study in Nepal

U. Shrestha[1], S. Rijal[1], Y.R. Sapkota[1], M. Cassell[2], P.K. Thakur[2], M. Kariuki[2], T. Weldegebreal[3], I. Lohar[3], N. Sedhain[1]

[1]FHI 360 Nepal, Strategic Information Unit, Kathmandu, , Nepal, Nepal, [2]FHI 360, North Carolina, United States, [3]USAID, Kathmandu, Nepal

Background: In Nepal, 87% of people living with HIV (PLHIV) who know their status had enrolled in antiretroviral therapy (ART) by 2023. This must be improved to meet the second 95 of the 95-95-95 target. The Meeting Targets and Maintaining Epidemic Control (EpiC) project in Nepal conducted a study to identify determinants of treatment retention among PLHIV.

Methods: We conducted a retrospective cohort study of clinical records of PLHIV who initiated ART between January 2021 and December 2022 at 55 EpiC-supported antiretroviral treatment facilities. Data were extracted from site electronic registers. The cohort was followed until the end of 2023 to analyze factors associated with treatment retention.

Data analysis was performed using binary logistic regression for independent variables: biological sex, World Health Organization (WHO) clinical stage, marital status, time from HIV diagnosis to ART initiation, multi-month dispensing (MMD) of antiretroviral medicines and linked to community care services (CCS). A p-value <0.05 was considered statistically significant.

Results: Treatment retention was 88.4% [4197/4746, 95% CI: 87.4%–89.3%) and 84.9% (1985/2339, 95% CI: 83.3%–86.3%) at 12 and 24 months respectively. Females (AOR: 1.3; p=0.003; 95% CI: 1.10–1.62), WHO stage 1 or 2 at baseline (AOR: 2.4; p=0.000; 95% CI: 1.90–3.10), linked with CCS (AOR: 7.8; p=0.000; 95% CI: 6.42–9.44) were more likely to retain in treatment at 12 months. All 140 individuals receiving MMD remained on treatment (p <0.05) at 12 months. Females (AOR: 1.5; p=0.001; 95% CI: 1.20–1.97), WHO stage 1 or 2 (AOR: 1.5; p=0.01; 95% CI: 1.10–2.11), married (AOR: 1.4; p=0.006; 95% CI: 1.10–1.84), linked with CCS (AOR: 6.7; p=0.000; 95% CI: 5.22–8.54), and rapid ART initiation (AOR: 1.4; p=0.02; 95% CI: 1.04–1.83) were more likely to retain in treatment at 24 months. All 336 individuals receiving MMD remained on treatment (p <0.05) at 24 months.

Conclusions: Retention on treatment at 12 and 24 months was associated with sex, marital status, WHO stage, rapid ART initiation, MMD, and linkage to CCS. These determinants should be considered when conducting adherence counseling and person tracking to minimize treatment interruption to improve ART initiation.

EP0483

The impact of hunger on HIV management in Zambia: insights from the 2024 crisis and implications for Africa's HIV response

C. Hakayuwa[1]

[1]Copperbelt University, Department of Public Health, Ndola, Zambia

Background: In 2024, Zambia faced its most severe hunger crisis in decades, affecting over 6 million people, including 20% of individuals living with HIV (PLHIV). Food insecurity undermined HIV care by compromising antiretroviral therapy (ART) adherence, reducing treatment efficacy, and increasing opportunistic infections. The SMART survey indicated worsening malnutrition, with Southern Province recording a wasting rate of 6.2%, more than double the 2019/2020 drought rate.

Pregnant and breastfeeding women were disproportionately affected, with nearly 112,000 projected to experience wasting, including 13,000 in severe forms. These conditions presented significant barriers to achieving the UNAIDS 95-95-95 targets.

Description: The hunger crisis disrupted ART delivery, with clinic visits declining by 40% in food-insecure areas due to hunger-induced migration. Among PLHIV, 65% missed ART doses due to food insecurity, leading to a 47% increase in cases of detectable viral load. Hospitalizations for opportunistic infections, such as tuberculosis and pneumonia, increased by 30%, with malnutrition complicating 75% of cases. Emergency interventions included mobile clinics and food aid, yet structural challenges, such as stigma and lack of sustainable solutions, persisted.

Lessons learned: Zambia's experience highlights the critical need to integrate nutritional support into HIV programs. Multisectoral collaboration is vital to address the intersection of food insecurity and HIV. Community-based solutions, such as mobile health units, effectively reduce access barriers during crises.

Evidence from Kenya and Malawi confirms that integrating nutritional support with ART improves adherence and health outcomes. Addressing stigma related to both food insecurity and HIV is essential for promoting timely care.

Conclusions/Next steps: A holistic approach that combines food security interventions with HIV care is essential for improving resilience among PLHIV during crises.

Proactive measures, such as including food security strategies in national HIV programs, are crucial for achieving global HIV targets.

Zambia's lessons provide a model for Africa's broader response to the combined challenges of food insecurity and HIV management.

EP0484

Factors associated with viral unsuppression among children and adolescent clients on antiretroviral therapy in Oyo State Nigeria: a mixed method study

D. Adetoye[1], O. Ibiloye[2], T. Oladipo[1], O. Olajide[1], K. Areola[1], A. Olafare[1], S. Adeyemi[1], F. Adurogbola[1], T. Omole[2], P. Jwanle[2], I. Onwuatuelo[2], J. Osi Samuels[2], P. Okonkwo[2]
[1]APIN Public Health Initiatives, Ibadan, Nigeria, [2]APIN Public Health Initiatives, Abuja, Nigeria

Background: Viral suppression is one of the goals of antiretroviral therapy (ART) for the management of HIV acquisition. Viral suppression is a viral load (VL) of less than 1000 copies per ml. Despite the availability of effective antiretroviral drugs (ARV), virological unsuppression remains a major issue in Nigeria. This is especially true with children and adolescents living with HIV (CALHIV).
This study was to determine the viral suppression rate among CALHIV receiving ART in three ART sites in Oyo state and factors associated with virological unsuppression.
Methods: We conducted a cross-sectional review of program data for all CALHIV on ART and with valid VL test results in three comprehensive ART sites. Client-level data were extracted from the electronic medical record (EMR) and analyzed using SPSS. Factors associated with viral unsuppression were examined using a chi-square test and logistic regression.
Additionally, healthcare workers and CALHIV were also purposively selected for in-depth interviews to elicit information on barriers and facilitators of viral suppression. Thematic content analysis was used to analyze qualitative data.
Results: Eight hundred and forty-nine CALHIV were enrolled in the study (n = 849). Of this 849, 82% (697) were virally suppressed. The mean age of participants was 12.17 years (SD-4.74) and more than half were male (52%, n = 438). Clients who were diagnosed with TB (aOR 9.66; 95%CI: 1.79- 27.20), unaware of HIV status (aOR 3.98; 95%CI: 2.46- 6.47), and having an HIV-negative caregiver (aOR 2.69; 95%CI: 1.58- 4.59) were at higher risk of viral unsuppression.
Healthcare workers identified stigma, drug refusal/drug fatigue, and non-disclosure of HIV status as barriers to viral suppression. Other barriers were delays in the initiation of enhanced adherence counseling (EAC) and suboptimal adherence counseling. Facilitators were age-appropriate disclosure and good family support.
Conclusions: Viral suppression rates are low compared to the UNAIDS 95% target. To improve viral load suppression and treatment outcomes among CALHIV in Nigeria, there is a need to strengthen adherence support and age-appropriate HIV disclosure to CALHIV and their caregivers. HIV program managers should implement continuous quality improvement (CQI) targeting identified barriers in healthcare facilities.

EP0485

Ending HIV transmission via community-led treatment monitoring and follow-up of exposed children with EID: findings from the AHANA project implemented in 13 states of India - Treatment scaling

K. Biswas[1], L. Rathore[1], S. Dasgupta[2], R. Rana[2]
[1]Plan International (India Chapter), Monitoring & Evaluation-GF, Delhi, India, [2]Plan International (India Chapter), Programme, Delhi, India

Background: While India has made a significant progress in arresting and reversing the HIV epidemic, testing coverage of pregnant women remained very low in many states during 2015. Evidence suggests access to HIV testing remained very low at 34% in the 13 Plan India project states with an estimated annual pregnancy of 14 million per year. Complementing Govt. of India's NACP, Plan India has been implementing AHANA project supported by The Global Fund towards attaining EMTCT.
Description: a) Investing in the capacities of 40 thousand community health worker at Govt. health facilities,
b) advocacy for procurement of Kits and ensuring a smooth supply of kits- consumables and
c) generating awareness among pregnant women to receive HIV testing during pregnancy Rigorous advocacy with Govt. at the national level as well as at the local level to ensure procurement and uninterrupted supplies of kits and consumables.
HIV testing expanded from district level to the all PHCs and to VHNDs taking the testing to the doorstep of Pregnant women.
Lessons learned: HIV testing among pregnant women increased from 34% during 2016-17 to 92% during 2023-24. Proportion of peripheral HIV testing has increased from 25% to 80% suggesting increased access of HIV testing among the pregnant women in village and rural areas. This has resulted in 25% increased identification between the periods of 2016-17 to 2023-24. More than Thirty thousand pregnant women were identified as HIV positive, linked to ART services and followed up for care and support during the period 2016-24. Early linkages were improved with ART treatment ensured during ANC phase improved from 79% to 88%, Institutional delivery has improved from 90% to 93% during the project period. More than 16 thousand babies confirmed as negative after receiving confirmatory tests at 18 months.
Conclusions/Next steps: With capacity enhancement in the peripheral public health units, HIV testing increased manifold through community driven HIV screening process. PMTCT outcome improved through a community led care cascade monitoring for HIV positive pregnant women. Plan India's AHANA project shows the pathways to expanding PMTCT services through a community led service delivery integrated with general health systems.

EP0486

Understanding mobility and interruption in HIV treatment differences by gender in Malawi: a case-control study

M. Thorp[1], K. Balakasi[2], J. Ayieko[3], K. Phiri[2], S. Phiri[2], R. Hoffman[1], S. Shoptaw[4], C.S. Camlin[5], K. Dovel[1,2]
[1]University of California Los Angeles, Division of Infectious Diseases, Los Angeles, United States, [2]Partners in Hope, Lilongwe, Malawi, [3]Kenya Medical Research Institute, Kisumu, Kenya, [4]University of California Los Angeles, Department of Family Medicine, Los Angeles, United States, [5]University of California San Francisco, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States

Background: Human mobility increases risk of interruption in treatment (IIT). Mobility patterns are known to differ by gender. We explored the role of mobility in IIT among women and men in Malawi to better understand what gender-specific mobility interventions are required.
Methods: We used stratified sampling to survey ART clients who were (1) re-initiating antiretroviral therapy (ART) after IIT (≥28 days late for scheduled ART pick-up) or (2) "stable" on ART (no IIT in last 12 months). Other eligibility criteria included ≥15 years and living in the catchment area of nine participating facilities. Sociodemographic characteristics, ART history, and mobility history were collected. We used multivariable conditional logistic regressions, t-test, and rank-sum tests to assess differences between recent IIT and stable clients by gender.
Results: From September 2023-April 2024, we enrolled 992 participants: 585 women (198 stable, 387 recent IIT) and 407 men (146 stable, 261 recent IIT). Mobility strongly predicted recent IIT for both sexes: clients with recent IIT were more likely to have taken a trip ≥30 nights in the last 12 months (women aOR 10.25 [95%CI 5.80-18.10], men 8.51 [4.20-17.24]) or with <2 days to prepare (women aOR 2.01 [1.30-3.11], men 2.43 [1.43-4.12]). Men were more likely than women to travel for income generation (13% women vs. 43% men, p<0.001), although women (but not men) who traveled for income generation had lower risk of IIT (aOR 0.43 [0.21-0.87]).

Table 1. Sociodemographics and mobility of women and men stable on ART and with recent IIT at nine facilities in Malawi (n=992)

	Total (n=992)	Women (n=589)			Men (n=414)			p-value (difference in aORs)
		Stable in care (n=198)	Recent IIT (n=387)	aOR (95%CI)	Stable in care (n=146)	Recent IIT (n=261)	aOR (95%CI)	
SOCIODEMOGRAPHICS								
Age ≥40, n (%)	508 (51%)	92 (46%)	149 (39%)	0.60 (0.39-0.93)	99 (68%)	166 (64%)	0.58 (0.33-1.02)	0.98
Married, n (%)	553 (60%)	119 (60%)	175 (45%)	0.53 (0.35-0.81)	114 (78%)	185 (71%)	0.79 (0.43-1.45)	0.32
Living with child under 2 years of age, n (%)	210 (21%)	48 (24%)	81 (21%)	0.63 (0.37-1.06)	19 (13%)	62 (24%)	1.41 (0.71-2.82)	0.06
Top wealth quintile, n (%)	195 (20%)	42 (21%)	72 (19%)	0.54 (0.29-0.99)	42 (29%)	39 (15%)	0.34 (0.18-0.66)	0.16
Attended any secondary school, n (%)	287 (29%)	61 (31%)	86 (22%)	0.56 (0.34-0.94)	55 (38%)	85 (33%)	1.02 (0.58-1.77)	0.22
MOBILITY IN LAST 12 MONTHS								
Took at least one trip ≥30 consecutive nights, n (%)	427 (43%)	21 (11%)	222 (58%)	10.25 (5.80-18.10)	22 (15%)	162 (62%)	8.51 (4.20-17.24)	0.49
Traveled for income generation, n (%)	254 (26%)	24 (12%)	54 (14%)	0.43 (0.21-0.87)	41 (28%)	135 (52%)	0.69 (0.36-1.33)	0.23
Took at least one trip with <2 days to prepare, n (%)	493 (50%)	72 (36%)	233 (60%)	2.01 (1.30-3.11)	41 (28%)	147 (56%)	2.43 (1.43-4.12)	0.34
Traveled outside Malawi, n (%)	156 (16%)	12 (6%)	60 (16%)	1.89 (0.78-4.60)	8 (5%)	76 (29%)	3.25 (1.30-8.10)	0.2

The most common purpose for women's travel was caregiving (36% of women with IIT). Mobility was the most common explanation for missed appointments for women (51%) and men (63%).
Conclusions: Mobility was the leading cause and a strong predictor of recent IIT for both genders, though purpose for travel differed by gender. Mobility-focused interventions are needed to reduce IIT but may require tailoring to address gendered forms of mobility.

EP0487

The effect of same-day HIV treatment initiation (SDI) on one-year outcomes in low- and middle-income countries: systematic review and meta-analysis of randomised trials

N. Saß[1], H. Havrylenko[1], A. Amstutz[1,2,3], S. Rosen[4,5], A.T. Brennan[6], M. Maskew[5], W. MacLeod[4], S.P. Koenig[7,8], N. Dorvil[9], S. Schandelmaier[1,10,11], N.D. Labhardt[1,12]
[1]University Hospital and University of Basel, Division of Clinical Epidemiology, Department of Clinical Research, Basel, Switzerland, [2]Oslo University Hospital, Oslo Center for Biostatistics and Epidemiology, Oslo, Norway, [3]University of Bristol, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom, [4]Boston University School of Public Health, Department of Global Health, Boston, United States, [5]University of the Witwatersrand, Health Economics and Epidemiology Research Office (HE2RO), Johannesburg, South Africa, [6]Boston University School of Public Health, Department of Global Health & Epidemiology, Boston, United States, [7]Brigham and Women's Hospital, Division of Global Health Equity and the Division of Infectious Diseases, Boston, United States, [8]Harvard Medical School, Boston, United States, [9]Haitian Group for the Study of Kaposi's Sarcoma and Opportunistic Infections (GHESKIO), Port-au-Prince, Haiti, [10]University College Cork, School of Public Health, Cork, Ireland, [11]University of Pécs, MTA–PTE Lendület "Momentum" Evidence in Medicine Research Group, Medical School, Pécs, Hungary, [12]University Hospital Basel, Department of Infectious Diseases, Basel, Switzerland

Background: Same-day initiation (SDI) of antiretroviral therapy (ART) is recommended for people presenting with HIV who do not have serious comorbidities (e.g. neurotuberculosis). We conducted a systematic review and aggregate data meta-analysis to evaluate the effect on retention in care and viral suppression of interventions that introduced or facilitated SDI in low- and middle-income countries (LMICs).
Methods: We searched MEDLINE, Embase and Cochrane Library (December 31st, 2024) for randomised controlled trials of SDI among eligible adults in LMICs.
We stratified the analyses into:
i. trials comparing introduction of SDI vs standard care not allowing SDI, and;
ii. trials comparing further facilitation of SDI vs standard care allowing SDI in eligible people.
Viral suppression and retention in care one year post enrolment were analysed using a random-effects meta-analysis, with results pooled by stratum. (PROSPERO ID: CRD42023482522).
Results: We identified 10 trials, 6 comparing introduction of SDI vs no SDI and 4 facilitating SDI vs standard care. In trials comparing introduction of SDI vs no SDI, pooled relative-risk estimates for one-year viral suppression and retention were 1.19 (95%CI: 1.09-1.29) and 1.17 (1.06-1.30), respectively. In trials comparing facilitation of SDI vs standard care, estimated relative risks were 1.01 (0.90-1.15) and 0.96 (0.91-1.02) for viral suppression and retention, respectively (figures 1 and 2).

Figure 1: Viral suppression 1 year after enrolment (*numbers adjusted for design effect)

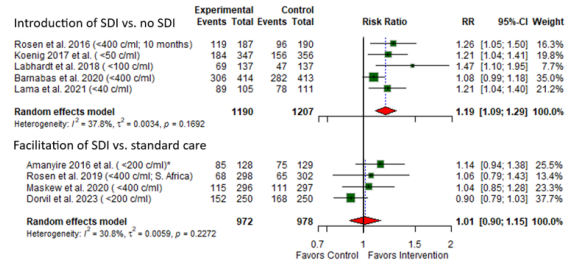

Figure 2: Retention in care 1 year after enrolment

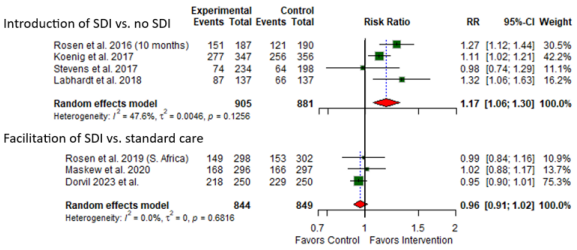


Conclusions: In LMICs where standard care did not allow for SDI, introduction of same-day ART improved one-year outcomes. Where SDI was already part of standard care, trials that tested approaches to further facilitate SDI had no effect on clinical outcomes.

EP0488

Exploring the dynamics of first and multiple treatment interruptions in antiretroviral therapy in Kenya

D. Salami[1], E. Koech[2], J. Turan[3], K. Stafford[1], L. Nyagah[4], S. Ohakanu[1], A. Ngugi[5], M. Charurat[1]
[1]University of Maryland, Center for International Health, Education and Biosecurity, Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [2]Center for International Health, Education and Biosecurity - Kenya, Nairobi, Kenya, [3]University of Alabama, Department of Health Policy and Organization, School of Public Health, Birmingham, United States, [4]Ministry of Health's National AIDS and STI Control Program Kenya, Strategic Information, Nairobi, Kenya, [5]Aga Khan University, Department of Population Health, Nairobi, Kenya

Background: Treatment interruptions in HIV care leads to viral rebound, increased transmission, drug resistance, and heightened morbidity, undermining epidemic control. Differentiated service delivery (DSD) aims to improve retention, however its impact on interruptions remains underexplored. Cox models often overlook multiple interruptions and time-varying factors, limiting their ability to capture interruption dynamics over time.
Methods: This retrospective study includes HIV-positive clients who started antiretroviral therapy between 2017 and 2023, in Kenya. Treatment interruption was defined as no clinical contact or antiretroviral drug (ARV) pick-up for more than 28 days after the last expected contact. We used Cox proportional hazards models to identify predictors in two analyses: time-invariant for first interruptions and time-varying for multiple interruptions.
Results: 621,115 clients were included in the analysis, 67% female and median age of 33 years. Median follow-up time was 5.87 months (IQR: 0.9–26.9) to first interruption and 42 months (IQR: 22–61 months) for multiple interruptions. Incidence rates were 50.7 (95% CI: 50.5–50.8) and 48.3 (95% CI: 48.2–48.4) per 100 person-years for first and multiple interruptions, respectively. Median time to first interruption was 7.5 months after ARV initiation, with 54% occurring within the first year. Median time to multiple interruptions was 16.4 months. Median time to return to care after an interruption was 87 days (IQR, 51–175).
Risk factors for both first and multiple treatment interruptions included older age at ARV initiation, male gender, marital status, lower education, pre-existing non-communicable diseases, non-adherence, clinical instability, advanced WHO stages, and high viral load.
Additional risks for multiple interruptions included being on second or third-line regimens and longer duration of interruptions. Less intensive DSD models were linked to an increased risk of first and multiple treatment interruptions, while multi-month drug dispensing (MMD), a DSD component, was associated with reduced risk. This suggests MMD may mediate the relationship between DSD models and treatment interruptions.
Conclusions: In conclusion, clients on less intensive DSD models had higher risk of both first and multiple treatment interruptions. Highlighting the need for strategic DSD transitions that effectively combine appropriate models with MMD to support treatment continuity, adherence, and long-term retention.

EP0489

Bridging gaps to HIV epidemic control: addressing treatment interruptions and strategies for left-behind sub-populations – A retrospective analysis in PEPFAR-USAID supported facilities across 15 South African districts

C. Trapence[1], B. Mugisa[1], L. Parmley[1], K. Kehoe[1], D. Mali[1], T. Hurter[1], L. Seshoka[2], J. Chehab[1]
[1]United States Agency for International Development (USAID), Pretoria, South Africa, [2]National Department of Health, South Africa, Pretoria, South Africa

Background: The UNAIDS global strategy aims to eliminate HIV/AIDS as a public health threat by 2030. Despite South Africa's progress towards achieving the global 95-95-95 targets at 96-81-93, antiretroviral therapy (ART) interruption poses a substantial challenge to reaching the 2030 goal.
Methods: We examined ART interruption rates between 2021 and 2024 using routine data reported in TIER/DATIM from 15 USAID supported districts in South Africa. The primary outcome was the number of interruptions, and the exposure variable was the number of individuals on treatment - the population of interest.
A quasi-Poisson regression model was utilized to account for the over-dispersed data, estimating incident rate ratios (IRRs) and 95% confidence intervals (CIs) to evaluate factors associated with treatment interruptions. We controlled for sex, age group, and fiscal year as fixed effects

while incorporating random intercepts to account for variation in baseline treatment interruption rates across sub-districts. Data analysis was conducted using R version 4.4.1.

Results: By the end of the 2024 fiscal year, a total of 2,210,534 individuals were receiving treatment, with at least 103,743 experiencing an interruption, representing approximately 4.69% of the total. Adult (20+ years) males (IRR = 1.35; 95%CI: 1.33-1.38) compared to adult females, and children <15 years (IRR = 2.99; 95%CI: 2.83-3.16) were more likely to experience treatment interruptions. Interruption rates decreased with older age, with young adults aged 15-19 years recording an IRR of 2.64 (95%CI: 2.90-3.10), 20-24 years recording 2.98 (95%CI: 2.90-3.01), and 25-49 years recording an IRR of 1.51 (95%CI: 1.49-1.54) compared to 50+ years.

Over time, interruption rates dropped significantly; 25% lower in 2022 (IRR = 0.75; 95%CI: 0.73-0.76) and 27.9% lower in 2023 (IRR = 0.72; 95%CI: 0.70-0.73) compared to 2021. Although there was a slight increase in 2024 compared to 2023, interruption rates remained 13.9% lower in 2024 than in 2021 (IRR = 0.86; 95%CI: 0.84-0.87).

Conclusions: Findings highlight an urgent need for targeted treatment continuity interventions, particularly for younger populations and males, as we accelerate efforts toward achieving the UNAIDS 2030 goal. Such strategies are essential to sustain and further reduce interruption rates, ensuring progress in HIV epidemic control.

EP0490

Prevalence of low-level viremia and correlates of viral load suppression in Ugandan pregnant women living with HIV (April 2022-March 2024)

E. Namara Lugolobi[1], P. Namukanja[1], J. Ssempiira[1], J. Ntale[1], B. Elur[1], C. Kavuma[1], R. Nakityo[1], G. Namazzi[1], G. Namayanja[1], J. Businge[1], S. Sendagala[1], L. Nabitaka Kisaakye[2], I. Ssewanyana[3], V. Bigiira[4,3], J. Kalamya[1], A. Delaney[5], A. G. Fitzmaurice[1]

[1]Division of Global HIV & TB, U.S. Centers for Disease Control and Prevention, Kampala, Uganda, [2]AIDS Control Program, Uganda Ministry of Health, Kampala, Uganda, [3]Central Public Health Laboratories, Kampala, Uganda, [4]Monitoring and Evaluation Technical Support Program, Makerere University School of Public Health, Kampala, Uganda, [5]Division of Global HIV & TB, U.S. Centers for Disease Control and Prevention, Atlanta, Georgia

Background: Viral load (VL) non-suppression is a key predictor of vertical HIV transmission. Suppression to undetectable levels optimizes individual treatment outcomes. We determined the prevalence of low-level viremia (LLV), high-level viremia (HLV), VL suppression (VLS) and correlates of VLS among pregnant women living with HIV (PWLHIV) to inform Uganda programming.

Methods: We conducted a retrospective cross-sectional analysis of all VL results for PWLHIV on antiretroviral therapy (ART) in the Uganda Central Public Health Laboratory Information Management System from April 2022 through March 2024. Results for clients with suspected/confirmed treatment failure (any repeat VL after initial VL ≥ 1000 copies) were excluded. HLV was defined as VL ≥1000 copies/mL, LLV as 201–999 copies/mL and VLS as VL ≤200 copies/mL. Independent variables were maternal age, duration on ART, indication for VL test and self-reported adherence.

Adherence to ART was defined as good (≥95%) and fair/poor (<95%). Indications for testing were routine monitoring or first antenatal care (ANC) visit. We used multivariate logistic regression to determine correlates of VLS.

Results: Prevalence of HLV was 7% (2,386/33,704); LLV was 37% (12,379/33,704) and VLS was 56% (18,939/33,704). Odds of VLS were higher for PWLHV 25–29 years (adjusted odds ratio [aOR]=1.36; 95% confidence interval [CI]: 1.25–1.47), 30–34 years (aOR=1.50, 95%CI: 1.37–1.64), and ≥35 years (aOR=1.54, 95%CI: 1.39–1.70), compared to PWLHIV 15–24 years. Odds of VLS were higher for PWLHIV receiving VL testing for routine monitoring (aOR=1.13, 95% CI: 1.01–1.27) compared to those receiving VL testing at first ANC visit and those with good adherence compared to those with fair/poor adherence (aOR=1.78, 95%CI:1.38–2.28). Odds of VLS were lower for PWLHIV on ART for 1–2 years (aOR=0.62, 95% CI:0.56–0.67) and >2 years (aOR=0.70, 95%CI:0.65–0.75) compared to PWLHIV on ART for <1 year.

Conclusions: VLS among PWLHIV was low, revealing a substantial gap. Routine monitoring of adherence and viremia (including LLV) particularly for women on ART for ≥ one-year, supportive preconception counselling, and innovative interventions for those aged <25 years might help improve VLS among PWLHIV.

EP0491

Client-Centered HIV Care Outcomes_Fahari Ya Jamii Project_2022-2024

A. Owino[1], G. Ruttoh[1], E. Kubo[1], C. Odhiambo[1], D. Achwoka[1], M.S. Mwangi[1], T. Simiyu[2], I. Yonga[3], S. Arodi[1], R. Marima[1], J. Mecha[1], C. Otieno[1]

[1]University of Nairobi School of Medicine-Fahari ya Jamii program, Department of Clinical Medicine and Therapeutics, Nairobi, Kenya, [2]USAID Kenya, Advisor, Nairobi, Kenya, [3]USAID Kenya, AOR, Nairobi, Kenya

Background: Improving client-centred HIV care outcomes is essential for ensuring long-term retention and equity, particularly in resource-limited settings. The *Fahari ya Jamii* Project has been operational in Nairobi and Kajiado counties since 2019. It has addressed these gaps through tailored interventions, including peer mentorship, psychosocial support, and community-based testing.

This analysis evaluates population-specific outcomes, client-reported experiences, and the impact of community-led monitoring (CLM) on improving HIV care delivery.

Methods: We conducted a retrospective programmatic data analysis from October 2022 to September 2024, incorporating quantitative and qualitative metrics. The program reached *870,009 individuals* across 165 healthcare facilities (104 in Nairobi and 61 in Kajiado counties). Quantitative metrics included client-reported health status, ART adherence, participation in psychosocial support programs, and re-engagement outcomes. Data were

stratified by hub, fiscal year, and population group (general, paediatric, and adolescent). Where available, community-led monitoring (CLM) data supplemented programmatic findings to identify client barriers and service delivery gaps.

Results: The analysis demonstrated that client-centered strategies yielded significant outcomes. Among the *870,009 individuals served*, re-engagement efforts successfully traced and re-enrolled 78% of clients lost to follow-up ($\chi^2 = 10.87$, $p < 0.05$); however, disparities were evident, with some hubs reporting re-engagement rates as low as 50%. Paediatric-specific interventions in Kajiado East & Central hubs achieved a 97% linkage-to-care rate, significantly outperforming other hubs ($\chi^2 = 14.32$, $p < 0.01$). Differentiated care models and psychosocial support programs contributed to improved quality-of-life outcomes, with 85% of clients reporting better health, 90% adherence to ART, and 70% participation in psychosocial programs ($p < 0.05$).

Community-led monitoring data identified persistent barriers to care, including stigma, transportation costs, and limited access to mental health services, which informed adjustments in service delivery approaches.

Conclusions: Fahari ya Jamii's population-specific interventions, reaching over *870,000 individuals*, have significantly improved re-engagement, retention, and client-reported outcomes in HIV care.

Despite these successes, disparities in re-engagement rates and barriers identified through CLM underscore the need for expanded mental health services and community-driven approaches.

These findings highlight the importance of integrating client-centered strategies into HIV programs to promote equitable, sustainable care outcomes in resource-limited settings.

EP0493

Impact of the Network of People Living with HIV/AIDS in Nigeria (NEPWHAN) on HIV disclosure interventions to enhance viral suppression among Children Living with HIV (CLHIV) in Anambra State, Nigeria

D. Ofiri[1], C. Ezeanya[1], M. Zamzu[2], U. Ugwoke[3], C. Ofoegbu[4], K. Ugwaunyi[4], C. Gweba[5], C. Mensah[6], P. Dakum[7], H. Bello[3], T. Adetiba[8], J.-T. Nouboussi[2], K. Tsujii[2], N. Workneh[2], P. Uzondu[9], A. Agbaje[10], O. Adebayo[8], O. Olupitan[6]

[1]Institue of Human Virology Nigeria, Prevention, Care, and Treatment, Asaba, Nigeria, [2]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, HIV/AIDS, Geneva, Switzerland, [3]Institue of Human Virology Nigeria, CQI, Abuja, Nigeria, [4]Institue of Human Virology Nigeria, SI, Abuja, Nigeria, [5]Institue of Human Virology Nigeria, Lab, Asaba, Nigeria, [6]Institue of Human Virology Nigeria, COO, Abuja, Nigeria, [7]Institue of Human Virology Nigeria, CEO, Abuja, Nigeria, [8]Institue of Human Virology Nigeria, Prevention, Care, and Treatment, Abuja, Nigeria, [9]Achieving Health Nigeria Initiative, SI, Awka, Nigeria, [10]Institue of Human Virology Nigeria, IRCE, Abuja, Nigeria

Background: HIV disclosure is essential for improving ART adherence and viral suppression in children but is often hindered by stigma, fear, cultural norms, and caregiver limitations, particularly in discordant households. NEPWHAN's interventions address these barriers to enhance health outcomes for those affected by HIV.

This study evaluates the effectiveness of these efforts in Anambra State to improve disclosure practices and optimize care for CLHIV.

Methods: This study retrospectively analyzed program data collected between January 2021 and April 2024, focusing on HIV disclosure sessions for children aged 10 to 24. The sessions aimed to address barriers faced by mothers in disclosing their HIV status to children and spouses. Data on disclosure status and viral load outcomes were retrieved from RADET files, compiled, and analyzed using Microsoft Excel. Statistical associations were evaluated using chi-square tests.

Results: From 2021 to 2024, the treatment cohort (Tx_Curr) for individuals aged 10 to 24 was 2,696 in 2021, 4,797 in 2022, 4,656 in 2023, and 3,986 by April 2024. The disclosure rate improved significantly, attributed to the NEPHWAN intervention, increasing from 890 (33% of Tx_Curr) in 2021 to 1,275 (27% of Tx_Curr) in 2022, 2,783 (60% Tx_Curr) in 2023, and 3,146 (79% of Tx_Curr) by April 2024. Suppressed viral load results increased from 1,605 in 2021 (85%) to 2,899 in 2022 (88%), 3,192 in 2023 (90%), and 2,726 by April 2024 (92%). There was a continuous improvement in viral suppression rate over the period, (85% in 2021 vs. 92% in 2024, p-value <0.05).

Conclusions: The findings show that targeted interventions, such as structured disclosure sessions, successfully addressed barriers to HIV status disclosure, leading to improved treatment adherence and better health outcomes. Supporting caregivers and overcoming disclosure challenges were key to enhancing viral load testing and treatment success.

EP0494

HIV cascade with the 95-95-95 achievements

A. Owino[1], C. Odhiambo[1], E. Kubo[1], M.G. Ruttoh[1], M.S. Mwangi[1], D. Achwoka[2], I. Yonga[3], S. Arodi[1], R. Marima[1], J. Mecha[1], P.C. Otieno[1]

[1]University of Nairobi School of Medicine-Fahari ya Jamii Program, Clinical Medicine and Therapeutics, Nairobi, Kenya, [2]USAID Kenya, Advisor, Nairobi, Kenya, [3]USAID Kenya, AOR, Nairobi, Kenya

Background: Achieving Fahari ya Jamii's 95-95-95 targets remains a significant challenge in resource-limited settings. The FYJ Project, operational since 2019 in Nairobi and Kajiado counties, has implemented targeted interventions to improve HIV testing, linkage to care, ART initiation, retention, and viral suppression rates.

This analysis evaluates the program's progress toward these goals, identifying successes and persistent gaps.

Methods: We conducted retrospective programmatic data analysis from October 2022 to September 2024. Data were drawn from 165 healthcare facilities (104 in Nairobi and 61 in Kajiado counties) and included 870,009 individuals tested for HIV during the study period. Quantitative metrics included HIV testing services (HTS) coverage, positivity rates, ART initiation, retention, and viral suppression. Statistical analyses, including chi-square tests and multivariate logistic regression, assessed trends and predictors of key outcomes. Data were stratified by hub, population group, and fiscal year.

Results: The program demonstrated substantial progress across the HIV cascade. HIV testing targets were met or exceeded during the study period, with 72% of targets achieved in FY22 (210,505 individuals tested), 86% in FY23 (281,927 tested), and 117% in FY24 (377,577 tested).

Positivity rates improved steadily from 90% in FY22 to 111% in FY24. ART linkage also increased significantly, improving from 70% in FY22 to 95% in FY24 ($\chi^2 = 12.56$, $p < 0.01$). Retention outcomes consistently improved, with first-year ART retention exceeding 85% across all hubs.

Viral suppression rates rose significantly, increasing from 60% in FY22 to 85% in FY24 ($\chi^2 = 10.45$, $p < 0.05$). These results highlight the success of differentiated care approaches and follow-up mechanisms in addressing gaps in the care cascade.

Conclusions: Fahari ya Jamii's targeted interventions have significantly advanced the 95-95-95 agenda, achieving substantial improvements in HIV testing, ART initiation, retention, and viral suppression. However, disparities in outcomes across hubs and population groups indicate the need for continued investment in tailored and scalable strategies to address barriers in resource-limited settings.

EP0495

Readmission: a risk for mortality among people living with HIV admitted to hospital in the Democratic Republic of Congo and Guinea

C. Mafu[1], O. Ibrahima[2], J. Falconer[3,4], P. Kisaka[1], A. Tshimungu[1], G. Mucinya[1], P. Isaakidis[4], E. Casas[4], S.-J. Steele[4], G. Abdala[4], B. Ibrahima[4], C. Diao[2], P. Mweze[2], N. Govender[5], J. Jarvis[6,7], AmbiOne study group

[1]Centre Hopital Kabinda, Kinshasa, Congo, the Democratic Republic of the, [2]Unite Sante Formation Recherche (USFR), Donka Hopital, Conakry, Guinea, [3]University of Witwatersrand, Clinical Microbiology and Infectious diseases, Johannesburg, South Africa, [4]Medecins Sans Frontieres, South African Medical Unit, Cape Town, South Africa, [5]University of Witwatersrand, Johannesburg, South Africa, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom, [7]Botswana Harvard Health Partnership, Gaborone, Botswana

Background: Despite advances in access to antiretroviral therapy, AIDS-related deaths remain high, particularly among hospitalised people living with HIV in low-resource settings. Mortality risks persist post-discharge and a systematic review in 2022 pooling data from 3717 people living with HIV in low- or middle-income settings found a readmission rate of 19%.

We present post-discharge outcomes in a cohort of 7632 hospitalized adults (aged ≥18 years) living with HIV in Guinea and the Democratic Republic of Congo (DRC).

Methods: Individual-level data were abstracted from electronic hospital records for admissions to inpatient HIV treatment units in Conakry, Guinea (January 2015 to May 2024) and Kinshasa, DRC (January 2021 to January 2024). Admission status, demographics, clinical characteristics, and inpatient mortality were summarised. Admission episodes were tagged by unique identifier codes to generate a list of readmissions.

Results: There were 11274 admissions among 7632 individuals (DRC: 5581 admissions, 3359 individuals; Guinea: 5693 admissions, 4273 individuals). Amongst those with available data, 71% (7578/10677) of the admissions were among people living with advanced HIV disease (AHD; defined as a CD4 count of <200 cells/uL) and 78% (7036/9408) were ART-experienced at admission.

The median age for admissions was 40 years (IQR: 32 - 50) and median CD4 count was 104 cells/uL (IQR: 40-232). 62% (6997/11274) of the admissions were among women.

The case-fatality ratio during the first admission was 29% (2169/7577). Amongst those who survived to discharge, 38% (2035/5408) were readmitted. 66% (1343/2035) of readmissions were within 180 days, with a median time to readmission of 66 days (IQR: 26-361).

Among those readmitted at least once, the cumulative mortality across subsequent readmissions was 38% (767/2035). The risk of readmission after the second admission was 48% (743/1540) and 53% (315/594) after the third admission.

Conclusions: We show a higher readmission risk amongst hospitalised people living with HIV in low-resource settings than previously reported. Without close outpatient follow-up between admissions, this is probably an un-

der-estimate of post-discharge adverse events (including readmissions and mortality). Both mortality and readmission risk were particularly high among people readmitted at least once, suggesting that this group could be a focus for tailored interventions.

EP0496

HIV care cascade among people experiencing homelessness in Porto Alegre, Brazil

V.J. da Silva Classmann[1], M. Espíndola de Moraes[2], J.H. Dias de Sousa[2], S.C. Lima de Souza[1], G. Lisboa Peixoto Dias[2], L. Martins Rangel[1], M. Oliveira Bastos[1], M. Secco Torres da Silva[1]
[1]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [2]Consultório na Rua Centro, Porto Alegre, Brazil

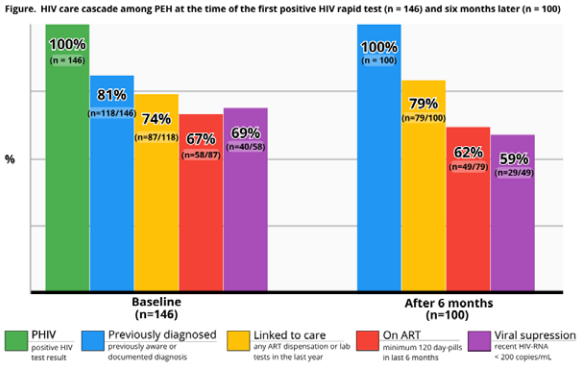
Background: Despite Brazil's long-standing commitment to addressing HIV, marginalized populations still face significant healthcare barriers. Street Clinic Teams (SCT) provide direct on-site care to people experiencing homelessness (PEH).
This study aims to assess HIV care cascade outcomes among PEH served by SCT in Southern Brazil.
Methods: We enrolled PEH approached by SCT in central and central-south districts of Porto Alegre (April/2023-November/2024) with at least one HIV test result. Characteristics were compared by HIV status (Wilcoxon and Fisher's/Chi-squared test for continuous and categorical variables, respectively).
We calculated the outcomes related to the HIV care cascade at baseline and six months later.
Results: 1,307 PEH were approached, of whom 11.1%(n=146) were PHIV. The median age was 39 years(IQR:31-48), and the majority of participants were white(53%,n=660/1,252). PHIV were more likely to identify as transgender women(12% vs 0,9%,p<0.01), had higher rates of syphilis(25.7% vs 16.9%,p=0.01), active hepatitis B(2.1% vs 0.3%,p=0.04) and hepatites C seroprevalence(12.7% vs 5.8%,p<0.01)(Table).

		Not living with HIV n = 1,161[1]	People with HIV n = 146[1]	Overall n = 1307	p-value[2]
Age (years)	Median (IQR)	39 (31, 48)	39 (32, 48)	39 (31, 48)	0.50
Race / color	Non white (Black, Pardo and Mixed, Indigenous, Asian)	519/1106 (47%)	73/146 (50%)	592/1252 (47%)	0.23
	White	587/1106 (53%)	73/146 (50%)	660/1252 (53%)	
Gender identity	Cisgender men	869/1108 (78%)	85/146 (58%)	959/1254 (76%)	<0.01
	Transgender men	6/1108 (0.5%)	0/146 (0%)	6/1254 (0.5%)	
	Cisgender women	223/1108 (20%)	43/146 (29%)	266/1254 (21%)	
	Transgender women	10/1108 (0.9%)	18/146 (12%)	28/1254 (2.2%)	

[1]Median (Q1, Q3); n (%); [2]Wilcoxon rank sum test; Fisher's exact test; Pearson's Chi-squared test

Table. Sociodemographic characteristics of PEH in Porto Alegre, Brazil according to HIV status (n = 1307).

Among PHIV, 80.8%(n=118/146) were aware of their diagnosis, and 73.7% (n=87/117) were linked to care at baseline. Of those linked, 66.7% (n=58/87) had regular ART dispensation, and 68.9% (n=40/58) achieved virological suppression (HIV-RNA<200 copies/mL). Six months later, 79% were linked to care, 62% had regular ART, and 59.2% reached suppression (Figure).



Conclusions: PEH are disproportionately burdened by the HIV epidemic in Porto Alegre and face significant barriers to accessing HIV care. Addressing gender and homelessness requires intersectoral action, with housing rights central to the HIV response. SCT could deliver injectable antiretrovirals to key populations but remains unavailable in Brazil, requiring further studies.

EP0498

Sustained maternal HIV viral load suppression and cascade of HIV testing among HIV exposed infants in Rwanda

Z.M. Ally[1], J. Sebeza[2], H.F. Fussi[3], H.M. Bakari[4], H.O. Ramadhani[5], P. Memiah[6], G. Rwibasira[7]
[1]CIHEB-Tanzania, Dar es Salaam, United Republic of Tanzania, [2]Center for Disease Control and Prevention, Kigali, Rwanda, [3]District Hospital, Dar es Salaam, United Republic of Tanzania, [4]University of Dar es Salaam, Dar es Salaam, United Republic of Tanzania, [5]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [6]Graduate School, University of Maryland, Baltimore, United States, [7]Rwanda Biomedical Center, Institute of HIV Disease Prevention and Control, HIV Division, Kigali, Rwanda

Background: To prevent mother to child transmission of HIV (MTCT), sustained maternal viral-load suppression and early HIV testing among HIV exposed infants (HEI) is critical. We explored maternal viral-load results and infant HIV testing uptake at 6- weeks, 9- and 18- months in Rwanda.
Methods: Between 2015 and 2022, we measured viral-load suppression (VLS<200 copies/mL) among pregnant-women living with HIV (WLHIV) from 38-healthcare facilities. Viral-loads (VL) were measured at 6-, 12- and 24- months, respectively. For maternal VL, the unit of analysis was visit-pair, which were created to define those with VL<200 copies/ml at two consecutive visits as having sustained VLS, persistent viremia (VL≥200 copies/ml at two consecutive visits), viral rebound (VL<200 copies/ml at prior visit only) and newly suppressed (VL<200 copies/ml at subsequent visit only). HEI is considered to have persistent HIV

testing if she/he had all three HIV tests. Poisson regression models with generalized estimating equations were used to estimate adjusted incidence rate ratio (aIRR) and 95% confidence intervals (CI) for factors associated with sustained VLS and persistent HIV testing.

Results: A total of 1,145 mother-infant pairs were analyzed. Infant HIV testing uptake at 6- weeks, 9- and 18- months were 1,145(100.0%), 1,089(95.1 %) 1,006(87.9%) respectively. Nine hundred ninety-nine HEI (87.3%) tested for HIV persistently. At 18- months, the incidence of HIV among HEI was 8(0.7%). Of 1,145 mothers, 1,076(94.0%) had ≥2 VL results making a total of 2,010 visit-pairs (142-single; 934-double visit-pairs). The incidence of sustained VLS, persistent viremia, viral rebound and new suppression were 91.0%, 1,3%, 3.6% and 4.0% respectively. Maternal disclosure of HIV status [aIRR = 1.08 95%CI (1.02–1.14)] was associated with increased likelihood of sustained VLS. Having peer support [aIRR = 1.05 95%CI (1.01–1.10)] was associated with persistent HIV testing among HEI.

Conclusions: Sustained VLS is high among pregnant WLHIV in Rwanda. Low incidence of HIV among HEI could be attributed to high levels of sustained VLS among these women. Targeted interventions focusing on HIV disclosure and peer support placement is critical to improve sustained VLS and infant HIV testing uptake in the efforts of reducing MTCT.

EP0499

Sustained HIV viral load suppression among transgender people assigned male at birth in Washington DC, USA

H.O. Ramadhani[1], S. Kattakuzhy[1], O. Harfouch[1], R. Eyasu[1], A. Davis[1], M. Zoltick[1], E. Ebah[1], R. Silk[1], S. Kottilil[1], E.S. Rosenthal[1]

[1]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States

Background: Sustained viral load suppression is an important indicator of successful treatment among people living with HIV. We evaluated trends of different viral load outcomes among transgender people assigned male at birth (TG-AMAB) at a community-based organization in Washington DC, USA.

Methods: Between 2021 and 2023, participants were enrolled in PATCH, a longitudinal natural history study of transgender individuals in Washington, DC. Surveys and HIV viral loads (VL) were assessed at approximately 3 month intervals. In this evaluation, the unit of analysis was visit-pair, with subjects across four visit-pair categories: (1) *sustained VLS* (VL<200 copies/ml at two consecutive visits); (2) *persistent viremia* (VL≥200 copies/ml at two consecutive visits), *viral rebound* (VL<200 copies/ml at prior visit only) and *newly suppressed* (VL<200 copies/ml at subsequent visit only). Poisson regression models with generalized estimating equations were used to estimate incidence rate ratio (IRR) and 95% confidence intervals (CI) for factors associated with sustained VLS.

Results: Of 54 TG-AMAB living with HIV, 48 (88.9%) had ≥2 VL results and were included in the final analysis. The median age was 37 (interquartile range:34-42.5) years. Forty-eight people contributed 159 visit pairs (2-single pair, 11-two pairs, 11-three pairs 19-four pairs,4-five pairs and 1-six pairs). Of the 159 pairs, 62.9% had sustained VLS, 11.3% had persistent viremia, 11.3% had viral rebound and 14.5% had new suppression. Participants who were African-American (IRR=0.69; 95%CI:0.50–0.94), identified as female (IRR=0.70; 95%CI:0.51–0.97) and reported missed doses >5 days/month (IRR=0.52; 95%CI:0.31–0.88) had a reduced likelihood of attaining sustained VLS. Individuals who were employed (IRR=1.88; 95%CI:1.37–2.56) and those with treated mental health diagnosis (IRR=1.67; 95%CI:1.08–2.60) had an increased likelihood of sustained VLS.

Conclusions: In a cohort of urban TG-AMAB, there was a low incidence of sustained VLS, which was associated with race, gender identity, employment status, mental health treatment, and antiretroviral therapy adherence. Interventions targeting these comorbidities and social determinants of health may be crucial for achieving sustained viral suppression and are critical to sustaining a global HIV elimination strategy.

EP0500

Uptake of PrEP among key populations participating in social network strategy testing in health facilities in Hai Phong City, Vietnam, October 2021 – June 2024

H. Nguyen[1], M. Nguyen[1], L. Nguyen[2], T. Nguyen[3], Y. Nguyen[3], T. Hoang[1], B. Nguyen[1], S. Vo[3], H. Le[2], H. Nguyen[2], H. Nguyen[1], M. Shah[1]

[1]Division of Global HIV&TB, U.S. Centers for Disease Control and Prevention, Vietnam, Ha Noi, Viet Nam, [2]Hai Phong Center for Disease Control and Prevention, Hai Phong, Viet Nam, [3]Enhancing HIV Program Innovations and Collaboration in Viet Nam (EPIC), Vietnam Ministry of Health/Vietnam Administration for AIDS Control (VAAC) – U.S. CDC Project, Ha Noi, Viet Nam

Background: Hai Phong City, Vietnam, has implemented multiple approaches to improve the uptake of HIV pre-exposure prophylaxis (PrEP) among key populations (KP), including men who have sex with men (MSM), people who inject drugs (PWID), and people engaged in commercial sex. Among these approaches, social network strategy (SNS) testing trains people living with HIV (PLHIV) or individuals at risk of HIV to use coupons to recruit and refer their social and risk network associates for HIV testing and linkage to PrEP or HIV treatment based on their HIV status. We analyzed PrEP uptake among clients recruited through SNS in Hai Phong City.

Methods: SNS client at age of 16 years old and above registers between October 2021 – June 2024 from 10 HIV and PrEP clinics in Hai Phong were analyzed. Among SNS-recruited clients who tested negative for HIV, we calculated the proportion of those who were successfully linked to and initiated PrEP. We assessed factors associated with PrEP uptake using bivariate and multivariate regression analyses.

Results: A total of 1645 individuals (median age: 37 years) tested HIV-negative through SNS; 72.7% (1,196) were male and 27.3% (449) were female. Only 24% (396) of clients re-

ceived PrEP through SNS-facilitated linkage. This varied by risk group: 41.4% among MSM; 19.2% among PWID; 5.6% among women engaged in commercial sex; and 30.8% among sex partners of PLHIV.
Among KP, PWID and women engaged in commercial sex were less likely to be successfully linked to PrEP compared to MSM [(aOR: 0.24; 95% CI: 0.16-0.34) and (aOR: 0.2; 95%CI: 0.10-0.40)]. Clients aged 25-29 years were less likely to link to PrEP compared to clients aged less than 25 years old (aOR: 0.53; 95 CI: 0.38-0.74).
Conclusions: SNS can reach high-risk KP to provide testing and PrEP linkage; PrEP uptake was low but varied by population; further research may be of use to identify barriers to PrEP initiation and develop effective PrEP education & demand creation strategies.

EP0501

A retrospective analysis of ART interruption patterns among adults in Malawi's HIV program

K. Phiri[1], N. Chihana[1], E. Lungu[1], E. Gulule[1], E. Chikuse[1], D. Smith[1,2], J. Njala[1], A. Worku[3], A. Moses[1], S. Phiri[1], R. Hoffman[2], J. J van Oosterhout[1,2]
[1]Partners in Hope, Lilongwe, Malawi, [2]University of California Los Angeles, David Gaffen School of Medicine, Los Angeles, United States, [3]USAID Malawi, Department of Health, Nutrition and Population, Lilongwe, Malawi

Background: Disengagement from HIV-treatment can result in viremia, adverse health-outcomes and increased HIV-transmission. We explored differences between individuals on antiretroviral-therapy (ART) with and without interruptions in treatment (IIT) in Malawi's HIV-program.
Methods: We conducted a retrospective-analysis of medical-records from 123-PEPFAR-supported health-facilities across nine districts in Malawi. Routinely collected data from individuals aged ≥15 years, enrolled on ART between September 2019-October 2021, were extracted from an electronic-monitoring-system, with all clients followed for 24-months from ART-initiation. IIT was defined as ≥28-days late for a scheduled appointment. Viral-load (VL) non-suppression was defined as a last available VL result ≥1,000 copies/mL. Individuals were categorized into: no-IIT, single-IIT, and ≥2-IITs. We compared demographic and treatment characteristics/outcomes between the 3 groups, using descriptive statistics.
Results: Among 44,615 individuals included, median age was 32-years (IQR:25-40), 81.5% had started ART within 7-days of HIV diagnosis, 94.4% on first-line dolutegravir-based ART, 60.9% were female of whom 20.5% were pregnant at ART-initiation. 66.1% had no-IIT, 22.8% single-IIT, and 11.1% ≥2-IITs. The median IIT duration was 70-days (IQR:42-122). IIT differed marginally by sex: among women, 65.5% no-IIT, 23.3% single-IIT, and 11.2% ≥2-IIT, compared to men 67.1%, 22.0%, and 10.9% respectively (p=0.002). IITs showed modest differences by age: among younger-adults aged 15-34-years 63.3% had no-IIT, 24.2% single-IIT, and 12.4% ≥2-IIT, compared to those aged ≥35-years (70.1%, 20.8%, and 9.1% respectively; p<0.001). Of all IIT-events (n=20,931), 24.0% occurred in 2019-20, 34.7% in 2020-21, 28.2% in 2021-22, and 12.0% in 2022-23 (p<0.001). Delayed ART-initiation (>7 days) was more frequent among those with IITs (17.5% no-IIT, 20.3% single-IIT, 20.0% ≥2-IITs, p<0.001). Among individuals with any VL-result (45.4%), prevalence of non-suppressed VL was higher in those with IITs (3.9% no-IIT; 6.7% single IIT; 10% ≥2-IITs; p<0.001). Pregnancy at ART-initiation was higher in women experiencing IIT (18.0% no-IIT; 24.8% single-IIT; 29.3% ≥2-IITs; p<0.001).
Conclusions: Over one-third of clients experienced an IIT within 24-months of ART-initiation. IITs occurred more frequently during COVID-19, after delayed ART-initiation, among younger individuals, and in women pregnant at ART-initiation. IITs were associated with viremia, particularly multiple interruptions. These findings highlight in whom interventions are most needed to support engagement in care.

EP0502

Antiretroviral therapy (ART) status and factor associated with ART use among orphaned and vulnerable children (OVC) living with HIV in Namibia: evidence from the project HOPE Namibia-implemented OVC program

H. Mangwana[1], E. Moyo[2], S. Takawira[1], E. Melese[3], B. Harases[1], C. Uakuramenua[1], B. Kwenda[1], L. Kapuka[1], J. Nekongo[1], E. Kandjeo[1], N. Zambwe[1], C. Gabone[1], L. Muzart[4]
[1]Project HOPE Namibia, Windhoek, Namibia, [2]University of Kwa-Zulu Natal, College of Health Sciences, School of Nursing & Public Health, Durban, South Africa, [3]Project HOPE- The People-to-People Health Foundation, Inc, Windhoek, Namibia, [4]United States Agency for International Development (USAID) Namibia, Windhoek, Namibia

Background: Prompt initiation of antiretroviral therapy (ART) minimizes immune impairment in the initial stage of HIV infection, a factor critical for influencing future disease progression. Children and adolescents living with HIV (C/ALHIV) encounter numerous obstacles in using ART. This analysis assessed ART status and factors associated with ART uptake among C/ALHIV enrolled in the Namibia Orphans and Vulnerable Children (OVC) program.
Description: The program functions as a vital intervention aimed at improving the welfare of children affected by HIV, violence, poverty, and other vulnerabilities. The program employs a structured case management system to identify, assess, and address beneficiaries' needs, facilitating their progression toward independence and graduation from program support. Using a targeted approach, the program identifies C/ALHIV through home visits, facility referrals, and HIV risk assessments. In collaboration with care and treatment partners, the program also ensures comprehensive documentation of HIV-positive households and OVC and links them to ART.
Lessons learned: Of 4,599 participants, 4,441 (96.6%) were on ART, with a 95% confidence interval (CI) (96.1% – 97.1%). ART uptake was higher among participants from households with little or no hunger (Crude Odds Ratio (COR) = 2.19, 95% CI (1.40 – 3.43)) and specific regions like Eenhana

(adjusted odds ratio (AOR) = 8.24, 95% CI (2.58 – 26.37)) and Okongo (AOR = 5.22, 95% CI (1.22 – 22.38)). Conversely, participants aged 0-9 years, those never enrolled in school (COR = 0.26, 95% CI (0.18 – 0.37)), and those diagnosed or presumed to be with TB (AOR = 0.10, 95% CI (0.01 – 0.73)) were less likely to be on ART. Lower ART uptake was also observed among those from child-headed households and those subjected to sexual abuse or exploitation, COR = 0.04, 95% CI (0.02 – 0.06), and COR = 0.12, 95% CI (0.10 – 0.15), respectively.

Conclusions/Next steps: Integrating food support into HIV programs may enhance ART uptake, particularly for children in hunger-affected households. Initiatives to improve OVC school enrolment and targeted educational programs on ART benefits for C/ALHIV are crucial.

EP0503

Determinants of successful ART outcomes in children and adolescents in Kenya, 2021-2023

W. Jiang[1], J. Kangai[2], C. Adhiambo Onditi[2], C.J. McGrath[1], A. Ojwang[3], F. Irene[2], B. Singa[4], G. John-Stewart[1], I. Mutisya[5], S. Benki-Nugent[1]

[1]University of Washington, Seattle, United States, [2]Christian Health Association of Kenya, Nairobi, Kenya, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Palladium Kenya, Nairobi, Kenya, [5]US Centers for Disease Control and Prevention, Division of Global HIV &TB, Global Health Center, Nairobi, Kenya

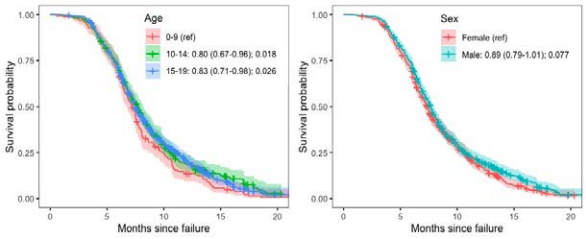
Background: Children and adolescents living with HIV (CALHIV) face unique challenges in achieving viral suppression, yet there is limited programmatic data to fully understand determinants of virologic failure (VF) and subsequent suppression.

Methods: We selected 40 HIV care clinics in Kenya to abstract data for CALHIV aged 0-19 years on antiretroviral therapy (ART) ≥6 months from 2021-2023. We abstracted clinical characteristics from electronic medical record system and routine viral load (VL) data from the National AIDS & STI Control Programme.

We used clinic-clustered generalized estimating equations to identify regimens associated with VF (≥1,000 copies/mL). Among CALHIV with VF, we used Cox proportional hazard models to evaluate factors of achieving suppression (<1,000 copies/mL).

Results: Among 7,429 CALHIV, median age was 12 years (interquartile range [IQR] 8-15) and 52% were female. A total of 20,386 VL results were obtained (median 3 [IQR 2-3] VL tests per person). Overall, 1,389 (19%) CALHIV ever had VF; risk of VF did not differ by age (0-9 years: 18.4%, 10-14 years: 18.7%, 15-19 years: 18.8%; p>0.9) or sex (female: 18.1%, male: 19.3%; p=0.2). In regression, VF was higher among those initiating lopinavir/ritonavir (LPV/r) than efavirenz (EFV)-based ART (prevalence ratio [PR] 1.29, [95% confidence interval 1.05-1.58]; p=0.01) and was similar between those initiating dolutegravir and EFV-based ART (PR 0.92 [0.69-1.23]; p=0.6).

Among 1,389 with VF, 1,117 (80%) had a next VL test and 972 (87%) attained suppression. Adolescents had lower suppression than children (0-9 years) (10-14 years: hazard ratio [HR] 0.80 [0.67-0.96]; p=0.01; 15-19 years: HR 0.83 [0.71-0.98]; p=0.03). Sex was not associated with suppression (males vs. females: HR 0.89 [0.79-1.01]; p=0.08).



Conclusions: Our findings highlight the importance of historical use of LPV/r and lower likelihood of maintaining suppression for 10-19 years adolescents. Strengthening care systems with adolescent-centered services may improve viral suppression in pediatric HIV care.

EP0504

Risk factors for treatment interruption among people with HIV in four African countries include HIV-associated negative social impacts, never disclosing HIV status to a partner, and history of viral failure

N. Burns[1,2], S. Frndak[1,2], E. Misicka[1,2], A. Parikh[1,2], J. Hern[1,2], H. Kibuuka[3], J. Owuoth[4,5], V. Sing'oei[4,5], J. Maswai[6,7], E. Bahemana[8,9], V. Anyebe[10,11], Z. Parker[12,2], T. Crowell[1,2], N. Shah[1], J. Ake[1], African Cohort Study (AFRICOS) group

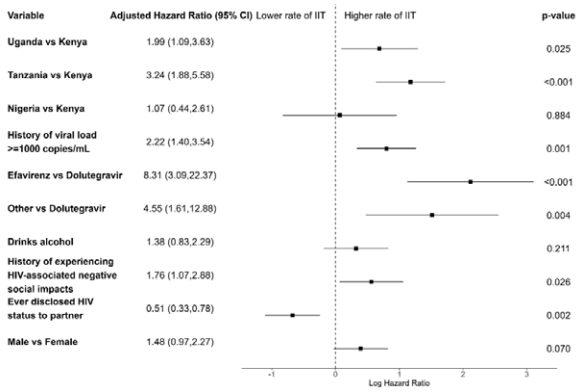
[1]U.S. Military HIV Research Program, CIDR, Walter Reed Army Institute of Research, Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, United States, [3]Makerere University Walter Reed Project, Kampala, Uganda, [4]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Kisumu, Kenya, [5]HJF Medical Research International, Kisumu, Kenya, [6]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Kericho, Kenya, [7]HJF Medical Research International, Kericho, Kenya, [8]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Mbeya, United Republic of Tanzania, [9]HJF Medical Research International, Mbeya, United Republic of Tanzania, [10]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Abuja, Nigeria, [11]HJF Medical Research International, Abuja, Nigeria, [12]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Lagos, Nigeria

Background: Adherence to antiretroviral therapy (ART) is necessary for viral suppression, which prevents negative health outcomes and HIV transmission. We identified factors associated with interruptions in treatment (IIT) among people with HIV (PWH) in four African countries.

Methods: The African Cohort Study enrolls people with and without HIV at 12 PEPFAR-supported sites in Kenya, Nigeria, Tanzania, and Uganda. At six-monthly visits, questionnaires are administered, which include reporting any of 14 types of HIV-associated negative social impacts experienced since last visit; ART data, including regimens and start/stop dates, are collected from medication re-

cords. These analyses included PWH with at least two study visits since starting ART. IIT was defined as any period ≥30 days not on ART. We estimated adjusted hazard ratios with 95% confidence intervals (CI) using a multivariable Andersen-Gill time-to-event model with robust standard errors, with independent variables chosen using purposeful variable selection.

Results: The analysis population included 3,071 PWH enrolled between January 2013 and August 2024. The median age was 36.7 years and 57.8% were female. Of these, 105 (3.4%) participants had at least one IIT. Participants with a history of experiencing HIV-associated negative social impacts had a 1.76 (CI=1.07-2.88, p=0.026) times higher rate of IIT than those who did not, and participants who had a history of viral failure had a 2.22 (CI=1.40-3.54, p=0.001) times higher rate of IIT than those who did not (Figure). Ever having disclosed HIV status to a partner was associated with a 0.51 (CI=0.33-0.78, p=0.002) times lower rate of IIT than never having disclosed. Country and ART anchor drug were also associated with IIT, with higher rates of IIT on efavirenz-based and other regimens compared to dolutegravir-based regimens (p<0.001 and p=0.004, respectively).



Conclusions: We identified several risk factors which can be used to characterize populations who may benefit from adherence-related interventions prior to experiencing an IIT.

EP0505

Spatiotemporal patterns and influencing factors of genotypic resistance testing utilization among people living with HIV: a decade-long retrospective analysis from Beijing Youan Hospital, China (2014-2023)

D. Yuan[1], F. Zhao[2], S. Liu[1], L. Li[2], H. Yan[2], L. Liu[2], T. Zhang[2], C. Moog[3], B. Wang[1], B. Su[2]

[1]Southeast University, Nanjing, China, [2]Capital Medical University, Beijing, China, [3]Université de Strasbourg, Strasbourg, France

Background: Nearly 90% of people living with HIV (PLWH) receive antiretroviral therapy (ART) worldwide, and genotypic resistance testing (GRT) provides important information for selecting ART regimens. However, no study systematically analyses the utilization patterns, temporal trends, and influencing factors of the GRT.

Methods: Data from 6,895 PLWH treated at Beijing Youan Hospital from 2014 to 2023 were analyzed. Temporal trends were identified using Joinpoint regression. Multivariable logistic regression assessed factors influencing GRT utilization, and spatial analysis was conducted with GeoDa and SatScan. Ethical approval for this study was granted by the Ethics Committee of Beijing Youan Hospital (Approval No: 2024-100).

Results: GRT rates showed a significant two-phase upward trend, increasing from 5.36% in 2014 to 74.17% in 2023, with an average annual percentage change of 31.30% (P < 0.001). Beijing residency (aOR = 2.596, 95% CI: 2.307-2.921) and older age were associated with higher GRT uptake. Specifically, 35-44 years (aOR = 1.207, 95% CI: 1.026-1.420), 45-54 years (aOR = 1.335, 95% CI: 1.104-1.613), and ≥55 years (aOR = 1.424, 95% CI: 1.126-1.802) had significantly higher odds of testing.

Lower testing rates were observed in individuals with lower education (high school or technical secondary: aOR = 0.827; junior high school: aOR = 0.835; primary school: aOR = 0.695), unknown STD history (aOR = 0.415), and non-heterosexual transmission routes (homosexual: aOR = 0.834). Spatial analysis identified GRT clustering across Beijing until 2021, with two space-time clusters identified in 2019-2023 and 2018-2022.

Conclusions: GRT uptake has substantially increased, with a more balanced distribution across districts since 2021. Age, education, STD history, and transmission route influence GRT utilization. Improving access, reducing costs, and targeted interventions are needed to optimize testing and guide ART decisions.

EP0506

Improving on-time antiretroviral clinic visits through total quality leadership and accountability: lessons from Southern Nigeria

E. Egbe[1], I. Ezekpeazu[2], K. Odey[1], S. Idowu[1], E. Isang[1], C. Obi[1], J. Umana[1], F. Abbah[2], E. Effiong[3], O. Onwah[1], U. Akpan[1], V. Otu[4], M. Morka[5], U. Omo-Emmanuel[5], D. Ogundehin[6], E. James[6], J. Pius[6], O. Oyelaran[6], O. Onyedinachi[1], A. Adegboye[1], A. Eyo[1]

[1]Excellence Community Education Welfare Scheme, Uyo, Nigeria, [2]FHI 360 Nigeria, Abuja, Nigeria, [3]Howard University Global Initiative Nigeria, Abuja, Nigeria, [4]Cross River Primary Health Care Development Agency, Calabar, Nigeria, [5]National Agency for the Control of AIDS, Abuja, Nigeria, Abuja, Nigeria, [6]United States Agency for International Development (USAID), Abuja, Nigeria

Background: Adherence to antiretroviral therapy (ART) is essential for achieving HIV viral suppression and improving the quality of life of people living with HIV (PLHIV). However, consistent adherence remains challenging due to various barriers. ECEWS, with funding from PEPFAR/USAID, implemented a Total Quality Leadership and Accountability (TQLA) intervention to improve adherence to ART clinic appointments among PLHIV in Cross River State, Nigeria. This study describes the outcomes of this intervention.

Description: This study involved 18 health facilities that accounted for 80% of missed ART clinic appointments across 64 PEPFAR-supported facilities in Cross River, from January to July 2024. TQLA was implemented in March 2024 and involved one-on-one sessions with clients who missed appointments and were contacted to identify clinic adherence barriers. Client-centred solutions like providing differentiated service delivery to address lack of transportation, treatment literacy to address misconceptions about ART, and updating inaccurate contact information in electronic medical records to facilitate pre-appointment reminders were implemented.
Regular situation room meetings were conducted to analyse facility-level data on attendance to clinic appointments, track progress with client follow-up, and maintain accountability. On-time ART refill data (proportion of clients who had an ART clinic appointment that showed up) was collected daily from electronic medical records and compared monthly over the study period, and key lessons learned were documented.
Lessons learned: There were 5,853 ART clinic appointments in January 2024, and 5,478 in July 2024. On-time ART refills increased from 40.3% (2,358/5,853) in January 2024 to 82.2% (4,505/5,478) in July 2024. Tailored treatment literacy sessions effectively addressed cultural and religious myths about ART, verifying and updating client contact details improved the effectiveness of pre-appointment reminders and follow-up calls, and the situation room meetings allowed for in-depth discussions based on real-time analysis of adherence data, to inform facility-specific interventions.
Conclusions/Next steps: The TQLA approach improved adherence to ART clinic appointments, highlighting the importance of targeted interventions, and regular use of granular data for performance improvement. This intervention is recommended for use by other programs to improve and sustain ART adherence.

EP0507

Factors associated with retention on antiretroviral therapy after 12 months of initiation among people living with HIV enrolled in case based surveillca in Rwanda from 2019 to 2023

G. Gatete[1], S. Karera[2], C. Kwizera[1], G. N.Rwibasira[1]
[1]Rwanda Biomedical Centre, National HIV Program, Kigali, Rwanda, [2]ICAP at Columbia University, Mailman School of Public Health, Kigali, Rwanda

Background: Retention on antiretroviral therapy (ART) is a key indicator of achieving optimal HIV treatment success as it improves adherence, and prevention of drug resistance. Understanding factors associated with retention is crucial for improving HIV care and achieving sustained HIV viral load suppression. This study assessed factors influencing retention on ART after 12 months of initiation among PLHIV enrolled on ART between 2019 and 2023.
Methods: This was a retrospective cohort study using secondary data from adult PLHIV enrolled on ART in 2019 to 2023 in all health facilities across the country. Data on socio-demographic, sexual behaviors and clinic characteristics was extracted from Rwanda's Case-Based Surveillance CBS system. Multivariate logistic regression was performed using R programming to determine factors independently associated with ART retention. Adjusted odds ratio at a 95% confidence interval was obtained, and a P-value <0.05 was considered statistically significant.
Results: A total of 23,869 PLHIV were included in the analysis, of whom 64.6% (15,426) were female, and 72.4% (17,288) were aged between 25 and 49 years. The majority of participants, 36.3% (8,672), resided in Kigali City, while 13.4% (3,171) were diagnosed with advanced HIV disease at enrollment. Overall retention on ART was 95.6% (22,828), with a higher retention rate (96%) observed among those aged 25–49 years. Multivariate logistic regression revealed that retention after 12 months was significantly associated with age, sex, and marital status. Participants aged 25–49 years (AOR: 1.4, 95% CI: 1.2–1.7) and those aged 50 years and above (AOR: 1.3, 95% CI: 1.0–1.7) were more likely to remain on ART. Conversely, males were less likely to retain (AOR: 0.7, 95% CI: 0.6–0.8). Additionally, being married or in a union was positively associated with retention (AOR: 1.3, 95% CI: 1.1–1.5). However, individuals diagnosed with advanced HIV disease at enrollment were less likely to remain on ART (AOR: 0.7, 95% CI: 0.6–0.8).
Conclusions: Retention on ART among PLHIV in Rwanda remains high, yet significant gaps exist for specific subpopulations. Targeted interventions addressing demographic and clinical risk factors could further improve ART retention and contribute to sustained viral suppression.

EP0508

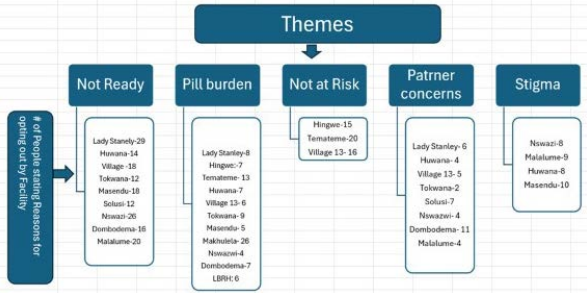
Exploring reasons for opting out of PrEP initiation in Bulilima district: a quantitative analysis of barriers and concerns

P. Hlongwane[1], T. Nhapi[1], K. Chishato[1]
[1]Organisation for Public Health Intervention and Development (OPHID), Programs, Harare, Zimbabwe

Background: According to the Zimbabwe Population HIV Impact Assessment 2022, Matabeleland South has the highest prevalence of HIV at 22%, double that of the nation. Implementing Pre-exposure Prophylaxis (PrEP) is beneficial in lowering HIV infections. However, its use is suboptimal, especially in vulnerable communities like Zimbabwe's rural district of Bulilima in Matabeleland South. Understanding the reasons for hesitancy in starting PrEP is crucial for developing effective interventions. This program aimed to quantify the barriers and concerns affecting PrEP acceptance in the district, addressing issues such as perceived risk, stigma, medication fears, and interpersonal relationships.
Description: We conducted this study from October 2024 to December 2024, during a period of stable PrEP supplies. We worked with community partners, peer educators, and local clinics to engage people who were at high risk of HIV to investigate reasons for not taking PrEP. Relevant interventions included health dialogues, safe-space education, and customized counseling to address medication issues and stigma. Person readiness to start PrEP

and the reasons for their opt-out were determined using a structured questionnaire, generating quantifiable data that guided the design of interventions with 392 people reached across 13 facilities.

Lessons learned: The project identified barriers that hinder PrEP initiation. Notably, 42% of respondents stated that they were "not ready," 25% concerns about pill burden across all the facilities. 11% stated partner concerns, and 13% thought they were "not at risk," suggesting a lack of understanding. Stigma and misconceptions affected 9% of participants. These reasons for non-uptake were systematically addressed resulting in an improvement of PREP uptake from 30% in 2022 to 58% by Dec 2024.



Conclusions/Next steps: PrEP uptake can be greatly increased by addressing barriers associated with risk knowledge, pill burden, and preparedness. To attain sustainable health outcomes in HIV care, future work will concentrate on enacting these tactics and modifying them for various situations.

EP0509

Clinical outcomes among ART clients enrolled in six-month dispensing after less than 6 months on treatment in Zambia

E. Kachingwe[1], M. Fox[1,2], V. Ntjikelane[1], I. Mokhele[1], K. Shumba[1], A. Kamanga[3], T. Makwaru[3], K. Kamayoyo[4], P.L. Mulenga[4], C. Sianyinda[4], P. Haimbe[3], H. Shakwelele[3], S. Rosen[1,2], S. Pascoe[1], A. Huber[1]

[1]Health Economics and Epidemiology Research Office, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Boston University School of Public Health, Department of Global Health, Boston, United States, [3]Clinton Health Access Initiative, Lusaka, Zambia, [4]Zambia Ministry of Health, Lusaka, Zambia

Background: Since 2017, Zambia has scaled up multi-month scripting and dispensing of antiretroviral therapy (ART) among established clients (viral load <1000 copies/ml) on ART for ≥6 months. During the COVID-19 pandemic (3/2020-1/2022), eligibility was extended to those on ART for ≥3 months to reduce clinic congestion.

We compared rates of interruption in treatment (IIT) between clients enrolled on six multi-month scripting (6MMD) at 3 to <6 months on ART ("early enrollers") and those enrolled at ≥6 to 12 months on ART ("standard enrollers").

Methods: We emulated a target trial using Zambian electronic medical records (SmartCare) from 12 public healthcare facilities. Established clients ≥15 years who initiated ART from 01/01/2019-01/12/2022 were included. We used a clone, censor, and weighting approach to estimate IIT rate differences (RD) and ratios (RR) with 95% Confidence Intervals (CI) up to 18 months post-ART initiation. IIT was defined as missed clinic/pharmacy appointment >28 days with no proof of re-engaging during the study period. We used pooled logistic regression to calculate inverse probability of censoring weights and used time-to-event analysis to estimate IIT rates, with person-time calculated from 3 to 18 months after ART initiation.

Results: We included 10,423 unique eligible clients (median age 32 [IQR: 26-39] years; 65% female), including 12% early enrollers, 28% standard enrollers, and 60% eligible but not enrolled in 6MMD ≤12 months after ART initiation. There were no differences in the rate of IIT between early enrollers and standard enrollers (RD: 0.03 [95% CI: -0.02 to 0.06], RR 1.06 [95% CI: 0.97-1.13]).

Conclusions: Our findings suggest that early enrollment into 6MMD, after 3-6 months on ART, does not increase IIT, suggesting it could be introduced after the initial two medication refill visits among established clients.

Although the TTE methodology reduces confounding, limitations include unmeasured confounders, potentially leading to under- or over-estimation of IIT rates. Lack of data for defining eligibility for early enrolment into 6MMD from EMR records may also have introduced selection bias.

EP0510

Treatment interruption among pregnant and breastfeeding women on antiretroviral therapy in Midlands and Manicaland Provinces of Zimbabwe, 2024

M. Ndlovu[1], K. Nyathi[1], S. Mupande[1], B. Chindove[1], J. Muguse[1], J. Mafara[1], R. Mataruse[1], M. Muzondo[1], G. Choga[1], T. Tafuma[1], T. Apollo[2], A. Mushavi[2], C. Mupanguri[2], M. Mukuzunga[1], M. Muchekeza[1], S. Mukungunugwa[1], M. Mhangara[1], E. Tachiwenyika[1], T.P. Sibanda[1], T. Nyamundaya[1]

[1]Zimbabwe Health Interventions, Harare, Zimbabwe, [2]Ministry of Health and Child Care, Harare, Zimbabwe

Background: Vertical transmission of HIV is a significant public health concern, accounting for more than 90% of paediatric infections globally. HIV morbidity and mortality have declined over the last decade due to increased Antiretroviral Therapy (ART) coverage and prevention of HIV transmission from mother to child (PMTCT). Despite these efforts, in 2023, Zimbabwe recorded an MTCT rate of 7.2% against a national target of < 5%. This underscores the need to ensure ART adherence among pregnant and breastfeeding women living with HIV. We assessed treatment interruption among pregnant and breastfeeding women living with HIV on ART in Midlands and Manicaland provinces.

Methods: We conducted an analytical cross-sectional study focusing on pregnant and breastfeeding women on ART in 317 purposively selected Tier 1 and Tier 2 health facilities (500 ART clients) across 9 districts of Midlands and Manicaland provinces for the period April to June 2024. Cli-

ent-level data were abstracted from facility registers, analysed using MS Excel generating proportions, and measures of central tendency. The assessment was approved by Medical Research Council of Zimbabwe (MRCZ/E/159).

Results: Data for 6,909 women were abstracted of which 1,677 (24%) were pregnant, and 5,232 (76%) were breastfeeding. Most pregnant women (24%) were in the 25-29-year-age group and 1,253 (23.9%) breastfeeding women were in the 30-34-year-age group. About 98.7% (1,656/1,677) pregnant women and 96.9% (5,072/5,232) breastfeeding women were on a Dolutegravir (DTG) ART regimen. About 0.89% (15/1,677) of pregnant women failed to continue with ART, of which 9 of them interrupted treatment i.e., failed to report to facilities within 28 days of their scheduled appointment, 5 stopped or refused treatment, and 1 died. Among breastfeeding women, 28 (0.5%) failed to continue with treatment of which 23 (82.1%) of these had treatment interruption, 2 (7.1%) stopped or refused treatment, and 3 (10.7%) died.

Conclusions: Treatment continuity was high among pregnant and breastfeeding women, with breastfeeding women having lower treatment interruption rates that pregnant women. We recommend developing targeted interventions including enhanced monitoring, education, and counselling to support pregnant women to continue ART, as well as further studies to understand determinants of treatment interruption and reasons for use of non-DTG-based ART regimens.

EP0511

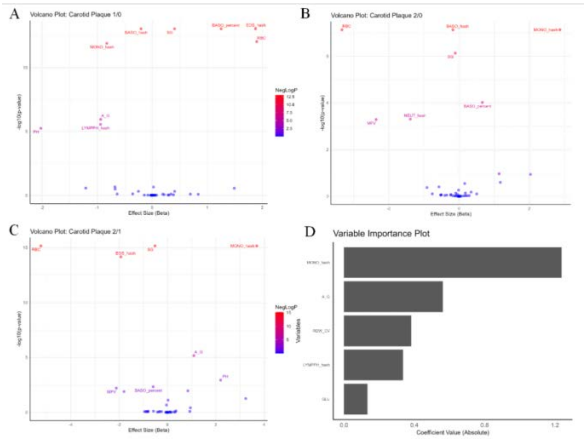
Clinical markers associated with carotid plaque status in people living with HIV: a cross-sectional analysis

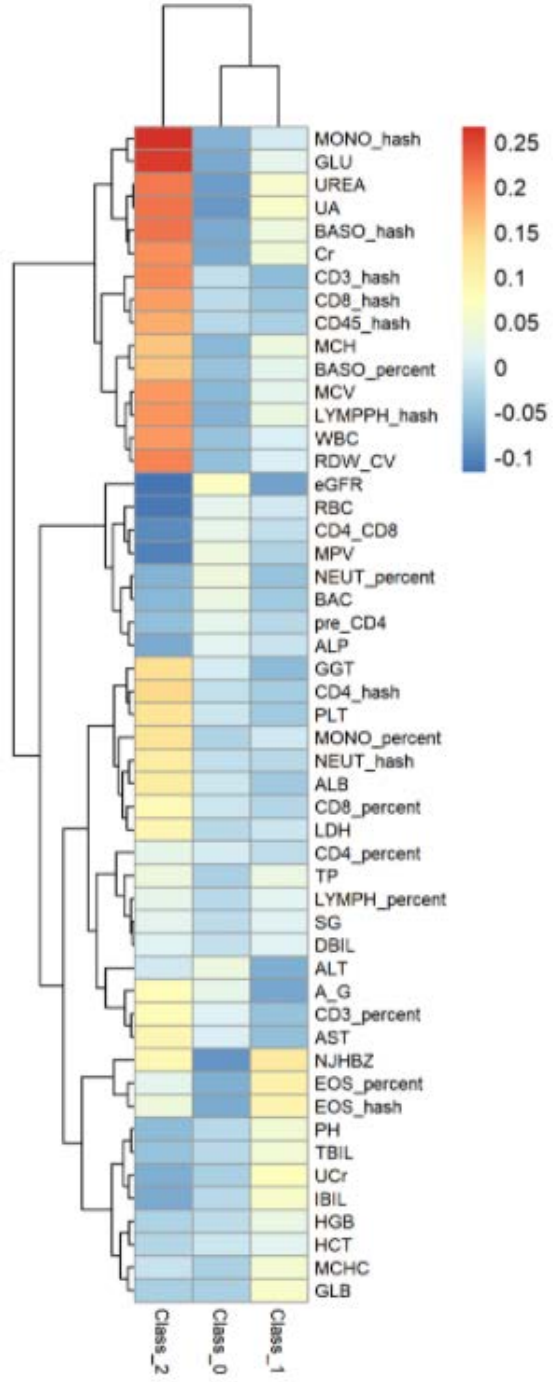
X. Li[1,2], L. Liu[2], J. Huang[2], J. Chen[2], L. Wang[2], R. Zhang[2], T. Qi[2], Y. Ding[3], Z. Wang[2], Z. Zhao[1,2], J. Wang[2], J. Sun[2], S. Xu[2], Y. Shen[2]

[1]Fudan University, Shanghai Institute of Infectious Disease and Biosecurity, Shanghai, China, [2]Shanghai Public Health Clinical Center, Fudan University, Shanghai, China, [3]School of Public Health, Fudan University, Shanghai, China

Background: Carotid artery plaques are considered one of the intermediate markers for atherosclerosis progression. By analyzing the influencing factors of carotid plaques based on 51 commonly measured clinical indicators during routine check-ups in PLWH, differences in the clinical characteristics of populations with varying carotid plaque statuses can be identified.

Methods: This cross-sectional study included 1,228 PLWH who underwent carotid ultrasound screening between March and October 2024. A total of 51 routine clinical laboratory markers, including hematologic and biochemical parameters, were extracted from electronic medical records based on proximity to the screening date. Hierarchical clustering heatmaps were employed to display the differences in standardized indicators across three groups: no plaque, unilateral plaque, and bilateral plaque. Stepwise logistic regression was used to rank the importance of variables, and a random forest model was subsequently trained to identify PLWH at high risk for bilateral carotid plaques.





Results: The heatmap analysis visually revealed an elevated trend in inflammation-related cell types within the bilateral carotid plaque group. The volcano plot gener-

ated from the logistic regression analysis indicated substantial differences across groups for several markers, including red blood cell count, absolute basophil count, absolute eosinophil count, absolute monocyte count, and urine specific gravity.

Conclusions: Significant differences in various routine laboratory indicators were observed among the three groups. These differences may be associated with inflammatory mechanisms underlying atherosclerosis progression.

Additionally, the potential for utilizing multiple routine clinical test results to screen high-risk populations presents promising opportunities for the targeted prevention and management of atherosclerotic cardiovascular disease in PLWH.

EP0512

Unveiling maternal and infant factors in childhood HIV transmission – insights from Ugandan military health facilities

B. Lwanga Matovu[1], H. Kasakye[2], D. Nambooze[1], D. Bwayo[1], M. Ssemmanda Kyambadde[1], T. Rwegyema[1]
[1]URC, Kampala, Uganda, [2]Uganda People's Defense Forces, Kampala, Uganda

Background: There has been significant progress in preventing mother-to-child transmission (MTCT) of HIV in Uganda, with MTCT rates now below 5% among infants born to mothers adhering to antiretroviral therapy (ART), in line with global prevention of mother-to-child transmission (PMTCT) goals.

However, challenges remain, particularly among young mothers who do not use safe delivery methods, those who discontinue ART during pregnancy or breastfeeding, and HIV-exposed infants (HEIs) who miss prophylactic treatment. The UNAIDS Spectrum Model estimates that 5,500 new childhood HIV infections occurred in 2021 due to MTCT, nearly half of which were linked to young mothers and HEIs with inadequate interventions.

Rural and underserved areas still report gaps in program delivery and outcomes. Identifying maternal and infant factors associated with MTCT and analyzing routine data from 31 high-volume military health facilities was crucial to address risks, guided by tailored interventions to close gaps in Uganda's PMTCT programs.

Description: A retrospective analysis was conducted on 1,630 HEIs registered from April 1, 2022, to September 30, 2024. Data on maternal age, education, family support, delivery methods, Nevirapine (NVP) prophylaxis, ART, viral suppression, and infant HIV status were collected. Descriptive analysis using STATA was conducted to identify positivity rates and associated factors.

Lessons learned: Results showed that 32 HEIs were diagnosed with HIV at an average age of 29 weeks (SD: 4.3), with 19% having received NVP prophylaxis. The mothers had an average age of 23.5 years (SD: 7.2), and 53% were not on ART at the time of presentation, while 47% had a negative HIV test result at their previous visit. Suppression rates were 50% among those on ART. Additionally, 22% of these mothers did not have safe deliveries at health facilities. Regarding education, 59% attended secondary school and 41% attended primary school, with 32% not living with their male partners.

Conclusions/Next steps: In conclusion, 2.3% of HEIs acquired HIV despite comprehensive PMTCT services. Most infections occurred postnatally, particularly among women who tested later than recommended, indicating disengagement from the PMTCT program. High vertical transmission rates during breastfeeding suggest a need for targeted interventions during postnatal care, especially for women who miss early infant diagnosis.

EP0513

Optimizing HIV care for children and adolescents with HIV in India: insights from a six-year national analysis of treatment outcomes

A. Shet[1], S.C. Ghosh[2], V. Arumugam[2], J. Bell[3], S. Sannigrahi[1], A. Singh[3], M. Bamrotiya[3], S. Mehta[4], S. Solomon[3]
[1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [2]YR Gaitonde Center for AIDS Research and Education, Chennai, India, [3]Johns Hopkins University School of Medicine, Baltimore, United States, [4]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States

Background: India has the largest population of children and adolescents living with HIV (C/ALHIV) in Asia, majority with perinatally-acquired HIV, who face heightened vulnerabilities. Despite India's robust public health system, large-scale data on treatment outcomes for C/ALHIV remain limited. We aimed to analyze treatment outcomes among C/ALHIV in India to inform targeted strategies for improving long-term care and support.

Methods: We conducted a six-year retrospective analysis of national-level data through ACCELERATE, a differentiated service delivery program within the national program in six high-burden states in India (Andhra Pradesh, Maharashtra, Telangana, Manipur, Mizoram and Nagaland) that collectively represent a third of the country's total HIV burden. Sociodemographic, health-related and longitudinal follow-up data were analyzed using descriptive statistics and logistic regression.

Results: Between 2020-2024, 12,446 C/ALHIV enrolled in ACCELERATE; 9,051 were active at analysis (17% transitioned, 4% migrated, 4% dropped out, 3% died). Median age at enrollment was 12 years (IQR 9-14); 53% were male, 47% female, and 1 transgender individual. Orphans constituted 55%, having lost one (36%) or both (19%) parents; 95% lived with parents/relatives, and 4% were in childcare institutions. School cessation was reported by 5%, and 13% reported incomplete vaccinations. Among 7,523 who underwent tuberculosis screening, 5% screened positive, of whom 15% were confirmed positive. Among 7,019 with a viral load test within 12 months, 94% were virally suppressed. Viral suppression trends increased from 72% in 2021 to 90% in 2024. Since the national government's timely introduction of Dolutegravir into the ART regimen in 2021-2022, viral suppression improved significantly among C/ALHIV on Dolutagravir-based ART (OR: 1.76, 95%CI: 1.44-

2.14). In univariate analysis, viral suppression was significantly higher among C/ALHIV on ART for ≥10 years (OR 2.18, 95%CI: 1.22-3.87), and those aged 6-17 years (OR 1.75, 95%CI: 1.33-2.29), suggestive of less optimal control while transitioning from adolescence to adult care.

Conclusions: This study highlights progress in C/ALHIV care in India, especially with Dolutegravir-based ART, showcasing the impact of optimized strategies and sustained programmatic efforts. Challenges like orphanhood, incomplete vaccinations, tuberculosis, and school cessation underscore the need for integrated medical, psychosocial and educational interventions for C/ALHIV to ensure successful long-term outcomes and adult care transition.

EP0514

Characterizing HIV positivity rate among previously negative pregnant and breastfeeding women by age in 15 PEPFAR/USAID-supported districts in South Africa: a cross sectional program analysis

A. Vrazo[1], B. Mugisa[2], C. Trapence[2], O. Mushakarara[2], H. Mabasa[2], J. Chehab[2], A. Amzel[1]

[1]Independent Consultant, Washington, United States, [2]Independent Consultant, Pretoria, South Africa

Background: In South Africa, maternal incident HIV acquisitions contribute to 48% of new infant HIV acquisitions yearly, 13% occurring during pregnancy and 35% during breastfeeding (BF). In fiscal year (FY) 2024 (October 1 2023 to September 30 2024), PEPFAR updated reporting guidance to include disaggregates for testing after the first antenatal care visit (post-ANC1) for previously-negative women by 1) pregnancy/labor and delivery (PLD), and 2) BF. We characterized the age-disaggregated positivity rates of previously-negative women retested for HIV during PLD and BF to inform age-specific prevention programming.

Description: We analyzed FY24 retrospective age-disaggregated program data reported for post-ANC1 testing collected from health facilities in 15 USAID/PEPFAR-supported districts. Data for women with a documented age ≥15 years was included. We calculated the positivity rate as: [Number of women with a positive test / (Number of women with a positive test + Number of women with a negative test)].

	PostANC1 Pregnancy / Labor and Delivery			PostANC1 Breastfeeding		
Age	Number of tests	Number of positive tests	Positivity rate (%)	Number of tests	Number of positive tests	Positivity rate (%)
15-19	101,105	81	0.1%	3,221	11	0.3%
20-24	181,957	234	0.1%	5,170	22	0.4%
25+	351,460	1,540	0.4%	9,468	103	1.1%
All Ages	634,522	1,855	0.3%	17,859	136	0.8%

Lessons learned: In FY24, 634,522 post-ANC1 tests were performed among women during PLD, with 17,859 post-ANC1 tests performed among women who were BF. The positivity rate was 0.3% for PLD and 0.8% for BF. The positivity rate for both testing modalities increased by age band, with 0.1% PLD and 0.3% BF among 15-19 year old women; 0.1% PLD and 0.4% BF among 20-24 year old women; and 0.4% PLD and 1.1% BF among 25+ year old women.

Conclusions/Next steps: The higher positivity rate among previously-negative BF women and women 25 years and older, both up to fourfold, compared to PLD and among younger women calls for urgent action to address the prevention needs for this sub-population during the postpartum period. To curb further incident HIV acquisitions, tailored comprehensive interventions for HIV-negative BF women remain key, including improving health literacy regarding risk awareness and empowerment to improve uptake of prevention services. As quality-assured post-ANC1 testing during BF scales up, future analyses aim to characterize the timing of maternal seroconversion to prevent vertical transmission and close gaps in South Africa.

EP0515

Exploring the relationship between multi-month dispensing of ART on viral load coverage and suppression among children living with HIV in USAID/PEPFAR-supported country programs

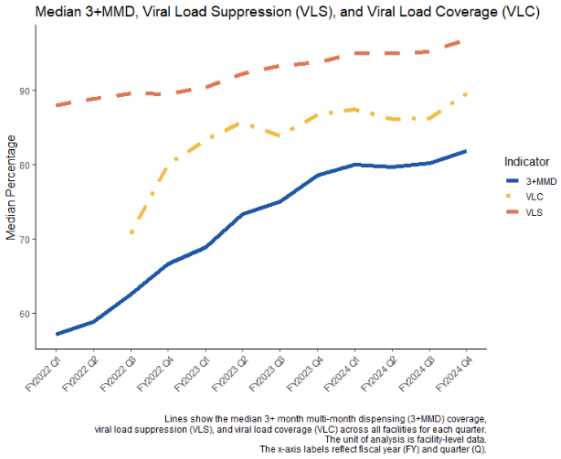
A. Vrazo[1], N. Buono[2], N. McDavid[3], T. Kunkyi[4], G. Lingenda[5]

[1]Independent Consultant, Philadelphia, United States, [2]Independent Consultant, Silver Spring, United States, [3]Independent Consultant, New York City, United States, [4]Independent Consultant, Minneapolis, United States, [5]U.S. Agency for International Development, Office of HIV/AIDS, Lusaka, Zambia

Background: Multi-month dispensing (MMD) of antiretroviral therapy (ART), which provides a 3+ month supply of medication, reduces the logistical burden on families of children living with HIV (CLHIV). However, most published research focuses on adults, and barriers to pediatric MMD implementation include concerns about decreased healthcare interactions negatively affecting virologic outcomes. We hypothesized that pediatric MMD, viral load coverage (VLC), and suppression (VLS) would increase at USAID/PEPFAR-supported facilities during the study period.

Methods: We analyzed routinely-collected pediatric (<15 years) PEPFAR data (FY2022-2024), which are reported at the facility level. Key facility-level measures included: 3+MMD (proportion of CLHIV on ART receiving an ART supply of ≥3-months); proxy VLC (number of CLHIV on ART with a viral load result documented in a given quarter / number of CLHIV on ART two quarters prior); and VLS (number of CLHIV with a suppressed viral load <1000c/mL / number of CLHIV with a viral load result).

Results: There were 8383 facilities from 22 countries included in the analysis. Increases in overall mean 3+MMD (54.9% in FY2022 to 70.2% in FY2024), proxy VLC (74.0% to 85.6%), and VLS (83.7% to 88.9%) were observed from FY2022-FY2024. Similarly, median 3+MMD increased from 61.1% (interquartile range (IQR) 20.0-87.8) in FY2022 to 80% (IQR 50-100) in FY2024, proxy VLC increased from 75% (IQR 50.0-97.1) to 87.5% (IQR 68.8-100), and VLS increased from median 88.9% (IQR 75-100) to 95.5% (IQR 83.3-100) (Figure).



Conclusions: 3+MMD, proxy VLC, and VLS increased from FY2022-FY2024 in USAID/PEPFAR supported facilities. Although the aggregated nature of the data and potential confounders, such as pediatric dolutegravir rollout and potential cross-site client mobility, limit causal inference and preclude client-level conclusions, we did not find evidence that scaling up 3+MMD negatively impacts proxy VLC or VLS. Further studies are needed to confirm these findings and address remaining questions about optimal pediatric MMD implementation.

EP0516

Optimization of the Vertical Transmission Prevention Program in South Sudan: impact of the improvement interventions on performance indicators in Western/Central Equatoria States

G. Jagwer[1], L.J. Gunde[1], J. George[1], H.M. Meba[1], P.Z. Alivule[1]
[1]Catholic Medical Mission Board, HIV/AIDS, Juba, South Sudan

Background: The use of services to prevent vertical transmission (VT) of HIV remains a major challenge in South Sudan; where it is estimated that VT of HIV to infants is at 25%. In the last year, the Catholic Medical Mission Board (CMMB) implemented targeted interventions to increase the use of VT prevention (VTP) services by pregnant and breast-feeding women. This analysis of program data aims to facilitate understanding of the progress and gaps in achieving the national and international targets towards the elimination of VT of HIV in Western (WES) and Central Equatoria States (CES).
Description: The CMMB with support from CDC/PEPFAR undertook targeted actions to eliminate VT in South Sudan. We assess trends in the uptake of VT services to enhance the VTP through a comprehensive quality improvement plan implemented across 13 counties of WES and CES from October 2023 to September 2024. Routine data on VTP were analyzed to compare VTP metrics during the implementation period following the VTP interventions and improvement initiatives implemented in the same period.
Lessons learned: Of the 18,929 women who attended their first Antenatal Care, 99% had their HIV status ascertained. Those whose HIV status was ascertained, 1,148 were identified as HIV positive of which 99% were initiated or already on ART. The implementation of this strategy significantly increased HIV status ascertainment and ART coverage among HIV infected Pregnant and Breast-Feeding Women.
The analysis revealed geographical disparities in the use of VTP services; however, the VTP strategy contributed to better care for mother–child pairs and significantly improved the VTP indicators.
Conclusions/Next steps: The VTP interventions enhanced HIV status ascertainment and ART use among PBFW, demonstrating the benefits of structured interventions and capacity development. Strengthening strategies to effectively engage women on the use of the VTP cascade services could help reduce VT of HIV transmission in South Sudan.
This analysis will support the adaptation of intervention strategies to enhance the care of HIV-infected pregnant and breast-feeding women and cascade to infants exposed to HIV in similar settings. Future initiatives aim to equip more facilities with essential resources and promote VTP in underserved areas of South Sudan.

Monitoring the epidemiology, impact and prevention of new or resurgent pathogens

EP0517

Exposure to toxic chemical elements and kidney function among people living with HIV/AIDS in Northern Tanzania

E.C. Nyanza[1,2], R.N. Peck[3,4], S.H. Kapiga[5,6], M.K. Nsanya[5], M. Cody[4]
[1]Catholic University of Health and Allied Sciences, Department of Environmental and Occupational Health, School of Public Health, Bugando, Mwanza, United Republic of Tanzania, [2]Mwanza Intervention Trial Unit, NIMR Mwanza, Mwatttnza, United Republic of Tanzania, [3]Mwanza Intervention Trials Unit & National Institute for Medical Research (MITU/NIMR), Mwanza, TANZANIA., Mwanza Intervention Trials Unit, Mwanza, United Republic of Tanzania, [4]Weill Cornell Medicine, Center for Global Health, Department of Internal Medicine, New York, United States, [5]Mwanza Intervention Trial Unit, NIMR Mwanza, Mwanza, United Republic of Tanzania, [6]London School of Hygiene and Tropical Medicine (LSHTM), London, United Kingdom

Background: Environmental exposure to toxic chemicals including cadmium (Cd), lead (Pb), and mercury (Hg), are known risk factors for kidney disease. In People living with HIV/AIDS (PLWH), kidney disease is the leading cause of death. Neither traditional risk factors nor markers of HIV infection fully explain such an increased risk.
This study aimed to determine the Toxic Chemical Elements exposure and its association with Kidney Function among People Living with HIV/AIDS in Northern Tanzania.

Methods: This was a Longitudinal Prospective Parallel-group Cohort study that compares toxic chemical levels (T-Cd, T-Pb, and T-Hg). A total of 500 HIV-infected and 500 non-HIV-infected subjects were analyzed. Spearman's rank correlations were used to examine the relationship between toxic chemical elements. Modified poison regression was used to determine the association between exposures and the outcome of interest among study participants.

Results: Irrespective of the HIV status, blood T-Cd, T-Pb, and T-Hg levels were found at levels above the reference value of 5, 50, and 20 µg/L, respectively. Overall, correlates of blood toxic chemical levels included vegetable serving per week, BMI, water sources, use of alcohol, and HIV status. Among HIV-positive naïve, weekly vegetable serving, provided a protective effect against T-Cd (Coeff=-0.03, 95%CI=- 0.06, -0.01) and T-Pb (Coeff=-0.05, 95%CI=- 0.09, -0.01) exposure among HIV-infected subjects.

Participants with cadmium level of >5(µg/L) had a 7% higher prevalence of kidney disease (aPR=1.07, 95%CI=0.59, 1.91) as compared to their control with cadmium level of ≤5 (µg/L).

Participants with Mercury level of >20(µg/L) had a 29% higher prevalence of kidney disease (aPR=1.29, 95%CI=0.92, 1.80) as compared to their control with Mercury level of ≤20 (µg/L).

Participants with Cadmium >5(µg/L) and Mercury level of >20(µg/L) had 2 times higher prevalence of kidney disease (aPR=2.12, 95%CI=0.49, 9.03) as compared to their control with Cadmium ≤5 (µg/L) and Mercury level of ≤20 (µg/L).

Conclusions: Individuals in northwestern Tanzania, including PLWH, have higher blood levels for T-Cd, T-Pb, and T-Hg. Correlates of such higher blood levels include water sources, nutrition status as indicated by BMI, use of alcohol, duration of exposure to indoor smoke, and HIV status. Higher levels of toxic chemical elements potentiate kidney disease.

EP0518

Epidemiological trends of mpox and HIV co-infection in Nigeria: a systematic review and meta-analysis from 2017-2024

J. Nwofe[1], C. Akueshi[2], E. Ekom[3], E. Ojo[1], U. Okezie[3], P. Jwanle[2], F. Owolagba[1], E. Ofuche[1], J. Samuels[1], P. Okonkwo[2]

[1]APIN Public Health Initiatives, Laboratory and Health System Strengthening, Abuja, Nigeria, [2]APIN Public Health Initiatives, Continuum of Care, Abuja, Nigeria, [3]APIN Public Health Initiatives, Strategic Information, Abuja, Nigeria

Background: Mpox, a re-emerging zoonotic viral disease, has become a significant public health concern, particularly in vulnerable populations such as people living with HIV (PLHIV). Immunosuppression in PLHIV may alter the course and severity of Mpox, increasing morbidity and mortality rates.

This study aims to assess the epidemiological trends of Mpox among PLHIV in Nigeria between 2014 and 2024, identifying factors influencing disease incidence, progression, and outcomes.

Methods: Seven studies out of 115 available articles were eligible and included in this systematic review. Relevant articles were searched, screened, and included in this study according to the criteria for Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). Databases such as PubMed, Scopus, and African Journals Online (AJOL) were searched using keywords "Mpox," "HIV," "Nigeria," "immunosuppression," and "epidemiology."

Studies focusing on Mpox among PLHIV in Nigeria were included between 2014 and 2024. The risk of bias in primary studies was assessed using Cochrane's method. Stata version-9 was used to estimate pooled prevalence and identify significant epidemiological trends. Logistics regression conducted to identify risk factors for Mpox at p-value of <0.05. Subgroup analyses assessed variations based on geographic location, age, and gender.

Results: Mpox incidence in PLHIV in Nigeria showed a fluctuating trend, with a peak in 2017 and subsequent waves in 2020 and 2022. Pooled prevalence of Mpox among PLHIV was 8.3% (95% CI: 6.5%-10.2%). PLHIV with lower CD4 counts (<200 cells/mm³) exhibited more severe clinical manifestations, including prolonged illness duration, higher rates of secondary bacterial infections, and increased case fatality rates (CFRs).

The CFR among Mpox cases in PLHIV was 12.6%, significantly higher than in the general population. Risky sexual behaviour and exposure to confirmed cases are associated risk factors.

Conclusions: The risk of contracting and dying from mpox was higher in those living with HIV. The findings suggest that immunosuppression contributes to worse clinical outcomes, emphasizing the need for targeted public health interventions.

Enhanced surveillance, early diagnosis, and integrated HIV-Mpox management strategies are critical to mitigating the impact of future outbreaks. Strengthening vaccination efforts and improving healthcare access for PLHIV should be prioritized to reduce the burden of Mpox in this vulnerable group.

EP0519

Silent circulation of Monkeypox virus in Mali: insights from pre-epidemic serological evidence among healthcare workers

A.I. Maiga[1,2], E. Ghidaoui[3], M. Saliou[4], E. Teyssou[3], A. Kodio[2], S. Marot[3], A.M. Traore[5], T. Cocherie[3], G. Dabo[6], O. Dolo[2], F.T. Traore[2], V. Calvez[3], A.-G. Marcelin[3], C. Soulie[3], E. Todesco[3]

[1]Centre Hospitalier Universitaire Gabriel Touré, Département de Biologie Médicale, Bamako, Mali, [2]University of Sciences Techniques and Technologies of Bamako (USTTB), Bamako, Mali, [3]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, AP-HP, Hôpital Pitié Salpêtrière, Service de Virologie, Paris, France, [4]Centre Hospitalier Universitaire Gabriel Touré, Service de Medecine Interne, Bamakomal, Mali, [5]Centre Hospitalier Universitaire du Point-G, Service de Maladies Infectieuses, Bamako, Mali, [6]Hôpital du Mali, Service de Médecine, Bamako, Mali

Background: Monkeypox virus (MPXV) outbreaks are recognized as a public health emergency of international concern. The increasing incidence and geographical spread of Mpox cases, particularly those attributed to clade Ib in Africa, highlight the insufficient control of Mpox epidemics. Despite this, data on Mpox epidemiology in Africa remains scarce. Like many other West African countries, Mali has not reported any Mpox cases. However, diagnostic systems have not yet been implemented, and potential rodent reservoirs, such as *Mastomys natalensis*, are present.

This study aimed to determine whether a high-exposure population in Mali has been in contact with Mpox.

Methods: A retrospective study was conducted among healthcare workers (HCWs) from referral hospitals in Bamako. The MesoScale Diagnostics® Orthopoxvirus assay, a multiplex electrochemiluminescence-based ELISA targeting five Mpox and five vaccinia antigens, was used. Seropositivity was defined as an E8L-MPXV response above 1500 AU/ml. Titers between 1000 and 1499 AU/ml were classified as borderline. Clinical and socio-demographic data were obtained from participants' records.

Ethical approval was granted by the Ethics Committee of the University of Sciences, Techniques, and Technologies of Bamako (2024/222/CE/USTTB).

Results: Samples from 195 HCWs collected in 2021 and 2022 were retrospectively analyzed. The median age of participants was 29 years; 42.6% were female, 33.3% were medical doctors, and 23.6% were paramedical staff. Two participants (1.02%), a 29-year-old male doctor and a 25-year-old female nurse, tested positive with E8L-MPXV titers of 8663 AU/ml and 1572 AU/ml, respectively.

Two additional participants (1.02%), a 33-year-old male doctor and a 29-year-old male nurse helper, had borderline titers of 1102 AU/ml and 1074 AU/ml, respectively. None of these individuals had relevant medical histories, and all resided in Bamako, an urban area.

Conclusions: Mali has not resumed Orthopoxvirus vaccination since the conclusion of the WHO smallpox eradication program. The detection of Mpox-positive serologies among HCWs under 30 years of age, using samples collected before 2022, suggests pre-epidemic circulation of Mpox in Mali. To contain Mpox epidemics effectively, it is critical to enhance our understanding of its epidemiology and develop targeted screening and response strategies.

EP0520

Cervical cancer screening at ART initiation among newly diagnosed HIV positive clients at AIDS Healthcare Foundation Clinic, Matsapha, Eswatini

L. Ngidie[1,2], T. Dludlu[3], B. Simelane[3], T. Mbhamali[4], M. Vilakati[3], N. Ndlovu[5], Y. Mafulu[5], N. Dube[6]

[1]AIDS Healthcare Foundation, ART, Matsapha, Eswatini, [2]University of Zambia, School of Nursing Sciences, Lusaka, Zambia, [3]AIDS Healthcare Foundation, Nursing, Matsapha, Eswatini, [4]AIDS Healthcare Foundation, Data and health information system, Matsapha, Eswatini, [5]AIDS Healthcare Foundation, Medicine, Matsapha, Eswatini, [6]AIDS Healthcare Foundation, Country Program Director, Matsapha, Eswatini

Background: Eswatini has the highest rate of cervical cancer (CxCa) in the world. However, CxCa screening uptake remains low in the country increasing risk of late stage cervical cancer detection among women living with HIV. Retrospective data showed that only 5% of HIV positive women enrolled on ART at AHF Matsapha clinic have been screened for CxCa.

In 2022, we implemented a "Test, Screen Cervical Cancer and Start ART" initiative to allow early detection and treatment of pre-cancerous cervical lesions among women initiated on ART at AHF Matsapha.

Description: AHF Matsapha clinic resolved to expand the Test and Start strategy to "Test, Screen CxCa and Start ART". Consolidating screening for cancer and starting ART on the same day of HIV diagnosis instils a good healthcare practice among newly diagnosed HIV positive women.

Lessons learned: Data collected in our AHF benchmarking tools demonstrates a sustained increase in the number of Visual Acetic Acid (VIA) screening procedures performed from January 1st 2023 to December 31st 2024. During the aforementioned period, 253 women were diagnosed HIV positive. Among those clients, 208 were eligible for cancer screening either by VIA or Pap Smear.

The remaining 45 clients were not eligible at the time of HIV diagnosis considering that they were either; pregnant (29), presenting with a painful genital lesion (11), had active heavy bleeding (9) or was a minor (2). Out of the eligible clients, 80% were screened by VIA or PAP smear on the day of HIV diagnosis.

The remaining portion were subsequently screened promptly after the impeding condition resolved making a total of 98% screened for VIA. A total of 17(8%) clients screened VIA positive and were treated by cryotherapy, Loop Electrosurgical Excision Procedure (LEEP) and specimens were sent for biopsy and referred for further management.

Of note, a significant figure, 96(38%) of the clients were syndromicaly diagnosed and treated for Sexually Transmitted Infections (STIs).

Conclusions/Next steps: CxCa screening at the start of ART is key for three reasons: enables early detection and treatment of precancerous lesions and STIs, promotes routine screening practice among clients, and integrates VIA into the ART monitoring package.

Social science theories, frameworks, concepts and methods

EP0521

Cannabis use for mental health and trauma management among older women living with and without HIV: a sociological perspective

J. Bobitt[1], D. Franceschini[2], A. Hernandez-Vallant[3,4], M. Afridi[1], R. Ross[5], S.M. Cahoon[6], M. Cohen[7], A. French[8]
[1]University of Illinois Chicago, Department of Medicine, Chicago, United States, [2]University of Illinois Chicago, College of Social Work, Chicago, United States, [3]University of Illinois Chicago, Department of Psychiatry, Chicago, United States, [4]University of New Mexico, Department of Psychology, Albuquerque, United States, [5]Rush University, Department of Anatomy & Cell Biology, Chicago, United States, [6]Rush University Medical Center, Department of Anatomy & Cell Biology, Chicago, United States, [7]Stroger Hospital of Cook County, Department of Medicine, Chicago, United States, [8]University of Illinois Chicago, Department of Infectious Disease, Chicago, United States

Background: Global cannabis use is rising among older adults. In the U.S., ~9% of adults >50 reported past-year use, with much higher prevalence (~27%) among women with HIV (WWH). Yet, motivations for cannabis use and contextual drivers remains underexplored, particularly among older WWH who are understudied.
Utilizing the Socioecological Framework, we examined cannabis use across individual, interpersonal, community and societal levels among older WWH and without HIV (WWoH).
Methods: We conducted semi-structured interviews between June-September 2024 with women enrolled in the Chicago-Cook County Research Site of the MACS/WIHS Combined Cohort Study. Interviews were conducted virtually utilizing audio features only, recorded, and transcribed verbatim. A codebook was developed deductively and inductively, and transcripts were coded by three researchers. We conducted thematic analysis, identifying patterns and synthesizing overarching themes.
Results: We interviewed 20 WWH and 10 WWoH. The mean age of participants was 66.5, and most identified as Black (73%) and Hispanic (10%). Women shared that primary motivations for cannabis use were mental health, pain management (e.g. arthritis), and sleep. WWH more frequently described cannabis use for managing "stress, anxiety, and coping" and linked cannabis use to trauma-related experiences including acquiring HIV. WWoH associated cannabis use with "relaxation and calming" reflecting different lived experiences despite similar socioeconomic backgrounds. WWH uniquely reported using cannabis to enhance motivation and energy, which some linked to being able to get up and "face the day". Early cannabis use was shaped by peer influence for both groups and trauma for WWH, while adult use was framed as therapeutic to address chronic conditions and as an alternative to other substances and prescribed medications. Trust emerged as a topic among both groups; women favored trusted resources over dispensaries, even post-legalization.
Conclusions: This study highlights the multi-level influences on cannabis use and the nuanced role of cannabis in addressing trauma and mental health, particularly among WWH, for whom it may serve as a means of emotional regulation and improving daily functioning. Future research should explore cannabis as a therapeutic tool for older WWH navigating complex health and social challenges, offering insights to inform global public health strategies and education.

EP0522

Understanding men's engagement in transactional sex: piloting a new measure and framework in an urban informal area in South Africa

S. Magni[1], N. Christofides[1], A. Hatcher[2], J. Wamoyi[3]
[1]University of the Witwatersrand, Johannesburg, South Africa, [2]University of North Carolina, Chapel Hill, United States, [3]National Institute for Medical Research, Mwanza, Tanzania, the United Republic of

Background: Transactional sex is a risk factor for HIV but our understanding of this behaviour in men is incomplete. Gaps include:
1. Measurement challenges,
2. Limited information about which men are most likely to engage in transactional sex, and;
3. No framework describing men's motivations for engagement in transactional sex exists.
Methods: We developed and piloted a new measure of transactional sex focusing on men's giving of gifts/money to women who are not sex workers or wives in an urban informal settlement near Johannesburg, South Africa. 1,509 men aged 18-42 years self-completed sociodemographic, criminal behaviour, sexual risk behaviour, Gender Equitable Men Scale, Sexual Relationship Power Scale, and violence perpetration (WHO-multi-country instrument) questions.
We conducted a latent class analysis (LCA) to explore how groups of men engage in transactional sex based on their violent and antisocial behaviours. Fit for each class was assessed using the likelihood ratio test, adjusted Bayesian Information Criterion and consistent Akaike Information Criterion. Multivariable logistic regression in Stata v17 examined associations between transactional sex and classes, adjusting for sociodemographic and attitudinal factors.
Results: Some 23% of sexually active men reported engaging in transactional sex with a casual or ongoing secondary partner in the past year.

The LCA identified three classes:
1. Nice enough guys (69%) had relatively low levels of violence,
2. Power and control seekers (24%) displayed higher levels of economic and emotional violence and risky sexual behaviours
3. Aggressors (7%) displayed consistently violent behaviour.
Power and control seekers were 2.6 times more likely than nice enough guys to engage in transactional sex (AOR 2.56, 95%CI 1.91–3.53). Aggressors were 4.5 times more likely to do so (95%CI 2.74-7.35).
Our proposed framework suggests that that motivations for men's engagement in transactional sex are related to hegemonic masculinities.
Conclusions: This was the first study to use the new measure of transactional sex and to do so in an urban informal area, where HIV incidence is high. Men who engage in violent and antisocial behaviours are more likely to engage in transactional sex, suggesting that it is related to seeking greater power and control.

EP0523

Development of the management guidelines for youth in HIV support groups in Eswatini

B. Tsabedze[1,2], T. Makua[3]
[1]University of South Africa, Public Health, Pretoria, South Africa, [2]Ministry of Health, National Aids Programme, Mbabaneesw, Eswatini, [3]UNISA, Public Health, Pretoria, South Africa

Background: The study consists of two related aims, which were to explore the lived experiences of youth in HIV support groups in Eswatini and to develop management guidelines for youth living with HIV (YLHIV) in Eswatini.
Methods: The research employed a qualitative approach following a descriptive phenomenological design to capture the subjective experiences of YLHIV. Data was collected from 30 participants aged 15-24 across four regional hospitals in Eswatini. In-depth unstructured interviews were conducted in English and SiSwati, following participants' informed consent. interviews are conducted using a language preferred by the participants.
The data was analysed using five steps for qualitative data explication. Research ethics were observed per the Belmont report and the University of South Africa's (UNISA) standards.
Results: Four major themes emerged:
1. Lived experiences of YLHIV in support groups,
2. Experiences of self-discharged YLHIV,
3. Reasons for self-discharge from HIV support groups, and;
4. Factors promoting retention or suitable discharge practices.
Participants reported both positive and negative aspects of YLHIV support groups. Additionally, the Management guidelines for YLHIV in support groups were developed to emphasize a comprehensive, multi-level approach to addressing their physical, psychosocial, and economic needs, with interventions spanning individual to policy levels.
Five guidelines were developed. Guideline (1) holistic approach to support YLHIV, guideline (2) regular evaluation and feedback for resilience improvement, guideline (3) supporting self-discharged, guideline (4) transition of YLHIV in youth Support Groups to adult support groups and guideline (5) introduction of vocational training.
Conclusions: The findings informed the development of management guidelines to enhance YLHIV support, focusing on psychosocial support, stigma reduction, and mechanisms for safe discharge or sustained group membership. Five guidelines were designed to contribute to improved YLHV retention in care, viral load suppression, and overall quality of life.
This study offers insights to policymakers and healthcare providers on strengthening YLHIV support in Eswatini, aligning with sustainable HIV response.

Social and behavioural aspects and approaches to HIV prevention and living with HIV

EP0524

Intimate partner violence among women living with HIV in Hanoi: prevalence, predictors, and pathways

T.T.T. Dinh[1], M.A. Vu[1], T.H. Dang[1], H. Dodson[2], K.M. Yount[3], S. Hussen[3], M. Swahn[4], M.G. Le[1]
[1]Hanoi Medical University, Center for Training and Research on Substance Abuse - HIV, Hanoi, Viet Nam, [2]Independent researcher, Atlanta, United States, [3]Emory University, Global Health Department, Rollins School of Public Health, Atlanta, United States, [4]Kennesaw State University, Wellstar College of Health and Human Services, Atlanta, United States

Background: Intimate partner violence (IPV) adversely affects health and human rights, particularly among women and those living with HIV. Vietnam, with a high prevalence of lifetime gender-based violence (61.9% as of 2019), lacks focused research on IPV among women living with HIV.
This study examines the prevalence of lifetime and prior-year exposure to IPV and its associated factors among women living with HIV in Hanoi.
Methods: A cross-sectional study was conducted in 2024 across six HIV outpatient clinics in Hanoi using the *WHO Multi-Country Study on Women's Health and Domestic Violence against Women* questionnaire. A total of 278 participants were randomly sampled. IPV was assessed through five indicators: physical, sexual, emotional, economic violence, and controlling behavior, and Structural Equation Modeling (SEM) was applied to explore association between IPV and latent variables, including sociocultural factors (gender power, family support), adverse childhood events, and women's and partner characteristics. Data were analyzed using RStudio 2024.09.1 software.

Results: Lifetime and prior-year IPV prevalence were 53.6% and 30.2%, respectively. Emotional violence has the highest factor loading in IPV construct (β=1.11, p<0.001). Women's characteristics (β =-1.22, p<0.001) and family support (β= -0.79, p<0.001) reduced IPV risk, while partner behaviors (β=0.36, p<0.05), including alcohol use (β= 0.22, p<0.01) and intoxication (β= 0.35, p<0.001) using illicit drug (β= 0.33, p<0.01), were associated with higher prior-year IPV risk.

Conclusions: Emotional violence is the most common form of IPV experienced among women living with HIV and attending clinics in Hanoi. Protective factors include women's higher schooling attainment and family support; whereas, partner characteristics including alcohol use/intoxication and using illicit drug are associated with elevated risks of exposure to IPV.

Promising interventions involve enhancing women's empowerment, increasing social support, and addressing harmful partner behaviors to reduce IPV.

EP0525

Using online platforms to reach men who have sex with men (MSM) with HIV and STI services during the Anti-LGBTQ+ Bill Debate in Ghana

B. Owusu-Hammond[1], S.E. Owusu[2], S. Owiredu Hanson[3]
[1]CEPEHRG, Programs, Accra, Ghana, [2]Maritime Life Precious Foundation, Programs, Kumasi, Ghana, [3]CEPEHRG, Technical Coordination, Accra, Ghana

Background: The ongoing debate surrounding the anti-LGBTQ+ bill in Ghana has exacerbated stigma and discrimination against sexual minorities, particularly men-who-have-sex-with-men (MSM). This hostile environment creates significant barriers for MSM in accessing HIV and STI services, as fear of exposure, harassment, and criminalization deter many from seeking care. In response, online platforms have become a vital tool to reach MSM with HIV prevention, testing, and treatment services while maintaining confidentiality and safety.

This study explores how online platforms were used to deliver HIV and STI services to MSM during the anti-LGBTQ+ bill debate in Ghana.

Methods: A mixed-methods approach was utilized, combining quantitative data from service utilization records with qualitative data from interviews with MSM who accessed HIV and STI services through online platforms. From April to September 2024, a digital outreach campaign was launched, using social media, messaging apps, and websites to promote HIV and STI awareness, prevention, and testing services. The campaign included targeted ads, peer-led online support groups, virtual counseling, and referrals to nearby clinics offering confidential care. MSM recruited online were offered flexible appointment times and encouraged to access in-person services at community Drop-In-Centers or the homes of peers at their convenience. Data were collected from 300 MSM participants who engaged with the campaign.

Results: Over six-months, 81% of participants accessed HIV testing via online referrals, with 19% being diagnosed as HIV-positive. Of those diagnosed, 92% initiated ART. Online platforms helped significantly reduce stigma-related barriers, with 85% of participants reporting feeling safe accessing services remotely. The use of online support groups also alleviated feelings of isolation, with many MSM reporting increased confidence in managing their sexual health. Key challenges included limited internet access in rural areas and reaching MSM who were not digitally connected.

Conclusions: Online platforms offer a promising approach to providing HIV and STI services to MSM during heightened stigma, such as the anti-LGBTQ+ bill debate in Ghana. This digital strategy improves access to care, ensuring safer and more confidential interactions. Expanding online interventions can enhance healthcare access for marginalized communities, particularly in areas where stigma is a barrier, making online programming crucial for reaching MSM in remote areas.

EP0526

Drivers of poor antiretroviral therapy (ART) adherence among young people living with HIV in Zambia

H. Zulu[1]
[1]University of Zambia, Public Health, Lusaka, Zambia

Background: Antiretroviral therapy (ART) has been highly effective in Zambia, significantly reducing HIV-related morbidity and mortality and improving the quality of life for individuals living with HIV. Despite these successes, challenges with ART adherence, particularly among young people, persist and threaten to reverse the progress made in controlling the HIV epidemic.

This study aimed to examine the socio-environmental, structural, psychosocial, and behavioral factors contributing to poor ART adherence among adolescents and young adults living with HIV.

Methods: This qualitative study used Focus Group Discussions (FGDs) with young people living with HIV (YPLHIV) aged 18-24 years at Matero and Kanyama Level 1 Hospitals in Lusaka, Zambia.

Participants were purposively selected to ensure representation of those with experiences of substance use. Six FGDs (three male and three female groups, 6–8 participants each) were conducted using a semi-structured discussion guide. The data were transcribed and analyzed thematically to identify key barriers to ART adherence.

Results: The analysis revealed that substance use, particularly alcohol and marijuana, was a significant barrier to ART adherence. Participants reported that substance use disrupted medication routines, led to forgetfulness, and heightened feelings of denial about their HIV status. Socio-environmental factors, such as stigma, discrimination, and lack of family support, exacerbated these challenges.

Structural barriers, including long distances to healthcare facilities and lack of transportation, disproportionately affected rural youth.

Economic hardships, including insufficient food, and time management issues further hindered adherence. Fear of inadvertently disclosing HIV status was also a concern.

Conclusions: This study highlights the complex barriers to ART adherence faced by young people in Zambia, with substance use being a major contributor. To address these challenges, integrated, youth-focused interventions are necessary. These include community-based ART distribution hubs, peer-driven support programs, and public education to counter misconceptions about HIV and ART. Specific interventions for substance use, such as counseling and community-based programs, are crucial. Expanding access to alternative ART delivery methods, such as injectables, can help ease the daily burden of adherence. The findings emphasize the urgent need for holistic interventions to improve ART adherence and health outcomes for young people living with HIV in Zambia.

EP0527

Introducing HIV self-test to increase index testing uptake in Lao PDR, Jan 2022 – Sept 2024

J. Danyuttapolchai[1], K. Banchongphanith[2], C. Thammachak[2], K. Thongkham[2], L. Sadettanh[2], A. Kanphukiew[1], B. Simanovong[2], V. Bounyavong[2], K. Koummarasy[2], D. Xaymounvong[3], S. Northbrook[1]
[1]Division of Global HIV and TB, U.S. Centers for Disease Control and Prevention, Thailand and Lao PDR, Bangkok, Thailand, [2]Center for HIV/AIDS and STIs (CHAS), MOH, Lao People's Democratic Republic, Vientiane capital, Lao People's Democratic Republic, the, [3]Division of Global HIV and TB, U.S. Centers for Disease Control and Prevention, Thailand and Lao PDR, Vientiane capital, Lao People's Democratic Republic, the

Background: Index cases hesitate to accept index testing (IT) services due to confidentiality concerns, stigma and discrimination, and logistical barriers. Lao PDR Ministry of Health recommended the use of an HIV self-test (HIVST) in 2022 as an alternative for testing partners of index cases to improve acceptance of IT services.
Description: Any persons living with HIV (PLHIV) with unsuppressed viral load, reporting a new partner, or interrupting treatment, and any newly diagnosed PLHIV ≥ 15 years seeking HIV services at any of 12 selected sites from January 2022 through September 2024 were offered IT services after providing informed consent.
Under this model, index cases were offered the option to have their partners screened with an HIV test at a health facility or with an HIVST conducted at a location of their preference. Those who accepted the HIVST option were given an oral HIVST (OraQuick®) or blood-based HIVST (iCARE®) for each elicited partner.
HIVST results were reported using a web-based system and all HIVST users were referred for confirmatory testing. The number of partners who reported HIVST use, were referred for confirmatory testing, and were linked to antiretroviral therapy (ART) or pre-exposure prophylaxis (PrEP) was summarized using STATA.
Lessons learned: Of 1,582 partners who received an HIVST, 883 (55.8%) reported using the web-based system. Of those reporting HIVST use, the median age was 28 years (IQR: 24-52 years), 69% (1,096/1,582) were male, 57% (907/1,582) lived in the metropolitan area, and 35% (551/1,582) self-reported as part of key populations. Of 848 partners who reported their HIVST results, 16% (135/848) tested reactive; of these, 96% (129/135) were confirmed positive and 99% (128/129) initiated ART. Of 713 partners who reported a non-reactive result, 52% (373/713) sought confirmatory testing, with 99% (370/373) confirmed as HIV-negative and 16% (50/370) prescribed PrEP.
Conclusions/Next steps: Introducing HIVST was an innovative strategy to encourage index cases to accept IT, facilitate the testing and linkage of undiagnosed PLHIV to ART, and refer high-risk partners to PrEP. Increasing HIVST awareness and promoting the use of the web-based system can enhance our understanding of HIVST uptake and its effectiveness in supporting IT services.

EP0528

Factors influencing the implementation of Undetectable = Untransmittable (U=U) counseling among healthcare providers in Nigeria: a cross-sectional study

O. Ekwebene[1], S. Adejumo[2], H. Chukwuma[3], G. Edeh[4], C. Njoku[5]
[1]Indiana University, Department of Pediatrics, Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States., Indianapolis, United States, [2]University of Waterloo, ON, Canada, School of Public Health Sciences, Ontario, Canada, [3]University of Minnesota, School of Statistics, Twin Cities, United States, [4]Nnamdi Azikiwe University, Medicine, Nnewi, Nigeria, [5]Nnamdi Azikiwe University Teaching Hospital, Obstetrics and Gynaecology, Nnewi, Nigeria

Background: The concept of Undetectable = Untransmittable (U=U) is crucial for reducing HIV-related stigma and improving treatment adherence. Despite its transformative potential, the implementation of U=U counseling by healthcare providers is often inconsistent.
This study assessed the factors influencing U=U counseling and examined healthcare providers' perceptions of its validity.
Methods: A cross-sectional study employing a snowball sampling technique was conducted from November 2024 to January 2025 among 415 healthcare providers in Nigeria, including medical doctors, nurses, and allied health professionals across primary, secondary, and tertiary care settings. Data were collected using structured questionnaires that assessed demographic characteristics, workplace environment, awareness of U=U (HeardUU), knowledge levels, perceived adequacy of training, and opinions on the scientific validity of U=U. Statistical analyses included bivariate chi-square tests and multivariate logistic regression to identify predictors of U=U counseling.
Results: Among participants, 36.1% actively provided U=U counseling. Providers aged 26–30 years were less likely to counsel compared to those aged over 40 (adjusted odds ratio [AOR]: 0.25; 95% confidence interval [CI]: 0.10–0.63). Primary healthcare workers were significantly more likely to engage in counseling than tertiary care providers (AOR: 7.61; 95% CI: 2.45–23.62).

Awareness of U=U (HeardUU) was high, with 73.0% reporting familiarity; those aware of U=U were more likely to provide counseling (AOR: 25.18; 95% CI: 7.38–85.90). Participants with high knowledge were over 37 times more likely to counsel compared to those with no knowledge (AOR: 37.15; 95% CI: 11.56–119.42).

Perceived adequacy of training was the strongest predictor (AOR: 41.64; 95% CI: 17.30–100.23). Regarding U=U's validity, 67.7% of providers agreed it is scientifically valid. Providers who perceived U=U as valid were significantly more likely to provide counseling (AOR: 4.53; 95% CI: 2.35–8.75).

Conclusions: This study highlights the role of training, knowledge, and acceptance of the scientific validity of U=U in improving counseling practices. Although most providers recognize the validity of U=U, there are still gaps in applying this awareness within counseling settings. Establishing regular training programs and fostering institutional support are essential for enhancing the adoption of U=U. These findings carry important implications for reducing stigma, preventing HIV, and enhancing patient care.

EP0529

"It seemed like something I couldn't ask for:" a qualitative analysis of cis- and transgender women's experiences along the PrEP cascade in the South Bronx, New York City

T. Abularrage[1], J. Franks[1], C. Wright[1], A. Kahn[1], S. Edwards[1], T. Chern[2], H. Harpaldas[2], S. Sia[2], E. Morrison[1], J. Justman[1]

[1]ICAP at Columbia University, New York, United States, [2]Columbia University School of Engineering and Applied Science, New York, United States

Background: Cis- and transgender women (C/TGW) in the US remain underserved by HIV pre-exposure prophylaxis (PrEP) initiatives, and most cascades designed to conceptualize and strengthen PrEP use do not capture their experiences.

This qualitative analysis explores the PrEP cascade as experienced by C/TGW who completed a 12-month PrEP study in the South Bronx, New York City.

Methods: We enrolled 40 non-pregnant adults self-identifying as C/TGW who met US PrEP eligibility criteria and reported inconsistent/no previous PrEP use. Participants received daily oral PrEP (TDF/FTC or TAF/FTC) and downloaded a study-specific adherence support smartphone app. Those who completed the 12-month study were invited to complete an in-depth interview (October 2023-August 2024). Recorded and transcribed interviews were analyzed in Dedoose using directed content analysis and a four-stage PrEP cascade assessing awareness of and willingness to use PrEP; access to healthcare; likelihood of receiving a prescription; and PrEP adherence and continuation.

Results: Of the 14 interviewed participants, median age was 29 years; 71% (n=10) identified as cisgender, 29% (n=4) as transgender, 43% (n=6) Hispanic, 36% (n=5) Black, and 29% (n=4) reported prior PrEP experience. Content analysis identified themes within the four PrEP cascade stages (Table).

Although many participants were aware of PrEP, limited representation of women in PrEP messaging and popular discourse impacted knowledge of eligibility and empowerment to request it. Factors associated with adherence included developing medication-taking skills, self-management, and supportive healthcare environments. All trans- and most cisgender women in our sample reported endorsing PrEP use within their social networks.

Stage in PrEP Cascade	Theme	Exemplary Quotes
PrEP Awareness/ willingness	PrEP Awareness	"I'd seen commercials on TV…but I didn't pay no attention to it…I didn't know nothing about PrEP" (cisgender woman)
	HIV risk perception	"Prior to this [study], yes, I did have an awareness of HIV. I was more in fantasy thinking like, 'Oh, it cannot happen to me'" (cisgender woman)
	Barrier: perceived PrEP stigma from partners	"Based on my experience…It can be pretty nerve-wracking to communicate with your partner. There's a lot of stigma when it comes to sex protection" (cisgender woman)
Access to healthcare	Practical barriers: access to health insurance, relationship with provider, transportation	"Just accessing healthcare is a whole other thing for a lotta people. Insurance is hard to obtain, you know, accessing a doctor in your area is hard, transportation to the doctor is hard" (cisgender woman)
Likely to receive a PrEP prescription	Client empowered to ask for PrEP	"I see a lot of commercials about PrEP, and they'll have women in it, but sometimes you're like, 'Well, maybe it's a trans woman. I don't know.' This might just not be a commercial for me" (cisgender woman)
PrEP Adherence/ continuation	Practical skills/ behaviors: Integrating PrEP into daily routines	"I have the pill container … right next to my bed, which I take at the same time every day. It's just something that's become a habit… It's just one extra pill in the pill box" (cisgender woman)
	Individual characteristics: Self-management and care	"I'm protecting myself and knowing my boundaries when it comes to being intimate with other people…Descovy helps with that." (transgender woman)
	Supportive healthcare environment: respectful, reassuring, and accessible care	"They help me learn about HIV…I know that if I have any questions…I can call here and [there is] always somebody to ask. If I have a question, if I have a doubt…[there is] always somebody to guide me" (cisgender woman)
	Social reinforcement: endorsing PrEP use in one's social network	"I'm educating [the young kids]. I'm helping them so that when they grow up, they won't be so scared and so unsure about things like taking PrEP" (transgender woman)

Table. PrEP cascade among C/TGW

Conclusions: This rigorous analysis from a small but diverse cohort of C/TGW enriches understanding of the PrEP cascade in C/TGW, particularly awareness and adherence stages. Both cis- and transgender women identified addressing stigma, increasing awareness, and fostering provider willingness to prescribe PrEP as strategies to strengthen the PrEP cascade for C/TGW.

EP0530

Opportunities and constraints to equitable implementation of the revised infant feeding guidelines for pregnant and lactating persons living with HIV in the United States: a qualitative study

A.J. Buckland[1], H. Schmedtje[2], A. Paramasivam[1], A.M. Powell[3], A. Livingston[3], S.M. Gross[2], A.L. Agwu[4,5], W.C. Golden[4], M.G. Fowler[6], L.R. Clark[7], C. Bunch[7], B. Wendling[8], A.J. Ruff[1,4], J.G. Rosen[1,9,10]
[1]Johns Hopkins University Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [2]Johns Hopkins University Bloomberg School of Public Health, Department of Population, Family, and Reproductive Health, Baltimore, United States, [3]Johns Hopkins University School of Medicine, Department of Gynecology and Obstetrics, Baltimore, United States, [4]Johns Hopkins University School of Medicine, Department of Pediatrics, Baltimore, United States, [5]Johns Hopkins University School of Medicine, Division of Infectious Diseases, Baltimore, United States, [6]Johns Hopkins University School of Medicine, Department of Pathology, Baltimore, United States, [7]Johns Hopkins University School of Medicine, Division of General Internal Medicine, Baltimore, United States, [8]Smith College, Department of Biological Sciences, Northampton, United States, [9]Rhode Island Hospital, Division of General Internal Medicine, Providence, United States, [10]Brown University Warren Alpert Medical School, Department of Medicine, Providence, United States

Background: In 2023-2024, the United States (US) Department of Health and Human Services and the American Academy of Pediatrics issued new pregnancy/lactation guidelines for persons living with HIV (PLWH), expanding infant feeding options to include breast/chestfeeding. Recent evidence highlighting the safety of—and clear preferences for—breast/chestfeeding among PLWH is promising. However, challenges like competing clinical demands and limited resources jeopardize the fair adoption and application of the revised guidelines.
Methods: Between February and October 2024, we conducted semi-structured, in-depth interviews with 15 HIV- and non-HIV-specializing service providers (i.e., physicians, nurses, lactation consultants, dietitians, case managers) and 7 pregnant/lactating PLWH in a US Mid-Atlantic city. Interviews explored perceptions of the revised guidelines, infant feeding preferences and experiences, and anticipated or realized implementation determinants of the updated guidelines.
Using team-based, iterative thematic analysis guided by the Health Equity Implementation Framework, we identified salient facilitators and barriers to equitable implementation of the revised guidelines across heterogeneous clinical and practice contexts.
Results: Providers (60% HIV-specializing) and PLWH (mean age: 33 years, 86% non-Hispanic Black, 86% currently pregnant, 71% nulliparous, 71% expressed breast/chestfeeding intentions) alike embraced the revised infant feeding guidelines—citing expanded autonomy over infant feeding choices, as well as opportunities to de-stigmatize and normalize breast/chestfeeding among PLWH, as key facilitators of guideline adoption. Nevertheless, PLWH and provider narratives illuminated overlapping barriers to implementation and universal adoption of the revised guidelines, including: individual (i.e., breast/chestfeeding reticence given quantifiable but negligible vertical HIV transmission risks), institutional (i.e., inconsistent provider/organizational knowledge, competencies, and/or resources to implement the guidelines with fidelity), and structural (i.e., policy-attributed siloing of antenatal and pediatric healthcare) hurdles.
Conclusions: Across 22 in-depth interviews, participants' enthusiasm towards the revised infant feeding guidelines was tempered by their unaddressed anxieties about vertical HIV transmission and perceived institutional/structural constraints to equitable guideline adoption and implementation.
Person-centered counseling that acknowledges the socio-cultural meanings of breast/chestfeeding; communication that effectively demystifies "negligible" vertical HIV transmission risks associated with breast/chestfeeding; and coordinated, public sector-led dissemination of updated recommendations across disparate healthcare practices are critical to optimizing equity in the rollout of the revised infant feeding guidelines for pregnant and lactating PLWH.

EP0531

The associations between intimate partner violence victimization and HIV PrEP adherence among gay, bisexual men, and other men who have sex with men in Ukraine

C. Hong[1], N. Lunchenkov[2,3,4], D. Schmidt[4], G. Ustinov[5], E. German[3], J.I. Steinert[2,6]
[1]University of Connecticut, School of Social Work, Hartford, United States, [2]Technical University of Munich, School of Social Sciences and Technology, Munich, Germany, [3]Eurasian Coalition on Health, Rights, Gender and Sexual Diversity, Health and Capacity Building Department, Tallinn, Estonia, [4]Robert Koch Institute, Department of Infectious Disease Epidemiology, Berlin, Germany, [5]Friedrich Schiller University, Jena, Germany, [6]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom

Background: Gay, bisexual, and other men who have sex with men (GBMSM) face elevated risks for HIV, with intimate partner violence (IPV) being a significant factor influencing health outcomes. IPV, encompassing physical, sexual, emotional, and other abuse forms, is linked to mental health challenges and may impact adherence to HIV prevention strategies like pre-exposure prophylaxis (PrEP). In Ukraine, where GBMSM face intersecting stigmas, the relationship between IPV and PrEP adherence remains underexplored. Investigating these dynamics is crucial for developing integrated interventions addressing IPV and promoting effective HIV prevention.
Methods: We conducted an online survey between January and February 2022 among GBMSM in a PrEP program in Ukraine. IPV victimization was assessed using an adapt-

ed IPV-GBM scale, categorizing experiences into different types of (physical, sexual, emotional, monitoring, controlling, and financial) and polyvictimization (>=2 types of IPV). PrEP adherence was self-reported as excellent or suboptimal, with thematic analysis capturing reasons for non-adherence.

Descriptive statistics summarized participant characteristics, and multivariate logistic regressions examined associations between IPV and PrEP adherence, adjusting for sociodemographic and behavioral covariates.

Results: Among 937 current PrEP users, the mean age was 31.0 years, 61.3% had a college degree, and 82.8% identified as gay. Excellent PrEP adherence was reported by only 35.4% of participants. IPV victimization was reported by 39.6% of respondents, with sexual (16.3%), emotional (16.0%), and monitoring IPV (12.6%) being the most common forms.

Polyvictimization was experienced by 19.2%. In multivariate models, experiencing sexual (AOR=1.82, 95%CI: 1.25-2.65), monitoring (AOR=1.83, 95%CI: 1.21-2.78), controlling IPV (AOR=1.92, 95%CI: 1.22-3.02), and polyvictimization (AOR=1.52, 95%CI: 1.06-2.15) were significantly associated with higher odds of reporting excellent PrEP adherence.

The most reported reasons for non-adherence included reduced sexual activity and disruptions caused by the COVID-19 pandemic.

Conclusions: This study underscores significant associations between IPV victimization and PrEP adherence among GBMSM in Ukraine, a population at elevated risk for HIV. These findings suggest that IPV experiences may shape health behaviors, potentially driving adherence to PrEP as a protective measure.

Integrating tailored IPV interventions and support services within PrEP programs is critical to enhancing both IPV prevention and adherence outcomes. Targeted efforts to address COVID-19-related disruptions to PrEP use remain essential.

EP0532

Acceptability of broad neutralising antibodies for post-natal prophylaxis, perceptions from communities in South Africa and Uganda

S. Kruger[1], L. Viljoen[2], T. Fikizolo[3], V. Magasana[4], A. Goga[4], M. Buthelezi[4], N. Ngcobo[4], G. Nanyonjo[5], A. Ssetaala[5], B. Okech[5], J. Mpendo[5], K. Ondeng'e[5], Y. Wangũi Machira[5], K. Chapman[6], S. Malhotra[6]

[1]Family Centre for Research with Ubuntu, Stellenbosch University, Department Pediatrics and Child Health, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [2]Desmond Tutu TB Centre, Stellenbosch University, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [3]Family Centre for Research with Ubuntu, Stellenbosch University, Department of Pediatrics and Child Health, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [4]South African Medical Research Council, Durban, South Africa, [5]Uganda Virus Research Institute, IAVI HIV Vaccine Programme, Entebbe, Uganda, [6]International AIDS Vaccine Initiative (IAVI), New York, United States

Background: Broadly neutralising antibodies (bNAbs) is potentially a safe, affordable and effective biomedical intervention likely to provide several weeks of protection for infants at risk of perinatal HIV acquisition. This study aimed to examine the acceptability of bNAbs for prevention of vertical HIV transmission among mothers from South Africa and Uganda.

Methods: Once-off in-depth interviews were conducted with three cohorts of mothers from two sites in South Africa and one in Uganda between February 2024 and October 2024.

This included:

1. Mothers with infants who participated in trials (n=19), examining the safety and pharmacokinetics of bNAbs in HIV-exposed infants (IMPAACT P1112, PedMAb1),
2. Mothers living with HIV whose infants received standard postnatal prophylaxis (n= 30), and;
3. HIV-free pregnant and lactating mothers (n=30).

We included the perspectives of (n=88) identified key community members using interviews and focus group discussions. Detailed and iterative case descriptions were created after each interview and verbatim quotes were included. Data were coded using the Theoretical Framework of Acceptability (TFA) and compared across participants and sites.

Results: Most mothers reported a positive response in anticipation of implementing long-acting bNAbs for infant postnatal prophylaxis. They cited practical reasons, including convenience, reduced administration burden, and fewer adherence challenges compared to daily medication. Participants noted perceived physical benefits, including lower stress from potential HIV risks, and social benefits, including privacy and protection from inadvertent HIV status disclosure. Mothers whose infants received bNABs attributed their infant's good health to bNAbs.

Although most mothers were keen to access bNAbs for additional infant protection, they highlighted societal barriers that could influence the acceptance of bNAbs including stigma, incurring costs to initiate and maintain

treatment, missing work and health workers' attitudes. While bNAbs were positively received, most participants reported a lack of knowledge on the functioning of bNAbs, including how long bNAbs would provide protection, the dose requirements, potential side effects and possible interference with scheduled vaccines.

Conclusions: Emerging data suggests a preference towards long-acting postnatal prophylaxis, with benefits of long-acting treatment and prevention strategies outweighing the challenges of accessing treatment. Advocacy for bNAbs is needed to address lack of knowledge about bNAbs in communities.

EP0533

The intersectionality of sexual and health stigmatisation for GBQMSM living with HIV/AIDS in Nigeria

G.-c. Offor[1], V.E. Ajinomoh[1], M. Zedomi[2], M. Olaniyi[2]
[1]Think Positive Live Positive Support Initiative, Research, Alimosho, Nigeria, [2]Think Positive Live Positive Support Initiative, Monitoring, Evaluation and Learning, Alimosho, Nigeria

Background: The intersection of HIV status, sexual orientation, and societal biases creates unique vulnerabilities for gay, bisexual, queer men, and men who have sex with men living with HIV/AIDS (GBQMSMLHIV). While policies and legislation exist to protect people living with HIV/AIDS in society, particularly in the workplace, these protections often fail GBQMSMLHIV due to the criminalization of their sexual orientation under the Same-Sex Marriage (Prohibition) Act of 2014 (SSMPA).

This research examines the lived experiences of GBQMSMLHIV, exploring the intersectional impacts of stigma and identifying strategies to foster inclusive workplace environments.

Methods: The study used a qualitative approach, conducting focus group discussions (FGDs) with 45 GBQMSMLHIV participants. Key Informant Interviews with legal practitioners, HR personnel, and advocates provided additional insights. The data gathered were analysed using thematic analysis approach.

Results: Five themes emerged from the thematic analysis:

Request for Medical Testing: The testimonies of GBQMSMLWHIV highlight how these tests are however weaponized to exclude them from employment opportunities, regardless of their qualifications or performance during interviews and other assessments.

Discrimination from colleagues: Discrimination in the workplace took forms like gossip, exclusion, and breaches of privacy which impacted participants professionally, emotionally and psychologically, shaping their overall work experience.

Intersectionality of Discrimination and Stigmatization: The narratives shared provide a lens into how the multiple layers of identity, such as sexual orientation, HIV status, and familial relations intersect, intensifying the stigma and marginalization that GBQMSMLHIV experience.

Impact of Antiretroviral Therapy: Participants shared the physical and psychological effects they experienced when they started taking ARVs and how it affected their productivity especially during the early stages of treatment.

Identified gaps in Legislations and Policies and their Implementations: The low domestication of nationally enacted laws, especially in workplaces and the crippling effect of the SSMPA, which criminalizes same-sex relationships and behavior combined together, creates a chilling effect that prevents GBQMSMLWHIV employees from fully utilizing protections available to the general population living with HIV.

Conclusions: Despite Nigeria's legal protections against HIV-related discrimination, weak enforcement and the SSMPA's criminalization of LGBTQI+ persons leave GBQMSMLHIV vulnerable to workplace exclusion and stigma. Addressing this requires targeted awareness, diversity training, and inclusive environments.

EP0534

Assessing the intersections of stigma, social support, and mental health on treatment adherence and quality of life among people living with HIV (PLHIV) in Ghana

R.S. Adzesi[1], B. Tetteh[2], C. Femeyibor[3], E.A. Ampofo[3], A.I. Tsiboe[4], J. Amoah-Larbi[3]
[1]University of Ghana, Statistics and Actuarial Science, Accra, Ghana, [2]Baldwin University College, Accra, Ghana, [3]Ghana National TB Voice Network, Accra, Ghana, [4]KEBA Africa, Accra, Ghana

Background: HIV-related stigma, lack of social support and mental health issues remain barriers to good health among people living with HIV, which adversely affect treatment adherence and quality of life at both societal and individual levels.

This study investigates the intersection between HIV-related stigma, mental health, social support on treatment adherence and quality of life among PLHIV in Ghana.

Methods: A facility-based cross-sectional study was conducted to recruit 1,374 people living with HIV in Greater Accra Regional Hospital and Korle Bu Teaching Hospital in the Greater Accra Region, Ghana from August to November 2024, using systematic sampling technique.

An adapted structured questionnaire was used to collect data on stigma (HIV Stigma Scale), discrimination (Discrimination Scale), mental health (using the PHQ-9 scale for depression and GAD-7 for anxiety), treatment adherence (using the Morisky Medication Adherence Scale), and quality of life (using the WHOQOL-BREF).

Multiple regression analysis was used to identify the predictors of treatment adherence and quality of life at 5% statistical significance level.

Results: The findings of the study revealed that the average age of the respondents was 35.8 ± 13.2 and had been living with HIV for an average years of 11.1 ± 7.6. Quality of life was significantly correlated with social support ($r = 0.506$, $p < 0.001$), HIV stigma ($r = 0.415$, $p < 0.001$) and mental health ($r = 0.227$, $p < 0.001$).

Multiple regression analysis revealed HIV-related stigma (β = 0.027, p = 0.320), mental health (β = 0.027, p = 0.430), or social support (β = 0.019, p = 0.335) have no statistically significant influence on treatment adherence among people living with HIV.

Nonetheless, quality of life among people living with HIV was significantly predicted by HIV-related stigma (β = 0.077, p < 0.001), mental health (β = 0.062, p < 0.001), and social support (β = 0.067, p < 0.001).

Conclusions: From the findings, although HIV-related stigma, mental health, and social support significantly influence quality of life among PLHIV, these factors did not significantly predict treatment adherence in this study. This suggests that quality of life interventions must focus on psychosocial and community support systems

EP0535

Predictors of sexual risk behaviors among HIV-positive adolescents in high-risk areas: a multivariate and logistic regression analysis in Northwest Nigeria

O. Alimi[1], A. Ananaba[1], N. Chuku[1], K. Alau[1], D. Popoola[1], L. Terhemba[2], C. Opiti[2], C. Ananaba[1], O. Oyelaran[3], J. Pius[3], E. James[3], D. Ogundehin[3], P. Gado[3], R. Eneogu[3], U. Omo-Emmanuel[3], M. Katbi[3], D. Kimanga[3], C. Obiora-Okafo[4], A. Idemudia[4], B. Oyawole[4], C. Nwadike[4], B. Adebobola[5], T. Ileri[6]

[1]Health Systems Consult Limited, Monitoring, Evaluation, Learning and Research, Abuja, Nigeria, [2]Health Systems Consult Limited, Technical and Programs, Abuja, Nigeria, [3]USAID Nigeria, Programs, Abuja, Nigeria, [4]USAID Nigeria, Monitoring and Evaluation, Abuja, Nigeria, [5]FMoH (NASCP), Technical and Programs, Abuja, Nigeria, [6]NACA, Technical and Programs, Abuja, Nigeria

Background: HIV-positive adolescents residing in high-security risk areas of Kebbi, Sokoto, and Zamfara States, Nigeria, encounter obstacles in managing their sexual health. The prevalent societal stigma, inadequate healthcare services, and limited sexual education amplify their susceptibility to engaging in risky sexual behaviors. It is imperative to comprehend the combined and anticipatory influence of these factors to formulate tailored interventions for this vulnerable demographic.

Methods: This comprehensive study integrated quantitative surveys and qualitative interviews with 60 HIV-positive adolescents recruited from Adolescent and Young People (AYP) support groups across three states. The quantitative data encompassed demographic particulars, healthcare accessibility, condom utilization, and encounters with stigma. Logistic regression was utilized to pinpoint predictors of risky behaviors, while multivariate analysis delved into the complexity of intersecting variables. The qualitative interviews offered nuanced insights into the societal and personal determinants influencing these behaviors.

Results: Logistic regression analysis identified stigma (OR: 2.5, 95% CI: 1.8–3.4), limited healthcare access (OR: 3.2, 95% CI: 2.1–4.8), and coercive relationship dynamics (OR: 1.9, 95% CI: 1.3–2.6) as significant predictors of inconsistent condom use among participants (p < 0.05). Adolescents experiencing higher levels of stigma were 2.5 times more likely to engage in risky sexual behaviors compared to their peers with lower stigma levels. Limited access to youth-friendly healthcare services further increased the odds by 3.2 times.

Multivariate analysis revealed a complex interplay among these predictors, showing how factors like insufficient sexual education (β = 1.4, p < 0.01) and transportation challenges (β = 1.7, p < 0.01) compounded the risks. The model explained 65% of the variance in inconsistent condom use behaviors (R^2 = 0.65), underscoring the multifaceted nature of these determinants.

Qualitative findings added depth to these quantitative results, highlighting how adolescents' apprehension about disclosing their HIV status and power imbalances in relationships influenced their decision-making regarding safe sexual practices.

Conclusions: This research highlights the systemic obstacles contributing to sexual risk behaviors among HIV-positive adolescents in Northwest Nigeria. Stigma, accessibility to healthcare, and dynamics within relationships are crucial factors necessitating targeted interventions, such as mobile clinics, comprehensive sexual education, and programs focused on reducing stigma.

EP0536

Leveraging technology in HIV prevention: the impact of WhatsApp chatbot in enhancing HIV awareness and prevention among Maseno university students

L. Lidoros[1], P. Omutere[2], O. Samwel[2]

[1]Health Rights Advocacy Forum (HERAF), Programs, Nairobi, Kenya, [2]Maseno University, Public Health, Kisumu, Kenya

Background: With the increasing rates of HIV among the adolescent and young population (AYP), there is a need for informative interventions resonating with the lifestyles of this demographic. According to the National Syndemic Diseases Control Council of Kenya, 52% of the new HIV cases in 2023 occurred among the AYP.

This abstract demystifies an intervention that aimed at leveraging the extensive use of WhatsApp among students to deliver HIV prevention information in a familiar and engaging way.

Description: During a 3-day outreach in November 2023 on ending the triple threat in Maseno University, Kenya, a specifically crafted WhatsApp chatbot referred to as "*Ask-Her*," later changed to "*ASKA*" was introduced by Population Service Kenya to spread HIV prevention information among students. *ASKA* offered virtual assistance as a conversational agent by responding to prompt questions and providing information on HIV testing, condom use, safe practices, PEP, PrEP, and stigma and discrimination to the users. University peer educators featured this intervention by mobilizing students to interact with *ASKA*.

Lessons learned: From the *ASKA* server, 13,157 from a total of 20,956 students, interacted with the chatbot by October 2023. The University Aids Control Unit reported an increase in condom use, HIV self-testing and general HIV

knowledge among students. Digital tools proved to be effective in disseminating health information among the AYP.
Furthermore, there was increased engagement due to population-specific interventions that conformed with the communication preferences of the AYP which enhanced confidentiality. Peer-led interventions promoted trust and empowerment among students.
Conclusions/Next steps: The success of the chatbot in revolutionizing HIV awareness in Maseno University underscores the potential of digital tools in delivering health information among the AYP. These outcomes propose a model that can be emulated in other learning institutions and integrated into the broader disease prevention programs for a wider reach.

EP0537

Intimate Partner Violence among HIV positive women on antiretroviral treatment in Kenya: are there protective factors which can mitigate the risk of IPV in HIV positive women?

M. Gituru[1], B. Biomndo[1]
[1]Institute of International Health, Charité - Universitätsmedizin Berlin, Berlin, Germany

Background: IPV and HIV have a deeply intertwined relationship, with each exacerbating the other. IPV not only violates human rights but severely impacts women's physical and mental health, **and in certain regions, raises their risk of contracting HIV**. Women living with HIV face a higher risk of IPV, which complicates disease management and worsens health outcomes.
This study examines the different forms of IPV faced by HIV positive women in Kenya receiving ART at free government clinics and explores whether certain socio-demographic factors and partner characteristics might offer protection against or increase vulnerability to IPV.It also analyses how partner violence drives HIV transmission.
Methods: A secondary analysis of data from a facility-based cross-sectional study of 408 women living with HIV was performed.
A multivariate logistic regression model was used to investigate the relationship between the independent variables and the different forms of IPV.
Results: The overall prevalence of IPV in this study group was alarmingly high (87.9%). Controlling behaviors were identified as the most common type of IPV reported by 65.4% of participants. Physical, emotional, and sexual IPV were reported by 57.1%, 57.6%, and 37.8%, respectively. A significant overlap between various types of IPV was also discovered. 44.9% of participants reported both physical and emotional violence, 44.4% experienced physical IPV in addition to controlling behaviors, 30.6% of women reported both physical and sexual IPV, and 22.8% of the women experienced all four types of IPV.
Polygamy, partner's alcohol consumption, fear of partner, and retaliatory behaviors were all found to be associated with an increased risk of experiencing IPV. Higher income, older age, being in a monogamous relationship, and having a HIV positive partner were each inversely associated with different forms of IPV indicating a potential protective effect. Among the 359 women who experienced any type of IPV in this study, less than half (46.8%) sought help.
Conclusions: To prevent IPV-related HIV transmissions, IPV in Kenya should be effectively addressed. These findings strongly suggest the need for routine screening for all forms of IPV within HIV care to allow for early identification and offer comprehensive support which goes beyond medical treatment.

EP0538

Exploring perceived utility of a clinic-integrated HIV prevention app for men who have sex with men in Malaysia: a qualitative think-aloud study

S.H. Sujan[1], J.A. Wickersham[2], A. Khati[3], K. Gautam[3], K. Paudel[3], I. Azwa[4], F.L. Altice[5], Y.K. Tan[4], N.S. Mohd Sahira[4], M.M. Copenhaver[3], R. Shrestha[3]
[1]University of Connecticut, Allied Health Sciences, Storrs, United States, [2]Yale School of Medicine, New Haven, United States, [3]University of Connecticut, Storrs, United States, [4]Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, [5]Department of Medicine, Yale School of Medicine, New Haven, United States

Background: HIV remains a global health concern, disproportionately affecting men who have sex with men (MSM), especially in Malaysia. Discrimination, stigma, and other barriers in healthcare settings are common issues for MSM in Malaysia, resulting in sub-optimal HIV testing and linkage to HIV prevention services. Based on our formative work, we created a clinic-integrated HIV prevention app called "JomPrEP" to scale up HIV prevention efforts among this vulnerable group.
This study aimed to explore the perceived utility, appeal, and functionality of the JomPrEP app for MSM in Malaysia to improve access to HIV prevention services.
Methods: We conducted one-on-one qualitative interviews with 10 MSM and 10 community stakeholders (i.e., physicians, administrators, and outreach workers) using the 'think-aloud' (TA) protocol. Participants were recruited from the Greater Kuala Lumpur region between February and April 2022. The TA procedure included 10 problem-solving tasks, followed by a semi-structured interview.
These interviews aimed to delve deeper into the users' feedback on the pre-specified tasks on nine features of the app. The TA sessions were video-recorded and then transcribed verbatim. Theme analysis was used to analyze qualitative data.
Results: Participants from both groups (i.e., MSM and community stakeholders) expressed most of the app features [e.g., app signup page, ordering HIV self-test (HIVST) kits, and pre-exposure prophylaxis (PrEP) medications] as being important and user-friendly.
Incorporating additional features, particularly MedManager (e.g., a feature that sends reminders to users and tracks their medications) and reward systems (i.e., incentives for specific actions such as ordering HIVST or tracking mood), were well-received.

Conversely, participants also suggested (i.e., introducing edit and update options for PrEP and HIVST kit orders and incorporating confirmation messages for clinic appointments) to refine the app further.

Conclusions: JomPrEP was found to be a functional, appealing, and useful platform to scale up HIV prevention services among MSM in Malaysia. Further refinement and pilot testing are needed to assess its impact on HIV prevention efforts for MSM in Malaysia.

EP0539

The acceptability of long-acting injectable antiretroviral therapy in Uganda and South Africa: a qualitative methods sub-study of the IMPALA trial

D. Bukenya[1,2], M. Zondi[3], A. Ssali[1], U. Bahemuka[1], U. Singh[3], N. Garrett[3], S. Nassiwa[4], N.C. Owarwo[4], V. Babirye Tumusiime[1], I. Eshun-Wilsonova[5], I. Awhonukeh[6], W. Rein van der Horst[7], F. V Cresswell[2,8,1], E. Ruzagira[1,2], J. Seeley[2], D. S Lawrence[2,9,10]

[1]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]CAPRISA, Durban, South Africa, [4]Infectious Disease Institute, Kampala, Uganda, [5]Johnson and Johnson, Cape Town, South Africa, [6]Johnson and Johnson, Lagos, Nigeria, [7]Johnson and Johnson, Holland, Netherlands, the, [8]Brighton & Sussex Medical School, Brighton, United Kingdom, [9]Botswana Harvard Health Partnership, Gaborone, Botswana, [10]University of the Witwatersrand, Johannesburg, South Africa

Background: Long-acting injectable antiretroviral therapy (ART) is increasingly available in high-income countries and has been found to be highly acceptable in these settings. Long-acting injectable cabotegravir and rilpivirine (CAB+RPV-LAI) may be a particularly attractive option for people with challenges adhering to oral ART. The IMPALA trial is comparing virological outcomes of 8-weekly CAB+RPV-LAI versus oral ART in individuals with a history of adherence challenges in East and Southern Africa. We embedded a qualitative methods sub-study within IMPALA with the aim of describing the acceptability of CAB+RPV-LAI within this population.

Methods: Participants from Uganda and South Africa were purposively recruited, aiming for an equal distribution by site, gender, and treatment allocation. In-depth interviews were conducted with participants on three occasions: after randomisation but before receiving any CAB+RPV-LAI, and at six and twelve months. Interviews were audio recorded, transcribed, translated, and analyzed thematically.

Results: Forty participants were recruited into the qualitative methods sub-study between July 2023 and March 2024: 20 in Uganda, 20 in South Africa; 18 female and 22 male; 22 receiving CAB+RPV-LAI and 18 receiving oral ART. There were high levels of anticipated acceptability by participants randomized to CAB+RPV-LAI.

Individuals randomized to the oral arm were generally disappointed, however some felt that given the investigational nature of the trial they would avoid any potential CAB+RPV-LAI-related side effects. Participants receiving CAB+RPV-LAI appreciated not having to remember to adhere to daily oral ART or carry noisy tablet bottles which could inadvertently reveal their HIV status.

Those on oral ART described repackaging their tablets to avoid this. Most participants receiving CAB+RPV-LAI described a reduction in HIV-related stigma as they could initiate and continue treatment in the privacy of the clinic and did not need to carry or take daily tablets.

Conclusions: Consistent with findings in high income settings, CAB+RPV-LAI was highly acceptable to trial participants with a history of challenges adhering to oral ART in East and Southern Africa.

HIV-related stigma did persist for participants with injectable ART, although for most it reduced. Further research is required to explore the feasibility of implementing this regimen in routine care in sub-Saharan Africa.

EP0540

Resilience, leadership, and crisis competence: lessons from people living with HIV during the COVID-19 pandemic

Y. Wu[1], J.E. Kaufman[1], J.A. Manalel[1], A. Gao[1], V. Antonios[2], C. Brandenburg[2], L. Scaccabarrozzi[2], J. Ernst[2], M. Brennan-Ing[1]

[1]Hunter College, City University of New York, Brookdale Center for Healthy Aging, New York, United States, [2]Amida Care, New York, United States

Background: While much research has described the COVID-19 pandemic disruptions to HIV care services, the strategies employed by people living with HIV (PLWH) to cope with these challenges remains understudied. Recognizing PLWH's active management of their health, this study examined sources of resilience and crisis competence among PLWH in the USA during the COVID pandemic. Our goal was to inform the design of future care engagement initiatives to strengthen crisis resilience in HIV care.

Methods: We conducted in-depth interviews with 40 participants (22 cisgender men, 10 cisgender women, 8 transgender/gender divers; aged between 23 and 64 years) in New York City during the fall of 2023.

We asked participants about their experiences during the pandemic, coping mechanisms, adaptation strategies to evolving challenges to care engagement, and resources they considered necessary to navigate the healthcare system during the pandemic and beyond.

Results: Proactive resource-seeking and self-advocacy, involving collaboration with multiple stakeholders across social agencies and their personal networks, enabled many participants to effectively manage their care needs and maintain the standard of care they desired.

Participants' prior and ongoing community engagement and leadership roles had fostered resilience, enabling them to navigate social mitigation efforts like lockdowns.

Despite challenges, participants demonstrated competency in managing their own care while also providing support to others in the HIV community.

Additionally, several participants advocated for greater involvement of PLWH in decisions about their health care and the design of healthcare systems overall.
Conclusions: Findings reveal how PLWH leverage the knowledge cultivated through years of managing their HIV to overcome pandemic-related care challenges.
This study further highlights the enduring value of community engagement in fostering crisis resilience. To build a more resilient healthcare delivery system for PLWH, clinical practice should work with community programs and peer-led interventions in a collaborative manner.
Moreover, it is important for PLWH to be acknowledged as leaders within their communities. Future research on HIV care engagement should avoid defining this population solely by their vulnerabilities but recognize their resilience, strengths, and leadership qualities as resources in maintaining engagement in care.

EP0541

Biomedical HIV research participation during pregnancy: perspectives of US adolescents

H.C. Baron[1], R.V. Masese[1], A.D. Lyerly[1], S. Day[2]
[1]University of North Carolina at Chapel Hill, Department of Medicine, Center for Bioethics, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Department of Medicine, Division of Infectious Diseases, Chapel Hill, United States

Background: Pregnant adolescents face increased risk of HIV acquisition, vertical transmission, and poor pregnancy outcomes, highlighting the urgent need for their inclusion in HIV prevention and treatment studies. To identify factors that may support or hinder pregnant adolescents' inclusion in biomedical HIV research, we examined views of adolescents in the United States related to research rules that may shape their participation.
Methods: In-depth interviews were conducted with ever-pregnant adolescents living with HIV (age 15-24 years old) and at-risk of HIV acquisition (age 15-20 years old) recruited from clinical research settings across the U.S.
The semi-structured interview guide explored adolescents' views on participating in biomedical HIV research during pregnancy with reference to three common rules:
1. Parental and non-gestational parent (NGP) consent,
2. Abuse disclosure, and;
3. Two required forms of contraception.
Interviews were transcribed verbatim and coded using NVivo software by three independent coders. A thematic analysis approach was used to identify emergent themes in the advantages and disadvantages of participation rules.
Results: Forty adolescent interviews were conducted in total, with 20 individuals living with HIV and 20 at-risk of HIV acquisition. Thematic analysis revealed mixed support for the three common rules, with adolescents describing both risks and benefits of each. While participants noted advantages of obtaining parental consent for adolescent research participation during pregnancy, some noted that pregnant individuals under 18 can provide independent consent. For NGP consent requirements, relationship dynamics emerged that could facilitate or hinder participation in HIV research during pregnancy. While most favored disclosure of abuse as a way of providing protection for the adolescent by authorities, some also noted the importance of consulting with the adolescent before reporting.
Finally, support for contraception requirements centered on pregnancy prevention, but participants emphasized that contraceptive uptake should be the adolescent's choice rather than a study participation requirement.
Conclusions: Adolescents identified advantages and disadvantages of common clinical research rules that would impact their decisions to participate in biomedical HIV studies during pregnancy. Mitigating concerns about disadvantages, while leveraging the advantages as facilitators of participation will be important in designing trials that foster respectful inclusion of this population.

EP0542

Enhancing TB preventive treatment uptake among people living with HIV: insights from a qualitative study in South Africa

L.M. Mlambo[1], M. Setlaleleng[2], K. Shearer[3], N.J. Mofokeng[4], P. Ndou[5], M. Milovanovic[6], L. Steiner[7], L. Genade[1], L. Lebina[8], N.A. Martinson[1], C.J. Hoffmann[7], J. Owczarzak[9]
[1]University of the Witwatersrand, Perinatal HIV Research Unit, Soweto, South Africa, [2]University of the Witwatersrand, Perinatal HIV Research Unit, Klerksdorp, South Africa, [3]Johns Hopkins University, School of Medicine, Baltimore, United States, [4]University of the Witwatersrand, Perinatal HIV Research Unit, Botshabelo, South Africa, [5]University of the Witwatersrand, Perinatal HIV Research Unit, Polokwane, South Africa, [6]University of the Witwatersrand, African Potential Collaborative, Midrand, South Africa, [7]John Hopkins University, School of Medicine, Baltimore, United States, [8]Africa Health Research Institute, Clinical Trials, Mtubatuba, South Africa, [9]Johns Hopkins Bloomberg School of Public Health, Department of Health, Behavior, and Society, Baltimore, South Africa

Background: Tuberculosis (TB) remains a major global health challenge, particularly for people living with HIV (PLWH). TB preventive treatment (TPT) has been found to reduce the risk of TB among PLWH. As TPT has become a standard component of HIV care, understanding client-level perceptions and knowledge of TB prevention is crucial to optimizing uptake.
Methods: This qualitative sub-study was conducted within a cluster-randomized trial evaluating a TPT initiation strategy in two provinces of South Africa. The qualitative component explored client understanding and experiences with HIV, TB, and TPT through in-depth interviews among PLWH receiving care at participating public-sector healthcare facilities who were purposively selected from North West and Free State provinces of South Africa. Thematic analysis was used to identify themes.
Results: Thirty-three adult PLWH were interviewed. Most participants understood TB and the high risk for household TB transmission, and understood PLWH have increased susceptibility to TB disease. Participants were

clear that TB is curable and they identified its risk and transmission to dirty environments, neglecting symptoms and habits such as alcohol use and smoking. Participants highlighted that a combination of health-seeking behaviors, treatment adherence and community-level TB-related stigma influence the TB burden, stressing that both TB and its treatment are community challenges. Understanding of TPT varied, with most participants emphasizing the need for clients to take initiative in their TPT treatment. Participants requested that healthcare workers provide more details about TPT through counselling, posters and pamphlets in clinics, and suggested community engagement to encourage adherence. Concerns about TPT were expressed, including side effects and the burden of taking both antiretroviral therapy (ART) and TPT treatment.

Conclusions: Individual and community social and health-related factors, along with participants' general acceptability of TPT, might affect its uptake and retention. While TPT was seen as important, concerns about the dual treatment burden highlight the need for improved education and support. Strengthening healthcare communication and community engagement could enhance TPT adherence and reduce TB risk among PLWH.

EP0543

Identifying best practices for offering telephonic adherence support to people diagnosed and on tuberculosis and/or HIV treatment or tuberculosis preventive therapy: a scoping review

Z. Mtwane[1], J. Boffa[1], S. Dladla[2], T. Mhlaba[1], B. Chibi[3], S. Moyo[4], Z. Gavu[3]

[1]University of KwaZuluNatal, School of Nursing and Public Health, Durban, South Africa, [2]University of KwaZuluNatal, School of Clinical Medicine, Durban, South Africa, [3]Human Sciences Research Council, Pietemaritzburg, South Africa, [4]Human Sciences Research Council, Durban, South Africa

Background: While completing treatment is essential to cure tuberculosis (TB), treatment duration, side effects and structural barriers pose challenges to adherence. COVID-19 made out-of-clinic adherence support options more desirable. Research on telephonic adherence support (TAS) for TB is limited. We conducted a scoping review of TAS outcomes among people on treatment for TB and/or HIV or TB Preventive Therapy (TPT).

Methods: We used Arksey & O'Malley's framework for scoping reviews. Articles were searched on PubMed & Ebscohost databases and by two independent reviewers. Included studies were published in English, from year 2000-present, and considered TAS versus a comparison group. Adherence measurement data and outcomes were extracted and improvements from baseline and/or comparison with comparison groups considered and described.

Results: Eighteen articles were included in analysis: 15 on antiretrovirals, three on TB treatment, and zero on TPT. TAS differed by frequency: daily, weekly, intermittent, or monthly; duration: median=6, range=3-40 months; and comparison group: standard of care (n=16), directly observed therapy (DOT) (n=3), and/or SMS reminders (n=1). TAS improved adherence from baseline in 6/9 studies (mean $^{improve=}$2.2%, range=-26.4-26.5%) and compared to controls in 10/15 studies ($^{meandiff=}$4.6%, range=-5.7-40.2%). In studies measuring clinical outcomes, TAS improved log_{10} VL from baseline in 5/5 studies and outperformed comparators in 3/5 studies (mean $^{VLimprove=}$1.8, range=0.6-3.2; mean $^{VLdiff=}$0.6, range=-0.5-1.7). CD4 counts improved from baseline in 4/4 studies and against comparators in 3/4 studies (mean $^{CD4improve=}$65.2, range=9.1-146.0$^{/mm3;}$ mean $^{CD4diff=}$19.6, range -32.0-75.4$^{/mm3}$).

One study showed a higher, but statistically insignificant, proportion of smear conversion for TAS compared to DOT (17.1% vs 13.1%, p=0.67).

Conclusions: There were few studies on TAS for TB; more for HIV. Overall TAS showed modest improvement, with wide variation between studies. Notably, TAS showed improvement from baseline for all clinical outcomes. Differences in TAS components and study design may explain the wide range in findings.

EP0544

Forgotten in the frontline: highlighting and addressing health staff and their access to HIV services in Zambia

M. Chonta[1], N. Muttau[1], S. Clay[1], N. Ilukena[2], N. Kasese[3], D. Milimo[3], M. Simwinga[1], P. Ndubani[4], L. Mlunde[5], B. Beston[6], J. Mbwambo[7], L. Nyblade[8], S. Roberts[8], E. Gymera[9], W.O. Mahama[10], V. Bond[11]

[1]Zambart, Social Sciences, Lusaka, Zambia, [2]Zambart, Health economics, Lusaka, Zambia, [3]Zambart, Data, Lusaka, Zambia, [4]Macha Research Trust, Research, Choma, Zambia, [5]Muhimbili University of Health and Allied Sciences, Research, Dar Es Salaam, Tanzania, the United Republic of, [6]Muhimbili National Hospital, Training, Dar Es Salaam, Tanzania, the United Republic of, [7]Muhimbili National Hospital, Psychiatrist, Dar Es Salaam, Tanzania, the United Republic of, [8]Research Triangle International, Research, Washington, United States, [9]Education Assessment and Research Centre, Research, Accra, Ghana, [10]Education Assessment and Research Centre, Consultant, Accra, Ghana, [11]Zambart/ London School of Hygiene, Social Sciences, Lusaka, Zambia

Background: Health staff are on the frontline of delivering HIV services. Although HIV stigma and discrimination (S&D) reduction tools have been developed for this population, they are not widely used. In 2024, a Total Facility Approach (TFA) S&D intervention was adapted for two hospitals in Zambia, including a new tool developed with health staff to address the HIV S&D they face

Methods: In 2024, a pre-intervention self-administered baseline stigma survey was conducted with all health staff (clinical and non-clinical) at two Zambian hospitals. 801 staff (44% men, 56% women) responded (80% and 78% response rate). The survey included observed, perceived and enacted S&D indicators for negative attitudes to health staff living with HIV, and institutional policy and

work environment items about staff access to services. Qualitative data was obtained from the tool's development workshop.

Results: In the baseline survey, 62% of clinical staff and 45% of non-clinical staff believed healthcare workers are at least a little hesitant to take an HIV test in their own facility; and 26% clinical staff and 15% non-clinical staff were not confident that their test result would be confidential. At the workshop, a nurse stated, "I would never test from our facility because if I test by 9 am, by the afternoon, the entire facility will know about my status". 52% clinical staff and 36% non-clinical staff thought a healthcare worker living with HIV would be hesitant to seek HIV care where they worked. In addition, 69% of clinical staff and 61% of non-clinical staff thought that healthcare workers living with HIV would not disclose their status for fear of losing their job. Health staff described traveling long distances to seek HIV services, incurring financial, time and absence costs. The newly developed tool focuses on 'professional stigma', successful navigation of HIV services and building co-worker encouragement and support. 'I have done many HIV trainings', one nursing officer said of the latter, 'but this one is finally about us!'

Conclusions: Conclusions: In Zambia, health staff face challenges accessing HIV services, particularly in facilities where they work. Similar to the TFA, HIV S&D interventions should address this.

EP0545

Using trained expert client approaches to inform HIV stigma and discrimination reduction interventions in sub-Saharan Africa: multi-country insights

N. Muttau[1], P. Ndubani[2], A.W.K. Katz[3], G. Marwerwe[4], E. Mankattah[5], F. Dambasea[5], E.T. Amponsah[5], L. Nyblade[3], S.T. Roberts[3], L. Mlunde[4], J. Mbwambo[6], B. Betson[6,7], E. Gyamera[5], W. Osafo-Mahama[5], M. Simwinga[1], V. Bond[1,8]
[1]Zambart, Lusaka, Zambia, [2]Macha Research Trust (MRT), Choma, Zambia, [3]RTI International, North Carolina, United States, [4]Muhimbili University of Health and Allied Sciences (MUHAS), Dar es Salaam, Tanzania, the United Republic of, [5]Education Assessment and Research Centre (EARC), Accra, Ghana, [6]Muhimbili National Hospital (MNH), Dar es Salaam, Tanzania, the United Republic of, [7]Muhimbili University College of Health and Allied Services (MUCOHAS), Daresalaam, Tanzania, the United Republic of, [8]London School of Hygiene and Tropical Medicine (LSHTM), London, United Kingdom

Background: Participatory approaches that capture lived experiences of marginalized populations affected by HIV across diverse African contexts can be valuable for adjusting and evaluating interventions. We utilized the Trained Expert Client (TEC) approach to assess healthcare provider performance, HIV- related service delivery and HIV stigma and discrimination in six public hospitals across Zambia, Ghana, and Tanzania. Multi-country baseline findings from this approach are informing development of an expanded Total Facility Approach (eTFA) multi-country intervention project.

Methods: At baseline, 82 participants aged ≥15 were purposively recruited through local stakeholders and trained as TECs. TECs were from marginalized groups: adolescents and young adults (AYAs) living with HIV (n=24); AYAs seeking HIV prevention services (n=11); young women accessing reproductive health services (n=12); men who have sex with men (MSM) (n=12); people who use drugs (n=11) and people living with HIV and co-morbidities (n=12).
A half-day participatory training covered ethics, observation techniques, hospital mapping and safety measures. During routine HIV care or identified hospital appointments, TECs discreetly observed HIV-related service delivery focusing on service quality, stigma, discrimination, overall impressions and motivation to return. Within 24 hours of the appointment, social scientists debriefed TECs using an interview guide and hospital maps. Rapidly analysed findings were shared with hospitals as part of the eTFA intervention.

Results: We use a case-study of a 19-year-old AYA TEC in Zambia to illustrate TEC data. Despite being born with HIV, this TEC chose to request HIV testing, having no earlier recollection of this experience. He reported initial disrespect from the healthcare worker, inadequate pre-counselling, failure to wear gloves and a change in tone following disclosure of his status. Multi-country TEC observations highlighted systemic issues: breaches of confidentiality, derogatory language, and excessive phone use. For example, healthcare workers publicly questioned young men about their HIV prevention service-seeking behaviours (Zambia & Ghana), used derogatory language based on perceived femininity of MSM clients (Ghana) and demonstrated lack of empathy when providing HIV test results compared to routine malaria results (Tanzania).

Conclusions: Multi-country findings show that the TEC approach is valuable in identifying barriers and informing HIV stigma and discrimination reduction interventions.

EP0546

Impact of misconceptions on discriminatory attitudes towards people living with HIV/AIDS in Sub-Saharan Africa: evidence from DHS data (2003–2023)

F. Effiong[1], A. Mohammed[2], D. Ibirogba[3], L. Vasanthan[4], D. Adewole[5]
[1]University of Calabar Teaching Hospital (UCTH), Medical Laboratory Services, Calabar, Nigeria, [2]APIN Public Health Initiatives, Jos, Nigeria, [3]Systematic Reviews Network (SRN), Calabar, Nigeria, [4]Christian Medical College, Vellore, India, [5]University of Ibadan, Department of Health Policy and Management, College of Medicine, Ibadan, Nigeria

Background: Stigma and discrimination undermine the health and well-being of people living with HIV/AIDS (PLWHIV), including sub-optimal medication, lower visit adherence, high tendencies to depression, and overall lower quality of life. This study explores the role of witnessing HIV-related stigmatization and the belief in foodborne transmission in shaping discriminatory attitudes among women aged 15–49 years in HIV-endemic Sub-Saharan African (SSA) countries.

Methods: Data were drawn from Demographic and Health Surveys (DHS) conducted between 2003 and 2023 across seven SSA countries with HIV prevalence exceeding 10% (based on 2017 data). Three discriminatory attitude questions were used to obtain the outcome variable (discriminatory attitude towards PLWHIV). Independent variables included in the model are witnessing HIV-related stigma, belief in foodborne transmission and sociodemographic characteristics. Countries without these data were excluded. Descriptive, bivariate, and multivariate analyses were performed using SPSS version 25 to assess the predictors of discriminatory attitudes.

Results: The final sample comprised 57,325 women across seven countries. Discriminatory attitudes towards PLWHIV varied significantly, from 33.7% in Eswatini to 72.4% in Tanzania. Factors such as being young, unmarried, uneducated, living in rural areas, or belonging to the poorest wealth quintile were associated with higher odds of discrimination.

Witnessing HIV-related stigma significantly increased discriminatory attitudes in Uganda (adjusted odds ratio [aOR]: 1.49; 95% CI: 1.34–1.65).

Additionally, belief in foodborne HIV transmission was a strong predictor of discrimination in all seven countries: Zimbabwe (aOR: 3.42, 95%CI:2.92-4.01), Zambia (aOR:3.46, 95%CI: 2.93-4.09), Lesotho (aOR:4.56, 95%CI:3.97-5.24), Eswatini (aOR: 2.82, 95%CI:2.36-3.40), Namibia (aOR: 2.07, 95%CI: 1.80-2.38), Uganda (aOR:3.07, 95%CI:2.63-3.57) and Tanzania (aOR:2.80, 95%CI:2.4-3.27).

Conclusions: This study highlights the influence of stigma and misconceptions on discriminatory attitudes towards PLWHIV in SSA. Witnessing stigmatization and false beliefs about HIV transmission, such as through food, exacerbate discrimination, disproportionately affecting vulnerable populations.

Comprehensive education campaigns addressing these myths, coupled with community-based anti-stigma interventions, are critical to fostering a supportive environment for PLWHIV and improving public health outcomes.

EP0547

Stigma and discrimination towards young men seeking sexual and reproductive health services among health facility staff in Ghana, Tanzania and Zambia

S.T. Roberts[1], A. Schaap[2], N. Kasese[2], R. Owusu[3], K. Baning[3], E. Valency[4], A. Lwanga[4], H.K. Matakala[5], N. Muttau[2], J. Mbwambo[6,4], L. Mlunde[4], E. Gyamera[3], W. Osafo-Mahama[3], P. Ndubani[5], M. Simwinga[2], L. Nyblade[7], V. Bond[2]

[1]RTI International, Women's Global Health Imperative, Oakland, United States, [2]Zambart, Lusaka, Zambia, [3]Education Assessment and Research Centre (EARC), Accra, Ghana, [4]Muhimbili University of Health and Allied Sciences (MUHAS), Dar es Salaam, Tanzania, the United Republic of, [5]Macha Research Trust, Macha, Zambia, [6]Muhimbili National Hospital (MNH), Dar es Salaam, Tanzania, the United Republic of, [7]RTI International, Washington, United States

Background: Young men in sub-Saharan Africa have been consistently under-engaged in HIV services. Although concerns about judgmental providers are a well-established barrier to care, few studies have measured stigma and discrimination (S&D) towards young men among health workers themselves.

In 2024, we assessed S&D towards young men ages 18-24 seeking sexual and reproductive health services (YMSSRH) among health facility staff in Ghana, Tanzania, and Zambia.

Methods: Data were collected through the baseline survey evaluating the Total Facility Approach (TFA), an intervention to reduce HIV-related S&D in health facilities. A total of 2197 clinical and non-clinical staff were recruited from two hospitals each in Zambia (n=801), Ghana (n=796), and Tanzania (n=600).

Participants self-administered a structured questionnaire assessing stigmatizing attitudes, perceived stigma, and observed discrimination towards YMSSRH, and features of the institutional environment influencing S&D. Responses were summarized descriptively and compared using chi-squared tests.

Results: Across countries, only 48-52% of staff thought it was normal for young men to engage in sexual activity, and 28-56% did not think most YMSSRH are responsible and hard working (see Table).

About 20-50% agreed that having sex brings disgrace and shame to a young man and his family and 25-33% agreed that most young men attending the health facility use drugs and alcohol.

Tanzanian staff were significantly more likely than Ghanaian or Zambian staff to hold stigmatizing attitudes, but less likely to have observed discrimination (range:36-45%) or to perceive that their co-workers were hesitant to care for this population (range:14-31%).

Ghanaian respondents were significantly less likely to agree that they would get into trouble if they discriminated against YMSSRH than respondents in Tanzania or Zambia (range:39-77%).

Domain	Item	Ghana (N=796) n (%)	Tanzania (N=600) n (%)	Zambia (N=801) n (%)	p-value
Stigmatizing Attitudes	It is normal for young men to engage in sexual activity (positive attitude)	384 (48)	294 (49)	420 (52)	0.21
	Most young men who come to this health facility are responsible and hard working (positive attitude)	458 (58)	265 (44)	576 (72)	<0.001
	Having sex as a young man brings disgrace and shame to a young man and his family	159 (20)	287 (48)	242 (30)	<0.001
	Most young men who come to this health facility are using drugs and alcohol	198 (25)	200 (33)	220 (27)	0.002
Observed discrimination	Observed co- workers unwilling to provide care, providing poorer quality of care, talking badly about, or disclosing care seeking in the past 6 months	362 (45)	213 (36)	349 (44)	0.001
Perceived stigma	Believes co-workers are hesitant to care for this group	247 (31)	86 (14)	187 (23)	<0.001
Institutional environment	Believes they will get into trouble if they discriminate against this group	307 (39)	373 (62)	619 (77)	<0.001

Conclusions: We found high levels of S&D towards YMSSRH in all three countries, with different manifestations across countries. Tailored interventions to reduce relevant forms of S&D could increase engagement in HIV prevention, testing and treatment among young men, supporting progress towards the UNAIDS targets.

EP0548

Unveiling the presence of stigma and discrimination towards adolescent girls accessing sexual reproductive health services among staff from four hospitals in Zambia and Ghana

K.H. Matakala[1], N. Muttau[2], K. Baning[3], N. Kasese[4], E. Gyamera[3], L. Mlunde[5], W. Osafo-Mahama[3], P. Ndubani[1], M. Simwinga[4], J. Mbwambo[6], L. Nyblade[7], V. Bond[4,8], S. Roberts[7]

[1]Macha Research Trust, Choma, Zambia, [2]Zambart, Choma, Zambia, [3]Education Assessment and Research Centre (EARC), Accra, Ghana, [4]Zambart, Lusaka, Zambia, [5]Muhimbili University of Health and Allied Sciences (MUHAS), Dar es Salaam, Tanzania, the United Republic of, [6]Muhimbili National Hospital (MNH), Dar es Salaam, Tanzania, the United Republic of, [7]Research Triangle International (RTI), Washington, United States, [8]London School of Hygiene and Tropical Medicine (LSHTM), London, United Kingdom

Background: In Sub-Saharan Africa, adolescent girls often face a nexus of stigma and discrimination (S&D) within health facilities, limiting their access to sexual reproductive health services (SRHS), with serious consequences. It is critical to measure the extent of S&D and address its influence on SRHS in health facilities, including family planning and HIV testing, prevention, and treatment.
Methods: In Zambia and Ghana, all health staff (clinical and non-clinical) in a total of four hospitals were recruited for a self-administered survey that collected data on S&D towards adolescent girls aged 15-19 years old seeking SRHS services, including negative attitudes, observed stigma, and the institutional environment. Data was analysed descriptively.
Results: Response rates were 80% in both Zambia (n=801; 469 clinical and 332 non-clinical staff) and Ghana (n=796; 575 clinical and 221 non-clinical).
Negative attitudes towards adolescent girls who are sexually active were widespread: 40% of clinical staff and 61% of non-clinical staff in Zambia and 24% of clinical staff and 38% of non-clinical staff in Ghana agreed that: 'Adolescent girls who are sexually active are promiscuous,' 'Adolescent girls who use modern family planning are promiscuous,' and 'If an adolescent girl is sexually active, she is probably a prostitute.'
Although most hospital staff in both countries were willing to provide SRH services to adolescent girls, many had observed co-workers unwilling to provide this care (Zambia: 23% of clinical staff and 32% of non-clinical staff; Ghana: 56% of the clinical staff and 36% of non- clinical staff).
More staff in Zambia (82% clinical and 70% non-clinical staff) than in Ghana (47% clinical and 56% non-clinical staff) believed that they would get into trouble if they discriminated against adolescent girls who seek SRHS.
About two-thirds (64%) of staff in Zambia and one-half (48%) in Ghana knew of written guidelines in their facility safeguarding adolescent girls from discrimination.
Conclusions: The levels of S&D towards adolescent girls who are sexually active and seeking services were concerning, with consequences for sexual and reproductive health and HIV prevention, diagnosis and treatment. Stigma-reduction interventions need to be tailored for this group to impact broader SRHS and specific HIV outcomes.

EP0549

Optimizing viral load suppression among men with unsuppressed viral load: the menstar coaching model

E. Kuushomwa[1], J. Tshimwanga[1], S. Kuudhingiliwa[2]

[1]Ministry of Health and Social Services, Directorate of Special Program, Windhoek, Namibia, [2]Total Control of the Epidemic / Development Aid from People to People (TCE/DAPP), Directorate of Special Program, Windhoek, Namibia

Background: In 2023, the HIV treatment cascade in Namibia achieved the 95-95-95 targets, but progress in viral suppression among men aged 24–34 years remained insufficient. To address this gap, the MenStar Coaching Model, adapted from South Africa's Coach Mpilo initiative, was introduced. This peer-support model leverages men living with HIV, stable on antiretroviral therapy (ART), to mentor others with unsuppressed viral loads. At Grootfontein ART Clinic, the model targeted men with viral loads ≥ 1000 copies/mL to improve adherence and achieve viral suppression defined as viral loads <40 copies/mL.
Objectives: To evaluate the impact of the MenStar Coaching Model on viral load suppression among men with high viral loads at Grootfontein ART Clinic over 12 months.
Description: A retrospective cohort design was used to assess the effectiveness of the intervention from September 2023 to September 2024. Fifteen men with viral loads ≥1000 copies/mL were identified and enrolled. A dedicated MenStar coach provided individualized support, focusing

on adherence, behavioural changes, and psychosocial empowerment. Data were collected monthly using facility-based and community-based registers. Outcomes were assessed by comparing viral suppression rates before and after the intervention using McNemar's test, with 95% confidence intervals (CIs) and significance threshold of $p < 0.05$.

Lessons learned: Results: Prior to the intervention, none of the 15 participants had achieved viral suppression. Following the intervention, 9 participants (60%) achieved suppression (target not detected), while 5 continued with high viral loads, and 1 interrupted treatment. The viral suppression rate improved significantly from 0.0% to 60.0% (95% CI: 47.57–86.32, $p = 0.0006$).

Discussion: The MenStar Coaching Model demonstrated substantial potential in improving viral suppression among men with unsuppressed viral loads. Peer-based coaching effectively addressed key barriers to adherence, including stigma, lack of male-cantered services, and psychosocial challenges. However, the remaining 40% with suboptimal outcomes emphasize the need for intensified, individualized interventions.

Conclusions/Next steps: The MenStar Coaching Model is an effective approach to enhancing viral suppression among men with high viral loads. To achieve Namibia's 2030 HIV targets, scaling up this customer-focused, peer-driven model is critical. Future efforts should address unmet needs to maximize adherence and treatment outcomes.

EP0550

The impact of a household intervention on Household HIV competency and ART adherence for people living with HIV in Cape Town, South Africa

L. Campbell[1,2], C. Masquillier[1], L. Knight[3], N. Sematlane[4], L.T. Dube[5], A. Delport[4], E. Wouters[1]

[1]University of Antwerp, Centre for Population, Family and Health, Antwerpen, Belgium, [2]University of Gent, Public Health and Primary Care, Gent, Belgium, [3]University of Cape Town, School of Public Health, Cape Town, South Africa, [4]University of the Western Cape, School of Public Health, Cape Town, South Africa, [5]University of the Western Cape, School of Pharmacy, Cape Town, South Africa

Background: In 2023, an estimated 39.9 million people globally were living with HIV, of whom 7.7 million in South Africa. Among people living with HIV (PLHIV) in South Africa in 2022 (>15 years old), 90% were aware of their status, 91% of those were on antiretroviral therapy (ART), and 94% of those on ART were virally suppressed. ART adherence is crucial for health outcomes of PLHIV, making effective adherence interventions critical. Households, as key micro-social environments, can significantly influence health behaviours, including ART adherence. This study evaluated a household-level intervention to improve ART adherence behaviour in Cape Town, South Africa.

Methods: Baseline data for a cluster-randomized control trial were collected from 316 PLHIV in 12 clinics in sub-districts of Cape Town between May 2021 and May 2022. Endline data were collected between December 2021 and July 2022. Clinics were randomly allocated to control or intervention, stratified by clinic size. Both arms received standard adherence visits from community health workers including a pill-count. The 7-month intervention additionally comprised sessions including around adherence and disclosure planning, healthy household communication, and HIV household competency.

Primary outcomes included 4 adherence measures, secondary outcomes included disclosure, HIV household competency, and stigma. Cluster-level measures were analysed to detect differences at endline between study arms.

Results: There was no evidence of a difference at endline between control and intervention arms for primary ART adherence outcomes. There was evidence at endline that mean scores for HIV household competency were lower in the control group than the intervention group (mean diff: -0.28, t=-2.44, p=0.04) after controlling for baseline scores and socio-demographic characteristics. HIV Household Competency was associated with three measures of ART adherence, including lower scores of poor self-rated adherence (β =-.014, t=-2.51, p=0.013), lower odds of not following ART schedules (aOR 0.98, t=-2.34, p=0.02) and lower odds of not following special instructions, (aOR 0.98, t=-2.38, p=0.018). No differences were observed for other secondary outcomes.

Conclusions: The study indicates that household-based interventions may have an impact on ART adherence by improving HIV household competency. Future interventions and research should include the context of the household when examining ART adherence.

EP0551

Unlocking tomorrow: peer PrEP champions scaling-up HIV oral PrEP uptake among adolescents and young women

U. Charlotte[1], D. Munyamisugi[1]

[1]African Evangelistic Enterprise, Programs, Kigali, Rwanda

Background: Rwanda's national HIV prevalence is 2.7%. Among women, the prevalence is 3.7% and an estimated 30% of new cases in Rwanda occurs amongst adolescent girls and young women (AGYW) aged 12-24 years. This high acquisition rate calls for targeted preventive strategies.

Since October 2022, Igire Ubaka Ejo (IUE) activity has provided referrals for PrEP to AGYW aged 18-24 who are at substantial risk of HIV acquisition.

However, USAID-IUE noted resistance to use of PrEP by at-risk AGYW for reasons including stigma and misconceptions around use of PrEP.

Description: AEE Rwanda introduced 40 PrEP Champions into USAID-IUE to address barriers to uptake of and adherence to PrEP. As young women already on PrEP, Champions became a bridge between AGYW and health services, capable of dispelling misconceptions around PrEP and helping health care providers understand concerns of AGYW. Together with mentors, champions are trained to do community screening for AGYW who have multiple sexual partners, or practice transactional sex and provides them with weekly social and behavioural change

communication (SBCC) sessions through digital messaging platforms, including WhatsApp deliver age-appropriate PrEP information to targeted AGYW. The project revised an Memorandum of Understanding (MOU) with health centers to formalize their working relationships with Champions.

Since its introduction, the Champions strategy, alongside differentiated services delivery to scale up oral PrEP services such as general PrEP awareness education provided to adolescent girls below age of 18, has enhanced HIV prevention among AGYW.

Lessons learned:

- Engaging AGYW on PrEP willing to be PrEP Champions is highly effective at increasing uptake and adherence to PrEP.
- PrEP Champions contributed to increasing AGYW accessing PrEP services from 547 in 2022 to 1,218 in 2024.
- MOUs with health facilities empowered Peer PrEP Champions to work effectively.

Conclusions/Next steps: PrEP Peer Champions is a model that works to encourage AGYW at substantial risk of HIV to take PrEP. AEE Rwanda expect that the continuation of this approach with lead to enduring and higher rates of PrEP among at-risk AGYW.

EP0552

Prevalence of alcohol and substance use disorders among recipients of HIV care in Zimbabwe

K.C. Takarinda[1], M. Kaiyo-Utete[2], T.E. Matson[3], Z. Senter[4], K. Webb[1], H.E. Jack[4]

[1]Organization for Public Health Interventions & Development (OPHID), Harare, Zimbabwe, [2]University of Zimbabwe, Department of Psychiatry, Harare, Zimbabwe, [3]Kaiser Permanente Washington Health Research Institute, Seattle, United States, [4]University of Washington, Department of Medicine, Division of General Internal Medicine, Seattle, United States

Background: Unhealthy drinking and substance use among people living with HIV (PLWH) are associated with poor antiretroviral therapy (ART) adherence, increased viral load, and mortality [1,2].

Treatments for alcohol and substance use can be offered in HIV care. However, understanding the local prevalence of alcohol use disorder (AUD) and substance use disorder (SUD) and what substances are used is important for planning services. Little prior research has explored alcohol and substance use in Zimbabwe despite anecdotal reports of increasing use.

Methods: As part of a larger study to validate AUD and SUD screening tools, we conducted a cross-sectional study among recipients of HIV care between November-December 2024 across 6 public health facilities offering ART in Bulawayo city and Gwanda rural districts. Recipients of HIV care aged ≥18 years who attended their scheduled ART refill and/or clinical review visit were randomly selected. Diagnostic assessments for AUD and SUD were conducted verbally using Ndebele-translated versions of the Composite International Diagnostic Interview (CIDI) Substance Abuse Module, which is based on a DSM-5 criteria [3]. AUD and SUD were defined as endorsing ≥2 symptoms regarding alcohol or substance use, respectively, on the CIDI. Participant demographic characteristics were also collected. Unweighted data analysis including the Chi-square test for associations were conducted using Stata Version 17.

Results: Of the, 1,064 study participants, the majority (62%, n=660) were females, and the median age was 44 years (IQR: 36-53). The prevalence of AUD was 19.9% (n=212) with the breakdown of mild, moderate and severe AUD being 8.9% (n=85), 4.4% (n=47) and 6.6% (n=70) respectively. Prevalence of SUD was 2.8% (n=30). Of those with SUD, 63% (19/30) had cannabis use disorder. Men had a higher prevalence of AUD (13.4% vs 4.8%, p<0.01) and SUD (7.3% vs 1.4%, p<0.01).

Conclusions: This large, cross-sectional study used diagnostic interviews administered by clinicians to show that there is a high burden of AUD and to a lesser extent, SUD among people attending ART clinics. Next steps will be integration of routine screening for AUD and SUD into HIV care and linking those who screen positive to treatment. Treatment programs may particularly target men, who are most affected.

EP0553

Tenuous transitions: exploring persistent challenges to retention in care for adolescent and young mothers living with HIV in rural South Africa

C. Laurenzi[1], N. Waluwalu[1], C. Busakhwe[2], M. Thabeng[3], S. Lindani[4], E. Toska[2,5], M. Tomlinson[1,6]

[1]Stellenbosch University, Institute for Life Course Health Research, Department of Global Health, Tygerberg, South Africa, [2]University of Cape Town, Accelerate Adolescent Hub, Centre for Social Science Research, Cape Town, South Africa, [3]Oxford Research South Africa, East London, South Africa, [4]One to One Africa Children's Fund, Cape Town, South Africa, [5]University of Oxford, Social Policy and Intervention, Oxford, United Kingdom, [6]Queens University Belfast, School of Nursing and Midwifery, Belfast, United Kingdom

Background: Adolescent mothers living with HIV have poorer treatment adherence and are likelier to experience disruptions in retention in care. However, there has been limited research with adolescent mothers who give birth before age 18—especially those in rural settings—on the barriers and facilitators to their retention in care.

This IAS CIPHER-funded study aimed to explore barriers to retention in HIV care, specifically focusing on social, psychosocial, and relational challenges that young women experience while navigating both HIV and new motherhood in rural South Africa.

Methods: In rural Eastern Cape, South Africa, we recruited adolescent girls and young women living with HIV who had given birth before age 18 (young mothers) between September-December 2024. Participants were recruited with support from our community-based partner, One-to-One Africa. A Xhosa-speaking researcher conducted semi-structured individual interviews, followed up by dyadic interviews with a trusted adult. Young mothers' indi-

vidual interviews included an arts-based activity to map their experiences accessing healthcare at clinics during and following their pregnancies. Data were analyzed using rapid qualitative analysis.

Results: In individual (n=8) and dyadic (n=4) interviews with young mothers and key adults in their lives, participants revealed tensions linked to accepting their statuses and envisioning their futures during the transition to motherhood. Several young mothers described forced or unintended disclosure of their HIV statuses by friends and family members, leading to school withdrawal and heightened isolation.

Significant structural factors, including chronic poverty, food insecurity, and school dropout and expulsion further disadvantaged participants leading up to, and following, pregnancy and birth. The most at-risk young mothers often lacked birth certificates and identity documents, limiting their ability to access government grants.

Instrumental and emotional support received from sisters, mothers, and grandmothers was vital, when available. While accessing healthcare was possible, if time-intensive, for most participants, daily routines to support adherence and general HIV status acceptance varied widely, posing challenges for their ongoing health.

Conclusions: Young rurally-based mothers require tailored psychosocial and practical support to enable them to stay retained in care. Young mothers could further benefit from services that ensure their rights to stay in school, and access government grants, can be fully realized.

EP0554

I am doing it for my child and myself": empowering autonomy and ethical participation of pregnant women living with HIV and their children in clinical research

E.R. Masese[1], M.S. McHenry[2,3], G. White[2], D.K. Kinyanjui[4], E. Were[5], J.G. Carlucci[6,3], J. Humphrey[2,3], E. Wahome[3], D. Munyoro[3], A. Nafiseh[2], K. Cunningham[2], M. Cory[2], M. Nyalumbe[3], R.A. Ombitsa[3], M.A. Ott[7], C. Halverson[8]

[1]Moi University, Sociology Psychology and Anthropology, Eldoret, Kenya, [2]Indiana University School of Medicine, Department of Pediatrics, Indianapolis, IN USA, United States, [3]Academic Model Providing Access to Healthcare (AMPATH) Kenya, Eldoret, Kenya, [4]Moi University, School of Medicine, Department of Mental Health and Psychiatry, Eldoret, Kenya, [5]Moi University, School of Medicine, Department of Reproductive Health, Eldoret, Kenya, [6]Indiana University School of Medicine, Department of Pediatrics, Indianapolis, IN USA, Kenya, [7]Icahn School of Medicine at Mount Sinai, Department of Pediatrics, New York, United States, [8]Indiana University School of Medicine, Center for Bioethics, Indianapolis, IN USA, United States

Background: During the decision-making process related to enrolling in longitudinal clinical research, the agency of pregnant and post-partum women living with HIV and their children is often overlooked, particularly in patriarchal, communitarian, and resource-limited settings that constrain their autonomy in decision-making. This qualitative study explores the strategies employed by pregnant women living with HIV to navigate these complex socioeconomic and cultural dynamics, assert their independence in decision-making, and examines the broader implications of these strategies for promoting ethical clinical practices.

Methods: Data were collected within a parent research study at Moi Teaching and Referral Hospital in Eldoret using a person-centered approach. The study involved 45 qualitative interviews, comprising 30 pregnant or post-partum women living with HIV and 15 mothers without HIV. Interviews were audio-recorded, transcribed, translated where necessary, and analyzed by a multidisciplinary team using a priori coding, constant comparison, axial coding, and triangulation.

Results: Results demonstrate challenges faced by participants in navigating relational and cultural norms to facilitate their and their children's participation in research. Women without strong social ties to their partners preferred to provide consent independently while married women commonly described discreet decision-making without involving their spouses. Leveraging caregiving roles, women sometimes framed research participation as routine clinic visits to avoid unwanted disclosure of their and their children participation in HIV research. Confidentiality and privacy were identified as key research practices to support the agency of pregnant women and children.

Some participants destroyed consent forms to prevent unwanted disclosure, most expressed a preference for clinical results to be communicated privately and directly to them. Additionally, participants voiced their preferences for home visit protocols, ensuring that their privacy was safeguarded and their unique needs were addressed due to perceptions of high HIV stigma within their communities.

Conclusions: This study demonstrates the ethical duty for clinical HIV research to prioritize women's agency, implement culturally sensitive and confidential consent processes, and address structural barriers such as caregiving inequities. Researchers should consider gender-sensitive approaches, strengthen privacy protections, and involve participants in shaping protocols. Ethical training for researchers is crucial for navigating relational and cultural complexities, ensuring research is inclusive, empowering, and contextually aware.

EP0555

Mbarara University nursing students' association on the frontline in creating HIV vaccine awareness in rural Southwestern Uganda

D. Akampumuza[1], H. Nabbulo[1], P. Musinguzi[1], E. Nduhuura[2]
[1]Mbarara University of Science and Technology, Nursing, Mbarara, Uganda, [2]Mbarara University, Medicine and Surgery, Mbarara, Uganda

Background: Nursing students play a crucial role in prevention and management of Human Immunodeficiency Virus (HIV) despite the increase in prevalence. HIV vaccine is among the current strategies for managing HIV however much its adoption and utilization are still poor.
This project aimed at equipping knowledge and information about HIV vaccine to the youth in Nyakagyeme, Rukungiri district, Southwestern Uganda.
Description: Mbarara University Nursing Students' Association conducted a 3-day community engagement campaign in Nyakagyeme Health Centre III, Rukungiri district, southwestern Uganda. This campaign aimed at addressing misconceptions and addressing knowledge gaps among community members seeking care at the facility. We used a cross-sectional, mixed-methods approach incorporated it with One Health framework.
Lessons learned: This project made a significant improvement in knowledge about availability and benefits of HIV vaccine through sensitization, educating 300 community members (188F, 112M) and 15 healthcare workers (9Nurses, 4midwives and 2 doctors).
The educated members also committed to be champions of promoting HIV vaccine awareness. Qualitative interviews revealed significant misconceptions about the vaccine, gaps in knowledge and information regarding HIV vaccine and readiness of primary healthcare facilities.
In conclusion, this project provided knowledge about HIV vaccine to 300 community members and 15 health care workers who were engaged, and led to the inception of formation of HIV vaccine awareness champions.
Conclusions/Next steps: There is need for scaling up to the entire district, other regions, and the entire country to effectively create awareness about HIV vaccine so that community members are ready to take it up when it is rolled out.
There is need for adequate training to medical and nursing students, and health care workers on proper use of HIV vaccine while caring for clients.

EP0556

Evaluating the uptake and retention on pre-exposure prophylaxis among female sex workers in Rwanda

V. Umubyeyi Mupenzi[1], G. Gatete[1], C. Kayitesi[1], G. Mujawamariya[1], B. Ikuzo[1], A. Taofeek Tope[2], E. Remera[1], G. N. Rwibasira[1]
[1]Rwanda Biomedical Centre, Kigali, Rwanda, [2]University of Rwanda, Kigali, Rwanda

Background: Pre-Exposure Prophylaxis (PrEP) is a proven HIV prevention strategy, yet uptake and adherence remain suboptimal among female sex workers (FSWs) in many settings. In Rwanda, where FSWs are at heightened risk of HIV, data on PrEP utilization and barriers to access are scarce.
This study aims to evaluate PrEP awareness, uptake, adherence, and associated factors among FSWs across Rwanda. We hypothesize that regional differences, age, and HIV knowledge significantly affect PrEP uptake and adherence among FSWs in Rwanda.
Methods: A cross-sectional biological and behavioral survey was conducted among FSWs aged 15 years and above using respondent-driven sampling to enroll 2,541 FSWs from May to June 2023 in all provinces and Kigali City. Data on PrEP awareness (ever heard of PrEP), uptake (ever used PrEP), and adherence (daily use) were collected using a structured questionnaire. We also collected data on age, gender, and HIV knowledge to assess demographic differences. Data were analyzed using STATA 17, with regional differences examined and logistic regression analysis identifying factors associated with PrEP uptake and discontinuation. Adjusted odds ratios and 95% confidence intervals were reported.
Results: Among the 2,541 FSWs, 57.4% (1,527) had heard of PrEP, and 39.8% (504) had ever used it, with uptake varying significantly by region: 17.3% in the Eastern Province and 53.3% in the Southern Province ($p<0.001$). However, 84.4% of users adhered to daily PrEp for the first six months, with the highest discontinuation rate in the Eastern Province (51.8%) and the lowest in the Western Province (8.9%).
Key reasons for discontinuation included feeling it was no longer necessary (30.7%), difficulty accessing PrEP (35.6%), and side effects (17.8%). Age and HIV knowledge were significantly associated with PrEP uptake and discontinuation.
Conclusions: These findings underscore the importance of targeted interventions to improve PrEP awareness, accessibility, and adherence among FSWs, particularly focusing on individuals aged 35 and above and enhancing HIV education to reduce discontinuation rates.
Further research on gender-specific interventions is needed to enhance PrEP uptake and adherence.

EP0557

Re-engaging the lost to care: innovative approaches for HIV treatment retention among migratory key populations in fishing communities along Lake Victoria

I. Mubiru[1], J. Senyonjo[2]
[1]African Diversity and Inclusion Center (ADIC), Entebbe, Uganda, [2]TASO Entebbe, Entebbe, Uganda

Background: Fishing communities along Lake Victoria face unique HIV prevention and treatment challenges, including high mobility, stigma, and limited access to healthcare. Migratory fisherfolk are disproportionately affected by HIV, with frequent interruptions in care leading to poor retention and adverse health outcomes. This project aimed to develop and implement strategies to re-engage individuals lost to follow-up, enhancing treatment retention among these key populations.

Description: From 2022 to 2024, a community-led intervention was implemented across five fishing villages along Lake Victoria in Uganda. The project targeted fisherfolk, including men, women, and adolescents, who had disengaged from antiretroviral therapy (ART). Key activities included:

1. Establishing mobile health clinics to provide decentralized ART services.
2. Training community health workers (CHWs) to act as treatment navigators.
3. Leveraging digital health tools, such as SMS reminders and geolocation, to track and re-engage clients.
4. Creating peer support groups to address stigma and provide psychosocial support.
5. Collaborating with local leaders to foster community ownership and reduce barriers to care.

Lessons learned: The intervention successfully re-engaged 72% of individuals lost to care (n=1,030). Mobile clinics increased ART accessibility, reducing transportation-related barriers.

CHWs were pivotal in identifying and supporting migratory clients, with 85% reporting improved trust in the healthcare system. SMS reminders facilitated timely ART refills, particularly for younger clients. Peer groups enhanced adherence, with participants reporting reduced stigma and a greater sense of belonging.

However, challenges included limited resources to scale interventions and addressing structural issues such as poverty and food insecurity.

Conclusions/Next steps: This project highlights the importance of tailored, community-driven approaches to improve HIV care retention among migratory populations. The integration of mobile health clinics, digital tools, and peer support is both scalable and replicable in similar settings.

Future efforts should focus on sustainable funding, addressing structural barriers, and expanding the intervention to other high-mobility key populations across Uganda and the East African region.

EP0558

Factors associated with anxiety among adolescents and young adults living with HIV in Rwanda: a cross-sectional study

F. K. Rubuga[1], J.D. Hagenimana[1], K. Mwiza[1], C. Karimba[1], J. Ndayisenga[2], E. Remera[2], O. Wane[2], G. N.Rwibasira[2], J.B. Tugirimana[3], D. Mutambuka[3], J. Condo[1]
[1]Centre for Impact, Innovation and Capacity Building for Health Information Systems and Nutrition (CIIC-HIN)., Kigali, Rwanda, [2]Rwanda Biomedical Center (RBC), Kigali, Rwanda, [3]Rwanda Network of People Living with HIV/AIDS (RRP+), Kigali, Rwanda

Background: Anxiety disorders are the most prevalent mental health conditions among adolescents globally, with 4.4% of 10–14-year-olds and 5.5% of 15–19-year-olds affected. For adolescents and young adults living with HIV (AYALWH), the challenges of managing a chronic illness alongside developmental changes can exacerbate anxiety symptoms. Untreated anxiety disorders have significant consequences including poor ART adherence, increased HIV transmission risk, lower quality of life and engagement in education and employment.

Given the high burden of anxiety among AYALWH and its potential impact on HIV management, this study aims to assess socio-demographic, clinical, and psychosocial characteristics associated with anxiety among AYALWH in Rwanda to inform targeted interventions and improve mental health outcomes for this vulnerable group.

Methods: This cross-sectional study was conducted between January and June 2024 at health facilities in Kigali and the secondary cities of Musanze, Muhanga, Rubavu and Nyagatare districts. A random sample of 457 AYALWH aged 10-24 years was recruited during their routine HIV clinic visits. Participants completed a structured questionnaire that included validated scales to measure anxiety (GAD-7) and depression (PHQ-9), as well as items on socio-demographic characteristics, HIV-related factors, and psychosocial experiences. Multivariate logistic regression was used to identify factors associated with anxiety and depression.

Results: Among the 457 participants, 41.5% reported experiencing anxiety at varying levels. Participants who had only completed primary education were 3.61 times more likely to experience anxiety (OR = 3.61, [1.092, 11.914] 95% CI) compared to those less than primary.

Additionally, those who experienced forced sex were 2.03 times more likely to experience anxiety (OR = 2.03, [1.013, 4.052] 95% CI) compared to those who did not experience forced sex. Individuals who experienced bullying were 3.32 times more likely to experience anxiety (OR = 3.32, [1.676, 6.595] 95% CI) compared to those who did not.

Conclusions: This study highlights the high prevalence of anxiety among AYALWH in urban and peri-urban Rwanda, highlighting the urgent need for integrating routine mental health screening and targeted interventions into HIV care services.

The findings call for policy changes to prioritize mental health as a key component of comprehensive HIV care, particularly for AYALWH.

EP0559

Consistent use of bi-weekly data quality assessments in achieving and sustaining high rates of pediatric HIV disclosure in Rundu State Hospital, Namibia

W. Bakari[1], M. Said[1], T. Danda[1], G. Barnabee[1], G. O'Bryan[1], E.-L. Kafidi[1], M. Shepard[1], M. Laurens[2], M. Chitemerere[2], R. Ndjengwa[3], K. Battey[3], P. Kalimugogo[3], S. Ashikoto[2], N. Forster[1]
[1]International Training and Education Centre for Health(I-TECH), Department of Global Health, University of Washington, Seattle, WA, USA and, Windhoek, Namibia, [2]Ministry of Health and Social Services, Windhoek, Namibia, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Windhoek, Namibia

Background: Paediatric HIV disclosure is a critical component of effective antiretroviral therapy (ART) management. In Namibia, pediatric HIV clients are enrolled in the pediatric HIV disclosure program between 5-8 years of age and full disclosure should occur between 9-14 years of age.
However, full disclosure rates fall well below the 95% national target.
We implemented a quality improvement (QI) initiative at Rundu Hospital, Namibia, focused on improving and sustaining enrolment and full disclosure rates.
Methods: From October 2020 through September 2021, a QI team employed Plan-Do-Study-Act cycles to test change ideas including bi-weekly client record data quality assurance (DQA) to identify and rectify documentation issues, healthcare worker (HCW) refresher training on disclosure guidelines, delegating a dedicated data clerk to capture disclosure data, dedicated weekly schedules to deliver disclosure activities, contacting caregivers to ensure involvement, disclosure information booklets for home-based education by caregivers, and stickers on client records to remind clinicians when clients turn five and nine years.
Routine data from client records and the disclosure register were used to measure the proportion of disclosure enrolment and full disclosure among pediatric clients aged 5-8 and 9-14 years, respectively.
Descriptive analysis was used to describe enrollment and full disclosure rates monthly across the 12-month project and bi-monthly for 36 months following. QI reports were reviewed to identify key initiatives contributing to improvements.
Results: Over 12-months, enrolment rates among pediatric clients aged 5-8 years increased from 40% (29/73) to 93% (62/67), while full disclosure rates among 9–14-year-olds improved from 57% (112/198) to 93% (168/181).
For 36 months following, enrolment was sustained above 92% and full disclosure above 90%. Enrolment and full disclosure reached 95% in 9 and 11 of the 16 bi-monthly measurement periods, respectively.
Bi-weekly DQA and reminder stickers in client records for clients turning five and nine years were identified as key to achieving and sustaining high rates of enrolment and full disclosure.
Conclusions: A DQA-driven approach led to substantial improvements in both disclosure program enrolment and full disclosure. These findings suggest structured and sustained QI initiatives may enhance healthcare outcomes for pediatric HIV clients.

EP0560

Enhancing antiretroviral therapy (ART) adherence and viral load suppression through comprehensive case management approach

F. Nuwagaba[1], G. Ndikumwenayo[1], I. Hitayezu[1], S. Abineza[1]
[1]Young Women's Christian Association, Programs, Kigali, Rwanda

Background: The Orphans and Vulnerable Children (OVC) Case Management, as implemented by USAID/Igire Wiyubake, refers to the process of managing the care plan of a household including planning, implementation, monitoring and evaluation. It serves to strengthen the resilience of vulnerable families and children living with HIV and AIDS through Case Management Volunteers (CMVs) that focuses on delivering timely, individualized, and family-centered services and aim to meet health, economic, protection, education, and social service needs of OVC.
Description: Since 2022, YWCA Rwanda has implemented the approach in Kicukiro District at grassroots by volunteers, formally known as CMVs and support 5 to 12 households each, with an average frequency of two visits per month. Visits target program participants such as children and adolescents living with HIV (C/ALHIV) newly enrolled on treatment, not stable on treatment, or not virally suppressed.
The CMVs undertake various activities including Risk Vulnerability Assessments (RVA), developing personalized care plans, providing direct services or referrals, monitoring progress, and facilitating participant's graduation upon successful case plan achievement.
Lessons learned: The Case Management Approach has effectively enhanced antiretroviral therapy (ART) adherence, retention, and viral load suppression among OVC. In 2023, the program enrolled 1,211 with the VL suppression rate of 96.3%. In 2024, the suppression increased to 99.5% for 1,367 participants. Intensive follow-ups for unsuppressed individuals yielded significant success, with 93.2% (41 out of 44 cases) in 2023 and 89.5% (17 out of 19 cases) in 2024. These outcomes underscore the effectiveness of personalized, home-based strategies in overcoming barriers and improving the well-being of OVC.
Conclusions/Next steps: This holistic approach has proven highly effective in enhancing ART adherence, retention, and viral load suppression among OVC with tailored care plans, and complements national interventions by addressing gaps and meeting the unique needs of each family. The model has led to significant health improvements for OVC, highlighting the need for replication in other districts.

EP0561

Attracting and retaining clients in prevention programs through friendly communication, accessible language, and materials developed by LGBTQI+ individuals

D. Gryazev[1], K. Alipova[1], A. Terlikbayeva[1], S. Primbetova[1], A. Davis[2], V. Frye[2], B. West[2]
[1]The Global Health Research Center of Central Asia (GHRCCA), Almaty, Kazakhstan, [2]Columbia University School of Social Work, New York, United States

Background: LGBTQI+ individuals in Kazakhstan face entrenched stigma, discrimination, and systemic barriers to healthcare. While same-sex relationships are not criminalized, the partial approval of a 2024 petition to ban "LGBTQI+ propaganda" has further constrained the delivery of inclusive health services, particularly for Kazakh-speaking LGBTQI+ persons. Tailored HIV prevention messaging remains limited, and organizations working in this area often encounter legal, financial, and social challenges.

Description: From 2018 to 2025, our team implemented a series of community-based HIV prevention initiatives targeting key LGBTQI+ populations. These included AmanBol (HIV self-testing among MSM and transgender persons), AmanBol PrEP (PrEP awareness), JasSpark (youth-focused HIV testing using crowdsourcing), and ORLEU (intersectional stigma reduction among women who use drugs).

A central innovation across these programs was the development and implementation of a Tone of Voice (ToV)—a communication approach characterized by affirming, community-centered, and accessible language. Drawing on principles from social marketing and inclusive design, the ToV aimed to build trust and reduce communication barriers by avoiding medical jargon, minimizing gendered language, and using culturally resonant messaging.

Materials were co-developed with LGBTQI+ community members who are fluent in Kazakh and Russian, ensuring linguistic inclusivity and local relevance.

This communication strategy contributed to increased uptake and retention in HIV prevention services, particularly among transgender, non-binary, and Kazakh-speaking clients.

While detailed outcomes vary across initiatives, results from these projects have been documented and published by co-authors of this abstract in high-impact, peer-reviewed journals.

Lessons learned:

- A consistent and inclusive ToV enhances engagement, retention, and trust among LGBTQI+ communities.
- Co-creation of content with LGBTQI+ individuals is essential for cultural and linguistic appropriateness.
- Providing materials in both Russian and Kazakh using plain, affirming language improves accessibility.
- Avoiding gendered and clinical terminology increases comfort, especially for transgender and non-binary clients.
- Community-led communication strategies are feasible, effective, and scalable—even in politically restrictive environments.

Conclusions/Next steps: The use of an inclusive, community-informed ToV represents a promising and low-cost strategy to improve the effectiveness of HIV prevention among marginalized LGBTQI+ populations. This approach is adaptable across contexts and may be valuable for both civil society and public health systems seeking to expand equitable access to HIV services.

EP0562

From awareness to action: unlocking demand creation for Pre-Exposure Prophylaxis (PrEP)

F. Nuwagaba[1], G. Ndikumwenayo[1], S. Abineza[1], I. Hitayezu[1], A. Uwase[1], YWCA Rwanda
[1]Young Women's Christian Association (YWCA) Rwanda, Programs, Kigali, Rwanda

Background: HIV prevalence in Rwanda is 3.0% among individuals aged 15–64, with adolescent girls and young women (AGYW) aged 14-24 disproportionately acquired HIV at 1.2% compared to 0.5% males with same age. HIV incidence in the country is still high at 0,08% (5,400 new cases per year), with 35 percent of new acquisitions coming from adolescents (RPHIA 2018-19).

To address this, Rwanda's Ministry of Health with PEPFAR support, introduced oral pre-exposure prophylaxis (PrEP) in 2018 for high-risk individuals aged 18+, prioritizing AGYW starting in 2021 to provide an additional prevention intervention to complement existing interventions like condoms. The USAID/Igire-Wiyubake Activity, implemented by Young Women's Christian Association, expanded PrEP access to 1,553 AGYW in Kicukiro, one of the high HIV prevalence districts, targeting AGYW at substantial risk of HIV, to increase awareness, uptake, and adherence to PrEP while reducing HIV incidence.

Description: The undertaken activities include AGYW sensitization and education aimed at creating awareness and demand for PrEP, delivered by program mentors through AGYW platforms formally known as DREAMS safe spaces. Mentors conduct screening to assess AGYW eligibility for PrEP, refer and link eligible AGYW to health facilities for initiation and assist in scheduling appointments and accompaniment to health facilities to access PrEP.

Lessons learned:

- By 2024, PrEP was provided to 1553 AGYW, with no new HIV case reported among PrEP users, demonstrating the program's effectiveness in PrEP demand and reducing HIV risk.
- Continuous community education and sensitization were essential to address cultural beliefs and misconceptions around PrEP.
- Trained mentors are vital in raising PrEP awareness, linking with health facilities, and ensuring high PrEP service uptake.

Conclusions/Next steps: When used correctly and consistently, PrEP shows promise in reducing HIV transmission among AGYW. To maximize its impact, efforts must focus on scaling up access to PrEP services in undeserved areas, strengthening community structures such as peer mentorship group and safe spaces to empower AGYW in making informed decisions and reduce HIV acquisition.

EP0563

Recommendations to improve caregivers' experiences of disclosing HIV status to children living with HIV in uMzinyathi District, KwaZulu-Natal, South Africa: insights from in-depth semi-structured interviews

T.C. Myeni[1,2], D.M. Mulqueeny[2]
[1]Department of Health, KwaZulu-Natal, South Africa, [2]University of Zululand, Department of Social Work, KwaZulu-Natal, South Africa

Background: Caregivers of children living with HIV are confronted with a diverse array of challenges associated with paediatric HIV disclosure. Non-disclosure contributes to poor adherence and poor viral suppression due to children's refusal to take treatment.
A study aimed at producing new knowledge on caregivers' experiences (successes and challenges) to share best practices and improve disclosure techniques was conducted.
Methods: An interpretivist, exploratory qualitative study was conducted at four public health clinics in uMzinyathi District, South Africa, between December 2023 and January 2024 using recorded in-depth, in person, semi-structured interviews to collect data from 20 caregivers of CLHIV who were between the ages of 6 and 12 years. The recorded and transcribed interviews were manually transcribed and thematically analysed.
Results: Majority of the participants (15) of this study had disclosed to their children and they have provided the following recommendations to assist others.
They indicated that:
1. They require the support of healthcare workers (HCW) to disclose as caregivers assume that HCWs are well trained in disclosing diagnosis and providing counselling and would perform a better task than them,
2. Caregivers need to be capacitated with disclosure skills and knowledge and prepared in advance for the disclosure process,
3. Full disclosure of child's HIV status should be done at the age of 10 with HCWs providing support during the process,
4. Caregivers should be provided with materials and tools entailing step-by-step guide to facilitate disclosure, and;
5. That HCWs should establish and facilitate caregiver support groups so they can have a safe space for learning and sharing experiences and challenges associated with disclosure.
Conclusions: Caregivers and healthcare workers including social workers play a pivotal role in ensuring that HIV disclosure process occurs to prevent negative consequences that may result from delayed and accidental disclosure and from not disclosing to a child.
Preparation and education can play a huge role in empowering caregivers with appropriate knowledge and skills to lead a successful health-promoting disclosure. The support of HCWs is essential in preparing caregivers for disclosure and during the disclosure process.

EP0564

The community treatment observatory: pilot phase in Western Jamaica

A. Davis[1], J.-A. Nugent[1]
[1]Jamaican Network of Seropositives, Kingston, Jamaica

Background: The study, a community-led initiative, aimed to assess the main clinical, structural and social factors impacting retention in care of PLHIV in the Western Region of Jamaica, to identify areas for improvement towards ending AIDS as a public health concern by 2030.
Methods: The Community Treatment Observatory (CTO) utilised a mixed methods approach through 158 recipients of care questionnaires, 2 surveys with 6 healthcare workers, and 17 focus groups between September and December 2022 in six treatment sites in the Western region. Participants were recruited using a random purposive sampling of clinic attendees each day, mindful of gender balance.
The quantitative data were captured and entered into an electronic database (Dropbox Paper) and analysed using Excel. Focus group data were analysed after identifying key themes to corroborate the quantitative findings.
Results: As of October 2022, 3,839 PLHIV were registered across 6 healthcare facilities. Among PLHIV on antiretroviral therapy (ART) for 12 months or more, 93% had undergone viral load testing. However, 43% of surveyed PLHIV did not receive the test results within six months. Overall, 70% of PLHIV linked to care were virally suppressed.
The study revealed that men aged 25-34 had the highest rate of lost-to-follow-up, while women aged 18-24 had the lowest rate of viral suppression. Retention in care was negatively impacted by long waiting times and challenges related to employment and medical appointments, with 29% of participants missing appointments due to work obligations.
Conclusions: The pilot highlighted that targeted interventions are needed to address the vulnerabilities of specific age, gender, and key population groups across the treatment cascade. Efforts to reduce waiting times and improve appointment scheduling flexibility may also improve retention in care.
Importantly, respondents reported generally positive experiences with confidentiality, stigma, discrimination, and service availability across all six healthcare facilities.
Acting as a baseline, the findings of the CTO will be utilised in 2025 to widen reach across a further 16 sites on the island.

EP0565

Social vulnerability and psychosocial factors associated with antiretroviral adherence among sexual and gender minorities living with HIV in Brazil, Mexico and Peru

H. Vega-Ramirez[1], K.A. Konda[2,3], T.S. Torres[4], J. Qquellon[2], C.F. Caceres[2], R. Robles-Garcia[1], P.M. Luz[4], B. Hoagland[4], C. Pimenta[4], M. Benedetti[4], V. Veloso[4], B. Grinsztejn[4]

[1]National Institute of Psychiatry Ramón de la Fuente Muñiz, Division of Epidemiology and Psychosocial Research, Mexico City, Mexico, [2]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, Sida y Sociedad, Lima, Peru, [3]USC Keck School of Medicine, Division Disease Prevention, Policy and Global Health, Department of Population and Public Health Sciences, Los Angeles, United States, [4]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz), Rio de Janeiro, Brazil

Background: Between 2010-2023, Latin America (LA) had a 9% rise in new persons acquiring HIV and a moderate reduction in HIV-related deaths (-38%), especially among sexual and gender minorities (SGM). Social vulnerability and psychosocial challenges often hinder antiretroviral adherence (ARV-Ad). We aimed to identify social and psychosocial factors associated with low ARV-Ad among SGM living with HIV in LA.

Methods: We conducted a web-based survey in Brazil, Mexico, and Peru from August to November 2024. Participants were ≥18 years old and self-reported living with HIV. We collected data on socio-demographics, time living with HIV, sexual behavior, and substance use, along with scales for depression (PHQ-9), mental health well-being (SF-36), homonegativity (Reactions to Homosexuality Scale), and HIV knowledge (HIV/AIDS Knowledge Assessment Tool). We included participants who reported taking ARV and defined optimal adherence as reporting ≥95% ARV-Ad in the last 30 days using a visual analog scale. We conducted multivariate logistic regression with the forward conditional method, keeping all significant variables ($p \leq 0.05$) in the final model.

	aOR* (95% CI) (n= 2552)	p-value
Country (ref. Brazil)		
Mexico	4.58 (3.49,6.01)	<0.001
Peru	1.10 (0.72,1.66)	0.668
Ethnicity (ref. White)		
Mixed	0.91 (0.71,1.16)	0.445
Afro-descendant	1.44 (0.99,2.09)	0.058
Other	0.79 (0.50,1.27)	0.340
Income (ref. >6 MW)		
None to <1 MW	2.06 (1.45,2.93)	<0.001
>1 to 2 MW	1.34 (0.94,1.91)	0.104
>2 to 6 MW	1.16 (0.86,1.56)	0.338
Transactional sex (yes vs. no)+	1.51 (1.11,2.04)	0.008
Stimulant use (yes vs. no)+	1.98 (1.48,2.64)	<0.001
Opioids use (yes vs. no)+	2.77 (1.08,7.10)	0.034
Depression (yes vs. no)	1.32 (1.07,1.63)	0.010
HIV knowledge (score)	0.85 (0.78,0.93)	0.001

Table 1. Social and Psychosocial Factors associated with Low Antiretroviral Adherence among Sexual and Gender Minorities living with HIV in Brazil, Mexico, and Peru.
**Adjusted for age, gender, and education; +In the last 6 months. CI: Confidence interval; MW: minimum wage; bold indicates p-value ≤0.05.*

Results: We had 2552 participants (Brazil: 66%, Mexico: 24.8, Peru: 9.2%); 95.1% were cisgender men, with a mean age of 42.3 (S.D. 10.1), and 80.5% had more than secondary education. Most (78.3%) reported optimal ARV-Ad. Being from Mexico, having no or low income, having recent transactional sex, stimulant and opioid drugs use, and having a positive screening for depression increased the odds of low ARV-Ad. Conversely, a higher HIV knowledge score decreased the odds of low ARV-Ad (Table 1).

Conclusions: Social vulnerability and psychosocial adversities continue to impact ARV adherence among SGM living with HIV in LA. The HIV response in the region still requires a more comprehensive approach to enhance ARV adherence for those particularly vulnerable.

EP0566

Examining the role of violence on PrEP use among Indigenous gay and bisexual men in Guatemala

C. Purnell[1], J. Yac[2], B. Saucedo Mérida[3], L. Weyer Johnson[1], E.R. Orellana[4], D.A. Davis[1,5]

[1]Duke Global Health Institute, Durham, United States, [2]Asociación de Investigación, Desarrollo, y Educación Integral (Asociación IDEI), Quetzaltenango, Guatemala, [3]Trabajando Unidos, Huehuetenango, Guatemala, [4]University of Washington, Seattle, United States, [5]Wake Forest University, Winston-Salem, United States

Background: Guatemalan Indigenous gay and bisexual men (GBM) experience high rates of violence due to their intersectional identity. Indigenous GBM experience physical, sexual, and institutional violence based on their sexual orientation (SO), and lasting impacts from the Internal Armed Conflict in Guatemala, which ended in 1996 and took the lives of more than 200,000 Guatemalans, mostly Indigenous.

We sought to assess the relationship between different forms of violence and PrEP use among Indigenous GBM in Guatemala to inform PrEP programming.

Methods: From June 2023 to March 2024, we administered a cross-sectional questionnaire with Indigenous GBM (n=395) in collaboration with two community-based organizations. We report the prevalence of different forms of violence (physical, sexual, and police violence due to SO; knowing someone injured, missing, or killed in the Internal Armed Conflict; forced migration during the Internal Armed Conflict) and PrEP use.

We examined the relationship between violence and PrEP use using logistic regression, controlling for age, education, Indigenous group, and department of residence.

Results: We found a high prevalence of violence due to SO: 41.9% of participants experienced physical violence, 37.2% experienced sexual violence, and 35.7% experienced police violence. 33.7% experienced forced migration from the Internal Armed Conflict and 41.3% had close friends or family who were missing, injured or killed in the conflict. In multivariate analysis, we found that participants who experienced police violence were twice as likely to take PrEP (aOR: 2.12, 95% CI: 1.26, 3.61, p=0.005), as were participants who had family or friends who were missing, injured, or killed in the conflict (aOR: 1.80, 95% CI: 1.05, 3.12, p=0.03).

Participants who forcibly migrated during the conflict were twice as likely to be currently using PrEP (aOR: 1.98, 95% CI: 1.08, 3.65, p=0.03). Physical or sexual violence due to SO was not significantly associated with PrEP use.
Conclusions: Indigenous Guatemalan GBM experience a high burden of violence which may affect their engagement with HIV prevention services, including PrEP.
Future research should explore how violence victimization affects perceived vulnerability to HIV, which may explain why Indigenous GBM who had experienced some violence were more likely to use PrEP.

EP0567

Best practice for reaching men and women with HIV testing through a faith-based initiative "Tuimbe Salama Campaign," in selected facilities at Kilolo district, Iringa region

M. Samson Kagwe[1]
[1]T-MARC Tanzania, Deloitte Consulting Limited, Social Behaviour Change & Gender and Youth, Dar es Salaam, Tanzania, the United Republic of

Background: Tanzania's HIV prevalence of 4.4% affects 1.8 million people. In Kilolo district, Iringa region, the uptake of HIV services among men and women in religious settings remains critically low due to entrenched cultural and religious norms and stigma. Many refuse to believe they are at risk, citing their religious lifestyles or perceived moral behavior. Additionally, HIV is often viewed as a punishment for sinful acts, causing fear of rejection by religious peers or leaders. Others worry about losing their roles in churches if diagnosed. These factors significantly hinder access to essential health services.
Description: The USAID Afya Yangu project launched the "Tuimbe Salama" campaign, integrating health and religious activities to address the fear and stigma of HIV testing. Faith-based organizations, trusted within communities, are uniquely positioned to reduce stigma and influence health behaviors (Schoepf, 2020).
The campaign leverages this trust by delivering health education through religious leaders during choir rehearsals and gatherings. Choir activities foster emotional connections and group cohesion, creating a supportive space for addressing sensitive topics like HIV and TB testing. Research shows group singing improves psychological well-being and strengthens social bonds (Clift et al., 2010).
This supportive environment helps normalize testing by reducing intimidation and stigma. Health messages framed within cultural or spiritual narratives resonate deeply, inspiring behavior change (UNAIDS, 2021).
By embedding health education into familiar settings, the campaign promotes open dialogue, debunks myths, and shares success stories of HIV-tested individuals. This approach builds trust in health services and empowers communities to advocate for testing, amplifying its impact.
Lessons learned: The campaign's impact is evident in the data. In FY24 Q3 and Q4, HIV testing increased from 566 tests in Q1-Q2 (with 10 positives) to 639 tests (with 21 positives). Of these, 289 tests and 7 positive cases were directly linked to the "Tuimbe Salama" activities. Training 15 religious leaders and linking them with health facilities proved effective in fostering trust and sustainability.
Conclusions/Next steps: The "Tuimbe Salama" campaign showcases how integrating faith, culture, and health enhances HIV services in underserved areas. Its scalable model fosters trust, reduces stigma, and ensures sustained HIV and TB service uptake through faith-based collaboration.

EP0568

Breaking barriers: perceptions of preexposure prophylaxis among cisgender Black women in New York

M. Walcott[1], J. Strong[1], V. Frye[2], J.M. Tesoriero[3], S.K. Dale[4], E. Richter[1], G.-M. Santos[5]
[1]University at Albany, Rensselaer, United States, [2]Columbia University, New York, United States, [3]New York State Department of Health, New York, United States, [4]University of Miami, Miami, United States, [5]University of California San Francisco, San Francisco, United States

Background: Black women represent over 50% of new HIV cases among women, yet they account for approximately 25% of women on PrEP in New York State (NYS). We examined the perceptions of cisgender Black women (CBW) regarding PrEP, focusing on the barriers they face and strategies to improve PrEP uptake.
Methods: The eligibility criteria for participating in this qualitative study included being age 18-54 years, self-reported condomless anal or vaginal sex within the past 6 months, living in New York State, and not taking PrEP. We conducted in-depth interviews with 25 CBW from August 2024 to January 2025. Participants were asked to complete a 30-minute survey via REDCap.
Thematic analysis was used to analyze the qualitative data. Here we present the preliminary findings from the surveys and 15 coded transcripts from the in-depth interviews.
Results: Of the 25 CBW (mean age 32.3 ± 10 years), 92% had health insurance and 24% were married or lived with a partner, 68% were tested for HIV in the past 12 months, and 60% rated their risk for HIV acquisition as low/very low. Primary care providers and OBGYNs were preferred sites for HIV testing sites; however, only 28.6% learned about PrEP from their health care providers. Key barriers to PrEP uptake include:
1. Cultural-familial beliefs and practices that discourage discussions about sex;
2. Fragmentation within the Black community, including the shift of some factors that were once protective into harmful ones;
3. Concerns about side-effects, accessibility and affordability; and
4. The lack of representation of cisgender Black women in PrEP promotional campaigns.
Strategies for promoting PrEP include offering clear information on the advantages and disadvantages of each PrEP option to support decision-making; sharing testimo-

nials from CBW who are currently using PrEP; incorporating sexual wellness into routine primary care and OBGYN visits; and engaging the faith-based community in HIV prevention/PrEP promotion efforts.

Conclusions: Routinizing sexual wellness in primary care and OBGYN visits may be central for increasing PrEP uptake among CBW.

EP0569

Impact of DREAMS initiatives on PrEP uptake and adherence among adolescent girls and young women in Iringa region, Tanzania

M. Mwenga[1]

[1]Deloitte Consulting Limited/T-MARC Tanzania, Social Behavior Change, Gender and Youth, Iringa, Tanzania, the United Republic of

Background: USAID Afya Yangu (My Health) Southern Project experienced a low uptake of PrEP services among AGYW aged 15 - 24. Over two years (FY21 & FY22), the Project provided new PrEP services to 325(8%) AGYW out of 3,984 and PrEP refills to 195 out of 325 AGYW in Iringa MC and Mufindi DC in the Iringa region. The low uptake was linked to limited awareness of PrEP services, perceived stigma, long distances to healthcare facilities, and the absence of youth-friendly services.

In response, PEPFAR is committing substantial resources to the DREAMS initiative (Determined, Resilient, Empowered, AIDS-free, Mentored, and Safe).

This initiative offers a comprehensive, evidence-based, age-appropriate package of biomedical, behavioral, and structural interventions aimed at addressing HIV risk factors and reducing HIV rates among AGYW.

The purpose of this study is to evaluate the impact of the DREAMS intervention on PrEP service access in Iringa MC and Mufindi DC before and after the intervention.

Methods: In FY23 Q1, the USAID Afya Yangu (My Health) Southern Project began implementing the DREAMS facility intervention, supporting 25 health facilities—9 in Iringa MC, and 16 in Mufindi DC. The support involved training healthcare workers and AGYW peer champions providing youth-friendly HIV services in line with national youth-friendly service standards.

The peer champions conduct Social and Behavior Change sessions through the "SITETEREKI" (Unshakable) small group and one-on-one approaches and facilitate linkages to youth HIV services (including HIV testing, PrEP, family planning, and GBV support) at the youth corners.

Results: The number of AGYW initiated on PrEP services grew five-fold, rising from 325 in FY21 & FY22 to 1,670(64%) out of 2,600 in FY23 & FY24. Additionally, there was an increase in the number of AGYW retained in PrEP services (PrEP CT), which went up from 195 (60%) to 1,180 (71%).

Conclusions: DREAMS intervention has successfully improved the uptake of PrEP services among AGYW through the establishment of adolescent-friendly conners in DREAMS sites and the effective use of AGYW peer champions to increase demand and strengthen linkage for HIV services. With the good results, the DREAMS initiative is commended for improving the uptake of PrEP services among AGYW.

EP0570

Intersections of violence and vulnerability: insights on GBV and HIV among women engaging in sex work in Zambia

C. Mwale[1,2], P. Maritim[3], J. Phiri[2], M. Zimba[4], R. Zyambo[5], M. Herce[6], M. Musheke[7], A. Sharma[2], R. Kumar[8,9]

[1]Emory University, Laney Graduate School, Masters in Development Practice, Atlanta, United States, [2]Centre for Infectious Disease Research in Zambia, Social Science, Lusaka, Zambia, [3]University of Zambia, School of Public Health, Lusaka, Zambia, [4]Zambia Sex Workers Alliance, Lusaka, Zambia, [5]Tithandizeni Umoyo Network, Lusaka, Zambia, [6]University of North Carolina, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [7]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [8]University of Washington, School of Public Health, Seattle, United States, [9]Centre for Infectious Disease Research in Zambia, Implementation Science, Lusaka, Zambia

Background: Women engaging in sex work (WESW) face disproportionate levels of gender-based violence (GBV), which both drives and results from HIV transmission. However, the roles of state actors and clients in this cycle remain underexamined. HIV prevalence among WESW is high in Zambia, therefore understanding how GBV contributes to HIV transmission, will inform effective prevention interventions.

We explore WESW experiences of physical, sexual, emotional, and economic violence from their clients and state actors, including police, and clinicians.

Methods: A secondary qualitative analysis was conducted on existing data with WESW throughout Zambia and their experiences of HIV prevention and GBV. Data were obtained from three separate sources: in-depth interviews from a prospective cohort study in Lusaka (n=18), formative research along the Kasumbalesa border (n=42), and a preliminary analysis of police interactions within Lusaka (n=39).

We used reflexive thematic analysis and applied the United States Agency for International Development's (USAID) Domains of Gender Analysis.

Results: WESW were vulnerable and had increased risk of both GBV and HIV transmission in four domains: laws and policies, control over resources, patterns of power, and personal safety.

When seeking HIV treatment, women experienced verbal abuse, discrimination and were denied services (ex: Antiretroviral Therapy or STI treatment) from government clinics, making them hesitant to return for testing and treatment [resources; power].

Participants also described how identities of migrant status and gender (trans- vs. cisgender identity) resulted in unique discrimination in a Christian nation "according to my beliefs I can't attend to you." [resources; power] When seeking justice, WESW experience sexual, physical and economic abuse from police officers who "want to sleep with you again instead of helping you." [laws; power; safety] Clients knowingly infected WESWs with HIV or threatened to kill them: "he pointed a gun at me and asked me to say my last prayers." [power; safety].

Conclusions: Threats to WESW health and safety are rooted in dehumanization and power dynamics, ultimately putting them at great risk of acquiring and spreading HIV. There is a need to further investigate sex workers' experiences of GBV and apply intersectional approaches to interventions that include state and non-state actors.

EP0571

PrEP my way: client preferences for accessing pre-exposure prophylaxis - a demographic analysis

T.H. Vu[1], V.T. Nguyen[1], M.P. Van[2], V.T. Nguyen[1], N.T. Vu[3]
[1]FHI 360 Vietnam, Hanoi, Viet Nam, [2]FHI 360 Vietnam, Ho Chi Minh City, Viet Nam, [3]Dong Nai Center for Disease Control, Bien Hoa, Viet Nam

Background: In Dong Nai, Vietnam, HIV pre-exposure prophylaxis (PrEP) service access points have evolved over time. Initiated in 2019 in public facilities, PrEP was expanded to private clinics meeting standard requirements by 2021. Since then, the province has seen increases in PrEP enrollment at private facilities, surpassing those in the public sector. The Meeting Targets and Maintaining Epidemic Control (EpiC) project aimed to identify demographic factors that may influence preferences for public versus private referral from community partners to help the province address client needs and improve performance.
Methods: We analyzed de-identified data from 1,041 clients who were successfully referred for PrEP from October 1, 2023, to May 31, 2024, after testing negative for HIV. Descriptive statistics and chi-square tests were used to investigate the relationship between factors and client choice of facility.
Results: Among the 1,041 clients, 58.3% opted for private clinics versus 41.7% who preferred public facilities. There were associations between choice of PrEP site and age, sex, population group, and testing modality ($p<0.0001$ for all variables). Males preferred private facilities more than females, and clients aged 15–34 favored them over those 35 and older. At-risk men chose private entities more than other groups, which included partners of individuals with high-risk of HIV-exposure, partners of people living with HIV, and the remaining group (people who inject drugs, at-risk females, and others). Clients from traditional outreach were more likely to choose private facilities compared to those from index testing.
Conclusions: This study underscores the importance of understanding client preferences in enhancing service delivery. By tailoring services to meet client needs based on their age, sex, population group, and other factors, we can better target enrollment at both public and private sites. Although PrEP is not yet included in the social health insurance program in Vietnam, greater preference for private PrEP services suggests a viable pathway toward sustainability in PrEP access. Addressing these preferences supports equity and access in HIV prevention and offers insights for health system improvements in Dong Nai and across Vietnam.

EP0572

Patient preferences for incentives in contingency management interventions in methadone treatment: a best-worst scale analysis

T. Dao[1,2], H. Nguyen[1], T. Nguyen[1], T. Phung[3], V. Hoang[1], G. Le[1], B. Pence[2], V. Go[2], W. Miller[2]
[1]Hanoi Medical University, Hanoi, Viet Nam, [2]University of North Carolina at Chapel Hill, Chapel Hill, United States, [3]Hanoi Center for Disease Control and Prevention, Hanoi, Viet Nam

Background: Contingency management (CM) has shown effectiveness in enhancing adherence and retention in methadone maintenance treatment (MMT). However, implementing CM in resource-limited settings can face many challenges, particularly due to costs associated with providing incentives.
This study aims to describe and quantify patient preferences regarding CM incentives to promote adherence and retention in MMT.
Methods: We conducted a cross-sectional survey using a best-worst scale (case 1) among 216 participants ages 18 or older undergoing MMT in six clinics in Hanoi, Vietnam. The study asked participants to complete 13 sets of best-worst scaling tasks. Each task presented a subset of four incentives chosen from a total of 13 incentives. Net scores for each incentive were calculated by subtracting the total times an incentive was rated as least appealing from the total times it was rated as most appealing.
Standardized scores were derived by dividing the net score by the sum of selections and then converted to weighted probabilities (WP) that ranged from 0% to 100% (intuition: an incentive with WP of 20% is twice as desired as an incentive with WP of 10%). The 95% confidence intervals (95% CI) were estimated using the bootstrap method. Data analyses were performed using RStudio (version: 2024.09.0-375).
Results: The mean age of participants was 44.7 (SD=8.0, range: 25-66). Most were male (94.9%), married (58.8%), and had not completed high school (69.4%). Nearly half (49.5%) had been on methadone treatment for more than five years. The most preferred incentives were "discount for monthly methadone fees" (WP=16.90, 95% CI: 15.98, 17.80) and "take-home methadone privileges" (WP=11.34, 95% CI: 10.14, 12.62), followed by "priority coupons for early medical examinations/consultations".
In contrast, the least preferred incentives were "being recognized/praised at their living area" (WP=4.49, 95% CI: 3.97, 4.97) and "being recognized/praised at their clinic" (WP=4.73, 95% CI: 4.13, 5.44).
Conclusions: Treatment fee support for methadone emerged as the most desirable incentive. Additionally, take-home methadone and getting coupons for early medical examination were also patients' priorities. These findings suggest potential low-cost CM strategies that could inform decision-making in MMT programs.

EP0573

Breaking barriers: mobilizing women and youth to address HIV stigma and improve prevention in marginalized African communities

A. Nasir[1]
[1]NAHDA University in Egypt, Medicine, Beni Suef, Egypt

Background: HIV-related stigma remains a significant obstacle in achieving effective prevention and care, particularly in marginalized African communities where cultural norms and gender inequality exacerbate the challenge. Women and youth are disproportionately affected, often silenced by stigma, which limits their access to vital health services.

This study explored a grassroots approach that directly empowered women and youth as change agents to dismantle stigma and foster inclusive HIV prevention efforts.

Methods: Between February 2022 and December 2023, this intervention engaged 750 participants (70% women, 30% youth aged 15-24) across underserved regions in Nigeria. A three-phase strategy was employed:

1. Capacity Building: Training women and youth leaders on HIV awareness, stigma reduction, and peer communication techniques.
2. Community Engagement: Hosting participatory workshops, drama performances, and storytelling sessions to initiate open conversations about HIV.
3. Service Linkage: Connecting participants to free HIV testing and counseling services facilitated by trusted community leaders.

Pre- and post-intervention surveys assessed changes in stigma perception, testing uptake, and HIV knowledge. Qualitative data were captured through community dialogues and personal testimonies.

Results: Post-intervention, stigma perception scores decreased by 47% ($p<0.01$), and HIV testing rates among women rose by 38%. Youth engagement in workshops saw a 60% attendance increase, with over 80% reporting greater confidence in discussing HIV openly. Participants cited the use of storytelling and culturally relevant content as key to reducing fear and misconceptions.

Conclusions: This study underscores the power of grassroots mobilization in transforming attitudes and behaviors toward HIV in marginalized communities. By centering women and youth as leaders, the intervention created a ripple effect of awareness, reducing stigma and promoting health-seeking behaviors.

EP0574

Strengthening family well-being through positive parenting

E. Mfateneza[1], B. Harushyabana[2], G. Uwizeye[3]
[1]University of Rwanda, Data Science, Kigali, Rwanda, [2]The Open University Tanzania, Education in Administration, Planning and Policy Studies, Dar es Salaam, Tanzania, the United Republic of, [3]Mount Kenya University, Public Health, Kigali, Rwanda

Background: The Families Matter! Program (FMP) is an evidence-based, parent-focused intervention aimed at promoting positive parenting and enhancing parent-child communication on sexuality, sexual risk reduction, and the prevention of child sexual abuse and gender-based violence (GBV). USAID IGIRE-JYAMBERE implemented this program to strengthen caregivers' skills on GBV prevention, harmful gender norms, and HIV status disclosure within families. It also aimed to improve sexual behavior, deliver key HIV, STI, and pregnancy prevention messages, and raise child protection awareness. By promoting positive parenting, the program sought to create safe and supportive home environments for Orphans and Vulnerable Children (OVC) and Adolescent Girls and Young Women (AGYW).

Description: USAID IGIRE-JYAMBERE organized evidence-based FMP sessions focusing on non-violent discipline, effective communication, and emotional support. Peer learning groups and community dialogues engaged caregivers and parents, while collaboration with local leaders reinforced positive parenting practices. These interventions significantly reduced harsh disciplinary practices and improved caregiver-child communication. Caregivers adopted positive discipline techniques, fostering safer home environments and strengthening positive family practices. Children and adolescents reported enhanced emotional well-being and increased school engagement. Parents and caregivers engaged in discussions on sexual reproductive health, GBV prevention, harmful gender norms, HIV testing, and disclosure, contributing to better health outcomes.

Lessons learned: The USAID IGIRE-JYAMBERE program demonstrated that positive parenting interventions effectively reduce harsh discipline and improve communication between parents and adolescents. These interventions created safer, more supportive home environments and strengthened family bonds. Engaging adolescents in open discussions on sexual health, GBV prevention, and HIV status disclosure improved their well-being and health outcomes. Fostering a trusting and supportive relationship between parents and children significantly contributes to healthier, more resilient families and reduces vulnerability to HIV.

Conclusions/Next steps: The Families Matter! Program has proven that positive parenting interventions can improve family dynamics and child well-being. USAID IGIRE-JYAMBERE will continue expanding the program to reach more caregivers, strengthen community engagement, and foster safe environments for vulnerable children and youth, contributing to better long-term health outcomes and family well-being.

EP0575

Acceptability of group-based HIV stigma reduction interventions for adolescents living with HIV and their caregivers in Uganda

P. Nabunya[1], J. Mugisha[2], H. Migadde[3], M. Naseh[1], A. Kabarambi[4], F.M. Ssewamala[1]
[1]Washington University in St. Louis, Social Work, St. Louis, United States, [2]Makerere University, Kampala, Uganda, [3]International Center for Child Health and Development, Masaka, Uganda, [4]Washington University in St. Louis, Public Health, St. Louis, United States

Background: Acceptability of interventions –defined as the extent to which people delivering or receiving a healthcare intervention consider it to be appropriate, based on anticipated or experienced cognitive and emotional responses to the intervention is critical for intervention success.
This study qualitatively explored acceptability and experiences of adolescents and caregivers participating in two group-based stigma reduction interventions in Uganda.
Methods: We conducted semi-structured in-depth interviews with 34 adolescents and their caregivers (dyads) upon completion of group-based cognitive behavioral therapy and a family strengthening intervention tested as part of a cluster randomized clinical trial (2020-2022). The larger trial recruited adolescent-caregiver dyads (N=178) from nine health care clinics in the greater Masaka region of Uganda.
Adolescents were eligible to participate if they were:
1) living with HIV and disclosed to;
2) between 10-14 years;
3) enrolled on ART at one of the participating health clinics, and;
4) living within a family, including extended family units.
In-depth interviews explored participants' motivation to participate, thoughts about the different aspects of the interventions, facilitators and barriers to session attendance, as well as perceived impact of the interventions on the different aspects of their lives. Data were analyzed using thematic analysis.
Results: Four main themes emerged from data analysis:
1) Anticipated outcomes, financial incentives, and ensured confidentiality as key motivators for participation;
2) Fear of stigma and uncertainty as initial concerns for participation;
3) Communication, incentives and facilitator support as key facilitators for attendance;
4) Miscommunication, sickness and family emergencies as barriers to participation;
5) Group-based learning, facilitator support, and content relevance among positive experiences related to program organization; and,
6) Evidence of awareness, building resilience, and connectedness as perceived impact of the interventions sessions.
Conclusions: Findings showed high intervention acceptability, as well as positive outcomes among adolescent and their caregivers. For adolescents, these benefits reduced loneliness, fostered a sense of belonging, and promoted resilience.
Caregivers valued the shared group experience, which strengthened family support networks and improved communication within households. These findings highlight the potential of group-based approaches to address the social and emotional needs of both adolescents and their caregivers.

EP0576

HIV testing and behavioral drivers of HIV risk among adolescent boys and young men in Kenya: evidence from a nationally representative survey

S. Ndwiga[1], K. Malama[2], T. Nyoni[3]
[1]University of Washington, Global Health, Nairobi, Kenya, [2]McGill University, Ingram School of Nursing, Montreal, Canada, [3]Dalhousie University, School of Social Work, Nova Costia, Canada

Background: Adolescents and young people in sub-Saharan Africa (SSA) bear a disproportionate HIV burden. Limited disaggregation of HIV prevention indicators between adolescents (15–19 years) and young people (20–24 years) hinders tailored interventions. This study compares HIV testing history and risk behaviors among adolescent boys and young men (ABYM) in Kenya.
Methods: Using data from the 2022 Kenya Demographic Health Survey (DHS), we analyzed a sub-sample of ABYM aged 15–24 years. Variables included socio-demographic characteristics, HIV testing history, and risk behaviors. Frequencies, proportions, chi-square tests, and logistic regression were used to examine age-related differences.
Results: Among 5,455 participants, 55.1% were adolescents and 44.9% were young men. HIV testing was significantly lower among adolescents (27.9%) compared to young men (44.5%; p<0.001).
Awareness of STIs (99.5% in young men vs. 99.4% in adolescent boys; p=0.784) and HIV prevention strategies such as consistent condom use (81.1%) and single-partner relationships (86.4%) was high across groups. However, condom use during the most recent sexual encounter was significantly higher among young men (85.7%) than adolescents (77.4%; p<0.001). Media exposure was more prevalent among young men.
Logistic regression revealed that young men were three times more likely to have tested for HIV than adolescents (aOR=3.49,95%CI:3.07–3.96, p<0.001). Education was a significant determinant; individuals with secondary education were nearly five times (aOR=4.63,95%CI:3.92–5.46, p<0.001) and those with higher education over six times (aOR=6.72,95%CI:5.19–8.71, p<0.001) more likely to test for HIV. Media exposure (radio: aOR=1.69; 95%CI: 1.46–1.95, p<0.001); television: aOR=1.35; 95%CI: 1.17–1.55, p<0.001) was also associated with higher odds of HIV testing. For condom use, higher education levels significantly increased the likelihood: secondary education (aOR=3.37; 95%CI: 2.84–3.97; p<0.001) and higher education (aOR=4.19; 95%CI: 3.12–5.62; p<0.001).
Conclusions: Age and education-related disparities in HIV testing and risk behaviors among ABYM in Kenya highlight the need for tailored interventions. Efforts should prioritize adolescent-focused testing, HIV education, and me-

dia-driven campaigns for young men. Overall, these findings highlight the importance of tailored approaches to mitigate HIV risk in ABYM in Kenya and similar contexts in SSA.

EP0577

Public and internalised stigma and discrimination experienced by teenagers living with HIV in a northern Nigeria state: a mixed-methods assessment of the double burden of the young

A. Isah[1,2], G. Ezenri[2], E.J. Ugochukwu[1,2], J.C. Onyehalu[2], C. Nwachuya[2], C.E. Agbo[2], A. Ngige[2], M.M. Abubakar[3,2], C. Idabor[2], B.O. Ukoha-Kalu[4,2]

[1]University of Nigeria, Clinical Pharmacy and Pharmacy Management, Nsukka, Nigeria, [2]University of Nigeria, Person-Centred HIV Research Group, Nsukka, Nigeria, [3]Nigerian Air Force, Directorate of Therapeutic Services, Medical Services Branch, Kaduna, Nigeria, [4]University of Nottingham, School of Medicine, Nottingham, United Kingdom

Background: Stigma and discrimination remain a significant challenge for teenagers living with HIV especially in regions with limited awareness and several cultural misconceptions about HIV. Understanding the extent and nature of these experiences is critical for addressing identified barriers. We explored the public and internalized stigma and discrimination experienced by teenagers living with HIV in a secondary healthcare institution in northcentral Nigeria.

Methods: We conducted a mixed-methods study in which 120 teenagers living with HIV responded to structured 21-item validated questionnaires (quantitative phase) while 10 provided insights through in-depth interviews. Data was collected from December 2024 to January 2025 at 15 treatment facilities in Kogi State, northcentral Nigeria, after obtaining institutional approval as well as consent from parents of respondents under the age of 18 years. With the aid of IBM-SPSS (Version-28), appropriate descriptive and inferential statistical analyses were conducted on the quantitative data while thematic analysis was used for the qualitative data.

Results: A total of 104 respondents participated in the study with a mean age of 15.4 ± 2.3 years. The majority [61 (58.7%)] of the respondents were females, while almost all the respondents (94.8%) perinatally acquired HIV. A little above half of the respondents [63 (60.6%)] reported experiencing internalized stigma. Lack of peer support (aOR: 2.9; 95% CI: 1.6–5.1) and poor caregiver communication (aOR: 3.2; 95% CI: 1.8–5.7) were contributing factors to internalized stigma. Similarly, the majority of the respondents [77 (74.0%)] reported being stigmatized by the public, identifying places of such abuse to be the treatment centres (86%) and schools (86%). "Bullying" and "healthcare discrimination" emerged as key themes from the interviews, with "avoidance" and "withdrawal" being common practices of the respondents.

Conclusions: Stigma and discrimination are prevalent among the young people living with HIV who participated in the study. This can lead to such negative outcomes as loss to follow-up and treatment failure. Further studies will consider interrogating the direct effect of both public and internalized stigma and discrimination on the teenagers living with HIV, possibly cocreating remedies the identified causes.

EP0578

Using an adherence plan tool to strengthen adherence counselling at anti-retroviral initiation in South Africa: lessons learnt from a national differentiated service delivery performance review

L. Malala[1], M. Manganye[1], P. Khoza[1], T. Dladlama[1], S. Wilson[2], V. Manasoe[2], R. Fritz[3,2], T. Chidarikire[4], M. Mulaudzi[5], M. Jumbe[6], K. Sachathep[7], W. Reidy[7], P. Preko[8], G. Shabangu[1]

[1]National Department of Health, HIV/AIDS Cluster, Pretoria, South Africa, [2]ANOVA Health Institute, Operation Phuthuma, Pretoria, South Africa, [3]National Department of Health, Department of Health, Pretoria, South Africa, [4]World Health Organization, HIV Prevention, Pretoria, South Africa, [5]University of Pretoria, Health Sciences, Pretoria, South Africa, [6]ICAP at Columbia University, Columbia University mailman School of Public Health, Nairobi, Kenya, [7]ICAP at Columbia University, Columbia University mailman School of Public Health, New York, United States, [8]ICAP at Columbia University, Columbia University Mailman School of Public Health, Mbabane, Eswatini

Background: In 2016, South Africa introduced integrated differentiated service delivery (DSD) for HIV, tuberculosis, and non-communicable diseases to support treatment adherence and retention. This guidance introduced adherence counselling standard operating procedures (SOPs) including an Adherence Plan (AP). In 2023, the guidance was updated and SOPs integrated into the country's ART clinical guidelines with the aim of increasing healthcare provider awareness and implementation.

Description: The AP is a structured tool designed to facilitate discussions between ROCs and healthcare providers on adherence, covering goal setting, medication schedules, appointment management, and psychosocial support (Figure 1).

It also serves as a record for future discussions and continuity of care across providers. In 2023, the National Department of Health (NDoH) conducted a Differentiated Service Delivery Performance Review (DPR) at 92 facilities across nine provinces to evaluate adherence-related interventions, including AP use. Among 6,557 ART ROC folders reviewed, only 3,654 included an AP, and just 1,362 were fully completed.

Lessons learned: Despite the AP's inclusion in national guidance since 2016, uptake remains limited, with substantial provincial variation (30–33% in Eastern Cape, Gauteng, KwaZulu-Natal, and Mpumalanga compared with >90% in North West and Western Cape). Low uptake and completion rates indicate missed opportunities for adherence support, potentially contributing to high facility disengagement rates observed during the DPR: 17% at six months, 24% at 12 months, and 34% at 24–36 months

post-ART initiation. Barriers include insufficient healthcare worker training and inconsistent integration into clinical workflows.

PATIENT ADHERENCE PLAN

Name and Surname:

FTIC Session 1 after chronic disease education session (date):

Adherence step 1: education on HIV ☐ TB ☐ Hypertension ☐ Diabetes ☐ Other ☐.....

Adherence step 2: Life goals:
My motivations to stay healthy are: (1).....(2).....(3).....
I will maintain a healthy lifestyle by ☐ adopting healthy eating habits ☐ getting regular exercise ☐ managing my stress

Adherence Step 3: Patient Support system
Agree for home visit: Yes ☐ No ☐ Preferred means of contact: SMS ☐ WhatsAapp ☐ Phone call ☐ Other ☐.....
Who can support me in my treatment: ☐ Family ☐ Friends ☐ Work ☐ School ☐ Church ☐ Other:

Adherence Step 4: Getting to appointments
I will come to my appointments by: ☐ walk ☐ public transport ☐ own transport
If I face a difficulty to come (money, transport, etc.), my alternative plan will be to ask for assistance from:
☐ family ☐ friends ☐ neighbour ☐ other .....
I will inform clinic I am unable to come to set appointment and request for an alternative appointment ☐

Adherence step 5: My readiness to start treatment
I feel ready and will start treatment:
☐ Yes
I am ready today ☐ Yes ☐ No but will be on..... (insert date)
☐ I do not feel ready and would like to discuss more with:
☐ peer ☐ family member ☐ other .....

Adherence Step 6: Medication schedule
The best time for me to take my treatment is: ☐ Morning ☐ Afternoon ☐ Evening

Adherence step 7: Managing missed doses
If I miss a dose, my plan is: (1) to take treatment as soon as I remember ☐

Adherence Step 8: Reminder strategies
To remind me to take medication I will use: ☐ watch ☐ cell phone alarm ☐ pill box ☐ buddy ☐ other .....

Adherence Step 9: Storing medication and extra doses
I will store my medication in: ☐ Safe place: ..... ☐ Far from reach of children
I will carry extra supply in: ☐ a bag ☐ pill box ☐ other:..... I will keep it in my: ☐ handbag ☐ pocket ☐ other:.....

Adherence Step 10: Dealing with side-effects
If I experience side effects, I will: Refer to treatment adherence pamphlet ☐
Inform clinic if side effects do not go away or are too worrying ☐

FTIC Session 2 (date):

Adherence Step 11: Understanding the treatment pathway ahead of me if I take my treatment well
☐ I understand the options for multi-month treatment supply and simplified collection available after one normal assessment result.

Adherence Step 12: Planning for trips
If I have some trips planned, before going away I will:
☐ Inform health facility before travelling to receive referral letter and treatment ☐ Get enough supply of treatment for trip
In case I cannot come to the facility before going away:
☐ I will report to the nearest health facility in the travel area as soon as I arrive to get access to treatment
☐ Carry evidence of my condition and evidence of the treatment I am taking

Adherence Step 13: Dealing with substance use
My plan to make sure I take my medication if I used alcohol or drugs is:
☐ To make sure I take treatment before starting to use drugs or alcohol
☐ Arrange for someone to remind me to take treatment in case I am intoxicated

Education on assessment: Viral load ☐ Sputum ☐ HbA1c ☐ BP ☐ Other: ..... ☐
☐ I understand that I can access multi-month treatment supply and simplified collection if my results are normal

Patients signature ..... **Date of signature** .....

EAC Session 1 (date):

EAC Session 2 (date):

Conclusions/Next steps: To address gaps, the NDoH has begun re-orientation sessions to improve healthcare provider understanding, uptake, filing and ongoing use of the AP, particularly in provinces with low uptake and/or completion rates.
These efforts include promoting AP printing and distribution by districts and provinces to all primary care facilities and integrating AP-related tasks into standard clinical workflows.

EP0579

Addressing chemsex practices in virtual spaces: lessons from a comprehensive harm reduction outreach

R. Sbaba[1], J. H. Thakker[1], A. Singh[1], D. Naren[2], V. Rai[2], D. Shankar[2], R. Kumar[2], S. Konnur[3]
[1]Johns Hopkins University School of Medicine, Infectious Disease, Baltimore, United States, [2]YR Gaitonde Center for AIDS Research and Education, Chennai, India, [3]Mist LGBTQ Foundation, Pune, India

Background: Chemsex, or sexualized substance use, involves using psychoactive drugs during sexual activities to enhance pleasure, reduce inhibitions, and/or minimize pain. This practice is increasingly prevalent in LGBTQIA+ communities, particularly among users of dating apps. In India, Chemsex poses significant risks for HIV and other blood-borne infections. The ACCELERATE project, a PEPFAR and USAID-supported initiative, aims to identify challenges faced by populations engaging in Chemsex and develop tailored service delivery packages to mitigate these risks and improve health outcomes.
Description: ACCELERATE operates the virtual platform - www.safezindagi.in to connect LGBTQIA+ individuals online with HIV-related services, such as testing, PrEP, and antiretroviral treatment. The platform specifically targets at-risk individuals using dating apps to seek sexual partners, where Sexual Health Managers (SHMs) guide clients through services. In June 2022, 100 Chemsex participants were reached via Grindr and Planet Romeo. Clients were interviewed about high-risk sexual behaviors (e.g., condomless sex, kink/BDSM) and their service needs.
Lessons learned: Analysis revealed significant health and mental health challenges, including genital injuries, histories of HIV/STI, and instances of rape or physical injury due to impaired consent. Clients experienced anxiety, depression, and drug dependence, with MDMA and Heroin as common drugs of choice. Many reported stigma-related barriers to seeking medical help. The assessment highlighted a strong demand for services addressing personal safety, mental health support, HIV, Hepatitis, and STI prevention/treatment, safe sex practices, and emergency responses. In response, tailored service packages focusing on HIV/STI support, mental health, and personal safety were developed.
Conclusions/Next steps: The outreach demonstrated the effectiveness of person-centric, harm reduction strategies through existing online platforms like Safe Zindagi. ACCELERATE plans to reach 1200 individuals to assess Chemsex-related needs and design an integrated approach with mental health, HIV/STI services, rehabilitation, harm reduction services and legal aid. High risk sites will be trained at providing crisis management support and linkage to virtual spaces, HIV/STI testing, ART linkage, harm reduction counseling, and mental health support in private and public sector.

EP0580

HIV sexual risk, stigma, mental health, and substance use among transgender people in Southeast Asia: the SEATrans study

T. Payuha[1], R. Janamnuaysook[1,2], N. Phanuphak[1,2], P. Pumphosuwan[1], S. Suriwong[1], W. Tasomboon[1], S. Saiwaew[3], R. Pagtakhan[4], T.M. Le[5], T. Sangpasert[3], P. Boonyawan[3], J.D.B. Ruanto[4], Z. Black[4], M.T. Tran[5], T.T. Lu[5], K. Samitpol[1,2], T. Amatsombat[1], R.A. Ramautarsing[1], J. Ross[6], SEATrans Study Team

[1]Institute of HIV Research and Innovation, Bangkok, Thailand, [2]Chulalongkorn University, Center for Excellence in Transgender Health, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]LoveYourself Inc., Mandaluyong, Philippines, the, [5]Glink Vietnam Social Enterprise Company Limited, Ho Chi Minh City, Viet Nam, [6]The Foundation for AIDS Research, amfAR's TREAT Asia, Bangkok, Thailand

Background: Transgender people are at high risk of HIV, mental illness, and other health issues due in part to various biomedical factors, behavioral risks, stigma, and discrimination. We established Asia's first prospective observational transgender cohort study to assess their HIV, mental health and other health behaviors, risks and impacts.

Methods: Transgender persons, aged ≥18 years, attending the Rainbow Sky Association of Thailand and Tangerine Clinic in Thailand, Glink in Vietnam, and Victoria by LoveYourself in the Philippines were enrolled between December 2022 to October 2024. Six-monthly study visits were conducted which included assessment of behavioral risks, stigma, discrimination, and experiences of physical, sexual, and psychological violations related to being transgender, using self-administered questionnaires. Depression, anxiety, and PTSD were screened using PHQ-9, GAD-7, and PCL-5, respectively. Associations between stigma, discrimination, violations, and mental health problems were analyzed using Fisher's exact or chi-squared test.

Results: At baseline, of 415 transgender people with a median (interquartile range, IQR) age of 28 (23-33) years), 381 (92%) were transgender women, 31 (7%) transgender men, and 3 (1%) non-binary. Two hundred eighty (67.5%) were Thai, 75 (18%) Filipino, and 60 (14.5%) Vietnamese. 121 (29%) were living with HIV. Sixty-six (16%) engaged in sex work, 28 (7%) used substances, 43/375 (11%) engaged in chemsex. Ninety-three (22%) participants had moderate depression (PHQ-9 ≥10), moderate anxiety (GAD-7 ≥10), or severe PTSD (PCL-5 ≥33). Two hundred sixty-five (64%) reported ever experiencing stigma, 343 (83%) discrimination, and 106 (26%) violations. Compared to those without, those with mental health problems were more likely to report experiencing stigma (13% vs 28%, p<0.001), discrimination (7% vs 26%, p=0.001) and violations (16% vs 42%, p<0.001).

Conclusions: Transgender people in our cohort had high rates of risk behaviors, HIV prevalence, mental health issues, substance use, stigma, discrimination and violations. Mental health challenges were associated with lifetime experience of stigma, discrimination, and violations, highlighting the need for transgender-specific integrated interventions.

EP0581

A novel self-administered behavioral risk assessment tool identifies young South African women with high risk for STIs and HIV

K. Reddy[1], J. Hao[2], M. Govindasami[1], N. Matswake[1], B. Jiane[1], R. Kgoa[1], L. Kew[1], N. Ndlovu[1], R. Stuurman[1], H. Mposula[1], J. Velloza[3], R. Heffron[2], T. Palanee-Phillips[1,4]

[1]Wits RHI, University of the Witwatersrand, Faculty of Health Sciences, School of Public Health, Johannesburg, South Africa, [2]University of Alabama at Birmingham, Heersink School of Medicine, Birmingham, United States, [3]University of California San Francisco, Division of Global Health and Infectious Disease Epidemiology, Department of Epidemiology & Biostatistics, San Francisco, United States, [4]University of Washington, School of Public Health, Seattle, United States

Background: For adolescent girls and young women (AGYW), the ability to self-assess their sexual risk behavior can be empowering and provide opportunity to adopt HIV/STI prevention strategies, including initiation of HIV pre-exposure prophylaxis (PrEP). Currently, no tool for behavioral risk self-assessment exists and it is unknown whether such a tool could be associated with STI detection and PrEP initiation.

Methods: PALESA was a pilot randomized trial conducted among sexually active AGYW aged 16–18 years from June 2023 to May 2024 in Johannesburg, South Africa. Participants attended monthly visits for six months (quarterly in-clinic and non-quarterly virtual), where they were offered oral PrEP. STI diagnostic testing (chlamydia, gonorrhea, trichomonas) was performed quarterly.

For this study, using literature review, in-depth interviews, and pilot testing, we designed and refined a 15-item behavioral risk self-assessment tool, capturing recent sexual behavior, partnership characteristics, and STI symptoms with participants scoring a point for each item where the response indicated potential risk.

The tool was deployed monthly via a web-based platform, with text message reminders including a personalized link to the tool. We quantified participant responses to the self-assessment tool and used a generalized linear mixed-effects model and an adjusted survival model to determine the associations of participants' self-assessment total scores with STI detection and PrEP initiation respectively.

Results: Among 55 participants (median age: 18 years, IQR: 17–18), 385 surveys were distributed, with 365 responses (94.8%) collected. The median behavioral tool total score was 1 (IQR: 1–3). Frequently reported items included older partners (38.4%), vaginal STI symptoms (26.3%), new sexual relationships (20.0%), and multiple partners (18.9%). Higher scores were associated with increased odds of STI detection (adjusted odds ratio: 2.64, 95% CI: 1.47–4.73) and earlier PrEP initiation (adjusted hazard ratio: 1.43, 95% CI: 0.56–3.63) although the latter was not statistically significant.

Conclusions: A self-administered online behavioral risk self-assessment tool was feasible to implement among this small cohort of AGYW and may be effective in identifying individuals at higher risk of STIs.

Further research is warranted to fully explore the predictive value of the self-assessment tool on STI diagnosis and PrEP use patterns.

EP0582

Addressing barriers to HIV testing in Nampula province, Mozambique: culturally tailored strategies to enhance differentiated HIV testing services

G. Amane[1], M. Lisboa[2], I. Sathane[3], I. Gaspar[1], A. Couto[4], S. Banze[5], A. Mahawa[2], M. Wing[6], T. Pinto[7], B. Ernesto[8], N. Massunda[9], E. Fernando[10], B. Manuel[10], S. Félix[10], F. Saide[10]
[1]Ministry of Health of Mozambique, National Program to Control STIs HIV/AIDS, MoH, Mozambique, Maputo, Mozambique, [2]USAID, Mozambique, United States Agency for International Development (USAID), Mozambique, Maputo, Mozambique, [3]National Program to Control STIs HIV/AIDS, MoH, Maputo, Mozambique, [4]MoH Mozambique, Public Health Directorate, Ministry of Health of Mozambique, Maputo, Mozambique, [5]MoH Mozambique, Department of Health Promotion, Maputo, Mozambique, [6]Health Collaboration Center, Mozambique, Maputo, Mozambique, [7]Ariel Glaser Foundation, Mozambique, Maputo, Mozambique, [8]ICAP, Columbia University, Mozambique, Maputo, Mozambique, [9]Independent Consultant, Maputo, Mozambique, [10]Provincial and Services Health Directorate, Nampula Province, Mozambique, Nampula, Mozambique

Background: In Mozambique, sociocultural diversity and entrenched beliefs about HIV/AIDS impede epidemic control efforts to combat the epidemic. Widespread myths, stigma, and misinformation discourage HIV testing and treatment, particularly in rural areas. Nampula province struggles with low HIV testing uptake (only 56.9% toward the first 95 goal), due to cultural and healthcare system barriers.
This study aimed to inform a differentiated HIV testing services pilot program intended to improve client centered approaches for HIV testing in the province.
Methods: A qualitative study was conducted in five selected districts of Nampula. Fifteen focus group discussions were held with adolescents and young people of both sexes and adult men, and health committee members to explore HIV testing perceptions, beliefs, stigma, cultural norms, and systemic barriers related to HIV testing. In-depth interviews with healthcare providers captured insights into systemic challenges, missed opportunities, and training needs. Data from audio recordings and written notes were analyzed using content analysis in Atlas.ti version 24.1.
Results: Findings revealed pervasive misconceptions, including the belief that HIV is incurable or exclusively linked to promiscuity. Key barriers included fear of discrimination, low health literacy, and lack of privacy in HIV testing facilities. Participants emphasized the importance of strengthening health literacy through community-based events and radio programs to promote dHTS demand, increase awareness, and reduce stigma. Culturally tailored messaging and improved community engagement were identified as key strategies for rebuilding trust in healthcare services. Improved provider-patient communication was also highlighted as a strategy to enhance testing uptake, particularly among groups at high-risk of HIV infection.
Conclusions: Strengthening community engagement to rebuild trust in healthcare providers, along with culturally tailored interventions, such as health literacy campaigns and enhanced communication strategies, have the potential to increase HIV testing uptake in Nampula. Scaling these efforts to other regions can significantly advance Mozambique's progress toward achieving the first 95 goal.

EP0583

Enhancing PrEP uptake among adolescents and young people in rural Kenya

L. Muthoni[1]
[1]Mwala Technical and Vocational College, Community Health, Machakos, Kenya

Background: Pre-exposure prophylaxis (PrEP), is a useful preventative measure against HIV, but its use among adolescents remains limited. A variety of factors influence the sexual health decisions of young people, including whether they will use or adhere to HIV preventive measures like PrEP.
This study's objective was to assess the knowledge and attitudes towards PrEP, and explore the factors influencing uptake among adolescents in rural Kenya.
Methods: A cross-sectional mixed-methods study was conducted between February and July 2024 in Mwala-Machakos County Kenya.
The study included 400 adolescents and young people aged 17-24 years, selected through Stratified Random Sampling and 15 service providers selected through purposive sampling.
Structured questionnaires were used for quantitative data collection. Qualitative data was collected through focus group discussions and key informant interviews with service providers. Quantitative data were analyzed using SPSS, while qualitative data were analyzed thematically using NVivo.
Results: Overall, only 48% of the participants were aware of PrEP, and only 22% had adequate knowledge of its preventive role. Of those, only 6 % had acquired PrEP knowledge from hospital settings. Only 2% had used PrEP. Girls were more likely than boys to have heard of PrEP and used PrEP..
Among adolescents with no prior use, 53% were willing to consider using PrEP, although boys were less willing than girls (49.7% vs. 55.9%; P = 0.001). While 60% expressed positive attitudes, stigma and misconceptions were prominent barriers. Key factors influencing uptake included lack of knowledge, risk perception, stigma, fear of side effects and lack of youth-friendly services.
Service providers described strategies such as Integration with routine Health Services and community outreaches as the most common strategies used to increase knowledge and promote uptake.

Conclusions: PrEP is a crucial prevention tool, especially for adolescents who are considered as a vulnerable group in HIV infection. Although many expressed willingness to use PrEP, low awareness, misconceptions, and the systemic barriers to use highlight the need to expand hospital-based initiatives into Community-based interventions to address stigma, enhance education, and strengthen service linkages to increase access and utilization.

EP0584

Lessons from the adaptation and delivery of Wakakosha (I am Worth it) peer-led internal stigma programme in Kigali, Rwanda

N. Manzi[1], F. Niwowegusa[1], B. Niyonkuru[1], P.G. Cyusa[1], S. Ingabire[1], N. Ferris France[2], R. Shumba[3], E. Gwenzi[3], T. Dongo[3], V. Jazi[4], E. Crehan[5], D. Ní Cheallaigh[6]
[1]Dreams Village, Kigali, Rwanda, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]Zvandiri, Harare, Zimbabwe, [4]Beyond Stigma, Harare, Zimbabwe, [5]Speak Up Sing Out, Kilkock, Ireland, [6]Beyond Stigma, Dublin, Ireland

Background: The Wakakosha peer-led programme, co-led by Zvandiri and Beyond Stigma, addresses internal stigma among adolescents and young people living with HIV. Pioneered in Zimbabwe, the six-day residential course was adapted and delivered in Kigali Rwanda, targeting 30 Community Adolescent Treatment Supporters (CATS) from Dream Village. It focused on building self-awareness, fostering resilience, and reducing stigma through a structured and interactive curriculum, incorporating creative activities, mindfulness, and peer exchange.
Description: A diverse team from Zimbabwe, Rwanda, and Ireland facilitated the programme, with Ghanaian participants joining as part of a peer exchange. Activities included meditation, storytelling, music, and role-play, supported by group discussions and journaling. The curriculum was delivered in an inclusive, contextually relevant manner, with daily evaluations used to adjust and improve content in real-time. Key features such as music integration, tailored group sizes, and structured sessions created a safe space for emotional sharing and self-reflection.
Lessons learned: Participants reported high engagement and enhanced self-awareness. Interactive activities, such as songwriting and storytelling, were particularly effective in fostering openness and peer connection. Daily evaluations enabled timely adaptations, while local modifications, such as grouping participants by language, improved communication and inclusivity. Challenges included time constraints, logistical issues, and the need for clearer pre-session briefings.
Recommendations included extending session durations, strengthening translation support, and incorporating more cultural elements, such as local songs and traditional dance. Ghanaian participants were able to directly experience the programme and to learn from its delivery in Rwanda to inform future adaptations.
Conclusions/Next steps: The evaluation demonstrated the programme's effectiveness in reducing stigma and fostering resilience among participants. Feedback has informed refinements, including enhancing creative components, integrating multimedia tools, and adapting the curriculum for diverse cultural contexts. The success of Wakakosha highlights its potential for scalability. The next phase involved implementation in Ghana with tailored adjustments, ensuring sustainability and broader impact. By prioritising continuous improvement, the programme aims to strengthen peer connections and foster community resilience, ultimately contributing to reducing internal stigma among adolescent and young people living with HIV on a larger scale in Rwanda and elsewhere.

EP0585

Disparities in PrEP use among female sex workers enrolled in "MAS por nosotras" cohort in Buenos Aires, Argentina

R. Acuña[1], C. Serrao[1], V. Zalazar[1], E. Frontini[1], A. Zeltman[1], M.C. Trejo[1], R. Caballero[1], S. Vulcano[2], N.F. Cardozo[1], M. Romero[3], G. Orellano[4], C. Cesar[1], Z. Ortiz[1], M.I. Figueroa[1], P. Cahn[1], A. Duran[2], M. Loufty[5], S. Walmsley[6], V. Fink[1], I. Arístegui[1], MAS por Nosotras study group
[1]Fundación Huésped, Research Department, Ciudad Autonoma de Buenos Aires, Argentina, [2]Ministry of Health of Buenos Aires, HIV and Sexually Transmitted Infections, Ciudad Autonoma de Buenos Aires, Argentina, [3]Asociación de Travestis, Transexuales y Transgénero de Argentina, Ciudad Autonoma de Buenos Aires, Argentina, [4]Sindicato de Trabajadorxs Sexuales de Argentina, Ciudad Autonoma de Buenos Aires, Argentina, [5]University of Toronto, Women's College Hospital, Toronto, Canada, [6]University of Toronto, University Health Network, Toronto, Canada

Background: Female sex workers (FSWs) in Latin America face elevated HIV-risk due to structural vulnerabilities. Although PrEP is an effective HIV prevention method, its use among FSWs remains low. We analyzed psychosocial factors influencing PrEP use in a prospective cohort of cisgender (CGW) and transgender (TGW) FSWs.
Methods: Baseline medical and psychosocial information from 157 FSWs without HIV was collected between June-2023 and August-2024. Questionnaires included sociodemographic information, PrEP use (prior or starting at enrollment), condom use, stigma in sex work (Grosso et al. 2019≥1), post-traumatic stress (PCL-5≥33), depression (CES-D≥16), childhood trauma and substance use (DAST-10≥3). Bivariate and multivariate binary logistic assessed correlates of PrEP use.
Results: 60.5% were CGW, 39.5% TGW, with median age 35.3 years (IQR=26.5–43); PrEP use, previous or after enrollment was 47.1% (n=74); 46.7% internal migrant and 28.4% international migrant, 37.2% unstable housing, and 49.7% engaging in street-based sex work.
Condom use (last sexual encounter) was 32%. Stigma related to sex work was experienced by 53.7% of participants. Mental health indicators:11% post-traumatic stress, and 53.9% depressive symptoms.
Childhood trauma: 49.7% experienced sexual abuse and 74.5% physical neglect. Substance use: 26.2% met criteria for substance dependence or higher, and 29.9% reported cocaine use (last year). Bivariate analyses showed

that PrEP use was more frequent among TGW [OR=5.13 (95%CI=2.55–10.33), p<0.001], internal migrants (OR=4.60, 95%CI=2.04–10.41, p<0.000), and lower age (OR=.96, 95%CI=.938-.994, p=.019).
No significant differences were found in mental health or trauma indicators between PrEP users and non-users. In the final multivariable model, PrEP use remained positively associated only with TGW gender identity [OR=7.55(95%-CI=3.15–18.10), p=.000].
Conclusions: FSWs exhibited social vulnerabilities, childhood trauma, poor mental health, and disparities in PrEP use, with CGW less likely to have used PrEP.
These results underscore the need for tailored strategies to promote PrEP use among CGW, integrate mental health support, and address structural barriers to reduce HIV prevention disparities in FSWs.

EP0586

Declining levels of internalized HIV-related stigma and associated factors in a cohort of antiretroviral-experienced people with HIV in Liberia, West Africa

I. Wachekwa[1,2], J.S. Moses[1], A.K. Pau[3], S. Kuriakose[4], G. Grandits[5], M. Mannah[1], J. Blie[1], C. Chorley[4], I. Morlu[1], J. Dorbor[1], O.T. Bongolee[1], R. Slewion[1], E. Akpa[4], B. Wilson[1], K.L. Johnson[1], S.A. Migueles[3]
[1]Partnership for Research on Vaccines and Infectious Diseases in Liberia (PREVAIL), Monrovia, Liberia, [2]John F. Kennedy Medical Center, Monrovia, Liberia, [3]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, United States, [4]Frederick National Laboratory for Cancer Research, Bethesda, United States, [5]University of Minnesota, Minneapolis, United States

Background: The impact of HIV-related stigma on treatment outcomes, including HIV-1 suppression, in West Africa remains unclear. We examined factors associated with internalized HIV-related stigma and trends over time among people with HIV (PWH) in Liberia.
Methods: PWH on ART > 12 years of age from the HONOR cohort study, representing five of the largest HIV clinics in Monrovia, Liberia, responded to an HIV stigma survey at enrollment and every six months thereafter for 24 months. Stigma levels were assessed using an internalized AIDS-related stigma scale, a validated tool with dichotomous responses (agree or disagree) to six items reflecting negative perceptions related to HIV. The stigma score was the sum of positive responses (values 0–6), with higher levels indicating higher stigma.
Variance analysis was used to compare stigma scores across demographic factors. Logistic regression was used to relate baseline stigma to follow-up ART adherence, visits attended, and viral load (VL) suppression.
Results: 1,226 participants completed the survey at enrollment with a median age of 42 years [IQR 36–51], and 73.3% were females. Stigma scores were higher in females than males, 2.9 ± 1.4 versus 2.6 ± 1.3 (p<0.001), respectively. Mean stigma decreased from 2.8 ± 1.4 at enrollment to 1.9 ± 0.8 at 24 months. The decline was more pronounced among females, 2.9 ± 1.4 to 1.9 ± 0.8, versus 2.6 ± 1.3 to 1.8 ± 0.8 among males (p=0.06). Younger age (p<0.001), unemployment (p=0.036), shorter duration since HIV diagnosis (p<0.001), higher HIV clinical stage (p=0.047), and lower CD4+ counts (p=0.003) were associated with higher stigma at baseline.
Stigma levels were not related to education, marital status, or transmission mode. Higher baseline stigma was associated with lower ART adherence, fewer follow-up visit attendance, and less consistent VL suppression (p<0.05 for each) during 24-month follow-up than participants with lower stigma.
Conclusions: In Liberia, female PWH reported higher HIV stigma than males at baseline, which declined significantly in both groups during follow-up. Participants with higher stigma scores at baseline were less likely to be ART adherent and virologically suppressed over 24 months. Efforts to reduce HIV stigma may improve ART adherence and VL suppression.

EP0587

Bridging dialogue and action in youth behavioral change, Insights and lesson learnt from Ruvuma, Tanzania

E. Shindano[1], G. Mwanakulya[1], C. Paresso[2], A. Mfaume[2], B. Christina[2], M. Njelekela[3], Z. Nessi[3], N. Fida[4], J. Kalimunda[4]
[1]T-MARC, Programs, Dar es Salaam, Tanzania, the United Republic of, [2]MDH, Programs, Dar es Salaam, Tanzania, the United Republic of, [3]Deloitte, Programs, Dar es Salaam, Tanzania, the United Republic of, [4]USAID, Programs, Dar es Salaam, Tanzania, the United Republic of

Background: Behavior Change and Communication is an interactive process that employs strategic communication channels to promote adoption of healthier and sustainable practices at both individual and community levels. Its goal is to ensure availability of accurate and relevant information, foster motivation, and overcome barriers to action. In sub-Saharan Africa, survey data from 35 countries revealed that only 36% of young men and 30% of young women correctly identified methods to prevent transmission of HIV and dispelled common misconceptions about HIV. The 2022/23 Tanzania HIV Indicator Survey reported a national HIV prevalence rate of 4.5%, with Ruvuma region ranking 8th highest at 4.9%.
Given the strong link between misinformation and the increased risk of HIV infection, the USAID Afya Yangu (My Health) Southern Project has amplified its communication efforts to provide accurate and up-to-date HIV service information during FY24. Our goal was to identify insights and lessons learned from youth engagement strategies using BCC.
Description: The methodology for disseminating accurate HIV information to youth involved communication pathways including interpersonal communication and peer-led small group discussions, facilitated by trained peers. Mass media was utilized through radio spots and interviews, social media influencers were engaged to create and share content on platforms such as Instagram, WhatsApp.

Lessons learned: After approximately 3,960 IPC sessions, 220 SGD engagements, 102 radio spots, and 206 social media posts, nearly 10,491 youths were reached. Among them, 5,836 received HTS, 14 cases were identified and linked to ART, 2,118 were connected to PrEP, and103,270 condoms were distributed. This proved that when BCC strategies align with characteristics of targeted population, cultural and geographical contexts, and desired behavioral outcomes, its possible to achieve a sustainable behavior change.
Challenges faced during implementation of these activities included gender dynamics, confidentiality, stigma, cultural barriers, Denial and Avoidance.
Conclusions/Next steps: The program has strategized in Creating safe spaces that focuses on interactive procedures when facilitating discussions among youth hence fostering comfortable environment for participants to fully engage despite of their gender, character or level of knowledge. This includes Youth Connect events that are conducted at a health facility which allows delivery of health services, health talks from trained facilitators and Entertainment.

EP0588

Correlates of viral suppression among adolescents living with HIV in Mozambique: results from a multi-center cross-sectional study

J. Falcao[1,2], E. J. Abrams[3,4,5], A. Couto[6], A. Zerbe[4], E. Pimentel de Gusmão[7], K. Manuel[7], N. D. Labhardt[1]
[1]University and University Hospital Basel, Clinical Epidemiology, Department of Clinical Research, Basel, Switzerland, [2]ICAP at Columbia University, Mailman School of Public Health, Maputo, Mozambique, [3]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [4]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [5]Vagelos College of Physicians and Surgeons, Columbia University, Department of Pediatrics, New York, United States, [6]Ministry of Health, National STI, HIV/AIDS Control Program, Maputo, Mozambique, [7]ICAP at Columbia University, Mailman School of Public Health, Maputo, Mozambique

Background: Despite enormous progress in the fight against HIV, adolescents and young people living with HIV (AYAHIV) have worse outcomes across the HIV care continuum compared to adults. In this analysis, we assessed correlates of viral suppression (VS) among AYAHIV 15 to 19 years old on ART in Mozambique.
Methods: Implemented in Nampula, Mozambique, the CombinADO trial (NCT04930367) was a cluster randomized trial comparing the effectiveness of a multilevel health services intervention to improve HIV outcomes among AYAHIV, to an enhanced standard of care on the primary outcome of VS (viral load [VL]<50 copies/mL).
The control condition was implemented at all study facilities (n=12); the intervention superadded to the control condition at a randomly selected half (n=6) of facilities and both intervention conditions were placed for 12 months. After 12 months of intervention implementation, AYAHIV age 10-24 years receiving care at each of the 12 HF were approached for enrollment into a post-intervention assessment that included questionnaires and a blood draw for VL measurement. This analysis includes participants aged 15 to 19 years who completed the post intervention assessment. Multivariate logistic regression reporting adjusted odds ratios (aOR) was used to quantify the association of different factors with VS. Data were collected between November 2022 and July 2023.
Results: Of 534 AYAHIV 15-19 years (72% female) included in this analysis, 295 (55%) had VS. AYAHIV who were married/cohabiting (aOR=2.96, 95% CI 1.41–6.23, p=0.004) and those who were aware of and said they understood their latest VL result (aOR=1.60, 95% CI 1.01–2.54, p=0.046) were more likely to have VS. VS was lower among AYAHIV who had high levels of internalized stigma (aOR=0.29, 95% CI 0.10–0.78, p=0.015) as well as those with a history of emotional or physical violence from a relative (aOR=0.52, 95% CI 0.33–0.81, p=0.004).
Conclusions: Increasing caregivers support, improving treatment literacy, and reducing internalized stigma may contribute to improving VS rates among AYAHIV in Mozambique. The overall low rate of VS among this population underscores the urgent need for AYAHIV tailored care in Mozambique.

EP0589

Intervention strategies for reducing HIV stigma and discrimination in Sub-Saharan Africa: a systematic review

O. Ola[1], F. Akinsolu[1], O. Abodunrin[2], M. Adelaja[1]
[1]Lead City University, Public Health, Ibadan, Nigeria, [2]Nanjing Medical University, Departments of Epidemiology and Health Statistics and Toxicology, School of Public Health, Nanjing, Jiangsu, China

Background: HIV-related stigma and discrimination remain a pervasive barrier to the effective prevention, diagnosis, and treatment of HIV, particularly in Sub-Saharan Africa (SSA), where the epidemic's impact is most severe. Despite global initiatives to combat HIV/AIDS, stigma continues to challenge the attainment of the 2030 goal to end AIDS.
The objective of this systematic review was to comprehensively examine and synthesize the existing evidence on effective strategies for reducing HIV-related stigma and discrimination in Sub-Saharan Africa.
Methods: A comprehensive search of studies published between 2000 and 2023 was conducted in databases including PubMed, Google Scholar, and Web of Science. Data was extracted from included studies, and study quality was assessed. The study population comprised individuals and groups from diverse settings, such as healthcare facilities, communities, schools, and workplaces across SSA. Inclusion criteria were applied using the PICOTS framework, and eligible studies were reviewed for intervention types, targeted stigma domains, socio-ecological levels, and outcomes.
Results: The twenty-four included studies featured interventions targeting diverse populations, including community members, people living with HIV, students, and

sexual and gender minorities (SGMs). Interventions to reduce HIV stigma often combined multiple approaches: skill-building (75%) and information-based (67%) were most common. 79% targeted a single stigma domain, while 21% addressed multiple domains. None targeted intersecting stigmas. Duration ranged from one to sixty months. Stigma reductions were significant in 71% of studies, partial in 21%, and minimal or none in a few cases. Interventions generally targeted individual-level changes, though some addressed multiple socioecological levels, combining strategies like information dissemination and policy revisions.

Conclusions: Stigma and discrimination continue to prevent individuals from seeking testing and adhering to treatment regimens, thereby exacerbating the public health burden caused by HIV/AIDS.

These findings underscore the need for more comprehensive and multi-dimensional strategies to address HIV stigma and discrimination. Further research is needed to find effective ways to reduce intersecting stigmas among key populations, especially in areas heavily affected by HIV.

EP0590

Understanding factors contributing to loss to follow-up in the AMP trials: insights from participant interviews (HVTN 704/HPTN 085)

H. Scott[1], L. Oseso[2], R. Gonzalez[2], H. Van Tieu[3,4], T. Malefo[5], M. Nebergall[2,5], R. Lott[6], E. Okafor[7], H. Mekkan[8], P. Mukwekwerere[9], J. Dietrich[10], S. Shoptaw[11], L.E. Nelson[12], K. Mayer[13,14,15], R. Frederick[16], S. Houshangi[17], S. Khalid[13], R. Fish[18], K. Stewart[3], C. Blades[11], F. Rentas[2], A. Gangerdine[19], E. Kumar[2], M. Andrasik[2]

[1]San Francisco Department of Public Health, Bridge HIV, San Francisco, United States, [2]Fred Hutchinson Cancer Center, Seattle, United States, [3]New York Blood Center, New York, United States, [4]Columbia University, Department of Medicine, New York, United States, [5]Hutchinson Centre Research Institute of South Africa, Johannesburg, South Africa, [6]University of Rochester, Rochester, United States, [7]The University of Texas Health Sciences Center at San Antonio, San Antonio, United States, [8]The Aurum Institute, Johannesburg, South Africa, [9]University of Zimbabwe, Harare, Zimbabwe, [10]University of Witwatersrand, Johannesburg, South Africa, [11]University of California, Los Angeles, Los Angeles, United States, [12]Yale University, New Haven, United States, [13]Fenway Health, Fenway Institute, Boston, United States, [14]Harvard University, Boston, United States, [15]Beth Isreal Deaconess Hospital, Infectious Disease Division, Boston, United States, [16]Emory University School of Medicine, Emory Hope Vaccine Center, Atlanta, United States, [17]Eating Disorder Therapy Los Angeles, Los Angeles, United States, [18]Dana Farber Cancer Institute, Boston, United States, [19]TB HIV Care, Cape Town, South Africa

Background: HVTN 704/HPTN 085 and HVTN703/HPTN 081 (the AMP studies) were two proof-of-concept clinical trials that demonstrated the feasibility of achieving HIV prevention using a broadly neutralizing antibody (bnAb) against sensitive viral strains.

Overall AMP study retention was high (96%), and the AMP behavioral study conducted interviews to evaluate factors associated with loss to follow-up (LTFU) among a subset of US participants.

Methods: LTFU participants (e.g., non-responsive to follow-up visit contact attempts) across a subset of 6 US-based sites were recruited for an individual semi-structured interview to elicit feedback on reasons for not completing study follow-up. All interviews were transcribed and coded by two study team members using a code book, and a framework analysis approach was used to identify themes associated with LTFU.

Results: Interviews were completed with 21 LTFU participants (median age: 32 years, 62% White, 24% Black, and 14% Hispanic). Four key themes emerged:

1. Positive and negative study participant experiences;
2. Fear and mistrust of the study product;
3. Challenging communication with friends and family about study participation, and;
4. The impact on HIV testing.

Logistical barriers, such as transportation challenges or relocation, were the primary reasons for being LTFU. Participants generally reported positive interactions with the clinic staff, but some described negative experiences during infusions since receiving IV infusions was unfamiliar. Concerns about the study product included fear of its safety and potential long-term health impacts.

Participants also shared that friends and family were concerned about their ongoing study participation and safety, requiring extensive explanations.

Finally, concern about HIV test results that could be misinterpreted as showing HIV acquisition and limitations on their HIV testing options were commonly reported.

Conclusions: Overall, LTFU participants in the US reported positive experiences in the study, despite some fear and mistrust of the study product. However, life circumstances such as relocation often prevented them from completing the study after enrollment more than concerns about safety or impact on their HIV testing.

Future bnAb studies should prioritize logistical support for participants, such as transportation assistance and flexible scheduling, while addressing fears about study products through transparent communication and education.

EP0591

The association of adherence counseling and virologic re-suppression in people living with HIV enrolled in the AFRICOS cohort on Tenofovir-Lamivudine-Dolutegravir: a retrospective cohort study, 2013-2024

N. Aitcheson[1], M. Tejan[1], S. Pals[1], J. Fatima da Silva[1], N. Burns[2,3], A. Parikh[3,2], H. Kibuuka[4], J. Maswai[5], V. Singoei[6], E. Bahemana[7], A. Tiamiyu[8], Z. Parker[9], S. Cavanaugh[2], N. Shah[2], J. Ake[2], AFRICOS Study Group

[1]Centers for Disease Control, Division of Global HIV and TB, Atlanta, United States, [2]U.S. Military HIV Research Program, CIDR, Walter Reed Army Institute of Research, Silver Springs, United States, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc, Bethesda, United States, [4]Makerere University Walter Reed Project, Kampala, Uganda, [5]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Kericho, Kenya, [6]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Kisumu, Kenya, [7]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Mbeya, Tanzania, the United Republic of, [8]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Abuja, Nigeria, [9]U.S. Military HIV Research Program, Walter Reed Army Institute of Research Africa, Lagos, Nigeria

Background: The World Health Organization recommends enhanced adherence counseling for people living with HIV (PLHIV) with a viral load (VL) >50 copies/mL. However, the efficacy of adherence counseling in the tenofovir-lamivudine-dolutegravir (TLD) era remains unclear. We examined the association between adherence counseling and virologic re-suppression among PLHIV on TLD in the African Cohort Study (AFRICOS).

Methods: We analyzed data from PLHIV ≥18 years in the AFRICOS cohort (participants enrolled in select PEPFAR-supported clinical sites in Nigeria, Uganda, Tanzania, and Kenya during January 2013-September 2024.

We identified participants with VL >50 copies/ml following TLD initiation, who had at least one pair of VL tests and a completed survey associated with the second VL test within two years of the first VL. The exposure of interest was receipt of adherence counseling, extracted from semi-annual surveys of participants.

We fit a random effects logistic regression model with an outcome of re-suppression of VL to <50 copies/ml, using receipt of counseling and participant's country as fixed effects, participant ID as random effect, and a categorical variable to account for the magnitude of the first VL test result.

Results: Among 3376 PLHIV enrolled in AFRICOS, we identified 753 participants with VL >50 copies/mL on TLD; 54.1% were female, median age was 41.9 years (IQR 30.1, 49.6) and median time on TLD was 1.99 years (IQR 0.99, 2.78). These participants contributed 1258 VL test pairs; VL re-suppression on the second VL test occurred among 75.8% of the pairs. Receipt and non-receipt of counseling was identified in 860 VL pairs; 55.3% of VL pairs were associated with receipt of counseling. Receipt of counseling was not associated with VL re-suppression (OR 1.16, 95% CI 0.79, 1.70).

Conclusions: While virologic re-suppression rates were high among PLHIV taking TLD, there was no association found between receipt of adherence counseling and viral re-suppression. These findings contribute to ongoing discussions about the paradigm shift that may be necessary for adherence support in the TLD era and highlight the need for more robust data on effective adherence interventions beyond counseling alone.

EP0592

From awareness to action: the Condom Boy initiative and community-led HIV solutions in Shamva District HIV hotspot areas

E. Kausiyo[1]

[1]Simukaupenye Integrated Youth Academy, Programming, Shamva, Zimbabwe

Background: The Condom Boy Initiative aims to reduce HIV transmission rates in Shamva District by improving access to condoms and empowering youth and individuals living with HIV. Utilizing a discreet dial delivery system, community members can request condoms, accompanied by educational outreach on safe practices and testing.

The initiative focuses on increasing condom access, empowering the community, enhancing education, reducing stigma, and implementing a robust monitoring framework to evaluate its impact, creating a sustainable model for HIV prevention.

Description: The Condom Boy Initiative was implemented in Ward 20, a mining hotspot with high HIV and STI prevalence due to transient populations and limited healthcare access. Recognizing these unique challenges, the initiative employs a dial delivery system for discreet condom requests, ensuring quick access while reducing stigma.

Alongside distribution, educational outreach promotes safe practices and the importance of regular testing. Engaging local stakeholders has increased visibility and usage, fostering a culture of awareness and empowering residents to manage their sexual health proactively.

Lessons learned: The Condom Boy Initiative has achieved significant outcomes since its launch in Ward 20, an area with high HIV and STI prevalence. Key findings include a 40% increase in condom usage, attributed to the convenience of the discreet delivery service.

Additionally, over 70% of participants reported improved knowledge of safe sex practices and the importance of regular testing. There was also a 30% rise in individuals seeking HIV and STI testing, driven by increased awareness. Positive feedback from 85% of users underscores the model's effectiveness.

Overall, the initiative exemplifies a successful approach to public health in high-risk communities, offering valuable insights for future programs.

Conclusions/Next steps: The Condom Boy Initiative in Ward 20 significantly improved public health outcomes, achieving a 40% increase in condom usage and a 30% rise in testing rates. Its dual approach of accessibility and education empowered individuals and destigmatized

sexual health discussions, with a 70% increase in awareness of safe practices. The initiative's discreet delivery model received 85% user satisfaction, highlighting the importance of confidentiality.
This successful template can guide future public health programs in addressing HIV and STIs in high-risk communities.

EP0593

Social network barriers and facilitators to early infant HIV testing: evidence from women living with HIV in Uganda

A. Comfort[1], J. Adong[2], C. Camlin[1], T. Ruel[1], S. Ashaba[2], J. Moody[3], C. Baguma[2], J. Perkins[4], E. Satinsky[5], J. Kananura[2], E.B. Namara[2], M. Juliet[2], B. Kakuhikire[2], C. Harper[1], A. Tsai[6]
[1]University of California San Francisco, San Francisco, United States, [2]Mbarara University of Science and Technology, Mbarara, Uganda, [3]Duke University, Durham, United States, [4]Vanderbilt University, Nashville, United States, [5]University of Southern California, Los Angeles, United States, [6]Massachusetts General Hospital, Boston, United States

Background: More than one million infants are exposed to HIV perinatally in high-burden African countries, leading to 120,000 infants acquiring HIV each year. Yet, only 60% of infants exposed to HIV worldwide receive guideline-concordant testing at 6 weeks of age.
Maternal factors associated with delays in early infant testing include uncertainty about maternal serostatus, non-disclosure, maternal age, parity, and education. Less is known about the role of social networks – the social ties that women have to others – in influencing early infant testing.
Methods: We conducted a study among women living with HIV who gave birth between 2010-2023. We embedded our study within an on-going longitudinal network study in 8 villages in Nyakabare Parish, southwestern Uganda. We collected social network data using a name generator to elicit all social ties.
We also collected data on social networks barriers and facilitators for infant testing. We present descriptive statistics given the small sample size (N=56).
Results: Only two-thirds of infants born to women living with HIV were tested at 6 weeks. Women had small health networks (size =2).
Three-quarters said they needed their partner's permission to seek infant testing. Half were worried about their partner's reaction if the infant tested positive.
Twenty percent worried about emotional abuse and 9% worried about being chased away.
Yet women had at least one social tie who encouraged infant testing (63%) and would provide financial support (61%), emotional support (80%), or informational support (52%).
More than half would be very likely to seek infant testing if a friend shared their experience with it.

Infant testing at 6 weeks of age	19 (61%)
Size of health network	2 (SD 1.3)
Needs partner's permission to seek infant testing	42 (75%)
Worried about partner's reaction if infant tests positive	24 (43%)
Worried about emotional abuse	11 (20%)
Worried about being chased away	5 (9%)
Has a social tie who encouraged infant testing	35 (63%)
Has social tie who would provide emotional support	45 (80%)
Very likely to seek infant testing if friend shares experience with infant testing	25 (45%)

Table 1. Social network characteristics among women living with HIV related to infant HIV testing.

Conclusions: Although partner involvement is a barrier to infant testing, women living with HIV have social support to facilitate access to infant testing. Friends sharing experience with infant testing can be a strong motivator to seeking early infant testing.

EP0594

Social vulnerability and CD4 cell count among people with HIV and tuberculosis in Uganda

S. Shangani[1], R. Kadel[2], F. Shafie Khorassani[2], N. Sanyu[3], W. Muyindike[3], S. Rossi[4], K. Lunze[4], B. Staitieh[5], T. Kim[4], K. So-Armah[6]
[1]Boston University School of Public Health, Community Health Sciences, Boston, United States, [2]Boston University School of Public Health, Boston, United States, [3]Mbarara University of Science and Technology, Mbarara, Uganda, [4]Boston Medical Center, Boston, United States, [5]Emory University School of Medicine, Atlanta, United States, [6]Boston University School of Medicine, Boston, United States

Background: Increased susceptibility to poor health outcomes due to intersecting socioeconomic and environmental factors (i.e, social vulnerability), affects health of people with HIV (PWH) and tuberculosis (TB). We assessed social vulnerability and CD4 cell count among PWH in TB treatment in Mbarara, Uganda.
Methods: We used data collected from an ongoing, prospective cohort study investigating TB, alcohol use, and lung health among PWH and TB. Using a deficit accumulation approach, we created a 26-item social vulnerability index (SVI) comprised of social determinants of health indicators, with higher scores representing greater social vulnerability. CD4 cell count (≥200 vs <200) was the primary outcome. We compared demographics, psychosocial factors, substance use, and self-rated health across SVI tertiles, with CD4 cell count as the primary outcome.
Results: Among 124 participants (mean age=37±11 years, 53% male), 53% had CD4 counts <200, with mean SVI score of 8.7±3.7. Factors increasing SVI score included economic instability (36% without clear employment, 77% and 66% with insufficient access to help with emergency funds or transportation, respectively); housing (90% without flush toilet, 93% using solid cooking fuel); and few (12%) completing education beyond secondary school. Conversely, access to social support was high with 59-73% reporting sufficient access to visitors who care about them and

provide useful advice including on home/work problems. Those in the highest vs. lowest SVI tertile showed higher rates of depression (76% vs 32%), alcohol dependence (49% vs 20%), illicit drug use (27% vs 15%), unhealthy alcohol use (61% vs. 37%), smoking (29% vs 10%), and poor self-rated health (89% vs 61%). Mean CD4 cell count was 209 (182), 288 (258), and 315 (282) in low, Medium, and high SVI tertile respectively.

Conclusions: Social vulnerability among PWH and TB is characterized by intersecting economic, educational, housing, and social support factors. We detected evidence of association of SVI and mental health symptoms and substance use but not with CD4.

Findings highlight the need to further assess SVI's impact on immune function, substance use, and mental symptoms and develop targeted interventions to address domains driving SVI, particularly mental health and substance use interventions.

EP0595

Pathways to continuity of care: understanding motivations and barriers to ART re-engagement

J. Pienaar[1], A. Manchia[1], T. Fellows[2], M. Harvey[2], S. Le Roux[1], M. Jones[3], T. Whitehead[1], S. Naude[2], J. Joffe[2], R. Knotts[4], B. Muzah[4]

[1]Project Last Mile, Pretoria, South Africa, [2]Genesis Analytics, Johannesburg, South Africa, [3]Project Last Mile, Austin, United States, [4]USAID, Pretoria, South Africa

Background: Despite global initiatives to expand antiretroviral therapy (ART), challenges in maintaining treatment continuity among people living with HIV (PLHIV) persist, which negatively affects both individual health outcomes and broader public health objectives. Approximately 1,141,314 PLHIV in South Africa remain off ART, despite 96% of South Africans being aware of their HIV status.

Project Last Mile aimed to examine the motivations and barriers impacting ART continuity and re-engagement, employing a multivariate analysis to identify key factors influencing these pathways in South Africa.

Methods: This mixed-methods study integrated quantitative analysis of self-reported treatment histories from 1,460 PLHIV with qualitative data derived from interviews with 72 PLHIV and 30 healthcare providers across five provinces. Participants were stratified into two groups: those currently on ART (adherent or previously interrupted but re-engaged) and those with current treatment interruptions. A mixed-effects logistic regression model analyzed the quantitative data, while thematic analysis was used to identify critical determinants and narratives related to ART disengagement and re-engagement.

Results: The quantitative findings revealed that ART interruptions were influenced by a range of factors, including mobility, ART side effects, fear of disclosure, and internalized stigma. Notably, one-third of treatment interruptions occurred within the first year of initiation. Psychosocial challenges, such as treatment fatigue (AOR 1.82; 95% CI 1.26-2.63), lack of social support (AOR 1.77; 95% CI 1.34-2.35), alcohol use (AOR 1.57; 95% CI 1.07-2.31), and substance use (AOR 1.57; 95% CI 1.04-2.37) were significantly associated with treatment disengagement. Qualitative data identified the desire to live healthily (reported by 80% of re-engagers) and caregiving responsibilities as primary motivators for re-engagement, while barriers included fear of judgmental healthcare staff and stigma. Factors such as changing clinics and the presence of supportive healthcare environments were also pivotal in decisions to re-engage.

Conclusions: The findings highlight the complex interplay of psychosocial, structural, and healthcare system-related factors influencing ART adherence. These results suggest that interventions should be tailored to address both individual and systemic barriers. Key strategies include expanding differentiated service delivery, improving healthcare provider attitudes, addressing stigma, and integrating psychosocial support within treatment programs.

EP0596

Re-organizing clinical processes, workflow and task-shifting to integrate HIV and NCD care: results of a formative mixed methods evaluation in Lusaka, Zambia

O. Mweemba[1], M.E. Herce[2,3], C. Mwila[2], C. Mandyata[2], C. Frimpong[2], M. Siame[2], P. Shankalala[2], P. Mbewe[2], T.F.L. Matenga[1], P. Chisenga[2], P. Sichone[2], W. Mutale[4]

[1]University of Zambia, School of Public Health, Department of Health Promotion and Education, Lusaka, Zambia, [2]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [3]Institute for Global Health and Infectious Diseases, University of North Carolina, Chapel Hill, Zambia, [4]University of Zambia, School of Public Health, Department of Health Policy and Management, Lusaka, Zambia

Background: The risk of cardiometabolic non-communicable diseases (NCD) is increasing in the aging global cohort of people living with HIV (PLHIV), calling for a dedicated response. This abstract describes the process of re-organizing clinical workflows in antiretroviral therapy (ART) clinics in readiness for integrating NCD screening, diagnosis, treatment, and care into HIV services in Lusaka, Zambia.

Methods: A qualitative study design was used at four health facilities in Lusaka, Zambia. The design included four consultative focus group discussions with healthcare providers, four consultative focus group discussions with community healthcare workers, and four consultative focus group discussions with policymakers. It also included 20 in-depth interviews with PLHIV with cardiometabolic NCDs and six key informant interviews with senior clinicians and policymakers. A thematic analysis incorporating inductive and deductive codes was used to analyze the data.

Results: Our findings showed that integrated HIV/NCD care delivery requires change within the HIV program. This includes task-shifting NCD screening to lay healthcare workers and NCD management to non-physician health workers given specific roles and responsibilities. Increased workload and limited capacity to manage new tasks, such as resistant hypertension in PLHIV with multi-

ple co-morbidities, may act as a barrier to HIV/ NCD integration. Increasing the availability of NCD medications, treatment guidelines, and diagnostic tools in the ART clinic can make integration more effective. PLHIV noted the increased client-centeredness that comes with integration: "*I felt good because firstly, you care, and second, there is no long process, no congestion because everything is done at one place.*" (Male IDI participant).
Healthcare providers were motivated to provide integrated services due to increased awareness of NCD co-morbidities in PLHIV and greater confidence in delivering NCD through training. To effectively integrate NCD services into HIV care, the participation and buy-in of Ministry of Health leadership is crucial.
Conclusions: Health facilities are ready to implement HIV/NCD integration in Zambia, but strengthening the essential health system is required to support smooth integration. This includes trained and motivated human resources, consistent drug supplies, diagnostic resources, and improved clinic flow for PLHIV, with a focus on a one-stop shop for receiving care for both HIV and NCDs by PLHIV.

EP0597

Data from the Positive Perspectives 3 Study highlights the continued need for expansion of awareness, belief and confidence in undetectable equals untransmittable (U=U)

R. Patel[1], B. Allan[2], G. Brough[3], M. Cascio[4], E. Castellanos[5], A. Cingolani[6], V. Dubula[7], W.D. Hardy[8], K. Iwahashi[9], S. Mbudwini[10], M. McBritton[11], M. Ndungu[12], B. Richman[13], M. Shibemba[14], A. Appiah[1], D. Fox[15], M. Mayer[16], S. Mellors[1], V. Vega[15], N. Nwokolo[1]
[1]ViiV Healthcare, London, United Kingdom, [2]National Association of People Living with HIV Australia,, Newtown, Australia, [3]Transformation Partners in Health and Care, London, United Kingdom, [4]European AIDS Treatment Group (EATG), Bruxelles, Belgium, [5]Global Action for Trans Equality (GATE), Mijdrecht, Netherlands, the, [6]Fondazione Policlinico A. Gemelli, IRCCS, Catholic University of the Sacred Heart, Roma, Italy, [7]The Global Fund, Geneva, Switzerland, [8]USC Rand Schrader (HIV) Clinic, Keck School of Medicine of USC, Los Angeles, United States, [9]Akta, Tokyo, Japan, [10]Nelson Mandela University, Port Elizabeth, South Africa, [11]Barong, São Paulo, Brazil, [12]Women's Health in Women's Hands Community Centre, Toronto, Canada, [13]Prevention Access Campaign, New York City, United States, [14]Independent Consultant, Manchester, United Kingdom, [15]ViiV Healthcare, Durham, United States, [16]ViiV Healthcare, Paris, France

Background: The Positive Perspectives studies are global, cross-sectional surveys of people living with HIV co-designed by community advocates, people living with HIV, healthcare providers and industry representatives. The third Wave of the Study launched in 2024.
Methods: This analysis utilized interim data from 834 participants in Positive Perspectives Study Wave 3 from adults living with HIV on antiretroviral therapy (ART) from Australia, Argentina, Chile, South Africa, Colombia, Italy, and USA. Variables examined included U=U awareness, stigma, and emotional challenges. Binary logistic regression was used to measure the relationship between awareness of U=U and various quality-of-life indicators, adjusting for age, gender, and income.
Results: 58.0% of people living with HIV reported being aware of U=U; of these, 64.1% reported being informed about U=U by their healthcare provider, 23.1% by other people living with HIV, 20.9% by the internet, 17.2% by social media, and 16.3% by general non-HIV healthcare personnel.
65.1% agreed that U=U-awareness had potential to increase confidence and enjoyment during intimacy. 67.7% and 64.7% recognized its potential to reduce internal and external stigma, respectively. However, of those aware of U=U, 35.0% did not feel confident explaining it to others and 39.9% expressed hesitancy about engaging in condomless sex with an HIV-negative partner, citing fears of residual transmission risk despite an undetectable viral load.
Among all participants with HIV-negative partners (n=148), HIV prevention strategies included condoms (64.2%), reliance on U=U (35.1%), and PrEP (29.1%).
Awareness of U=U was associated with improved perceptions of ART's impact on daily well-being (AOR=1.89, 95% CI:1.02–3.50), self-reported viral suppression (AOR=5.43, 95% CI:2.83–10.43), optimal sexual health (AOR=1.91, 95% CI:1.02–3.57), treatment satisfaction (AOR=2.42, 95% CI:1.31–4.49), and comfort discussing specific medications with healthcare providers (AOR=2.49, 95% CI:1.36–4.54).
Conclusions: U=U awareness was reported by a small majority of people (58%), and even amongst those, there was a lack of belief in the message; almost 40% of those aware of U=U did not feel comfortable having condomless sex even if they were virally suppressed. This highlights the need for more clear and effective communication to raise awareness, belief and confidence in U=U, and its impact on people's lives.

EP0598

Understanding preference trade-offs among South African adolescent boys and young men (ABYM) to inform user-centric target product profiles for next generation HIV vaccine design – is vaccines solely preferred?

H. Makkan[1,2], P. Saha[3], P. Masibi[4], L. Raseroka[4], P. Makhakha[1], F. Mthembu[4], K. Ondeng'e[5], Y.W. Machira[5], P. Maenetje[1,6], V.A. Edward[1,2,7,6], J. Mukherjee[8], S. ul Hadi[8]

[1]The Aurum Institute, Rustenburg Clinical Research Centre, Rustenburg, South Africa, [2]Utrecht University, Department of Interdisciplinary Social Science, Public Health, Utrecht, Netherlands, the, [3]Independent Researcher, Gurugram, India, [4]Independent Researcher, Rustenburg, South Africa, [5]Independent Researcher, Nairobi, Kenya, [6]Vanderbilt University, Department of Medicine, Nashville, United States, [7]University of KwaZulu-Natal, School of Health Sciences, College of Health Sciences, Durban, South Africa, [8]IAVI, Gurugram, India

Background: Adolescent boys and young men (ABYM) are at high-risk for acquiring HIV and require highly effective HIV vaccines. In developing next generation HIV vaccines, considerations for understanding user-centric target product profiles to inform vaccine design is important. Thus, this study aims to understand the drivers in product choice and unique vaccine value perceptions among South African ABYM.

Methods: We recruited ABYM 15-24-years-old within Rustenburg, South Africa. Ethical approval was received, and participants appropriately assented/consented. A cloud-based App choice experimentation tool was developed, testing thresholds of maximum vaccine burden for minimum benefits. Vaccine scenarios included combinations of trade-off attributes: increasing/decreasing burden (number of vaccinations (shots), side effect (SE) intensity, SE likelihood of occurrence); varying vaccine benefits (degree of protection, duration (period) of protection, and possible disease elimination).

A skip logic algorithm informed the next vaccine combination to propose, dependent on acceptance or rejection response to previous combination.

Results: Among the 75 ABYMs, 76.0% were 15-19 years old, 54.7% obtained secondary level education, and 82.7% believed they were ≤50% at-risk of acquiring HIV. Scenario1 included degrees and durations of protection as benefit combined with the burden for numerous vaccine shots, where 93.0% were accepting high burden (6-8 shot over 2.5 years), wherein 25% opted for the lowest benefit (40-60% protection over 2-3 years) and 49% opting for greater duration of protection (≥40% degree and ≥4 years protection). Scenario2 included the possibility of diseases elimination by vaccine alone or a vaccine in combination with a drug regimen, where 57% preferred the vaccine only option, and 21% were accepting of highest SE burden (severe SEs occurring rarely). 17% did not accept any SE burden even when offered the vaccine only option to achieve disease elimination.

Conclusions: ABYM prefer vaccines alone as an option to reach disease elimination and were accepting of multiple shots within vaccination schedules. SEs and duration of protection are considerable drivers in vaccine choices too. These findings provide critical evidence toward vaccine design considerations for next generation vaccines for ABYM in Rustenburg and possibly South Africa.

EP0599

Identifying African American women's-specific barriers and strategies to increase pre-exposure prophylaxis (PrEP) use among them

S.D. Ayangeakaa[1], B.R. Fortino[2], F. Hammond[2], N.J. Molokwu[2], B.J. Ncube[2], D. Scott[3], J. Iradukunda[2], I. Navarro[2], J. Benner[4], T. Michel[4], R. McDaniel[5], T. Stancil[6], J.D. Prayer[7], L.F. Riggins[8], A. Corneli[2]

[1]Duke University, Department of Population Health Sciences; Duke Global Health Institute, Durham, United States, [2]Duke University, Department of Population Health Sciences, Durham, United States, [3]North Carolina A&T State University, Greensboro, United States, [4]North Carolina Central University, Durham, United States, [5]NC AIDS Action Network, North Carolina, United States, [6]Health Education Services, North Carolina, United States, [7]NC AIDS Action Network; Center for Black Health & Equity, North Carolina, United States, [8]North Carolina State University, Raleigh, United States

Background: African American cisgender women (AACW) face disproportionately high rates of HIV among women in the U.S. Pre-exposure prophylaxis (PrEP) effectively prevents HIV, but few AACW use it. Our study identified AACW-specific PrEP use barriers and strategies to inform a culturally responsive, strength-based intervention to increase PrEP use.

Methods: Guided by an intersectional lens, we conducted in-depth interviews (IDIs) with 12 AACW and three focus group discussions (FGDs) with 21 AACW in a southern U.S. metropolitan area. Interviews explored stigma and perceptions of HIV/PrEP, while focus groups confirmed IDI findings and identified intervention preferences.

We identified key themes across IDI participants through rapid qualitative analysis and a review of FGD notes and transcripts.

Results: IDI and FGD participants were on average 35 years old (range:19–54) and 33 years old (range:19–53), respectively. IDI participants were aware of PrEP but viewed it as intended for sexual minorities, sex workers, or persons who use drugs.

Participants also noted poor community perception of HIV vulnerability. Nearly all described facing stigma related to race, gender, or sexuality with half reporting healthcare discrimination. While anticipated PrEP stigma was not tied to their identities, several identified stigma around sexual health discussions and difficulty discussing HIV prevention with partners as barriers.

Similarly, FGD participants showed PrEP awareness, but several had misconceptions about its purpose and or their eligibility. Participants confirmed low PrEP awareness and HIV vulnerability perception among AACW.

They also shared preferred intervention strategies including: i) plain language messaging, relatable stories, age-specific group education by gender, and race-con-

cordant facilitators; ii) normalizing HIV/STI conversations and framing sexual health (e.g., STI testing) as self-care; iii) acceptance of self-empowerment and cognitive behavioral techniques (e.g., role-playing) for stigma reduction and resilience-building; iv) virtual or hybrid sessions with gender/race concordant PrEP providers for transparent communication about costs, side effects, and PrEP options; v) optional sessions for AACW's support system, including partners, family, or peers; and vi) prioritizing intervention towards younger more sexually active AACW.
Conclusions: Findings highlight the need for culturally responsive interventions that leverage community strengths to improve PrEP use, reduce stigma, empower AACW, foster partner communication, and address HIV disparities.

EP0600

Elicitation of eligible children through family index testing: insights from the FCT pilot in Nigeria

M.C. Morka[1], A. Bashorun[1], O. Omongbale[1], E. Etiobhio[1], Nigeria FIT team
[1]*Federal Ministry of Health, Public Health, Abuja, Nigeria*

Background: Family Index Testing (FIT) programs aim to identify HIV-positive children by tracing and testing eligible contacts of HIV-positive individuals. The FCT pilot evaluated the effectiveness of eliciting eligible children, informing the program's expansion.
Methods: Data from the FCT pilot were analyzed to assess the number of index clients enrolled, the responses obtained, and the number of eligible children elicited for HIV testing. Index clients provided information on their family contacts, including children eligible for testing based on program criteria.
Data from 5,432 index clients were analyzed to assess response rates and the average number of children elicited per client. Inferential statistics included a z-test for response rates and a t-test for elicitation averages.
Results: Of the 5,432 index clients, 4,999 (92%) provided family contact information. The z-test confirmed this response rate was significantly higher than the expected 90% ($z = 4.98$, $p < 0.001$). From these responses, 1,046 children were identified for testing, with an average of 0.21 children elicited per client highlighting variability based on family structure and disclosure dynamics. A t-test revealed this average was significantly lower than the expected 0.25 ($t = -533.45$, $p < 0.001$).
Conclusions: The FCT pilot demonstrates the feasibility of eliciting eligible children for HIV testing through family index testing. The high response rate among index clients underscores the acceptability of the approach.
However, the lower-than-expected elicitation per client suggests the need for targeted strategies to optimize engagement. It also highlights the need for tailored strategies to optimize contact tracing and engagement.
These insights are critical as the FIT program scales nationwide to strengthen pediatric HIV identification and linkage to care.

EP0601

Addressing silent barriers affecting HIV-positive young mothers with HIV-positive infants in adhering to antiretroviral therapy

M. Banda[1]
[1]*Women IN Climate Action, Programmes Coordination, Harare, Zimbabwe*

Background: HIV-positive young mothers with HIV-positive infants face multiple barriers to adhering to antiretroviral therapy (ART), including stigma, poor mental health support, and socioeconomic vulnerabilities. Key drivers such as gender inequality, limited healthcare access, and cultural norms exacerbate these challenges. Determinants including age, education levels, and lack of social support significantly influence ART adherence.
To address these issues, Women in Climate Action implemented a community-based initiative aimed at improving adherence rates and enhancing health outcomes for young mothers and their infants.
Description: The program, conducted from 2022 to 2024 in rural districts of Zimbabwe, focused on young mothers aged 16–25. Key interventions included establishing peer-led support groups, providing tailored mental health counselling, and conducting home-based follow-ups by trained community health workers.
Nutrition support and health literacy workshops addressed key determinants such as misinformation, poverty, and poor dietary practices.
Strong partnerships with local healthcare facilities ensured alignment with national HIV care strategies and facilitated seamless referrals for specialized medical care.
Lessons learned: The initiative led to a 40% increase in ART adherence among participants, with noticeable improvements in maternal mental health and empowerment. Peer-led support groups were highly effective in reducing stigma and building emotional resilience, while home-based care minimized clinic-associated stigma.
Addressing key determinants, such as poverty and misinformation, contributed to sustained adherence. Challenges like resource limitations and cultural resistance were mitigated through community engagement and collaborations with local stakeholders.
Conclusions/Next steps: The program demonstrates that addressing key drivers and determinants such as stigma, economic barriers, and lack of healthcare access is critical to improving ART adherence.
Expanding the initiative to underserved areas and incorporating digital health tools for education and monitoring can enhance its reach and impact.
This approach offers a scalable framework for addressing the unique barriers faced by young mothers living with HIV, contributing to global HIV prevention and treatment goals while promoting maternal and child health.

EP0602

Enhancing HIV treatment adherence through behavioral interventions: tackling stigma, discrimination, and human rights violations in healthcare settings

S. Ntamo[1], T. Mpitso[2], T.M. Ndhlovu[3], C. Moyo[3], M. Malahlela[3], N. Tshuma[3]

[1]Women Believes Connection, Community Based Organisation, Mangaung, South Africa, [2]Office of the Premier, Provincial Council on AIDS, Bloemfontein, South Africa, [3]Best Health Solutions, Public Health, Johannesburg, South Africa

Background: In Mangaung's Batho location, significant progress has been made in managing HIV, TB, and STIs. However, stigma and discriminatory behaviors from some healthcare workers continue to impact client retention and adherence, contributing to a 29% treatment default rate and increased risk of disease progression.

This project aimed to address these challenges through targeted behavioral interventions designed to improve adherence by fostering stigma-free, supportive healthcare environments.

Methods: Implemented across four healthcare facilities over 12 months, the program focused on training 150 healthcare workers on stigma reduction, human rights, and patient-centered care. A confidential patient feedback mechanism, utilized by 2,450 client, provided insights into barriers to treatment adherence, identifying key themes such as fear of disclosure (67%), perceived judgment (54%), and inadequate support structures (39%). Linkage officers engaged with 1,209 patients, facilitating referrals and supporting adherence monitoring through individualized counseling sessions.

Community dialogues and support group formations were introduced to strengthen social support networks and reinforce adherence messaging.

Results: Findings indicate that targeted behavioral interventions contributed to a 36% increase in adherence rates, with viral suppression improving from 64% to 71% within the intervention period.

Notably, healthcare worker attitudes showed a measurable shift, with 75% of trained personnel demonstrating improved patient interaction scores based on post-training evaluations.

Furthermore, patient-reported stigma experiences decreased by 41%, highlighting the intervention's impact on fostering more inclusive healthcare environments. The program also identified critical factors influencing adherence, including healthcare worker sensitivity, peer support utilization, and family engagement.

Facilities that incorporated routine client feedback saw a 25% improvement in service satisfaction scores, indicating the value of ongoing participatory approaches.

Conclusions: The findings underscore the effectiveness of behavioral interventions in enhancing adherence and addressing stigma at systemic and interpersonal levels. Future efforts should focus on scaling up the program, integrating digital adherence monitoring tools, and advocating for policy changes to institutionalize stigma reduction training within healthcare facilities.

Sustained investment in patient-centered approaches will be crucial to achieving long-term HIV treatment outcomes and reducing health gaps.

EP0603

HIV 95-95-95 global epidemic control targets: achieving the 3rd 95 in children and adolescents living with HIV through a comprehensive program targeting vulnerable children and adolescents in Zambia

C.K. Mukelabai[1], Y. Mulenga[2], G. Mwiinga[3], V. Mulubwa[4]

[1]Project Concern Zambia, Strategic Information, Lusaka, Zambia, [2]Project Concern Zambia, Technical Advisor, Lusaka, Zambia, [3]Project Concern Zambia, Chief of Party, Lusaka, Zambia, [4]Project Concern Zambia, Deputy Chief of Party, Lusaka, Zambia

Background: Zambia has generally achieved HIV epidemic control as set in the global 95-95-95 targets, however, not all the three targets have been achieved in sub populations including children and adolescents. As part of the USAID-funded Empowered Children and Adolescent Program II (ECAPII), Project Concern Zambia is reaching vulnerable children and adolescents (VCA) with person-centered HIV services across the prevention and care cascade and their households are reached with family-centered socioeconomic services to address the social determinants of health. The program aims to contribute to the achievement and sustenance of HIV epidemic control in children and adolescents.

Description: Between 2020 and 2024, PCZ trained 467 Community Case Workers (CCWs) in case management and HIV treatment literacy and adherence emphasizing "U=U" (Undetectable = Untransmissible) messaging to achieve viral load (VL) suppression in 171 highly unsuppressed children and adolescents (0-20 years) living with HIV (C/ALHIV).

Through home visits informed by case plans, CCWs reached the C/ALHIV with adherence support and care services, including daily assisted administration of ART (DAART) for 3-6 months, escort to VL testing services and home-based collection of VL samples in partnership with healthcare workers, and tracked VL suppression. VL ranged from 1,100 to 8,060,000 copies. The goal was to improve treatment outcomes through targeted interventions.

Lessons learned: Of the 171 virally unsuppressed C/ALHIV enrolled in the program, 84 % (144/177) were virally suppressed successfully receiving DAART and other adherence support services outlined in their case plans. Other outcomes included 8 C/ALHIV who had VL results pending at the close of the reporting period, 1 was transferred to another care program, and 18 remained unsuppressed and continued to receive care.

	n	%
Total with Suppressed VL at the end of the follow-up period	144	84
Total Unsuppressed C/ALHIV with Other outcomes	27	16
Total	171	100

Conclusions/Next steps: The program was effective for the majority of C/ALHIV, indicating the effectiveness of person-and family-centered adherence support case management services in achieving VL suppression in C/ALHIV and improving HIV treatment outcomes.
The virally unsuppressed participants documented suggests need for further targeted support to address barriers to viral suppression, including the social determinants of health that the program is also seeking to address.

EP0604

Bridging gaps in HIV prevention in high-risk prison environment: a bespoke psychosocial intervention achieved a breakthrough in Kyrgyzstan

J. Rozanova[1,2], A.A. Deac[3,4], V. Fedorchenko[5], S.V. Shenoi[1,2], O. Zeziulin[6], N. Shumskaya[7]
[1]Yale University School of Medicine, Section of Infectious Diseases, New Haven, United States, [2]Yale University School of Public Health, Centre for Interdisciplinary Research on AIDS (CIRA), New Haven, United States, [3]University of East London, Institute for Connected Communities, London, United Kingdom, [4]King's College London, Department of Health Services & Population Research, London, United Kingdom, [5]SI "Public Health Center of the Ministry of Health of Ukraine", Kyiv, Ukraine, [6]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [7]AIDS Foundation East-West in the Kyrgyz Republic, Bishkek, Kyrgyzstan

Background: Kyrgyzstan provides in-prison opioid agonist therapy (OAT). With 9,500 inmates, of which 75% have a history of injecting drug use (IDU) including one-third within the prison, and an HIV prevalence rate of 10.3%, Kyrgyzstan offers crucial opportunities for studying HIV prevention improvement.
Methods: We developed and piloted a 12-week intervention HOPE (Help OAT Prison Engagement) from October 2022 to January 2024 to assess its feasibility, acceptability, and preliminary efficacy in linking eligible individuals to OAT in two male prisons compared with two male comparison prisons. HOPE included twice-weekly group psycho-educational sessions to improve mental health and boost motivation for addiction self-management.
Ninety-eight participants who are HIV-negative persons and have a history of IDU but not on OAT at enrollment were surveyed at baseline, at 3-, 6-, and 12-months follow-up. Multivariable logistic regression models were used in R version 4.0.0 to identify factors associated with changes in mental health and OAT initiation.
Results: Mean age was 45 years (SD = 9.1). By 6 months, six (11.54%; 95% CI 4.78- 24.13) HOPE participants-initiated OAT compared to 1 (2.27%, 95% CI, 0.12-13.51) of controls. The difference was not statistically significant (p=0.12).
Life satisfaction score increased significantly in HOPE group, from 20.3 at screening to 26.1 at 12 months (p<0.001). Depressive symptoms decreased significantly in HOPE group (p<0.001), from 19.0 at screening to 12.5 at 12 months but increased in control group from 17.0 to 18.6 (p<0.001). The HOPE group's self-reported resilience scores significantly improved from 2.9 (p= 0.019) at screening to 3.5 at 12 months (p=0.002).
Factors significantly associated with positive mental health changes were HOPE participation (β = 3.3; 95% CI: 0.73 -5.9, p=0.012), colony type (β = 7.4; 95% CI: 5.1–9.7; p < 0.001) and having children (β = 2.9; 95% CI: 0.82 - 4.9, p=0.006).
Conclusions: People in prison with IDU history can benefit from culturally tailored psychosocial intervention to improve OAT uptake as part of HIV prevention. This approach promotes positive behavioural change, improves their resilience and life satisfaction, and reduces depressive symptoms. Investigating the overall impact, cost-effectiveness, and barriers to scale-up will help improve HIV prevention and well-being in prisons worldwide.

EP0605

Increasing access to HIV testing services (HTS) for adolescent girls through OVC case management in southern and central provinces, Zambia

G. Mwiinga[1], V. Mulumbwa[2], C. Mukelabai[3], Y. Mulenga[4]
[1]Project Concern Zambia, Chief of Party, Lusaka, Zambia, [2]Project Concern Zambia, Deputy Chief of Party, Lusaka, Zambia, [3]Project Concern Zambia, Strategic Information, Lusaka, Zambia, [4]Project Concern Zambia, Technical Advisor, Lusaka, Zambia

Background: In 2024, Adolescents and Young People (AYP) accounted for 48% of new HIV acquisition in Zambia and Adolescent Girls accounted for more HIV acquisition than Adolescent Boys. Project Concern Zambia (PCZ), through USAID ECAPII, implements the Orphans and Vulnerable Children (OVC) Case Management Program that includes targeting vulnerable AYP at elevated risk of HIV acquisition and reaching them with long term and high impact community-based HIV prevention services.
Description: Between 2023 and 2024, PCZ integrated HIV testing services into the OVC Case Management program, trained, and certified 100 Case Workers to reach AYP at elevated risk of HIV with high impact HIV prevention services as part of OVC case management.
The HIV risk assessment tool was integrated into a vulnerability assessment tool to identify AYP at elevated risk. 12 Adolescents Agents of Change were mobilized, and they fostered adolescents access to non-discriminatory HIV testing services including index and social network testing, socioeconomic, and sexual and reproductive (SRH) services. AYP testing HIV-positive were linked to treatment services and those testing HIV-negative continued to receive HIV prevention services as part of OVC case Management.

FY	Total Tested		Grand Total Tested	Total Positive		Grand Total Positive
	Male	Female		Male	Female	
2023	997	1,498	2,495	4(0.4%)	6(0.4%)	10(0.4%)
2024	832	1,654	2,486	12(1.4%)	69(4%)	81(3%)
Total	1,829	3,152	4,981	16(0.8%)	75(2%)	91(2%)

Lessons learned: A total of 4,981 AYP at elevated risk of HIV acquisition were reached with HIV Testing services and other primary prevention interventions including

Pre-Exposure Prophylaxis (PrEP) and social care services such as Social Cash Transfers. A total of 91 (2%) AYP tested HIV- positive.

More Adolescent Girls (2% positivity yield) tested HIV-positive relative to Adolescent Boys (0.8%). After integration of index testing and social network testing in 2024, the positivity yield in adolescent girls significantly increased to 4% from 0.4% in 2023.

Conclusions/Next steps: The project's interventions led to a significant increase in HIV case finding among Adolescent Girls. The findings also indicate that community HIV programs should target adolescent girls with comprehensive primary prevention interventions as they are more at risk of HIV acquisition relative to their male counterparts.

EP0606

Advancing adolescent SRHR: a holistic approach to integrated care and service delivery for young people in Tanzania

D. Lyimo[1], A. Massawe[1], A. Mtuga[1]
[1]Children's Dignity Forum, Programs, Dar es Salaam, Tanzania, the United Republic of

Background: Adolescents and young people (AYP) aged 10–25 face critical sexual and reproductive health (SRH) challenges, including teenage pregnancies, unsafe abortions, sexually transmitted infections (STIs), and HIV. The You(th) Care Project, implemented by the Children's Dignity Forum (CDF) and Network of Young People Living with HIV (NYP+), in Tanzania's Tarime District, seeks to empower AYP especially girls and vulnerable adolescents to advocate for SRHR, practice self-care, and access digital self-care services.

Implementing the Youth Care (YC) project effectively requires a strategic approach that addresses the unique needs of young people while ensuring sustainability and impact. Key approaches include Stakeholder Engagement and Collaboration, Capacity Building and Training and Community Sensitization and Awareness Creation.

Methods: A mixed-methods evaluation approach was employed, including case study design, with data collected from 100 participants across six health facilities in Tanzania. Methods comprised questionnaires, semi-structured interviews, focus group discussions, and document reviews.

Quantitative data were analysed using SPSS, while qualitative data were transcribed and thematically analysed. Policies and laws related to SRHR were also reviewed to identify gaps and propose necessary reforms.

Results: The project achieved significant improvements in SRH outcomes for AYP, with 96% reporting knowledge of safe contraceptive use, 94% aware of HIV testing procedures, and 68% understanding family planning methods. Positive attitudinal shifts included reduced HIV stigma 93% and greater comfort discussing HIV with partners 72%.

Behavioural changes included increased condom use 81% and regular HIV testing 69%. AYP demonstrated greater agency, with 79% serving as referral points and 73% actively demanding SRH commodities. Social norm changes were noted, including enhanced support from decision-makers and reduced stigma by healthcare workers. However, barriers such as limited youth-friendly infrastructure and restrictive policies persisted.

Conclusions: The You(th) Care Project has effectively increased SRHR knowledge, attitudes, and behaviors among AYP while promoting supportive social norms.

However, challenges, including inadequate budget allocations, policy barriers, and limited health infrastructure, underscore the need for:

- Policy amendments to reduce barriers, such as age restrictions for SRH services.
- Increased funding to expand youth-friendly services.
- Investments in community-based education and infrastructure to sustain progress.

EP0607

Why PrEP fails: drivers of PrEP discontinuation among adolescent girls and young women who subsequently acquired HIV in five HIV high prevalence districts in South Africa

P. Potsane[1], C. Sokhela[1], N. Mtshali[1]
[1]Shout-It-Now, Centurion, South Africa

Background: Pre-Exposure Prophylaxis (PrEP) has demonstrated a 99% reduction in HIV acquisition when taken as directed. However, poor adherence to PrEP is common, especially among young people, resulting in breakthrough HIV acquisitions.

This study aimed to understand the lived experiences, challenges, and perceptions of Adolescent Girls and Young Women (AGYW) who initiated but discontinued PrEP use, and then subsequently acquired HIV.

Methods: A mixed-methods study combining quantitative and qualitative approaches was conducted among AGYW aged 18-31 years who acquired HIV after discontinuing oral PrEP use from January 1, 2023 to December 31, 2023. Outreach nurses at mobile clinics conducted a clinical file audit of 243 clients who received oral PrEP but subsequently seroconverted following PrEP interruption.

Additionally, semi-structured telephonic interviews were conducted by nurses with these clients to explore contributing factors to their PrEP interruption.

Results: The results from the file audit and semi-structured interviews found that the primary reasons for PrEP discontinuation were forgetfulness 58.8% (n=143), perceived lack of HIV risk/perceived lack of need for PrEP 25.5% (n=62), and side effects from PrEP medication 15.6% (n=38).

Furthermore, this cohort's risk for HIV acquisition was highlighted by the fact that 85.2% (n=207) of participants were unaware of their partner's HIV status, and 63.1% (n=152) reported inconsistent condom use.

Conclusions: The findings highlight the importance of delivering consistent client reminders to address forgetfulness, promoting continuous provided-initiated HIV risk assessments, and providing ongoing PrEP literacy.

Additionally, the findings support the critical encouragement of young women on PrEP to utilize dual protection HIV methods (e.g., PrEP and condoms). Utilizing these ap-

proaches, programs providing PrEP to AGYW can strengthen adherence support to optimize PrEP effectiveness and prevent HIV transmission in this vulnerable population.

EP0608

Joint patient-provider decision making was associated with improvements in quality of life, adherence and treatment satisfaction for people living with HIV in the Positive Perspectives 3 study

R. Patel[1], B. Allan[2], G. Brough[3], M. Cascio[4], E. Castellanos[5], A. Cingolani[6], V. Dubula[7], W.D. Hardy[8], K. Iwahashi[9], S. Mbudwini[10], M. McBritton[11], M. Ndungu[12], B. Richman[13], M. Shibemba[14], A. Appiah[1], D. Fox[15], M. Mayer[16], S. Mellors[1], V. Vega[15], N. Nwokolo[1]
[1]ViiV Healthcare, London, United Kingdom, [2]National Association of People Living with HIV Australia, Newtown, Australia, [3]Transformation Partners in Health and Care, London, United Kingdom, [4]European AIDS Treatment Group (EATG), Bruxelles, Belgium, [5]Global Action for Trans Equality (GATE), Mijdrecht, Netherlands, the, [6]Fondazione Policlinico A. Gemelli, IRCCS, Catholic University of the Sacred Heart, Roma, Italy, [7]The Global Fund, Geneva, Switzerland, [8]USC Rand Schrader (HIV) Clinic, Keck School of Medicine of USC, Los Angeles, United States, [9]Akta, Tokyo, Japan, [10]Nelson Mandela University, Port Elizabeth, South Africa, [11]Barong, São Paulo, Brazil, [12]Women's Health in Women's Hands Community Centre, Toronto, Canada, [13]Prevention Access Campaign, New York City, United States, [14]Independent Consultant, Manchester, United Kingdom, [15]ViiV Healthcare, Durham, United States, [16]ViiV Healthcare, Paris, France

Background: For people living with HIV, improving quality of life can, in part, depend on a strong relationship with healthcare providers (HCPs) to navigate treatment and optimise care. This analysis assessed the quality of relationships between people living with HIV and their HCPs, focusing on trust, comfort in discussing sensitive issues, and satisfaction with care.
Methods: This analysis utilized interim data from 834 participants in Positive Perspectives Study Wave 3 from adults on antiretroviral therapy (ART) from Australia, Argentina, Chile, South Africa, Colombia, Italy, and USA. Descriptive data were summarized with percentages, and logistic regression analysis was used to explore how involvement in treatment decisions influenced treatment-related outcomes. Multivariable analysis adjusted for age, gender and income.
Results: Overall, 62.7% reported high trust in their HCPs, however, 45.5% did not feel comfortable discussing sensitive issues (e.g., sexual health), 50.1% reported that they were not consulted by their HCP before prescribing their current HIV medication, and 43.9% were not satisfied with their involvement in treatment decisions. Additionally, 54.2% indicated that their HCP did not regularly check their satisfaction with their treatment.
48% (405 participants) indicated they were dissatisfied with an aspect of their visit in the past 12 months, and as a result 19.0% of those individuals sought clarifying information on their own, 12.0% sought a second opinion from another provider, 11% reported missing their HIV medication because of their dissatisfaction, 10.6% consulted friends for advice, and 8.9% missed their next scheduled visit.
People living with HIV who reported being involved in the treatment decision for their current HIV medication were more likely to report satisfaction with the treatment (AOR=2.17, 95% CI:1.47–3.20), compatibility with other non-HIV medications they were taking (AOR=1.76, 95% CI:1.21–2.57), alignment with their lifestyle (AOR=2.53, 95% CI:1.72–3.73), improvement in quality of life (AOR=2.14, 95% CI:1.45–3.14), and less likely to skip their medication (AOR=0.41, 95% CI:0.23–0.65).
Conclusions: These findings highlight the need to enhance patient-provider interactions and encourage collaborative decision-making. Strengthening these aspects may minimise loss-to-care, improve adherence, and enhance overall care quality, leading to better health outcomes for people living with HIV.

EP0609

Determinants of cervical cancer screening uptake among women living with HIV in Rwanda

A. Tuyishime[1], G. Gatete[1], F. Uwinkindi[1], G. Rwibasira[1]
[1]Rwanda Biomedical Centre, HIV/AIDS Disease Prevention and Control, Kigali, Rwanda

Background: Women living with HIV (WLHIV) face a higher risk of developing cervical cancer due to persistent human papillomavirus (HPV) infections. Despite this risk, cervical cancer screening uptake remains suboptimal in Rwanda. Identifying determinants of screening uptake is essential for targeted interventions.
Methods: A national cross-sectional study was conducted among 5,606 WLHIV aged 15 years and above, from January to July 2024. Participants were recruited from 115 HIV care clinics across all provinces and the City of Kigali in Rwanda. Data on cervical cancer screening history, sociodemographic characteristics, clinical profiles were collected via structured interviews and medical record reviews. Cervical cancer screening was performed in WLHIV aged 25-65 years as per the national cervical cancer screening guideline.
Multivariate logistic regression was used to identify factors associated with screening uptake within the past five years. Adjusted odds ratios, and corresponding 95% confidence intervals (CI) were reported.
Results: The study included 5,606 WLHIV, of whom 5,284 were eligible for cervical cancer screening. Among these eligible participants, 44% (n = 2,375) reported undergoing cervical cancer screening before the survey, and 2,091 WLHIV aged 25-65 years were screened during the survey. Screening uptake was significantly higher among women aged 45-54 years (50%, p= <0.001). Among those who had not been screened, 76.2% reported lack of awareness about cervical cancer screening, and 17.3 % lack of cervical cancer screening services at the nearest health facility as a reason for not undergoing screening.
Conversely, among those who had been screened, 20.8% attributed their decision to health education by health care providers, 46.5% to the availability of screening ser-

vices at the nearest health facility and 17 % to shared experiences from peer influence. In the multivariable logistic regression analysis, lower screening uptake was independently associated with being aged 55-65 years (aOR:1.7, 95%CI:1.5-2.0), those without health insurance (aOR:1.5, 95%CI:1.3-1.8) and those with a history of ART use for <5 years (aOR:1.3, 95%CI:1.1-1.6).

Conclusions: Cervical cancer screening uptake among WLHIV in Rwanda remains suboptimal, influenced by a combination of individual, social, and healthcare system factors. Tailored health education, and integration of screening into HIV care are critical to improving screening rates.

EP0610

Improving uptake of cervical cancer screening services among women living with HIV in Northern Nigeria: an interventional study

E. Bayan Paul[1], I.B. Gobir[1], M. Niyang[1], B. Zubyr[1], J. Shallangwa[1], M. Adeoye[1], B. Adebobola[2], M. Morka[2], T. Ilori[3], F. Jejere[3], R. Agulu[3], O. Oyelaran[4], J.P. Pius[4], E. James[4], D. Ogundehin[4], C. Obiora-Okafor[4], A. Idemudia[4], M. Ikpeme[4]

[1]Georgetown Global Health Nigeria, Abuja, Nigeria, [2]National AIDS, Sexually Transmitted Infections Control and Hepatitis Programme (NASCP), Federal Ministry of Health, Abuja, Nigeria, [3]National Agency for the Control of AIDS (NACA), Abuja, Nigeria, [4]Office of HIV/AIDS and TB, United States Agency for International Development (USAID), Abuja, Nigeria

Background: Cervical cancer accounts for approximately 604,000 new cases annually globally. It causes an estimated 342,000 deaths annually, making it the 4th most common cancer among women in both incidence and mortality after breast, colorectal and lung cancers. Annually, approximately 12,075 women are diagnosed with cervical cancer in Nigeria and about 7,968 women die from the disease. To address this, GGHN through its PEPFAR funded program, scaled up cervical cancer screening as part of the comprehensive package of care among WLHIV across three states in northern Nigeria.

Methods: This interventional study implemented a comprehensive package of interventions in January 2024 following interviews with healthcare providers to identify obstacles within the healthcare system and Focus Group Discussions with support groups of PLHIV to explore barriers to screening and community perceptions of cervical cancer. The interventions included client education and community awareness campaigns to reduce stigma and misconceptions, and community mobilization efforts. Additionally, traditional leaders and gatekeepers were sensitized about the benefits of cervical cancer screening to educate further and encourage women to accept screening services. Over nine months, the uptake of cervical cancer screening services was monitored quarterly.

Results: The uptake at the end of quarter 1 (October-December 2023) before deployment of the intervention package was as low as 85 cases/quarter and there was a 93-folds increment in uptake in the 4th quarter of 2024 (Jul – Sep). The quarterly uptakes after interventions were 559,1692 and 7893 cases/quarter for January – March, April-June, and July – September 2024 respectively. The Initial screening rates were below 1%, with a significant increase to 76% by September 2024 following the implementation of targeted interventions.

Conclusions: There was considerable improvement in cervical cancer screening uptake after the deployment of the intervention package, with an upward trajectory among the 3 quarters in 2024. Sustained efforts, including community mobilization and educational initiatives, are essential for maintaining high cervical cancer screening rates in the study locations.

This study demonstrated tremendous improvement in the uptake of cervical cancer screening services. Therefore, the interventions reported in this study may likely yield the same effects in similar settings in Nigeria and beyond.

EP0611

Unpacking the feasibility of continuous HIV testing among sexually active adolescents and young people as a prevention strategy

M. Nathane[1], T.M. Ndhlovu[2], C. Caroline[3], N. Tshuma[2], D. Mphuthi[4], M. Mokgatle[5]

[1]Civil Society Forum, Youth Sector, Klerksdorp, South Africa, [2]Best Health Solutions, Public Health, Johannesburg, South Africa, [3]Civil Society Forum, Research Sector, Rusternberg, South Africa, [4]University of South Africa, Pretoria, South Africa, [5]Sefako Makgatho University, Pretoria, South Africa

Background: Continuous HIV testing is a critical strategy for early diagnosis and linkage to care, particularly among sexually active adolescents and young people (AYP). Despite global recommendations, testing uptake remains suboptimal within this demographic.

This study examines the feasibility of continuous HIV testing by analyzing prevalence, demographic determinants, and behavioral correlates to inform targeted prevention strategies.

Methods: A cross-sectional analysis was conducted using data from the Youth Risk Behavior Survey (YRBS) to estimate HIV testing prevalence among 157 sexually active AYP aged 15-24 across urban and peri-urban settings. The study period covered the past 18 months, focusing exclusively on HIV testing uptake.

Bivariate analyses assessed associations between HIV testing and demographic variables (sex, age, race, ethnicity, and sexual identity), as well as behavioral factors (age at sexual debut, number of sexual partners, condom use, and substance use during intercourse). Multivariable logistic regression models stratified by sex were applied to adjust for potential confounders.

Results: Analysis revealed that overall HIV testing prevalence among sexually active AYP was 31% (95% CI: 24%-38%). Female participants reported significantly higher testing rates (43%; 95% CI: 36%-50%) compared to males (9%; 95% CI: 4%-14%). Among females, age was a strong predictor of testing uptake, with those aged 20-24 having an adjusted odds ratio (aOR) of 2.3 (95% CI: 1.4-3.7)

compared to younger counterparts. Condom use during the last sexual encounter was associated with a 1.8-fold (95% CI: 1.1-2.9) increased likelihood of testing. Conversely, males engaging in multiple partnerships showed a moderate but statistically non-significant increase in testing (aOR=1.4; 95% CI: 0.8-2.6). Substance use during sex was linked to lower odds of testing (aOR=0.7; 95% CI: 0.3-1.5), highlighting behavioral risk factors influencing testing uptake.

Conclusions: Findings underscore the need for gender-responsive interventions aimed at increasing HIV testing among AYP, particularly adolescent boys and young men. Future initiatives should prioritize peer-led outreach, digital health interventions, and community-based approaches to address accessibility and stigma barriers. Strengthening school-based programs and integrating routine screening in youth-friendly healthcare services are essential for scaling up continuous HIV testing.

EP0612

Peer-led tailored biosocial support and sexual health reaches adolescent boys and young men: aA process evaluation of Thetha Nami (Lets' Talk) in rural KwaZulu-Natal, South Africa

M. Luthuli[1], T. Zuma[1], J. Busang[1], S. Hlongwane[1], S. Nkwanyana[1], P. Khanyile[1], L. Lebina[1], J. Seeley[1,2], M. Shahmanesh[1,3]
[1]Africa Health Research Institute, Durban, South Africa, [2]London of School of Hygiene and Tropical Medicine, London, United Kingdom, [3]University College London, London, United Kingdom

Background: Men are missing from the HIV prevention and care cascade. The Thetha Nami trial in rural KwaZulu-Natal, South Africa, uses peer-led social mobilization to engage adolescents and young people (AYP) aged 15–30 with mobile sexual and reproductive health (SRH) services that offer gender neutral and status-neutral HIV care and prevention. We used a mixed methods process evaluation from July 2023 to December 2024 to assess the intervention's implementation amongst adolescent boys and young men (ABYM).

Methods: We collected routine programmatic data electronically to evaluate uptake, reach and dose. In-depth interviews (n=49 AYP, n=22 with implementation staff) and group discussions (n=2 peer navigators (PN), n=2 clinical staff) provided insights into intervention fidelity and participants' experiences. Qualitative data were transcribed and analysed thematically.

Results: 17125 AYP reached by PN, 8190 (48%) ABYM for health promotion and needs assessments. Engagement increased intervention acceptability, helping ABYM recognize themselves as candidates for tailored HIV prevention and SRH services, including awareness of PrEP. 74 (0.9%) ABYM refused peer support, citing low risk perception and stigma.

Case-based management and follow-ups by PN's facilitated service linkage. A total of 4039 participants,1696 (42%) ABYM, referred to mobile SRH services by peer navigators attended the services. N=3600 point of care HIV tests were conducted; n=1616 (45%) amongst ABYM and 139 (4%) were newly diagnosed as living with HIV, including 53/1616 (3%) in ABYM. 1392 (82%) of the ABYM who attended the services were at risk of HIV acquisition and offered oral PrEP and 839 (6%) refused oral PrEP due to stigma, pill burden, and migration. 1021 (60%) ABYM were screened and tested for STI's, with 191 (19%) testing positive and 160/191 (84%) were treated. 111/224 (46%) uncircumcised ABYM were referred for VMMC.

Interviews revealed that that community stigma towards SRH services persists, particularly among men, creating a barrier to service access. Peer support, health promotion, partner and family support were facilitators for their engagement with SRH services.

Conclusions: Peer-led tailored biosocial community-based care with SRH effectively engages with a high-risk group of ABYM in this rural setting. However, stigma and low risk perception continue to limit service uptake.

EP0613

Risk factors and behavioral patterns contributing to HIV susceptibility among people who use drugs (PWUDs)

L. Ngabonzima[1], D. Ndagijimana[1], N. Kabanyana[1], S. Murindanyi[1], J.P. Ayingoma[1], G. Rwibasira[2], B. Ikuzo[2]
[1]Rwanda NGOs Forum on HIV/AIDS and Health Promotion, Kigali, Rwanda, [2]Rwanda Biomedical Center, Kigali, Rwanda

Background: People who use drugs (PWUDs) are disproportionately affected by HIV due to risky behaviors such as needle sharing and unprotected sex. Limited data on HIV risk factors among PWUDs in Rwanda hinders the development of targeted interventions.

This study identifies behavioral and contextual risk factors contributing to HIV susceptibility among PWUDs.

Methods: A cross-sectional survey of 1,114 PWUDs in 10 urban districts of Rwanda was conducted in 2024 using respondent-driven sampling. Data on demographics, drug use, sexual behaviors, and access to harm reduction services were collected. Multivariable logistic regression identified associations between risk behaviors and HIV seropositivity, adjusted for confounders.

Results: Most participants are aged 25-34 (49.4%), followed by 18-24 (29.1%) and 35+ (21.5%). Of the participants, 977 (87.7%) were male, while 137 (12.3%) were female. The majority are from Kigali (43.3%), with 22.9% from the West. HIV prevalence among PWUDs was 12%. Risk factors significantly associated with HIV included needle sharing (AOR=3.6; 95% CI: 2.1-6.3, p<0.001), transactional sex (AOR=2.8; 95% CI: 1.7-4.9, p<0.001), and inconsistent condom use (AOR=2.4; 95% CI: 1.5-3.8, p<0.001). Lack of harm reduction services increased risk (AOR=4.1; 95% CI: 2.3-7.3, p<0.001). Participants aged <25 had lower odds of HIV (AOR=0.6; 95% CI: 0.3-0.9, p=0.021). Limited harm reduction access (22%) significantly increased infection risks, with odds reduced by half upon access (OR = 0.5).

Conclusions: HIV risk among PWUDs is strongly linked to needle sharing, transactional sex, and limited harm reduction services. Expanding access to harm reduction

programs and sexual health education is critical to reducing HIV transmission in this vulnerable group. Addressing these factors can enhance HIV prevention efforts in Rwanda.

Social, cultural, political, legal, environmental and structural determinants of health in different contexts

EP0614

Navigating stigma and strength: social and behavioural dimensions of HIV prevention and coping mechanisms in Bangladesh

I. Hossain[1], A. Mumitu[1]
[1]Shahjalal University of Science and Technology, Social Work, Sylhet, Bangladesh

Background: Bangladesh, while maintaining a relatively low prevalence of HIV, faces significant social and behavioral challenges in preventing HIV transmission and supporting people living with HIV (PLHIV). Stigma, cultural norms, and behavioral practices create barriers to accessing testing, counseling, and treatment services. This study aims to explore the interplay of these factors in shaping HIV prevention strategies and the lived experiences of PLHIV in both urban and rural settings.
The objective is to identify the obstacles and opportunities for improving prevention and care initiatives, particularly for high-risk and marginalized populations.
Methods: The study was conducted over six months in both urban and rural regions of Bangladesh. A mixed-methods approach was employed, combining quantitative and qualitative data. The study population included 200 survey participants from high-risk groups, healthcare providers, and community members, as well as 30 in-depth interviews with PLHIV. Surveys captured demographic and behavioral data, while interviews explored personal experiences and perceptions.
Data were analyzed using thematic analysis for qualitative insights and statistical techniques for quantitative findings, disaggregated by age and gender to identify trends and disparities.
Results: The study found that pervasive stigma and misinformation about HIV significantly limit access to testing, counseling, and treatment. Women, particularly in marginalized communities, face heightened vulnerability due to gender disparities and sociocultural barriers. Structural gaps in healthcare infrastructure further exacerbate these challenges.
However, community-led initiatives, such as targeted education programs and peer support networks, have shown promise in fostering behavioral changes, reducing stigma, and building resilience among PLHIV.
These interventions have been particularly effective in promoting safer practices and improving access to support systems.
Conclusions: The findings highlight the urgent need for culturally sensitive, inclusive approaches to HIV prevention and care in Bangladesh. Strategies must integrate stigma reduction, gender empowerment, and education while strengthening community engagement and behavioral interventions.
By addressing these social dimensions, policymakers and practitioners can develop more effective HIV prevention and care programs. Future implications include enhancing collaborative efforts among stakeholders to close gaps in access and ensure sustainable support for PLHIV.

EP0615

"Because being gay is stigmatized in society, being HIV positive is stigmatized as well": Indian physicians' perceptions of stigmas related to LGBTQ HIV/AIDS individuals

H.J. Peguero Caballero[1], D. Stephens[1], A. S.K.[2], R. Pramathesh[2], J. Navarro[1]
[1]Florida International University, Psychology, Miami, United States, [2]The Public Health Research Institute of India, Mysore, India

Background: While there has been significant research examining HIV/AIDS stigma and the barriers faced by LGBTQ people in India, little is known about how Indian healthcare providers perceive their own beliefs and preparedness to address these issues. This lack of understanding is concerning given the rising number of people in India living with HIV (Lyons et al., 2022), as well as the increasing number of HIV in people self-identifying as LGBTQ (Majumder & Kar, 2022). This study aimed to understand Indian physicians' perceptions of their work and training with LGBTQ individuals in HIV/AIDS healthcare settings.
Specifically, it focused on how these physicians view their roles as healthcare providers and how they may contribute to or hinder LGBTQ HIV/AIDS people's willingness to engage with healthcare services. Unfortunately, there is limited research on how well-prepared healthcare providers are to meet the intersecting health needs of these populations.
To address this gap, the project aims to explore the reported attitudes and levels of preparation of Indian physicians regarding HIV/AIDS issues specific to LGBTQ populations.
Methods: One-on-one interviews were conducted with twelve physicians currently working with LGBTQ HIV/AIDS healthcare clients in order to gather insights into their motivations and desired training norms.
Using thematic analysis, results identified four major themes that shape the participants' experiences and perceptions of their work and readiness to support LGBTQ HIV/AIDS people:
a. HIV/AIDS stigma,
b. LGBTQ stigma,
c. Support from colleagues, and;
d. Support from the healthcare system.
Results: Most participants noted the prevalence of LGBTQ and HIV/AIDS stigma and stereotypes within both the healthcare system and the broader Indian communi-

ty. Moreover, many in the medical field still hold negative associations with HIV/AIDS, viewing it as fearing actual transmission. It was also reported that LGBTQ HIV/AIDS communities face significant barriers to accessing healthcare services, with only those in more comfortable economic situations being able to obtain the necessary support.

Conclusions: These findings highlight the importance of medical providers as gatekeepers to HIV/AIDS services for LGBTQ individuals, including dissemination of health care.

EP0616

Analysis of disparities in the HIV care cascade between indigenous and non-indigenous peoples in Brazil

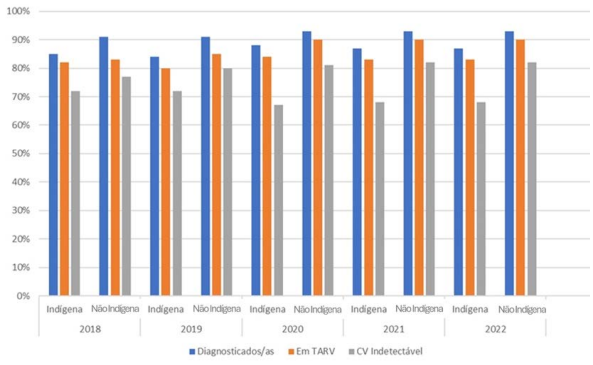
D.A. Calixto[1], J.d.F. Sena[1]
[1]Fundação Oswaldo Cruz, Public Health, Brasília, Brazil

Background: Although Brazil has made significant progress toward the global 95-95-95 HIV targets, indigenous peoples continue to face barriers that compromise access to treatment and viral suppression.

This study aims to assess the magnitude of such disparities by analysing the Social Determinants of Health (SDOH) that impact the health of indigenous communities and hinder adherence to Antiretroviral Therapy (ART).

Methods: This study applied a triangulated approach, combining quantitative and qualitative analyses. Epidemiological data from the Brazilian Ministry of Health (2018-2022) on ART coverage and viral suppression rates among Indigenous and non-Indigenous peoples were analysed. Simultaneously, qualitative analyses of health policy were conducted, focusing on their implications for access to and adherence to treatment. The combination of those approaches provided a comprehensive understanding of the disparities in HIV care.

Results: From 2018 to 2022, ART coverage between Indigenous peoples decreased from 68% to 62%, compared to stable rates of 78% between non-Indigenous peoples. Viral suppression between Indigenous peoples also decreased from 64% to 58%, while remaining stable at 74% in non-Indigenous peoples.



Furthermore, COVID-19 pandemic represented an external factor, intensifying disparities in HIV care due to disruptions in health services and its impact on the socio-economic conditions of Indigenous peoples. Despite advancements in HIV-related public health policies, those disparities persist, highlighting structural inequalities that negatively affect equitable access to ART.

Conclusions: Culturally adapted interventions are essential to mitigate disparities in HIV care among Indigenous peoples. Strengthening primary healthcare, through the training of healthcare professionals and the establishment of Indigenous Health Agents (AIS, acronym in Portuguese), is key to improving ART adherence. AIS profession, regulated in Brazil, holds prevention and health promotion activities while incorporating traditional knowledge. Additionally, the implementation of HIV educational programs sensitive to local cultural realities can optimize access to information and increase viral suppression rates.

EP0617

Associations between Sexual Orientation and Gender Identity Change Efforts (SOGICE) and mental health outcomes among people living with HIV in Chengdu, China

P. Zhao[1], H. Song[2], D. Wu[1]
[1]Nanjing Medical University, School of Public Health, Nanjing, China, [2]Sichuan University, Chengdu, China

Background: People living with HIV (PLWH) are disproportionately affected by poor mental health outcomes. Sexual Orientation and Gender Identity Change Efforts (SOGICE) are harmful practices aimed at changing an individual's sexual orientation or gender identity. PLWH with prior exposure to SOGICE may be at a higher risk of mental health disorders.

This study explores the associations between SOGICE exposure and mental health outcomes among PLWH.

Methods: Data were collected from an LGBTQ+ cohort study conducted in Chengdu City from November 2023 to December 2024. Participants were eligible if they were 16 years or older, self-identified as LGBTQ+, and lived in Chengdu City and surrounding areas. SOGICE exposure was assessed by asking if participants had ever undergone practices that attempted to change their sexual orientation and gender identity into cis-heteronormativity. The mental health outcomes assessed included depressive symptoms (PHQ-9), non-suicidal self-injury, suicidal behaviors (SBQ_R), PTSD symptoms (PCL-5). Multivariable logistic regressions were conducted to examine the associations between SOGICE and mental health outcomes.

Results: In total, 8039 LGBTQ+ participants were included in the cohort and 642 (8.0%) were PLWH. The average age of the PLWH was 35.5 years old. The majority of PLWH were men who have sex with men (MSM) (92.5%), cisgender individuals (66.2%), had full-time jobs (60.8%), and in relationships (64.14%). Nearly half of PLWH (47.2%) reported having suicidal ideation or attempts, 23.4% reported non-suicidal self-injury, 26.3% reported depressive symptoms, and 32.2% had PTSD symptoms.

Among PLWH, 64 (10.0%) reported they had undergone SOGICE, with psychotherapy (27), verbal insult (25), and forced change dressing style (19) being the most reported forms. PLWH exposed to SOGICE were more likely to

report depressive symptoms (aOR=2.73, 95% CI:1.40-5.37), non-suicidal self-injury (aOR=2.77, 95% CI:1.41-5.47), and PTSD symptoms (aOR=4.01, 95% CI:1.95-8.24). No significant association was found between SOGICE and suicidal ideation or attempts among PLWH.

Conclusions: Exposure to SOGICE practices among PLWH in this cohort was associated with the increased likelihood of poor mental health outcomes. These findings highlight the need for targeted mental health support for PLWH, particularly those with a history of SOGICE exposure, to address the elevated risk of mental health disorders.

EP0618

Exploring changes in stigma and its impact on People Living with HIV in Addis Ababa: a qualitative study

T.F. Mekonnen[1], S.A. Argaw[1], S. Hadera[1], Y. Tadesse[2], N. Gelana[3], S.A. Hussen[1], E.F. Azerefegne[4], D. Kebede[5], E.G. Kidane[2]

[1]Emory University, Hubert Department of Global Health, Atlanta, Georgia, [2]Addis Ababa University, School of Public Health, Addis Ababa, Ethiopia, [3]Ethiopian Health Education and Promotion Professionals Association (EHEPA), Addis Ababa, Ethiopia, [4]Addis Ababa University, College of Health Sciences, Addis Ababa, Ethiopia, [5]Addis Ababa University, Department of Internal Medicine, Addis Ababa, Ethiopia

Background: An estimated 620,000 people are living with HIV (PLH) in Ethiopia. Access to antiretroviral therapy (ART) has become nearly universal, particularly in the capital city of Addis Ababa. HIV-related stigma has been cited as a significant barrier to effective HIV prevention and treatment; however, little is known about how stigma in Ethiopia has changed over time since the widespread implementation of ART.

To address this gap, we conducted a qualitative exploratory study with frontline healthcare workers to capture their perspectives on stigma over time and its impacts on PLH in Addis Ababa.

Methods: We conducted 17 in-depth interviews with healthcare providers from three major ART clinics in Addis Ababa: Zewditu Memorial General Hospital, St.Peter's TB Specialized Hospital, and Tikur Anbessa Specialized Hospital.

The participants included physicians, nurses, and case-workers with experience in HIV care service delivery. Data collection utilized a semi-structured interview guide, Interviews were recorded, transcribed, and thematically analyzed using a combination of deductive and inductive approaches.

Results: Participants reported a notable decrease in HIV-related stigma in Addis Ababa over time, driven by increased awareness, improved social support, and wide availability and access to effective ART.

Key improvements included increased openness in disclosing HIV status, reduced avoidance of large ART clinics, and improved social interactions among PLH. Despite these gains, significant challenges persist, particularly for women, adolescents, and individuals in rural settings or with lower socioeconomic status. Stigma continues to manifest in various forms, including gossip, exclusion, and fear of disclosure, often exacerbated by misconceptions about transmission. Healthcare providers emphasized the impact of ongoing stigma on ART adherence, mental health, and interpersonal relationships, particularly among women and youth.

Conclusions: The findings highlight both progress and persistent challenges in addressing HIV-related stigma in Ethiopia. While education and targeted interventions have reduced stigma in urban settings, its prevalence remains significant, particularly in rural areas and marginalized groups. To enhance HIV prevention and treatment outcomes, strategies must address the cultural, social, and economic factors driving stigma.

Culturally sensitive, community-specific interventions are critical, to strengthen public education and support systems. Future research should focus on stigma in subpopulations and rural communities to inform more inclusive strategies.

EP0619

"I wanted to fall pregnant and stay on study product": Experiences of women who became pregnant during HIV prevention trials and were discontinued from study product in Zimbabwe

D. Nhamo[1], C. Mpaso[1], R. Manyanga[1], I. Mahaka[1], N. Eley[2], M. Chatani Gadha[3], R. Sutton[3], L. Lorenzetti[2]

[1]Pangaea Zimbabwe, Programs, Harare, Zimbabwe, [2]FHI-360, Research, Durham, United States, [3]AVAC, Programs, New York, United States

Background: Women spend about ten years of their lives pregnant or breastfeeding, a period during which they face an increased risk of contracting HIV due to biological and social factors. Despite this heightened vulnerability, pregnancy is often an exclusionary criterion in biomedical clinical trials. This measure aims to protect both the mother and the fetus from potential side effects of experimental drugs but is often set without consulting women about their preferences. Growing advocacy now calls for the inclusion of pregnant and breastfeeding women in research to ensure access to safe and effective HIV prevention options. This study explored the experiences of women in Zimbabwe who discontinued HIV prevention study products due to pregnancy to inform more inclusive research practices.

Methods: Twelve in-depth interviews were conducted with young women in Zimbabwe who became pregnant and discontinued study products in the MTN 034 and HPTN 084 HIV prevention trials. Participants were purposively selected to capture diverse experiences. Interviews explored their feelings about discontinuing the product, understanding of risks and benefits, and perspectives on inclusion in future research. Data were collected in private settings, audio-recorded, transcribed, and thematically analyzed.

Results: Most women wanted to continue the trial product, as it gave them peace of mind knowing they were protected from HIV. They felt continuing on the product

after becoming pregnant would have allowed them to contribute to science in women's health. Some believed the study missed an opportunity to understand the product's effects on pregnant women and their unborn babies. However, some women supported discontinuation, fearing unknown side effects on their unborn child, as the product was still under study.
A few noted spousal pressure to become pregnant despite the study discouraging pregnancy while on the product. Women valued having adequate knowledge to guide their decision-making.
Conclusions: Future studies should prioritize pregnant women's right to clear, accurate information on study product risks and benefits, enabling informed choices.
Trials must provide direct access to healthcare professionals, user-friendly materials, and trained staff to support participants' decisions. Including pregnant women in research enhances both participant autonomy and the safety and effectiveness of HIV prevention methods.

EP0620

Lost and found: exploring return to HIV care and treatment continuity in a fragmented health care system. a single center cross-sectional study in Mexico City

A.F. Ramos-Menchelli[1], B.E. Crabtree-Ramírez[1], Á. Lopez-Iñiguez[1], R. Ville-Benavides[1], Y. Caro-Vega[1], M.F. Vargas-Morales[1], A. Trujillo-Gamboa[1], J.G. Sierra-Madero[1]
[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Department of Infectious Disease, Mexico City, Mexico

Background: Disengagement from care in people living with HIV (PWH) is one of the main factors that threatens the long-term success of ART programs globally and may contribute to interruption of ART and advanced disease. We aimed to clinically characterize individuals returning to care (RC), after a period of being lost to follow-up (LTFU), and to determine the self-reported reasons for loss of continuity of care in our institution.
Methods: This was a cross-sectional, single-center study to describe virological and clinical status of PWH who RC to Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán in Mexico City, before and after a period of LTFU (defined as those individuals who were readmitted after a period of ≥6 months of not attending clinic visits, ARV pickup and lab testing) between January 2023 to December 2024. Clinical and laboratory information was obtained through a review of medical records. We applied a questionnaire to evaluate reasons for disengagement, clinical events and ART continuity.
Results: There were 121 readmissions during the study period and 70 were included in the analysis. Prior to LTFU, the median CD4 count was 558 (IQR 793-344) cells/mm³, 81.4% had an undetectable viral load (<200 copies/mL) and 7.1% had CD4 count<200 cells/mm³.
After RC, the median CD4 count was 437 (732-113) cells/mm³, 52.8% had<200 copies/mL, and 27.1% had a CD4 count <200 cells /mm³. 45.7% of individuals referred having stopped ART or took it intermittently during the period of LTFU. 7/70 (10%) of the individuals who RC were hospitalized and one died due to advanced disease.
The main reasons self-reported by participants for disengagement in care were: migration to another health system (38.57%), travelled/moved away (14.28%), mental health issues (10%), and were busy at work (10%) Of the PWH that migrated, 30% stopped or took ART intermittently.
Conclusions: In this study, those returning to care commonly presented with advanced disease and virological failure. The primary reason for disengagement in care was migration to another health care system, and up to a third of these individuals discontinued ART. Strategies tailored to facilitate the continuity of antiretroviral treatment across healthcare systems are needed.

EP0621

Assessing awareness of non-communicable diseases (NCDs) among aging people living with HIV in Pune, India

P. Kannan[1], S. Taneja[1], M. Kariuki[2], V. Ranebennur[3]
[1]FHI 360, Delhi, India, [2]FHI 360, Durham, United States, [3]FHI 360, Washington, United States

Background: Advancements in antiretroviral therapy (ART) and expanded access have substantially increased life expectancy of people living with HIV (PLHIV). It is projected that the proportion of PLHIV ages 50 years or older will reach 37% by 2025, up from only 19% in 2005. Non-communicable diseases (NCD) such as diabetes mellitus (DM), hypertension, cardiovascular diseases, and cancer occur both at a greater prevalence and earlier than anticipated among PLHIV, including those on ART. Hence, it is important to assess the awareness of NCDs among PLHIV to guide the development of knowledge products.
Methods: The Meeting Targets and Maintaining Epidemic Control (EpiC) project in India led by FHI 360 conducted a baseline assessment with 1,024 PLHIV (≥40 years) who were receiving HIV services at either government or private health facilities. The assessment was implemented by outreach workers during routine ART adherence home visits. A structured questionnaire collected cross-sectional data on their physical and emotional well-being, lifestyle, and knowledge about NCDs. Data were collected and analyzed using KoBo collect and Power BI.
Results: Of the 1,024 PLHIV, 52% were females and 42% males. Fifty-eight percent were aged 40–49 years, 33% were 50–59 years, and 9% were ≥60 years. Seven percent self-reported having DM, and 8% reported being hypertensives. Notably, 66%were not aware of any symptom of diabetes, and 73% did not know any symptoms of hypertension. Among female respondents, 70% were unaware of symptoms of breast or cervical cancer, while 68% of female respondents did not know how to perform breast self-examination. Additionally, 11%expressed concerns about their emotional well-being, and 17% reported tobacco use.
Conclusions: This study highlights a significant gap in NCD awareness among aging PLHIV in Pune, which could

be an impediment to early detection and management of these conditions. EpiC India is therefore implementing a community-based self-care model to enhance NCD awareness and health seeking behavior among this population. The findings emphasize the need for educational interventions and integrated care models to address the dual burden of HIV and NCDs in aging PLHIV populations.

EP0622

Recent progress and setbacks in HIV criminalisation around the world

E. Bernard[1], S. Beaumont[1], E. Hatt[1], P. Kidd[1]
[1]HIV Justice Network, Amsterdam, Netherlands, the

Background: HIV criminalisation refers to the unjust use of criminal laws against people living with HIV based on their HIV status, through HIV-specific statutes or general criminal laws. This practice undermines access to HIV prevention, testing, treatment, and care while perpetuating stigma and human rights violations. Addressing HIV criminalisation is critical for achieving global health and human rights goals.
Methods: This analysis focuses on cases and legal developments documented in the HIV Justice Network's Global HIV Criminalisation Database throughout 2024. Data were reviewed to capture trends in the application, reform, or repeal of HIV-specific and general criminal laws globally. Updated data to June 2025 will be presented. Disaggregation by demographics will be conducted where possible.
Results: In 2024, 65 new cases were reported by the media across 20 countries, marking a continued rise in prosecutions post-COVID-19. Most cases occurred in Eastern Europe, Central Asia, and North America, with first-ever cases reported in Panama and Uruguay. Reforms or repeals of HIV laws occurred in three jurisdictions in North America; positive court rulings were recorded in Italy, Greece, and Kenya, and policy improvements benefiting people living with HIV were seen in Singapore and Uzbekistan.
However, setbacks included Canada's abandonment of its federal review of aggravated sexual assault laws inappropriately applied to HIV non-disclosure; Guinea's harsher penalties for "intentional HIV transmission", Tennessee's expansion of aggravated rape provisions to include people living with HIV; and reports from China that Chongqing was revising STI laws as part of a broader crackdown on HIV. In Uganda, the Constitutional Court struck down the death penalty provision in the Anti-Homosexuality Act 2023 but upheld other regressive aspects. Sub-Saharan Africa retained the highest concentration of HIV-specific laws, with 30 countries maintaining such statutes.
Conclusions: In 2024, data reveal both progress and ongoing challenges in addressing HIV criminalisation. While reforms in several countries signal growing momentum, the persistence of HIV-specific criminal laws in 79 countries and recent cases in 20 countries underscore the need for accelerated advocacy and resources.
Achieving the UNAIDS target of fewer than 10% of countries with punitive laws by 2030 requires sustained global focus and investment.

EP0623

Addressing HIV-related travel restrictions: progress and challenges in eliminating discriminatory policies

E. Bernard[1], S. Beaumont[1], E. Hatt[1], S. Varguez[1], B. Allan[1]
[1]HIV Justice Network, Amsterdam, Netherlands, the

Background: HIV-related restrictions on entry, stay, and residence continue to undermine the rights and mobility of people living with HIV worldwide. These policies are rooted in stigma and discrimination rather than public health evidence, creating barriers to employment, education, and family unity.
Methods: Data were collected between June – December 2024 for Positive Destinations, the new home for The Global Database on HIV-Specific Travel and Residence Restrictions (hivtravel.org), now hosted by the HIV Justice Network. We analysed data from official government sources, international bodies, civil society organisations, and feedback from site users. Conflicting information is presented transparently, prioritising official government positions when available.
We categorised restriction classifications as: none, partial (1 or 2) or severe (3 or more), depending on the number of restrictions relating to entry, short- or long-term stay. Additional data based on user feedback / lived experience in 2025 will further enhance the data.
Results: As of January 2025, Positive Destinations data reveals 83 countries with no restrictions and 68 countries with no or unclear information. Severe restrictions were identified in 17 countries: Bhutan, Brunei Darussalam, Cook Islands, Djibouti, Dominican Republic, Egypt, Iran, Iraq, Jordan, Kuwait, Malaysia, Marshall Islands, Oman, Russian Federation, Syria, Turkmenistan, and the United Arab Emirates.
These policies often result in outright bans on entry or deportation based on HIV status. Partial restrictions were present in 33 countries, including Angola, Antigua and Barbuda, Australia, Azerbaijan, Bahrain, Belize, Canada, Cuba, Dominica, Equatorial Guinea, Grenada, Hungary, Kazakhstan, Kiribati, Kyrgyzstan, Liberia, Maldives, Mauritius, Papua New Guinea, Paraguay, Philippines, Qatar, St. Kitts & Nevis, Saudi Arabia, Singapore, Slovakia, Sri Lanka, Sudan, Tajikistan, Tonga, Tuvalu, Vanuatu, and Yemen. Migrant workers, students, and women were disproportionately affected.
Conclusions: The findings underscore the urgent need to eliminate HIV-related travel restrictions, which perpetuate stigma and violate human rights. Advocacy must prioritise evidence-based policy reform, leveraging international frameworks and cross-sector partnerships.
Eliminating these restrictions is vital for advancing global health equity, reducing stigma, and ensuring the dignity and mobility of people living with HIV. Future efforts should focus on capacity-building for advocacy, legal reform, and community engagement to create lasting change.

EP0624

Starved for justice: examining food insecurity, discrimination, and health-related quality of life among people living with HIV in Pune, India

R. Borse[1], S. Nimkar[2], S. Surwase[3], K. Zarekar[3], A. Pawar[3], G. Lele[3], V. Potphode[3], V. Mave[2,4], I. Marbaniang[2,5]
[1]BJ Government Medical College, Pune, India, [2]Center for Infectious Diseases in India, Johns Hopkins University, Pune, India, [3]BJ Government Medical College-JHU Clinical Research Site, Pune, India, [4]Johns Hopkins University, Division of Infectious Diseases, Baltimore, India, [5]McGill University, Montreal, Canada

Background: Poor health-related quality of life (HRQoL) is a key patient-reported outcome (PRO) linked to adverse clinical outcomes in people living with HIV (PLHIV). The relationship between systemic factors and HRQoL is underexplored in resource-limited settings.
Here, we examine associations between food insecurity, discrimination, and HRQoL in PLHIV.
Methods: We used baseline data (January 2023–October 2024) from 477 adult (≥18 years) enrollees in a lung health cohort study among PLHIV, recruited at a publicly funded ART clinic in Pune, India.
We included only virally suppressed PLHIV. HRQoL was assessed using the PROQOL-HIV, food insecurity using the Household Food Insecurity Access Scale (HFIAS), and discrimination using the Everyday Discrimination Scale (EDS), as continuous measures.
Higher PROQOL-HIV scores indicate better HRQoL; higher EDS and HFIAS scores reflect greater perceived discrimination and food insecurity. PROQOL-HIV scores were scaled 0-100%;HFIAS and EDS scores were mean-centered.
Beta regression (logit link) was used to assess associations between HRQoL, food insecurity, discrimination, and their interaction.Covariates included age, sex, polypharmacy, CD4count, TB history, education, income, and employment.

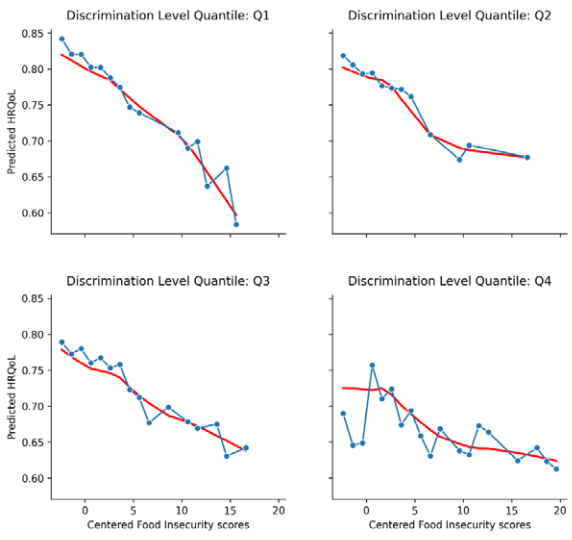


Figure 1.

Results: The median scaled PROQOL-HIV score was 82% (IQR: 71–88%). Higher EDS scores (Odds Ratio [OR]: 0.96, 95% CI: 0.95–0.97) and higher HFIAS scores (OR: 0.95, 95% CI: 0.94–0.96) were each associated with lower HRQoL. However, their interaction was associated with higher HRQoL (OR: 1.002, 95% CI: 1.001–1.004).
While counterintuitive, the decline in HRQoL with increasing HFIAS scores was steeper at lower EDS scores and less pronounced at higher EDS scores (Figure 1), which may explain the positive interaction effect.
Conclusions: Food insecurity and discrimination are both negatively associated with HRQoL, though the strength of association between food insecurity and HRQoL varies across discrimination levels.
Whether these findings reflect effective coping strategies at higher discrimination levels, desensitization due to chronic exposure to discrimination, or other mechanisms warrants further investigation

EP0625

Bridging barriers to HIV/SRH healthcare for young women in Lesotho through hair salons: a qualitative acceptability and feasibility study

M. Kopeka[1], M. Chiaborelli[2], P. Sekhesa[3], M. Sehrt[4], T. Mohloanyane[5], T. Ballouz[6], D. Menges[6,7], J.A. Brown[2,8,9], J.M. Belus[2], F. Gerber[2], F. Raeber[2], A. Williams[2], D. Jackson-Perry[10,11], M. Hyöky[3], D.F. Conserve[1], A. Amstutz[2,12,13], K. Hampanda[4], T. Hair SALON Expert Group[3]
[1]George Washington University, Prevention and Community Health, Washington DC, United States, [2]University Hospital Basel and University of Basel, Division of Clinical Research, Basel, Switzerland, [3]The HUB, Morija, Lesotho, [4]University of Colorado Anschutz Medical Campus, Department of Obstetrics and Gynecology, Aurora, United States, [5]Central University of Technology, Bloemfontein, South Africa, [6]University of Zurich, Biostatistics and Prevention Institute, Zurich, Switzerland, [7]Karolinska Institutet (KI), Department of Medical Epidemiology and Biostatistics (MEB), Stockholm, Sweden, [8]University of KwaZulu-Natal, Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [9]University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom, [10]Lausanne University Hospital, Infectious Diseases Service, Lausanne, Switzerland, [11]Queen's University, Education and Social Work, Belfastunited, United Kingdom, [12]Oslo University Hospital, Oslo Center for Biostatistics and Epidemiology, Oslo, Norway, [13]University of Bristol, Population Health Sciences, Bristoluniun, United Kingdom

Background: Young women in Lesotho are at elevated risk for acquiring HIV, and yet, uptake of Pre-Exposure Prophylaxis (PrEP) remains low. In addition, there is limited information about and access to sexual and reproductive health services (SRH) at healthcare facilities. The Hair SALON project surveyed hair stylists and their clients throughout Lesotho to explore the acceptability and feasibility of providing HIV prevention and other SRH services

at hair salons as a novel venue to reduce some of the structural and cultural barriers of seeking care. Here, we report qualitative findings accompanying the survey.

Methods: We recruited 6 hair salon stylists and 8 hair salon clients who had completed the study survey for an interview in June-July 2024.

We used purposive sampling to select survey respondents who reported different acceptability levels of providing and/or receiving certain HIV/SRH in hair salons on the survey.

A trained member of the research team conducted individual, semi-structured interviews in both Sesotho and English at the study site in Morija, Lesotho.

The interviews were audio-recorded, translated to English where applicable, and transcribed. We analyzed the transcripts using rapid thematic analysis supported by Avidnote AI software. We disseminated a short documentary on the findings and solicited feedback from project participants and the wider community.

Results: Following analysis, three main themes were identified from the data: 1. Participants avoided accessing preventative HIV/SRH services provided by public healthcare facilities due to anticipated and experienced ill-treatment from healthcare staff, 2.

Participants identified an intersection of HIV-related stigma and social stigma against sexual activity as main barriers to accessing and using HIV/SRH services in health facilities, 3.

Most participants felt that due to the flexibility of hair salons, they were a more accessible space for HIV/SRH service needs, including HIV self-testing, PrEP and PEP, compared to healthcare settings.

Conclusions: The results suggest that hair salons could be an acceptable and feasible alternative safe space for offering HIV/SRH services. Based on the results, the study team is planning to pilot an HIV/SRH service package provided by trained salon stylists at selected hair salons across Lesotho.

EP0626

Transforming access to Combo HTM Care for key population women living with HIV in Lagos and Ogun States, Nigeria

O. Olajubu[1], H. Adegbite[1], M. Remilekun[1], G. Samuel[1]
[1]The Rainbow Alive Hub Initiative, Lagos, Nigeria

Background: Key population (KP) women living with HIV in Lagos and Ogun state, Nigeria, including trans women, lesbian, bisexual, or queer (LBQ) women, female sex workers, and women who inject drugs face intersecting barriers to accessing HIV, TB, and malaria (HTM) services. Challenges such as systemic stigma, economic marginalization, low preventive care awareness, and fragmented service delivery undermine their health outcomes and care engagement.

This study funded by GlobalFund Gender Equality Fund explores these barriers in Lagos and Ogun States, offering critical insights to inform equitable and integrated healthcare solutions tailored to the unique needs of these vulnerable populations.

Methods: A mixed-methods approach was adopted, engaging 209 participants across Lagos and Ogun States, comprising 16% trans women, 22% LBQ women, 38% female sex workers, and 24% women who inject drugs. Participants ranged from 18–35+ years, with 60% based in Lagos and 40% in Ogun. Snowball sampling was used to recruit diverse KP women. Semi-structured interviews and surveys explored service fragmentation, economic impacts, and awareness of preventive measures. The data was analyzed through Inductive Thematic Analysis and validated using triangulation to ensure reliability.

Results: Among other issues, fragmented healthcare delivery emerged as a critical barrier among respondents, with only 42% reporting access to both HIV and TB services at the same facility. 31% of respondents abandoned HIV and TB treatment entirely due to travel fatigue or logistical challenges, with 48% of respondents missing work due to prolonged clinic visits, and 32% reporting a daily income loss of NGN5,000–10,000. Among female sex workers, 26% admitted avoiding ARV refill appointments to prevent loss of earnings, with TB symptoms misinterpreted as general fatigue by 29%.

Conclusions: The findings underscore the impact of service fragmentation, economic hardship, and systemic biases on KP women living with HIV's access to HTM care. Tailored solutions are imperative, including KP-specific one-stop-shop models offering combo HTM service and targeted preventive education for these vulnerable women.

By addressing these diverse and deeply entrenched challenges, Nigeria can foster equitable healthcare systems that contribute to eradicating the co-acquisition of HIV, TB, and Malaria for its most marginalized populations.

EP0627

Clients experiences following an economic shock in Malawi: a descriptive cross-sectional study

K. Balakasi[1], M. Thorp[2], I. Robson[1,2], K. Phiri[1], C. Lemani[1], A. Choko[1,3], S. Phiri[1,4], K. Dovel[1,2]
[1]Partners in Hope, Implementation Science, Lilongwe, Malawi, [2]University of California Los Angeles, Division of Infectious Diseases, David Geffen School of Medicine, Los Angeles, United States, [3]Malawi Liverpool Wellcome Trust Clinical Research Program, Department of Public Health, Blantyre, Malawi, [4]Kamuzu University of Health Sciences, School of Global and Public Health, Lilongwe, Malawi

Background: Largescale economic shocks are increasing throughout eastern and southern Africa. Such shocks have disproportionately negative impacts on already poor individuals who have limited social protections. The devaluation of the Malawi Kwacha in November 2023 by 44% presents a unique opportunity to examine how economic shocks affect antiretroviral therapy (ART) clients' engagement with HIV services. We investigated the impact of devaluation on ART clients' use of health services, ability to meet basic needs, and their coping strategies.

Methods: We implemented a cross-sectional survey with ART clients in eight health facilities across four districts in Malawi. ART clients were randomly sampled from clinic

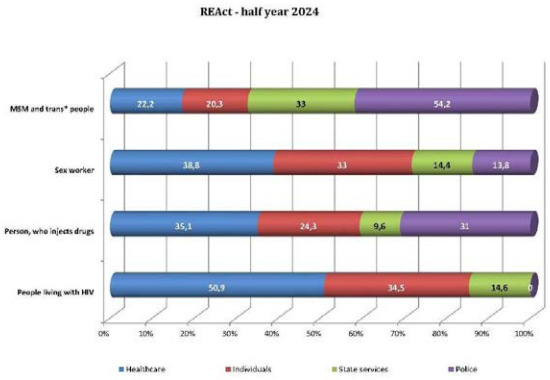
waiting spaces. Eligibility criteria: age ≥18 years; attending ART clinic for own health care; and initiated ART ≥1 year ago.
Survey modules included sociodemographics, use of ART services pre/post devaluation, and devaluation's impact on livelihoods, meeting basic needs (i.e., housing, food, clothing, and schooling), and use of HIV and other health services. We conducted descriptive statistics.
Results: A total of 355 clients were surveyed between February-April 2024. Of these, 153 (43%) were male, median age of 41 years (IQR 33-47 years), 242 (68%) were married and 118 (33%) had attended secondary or higher education. Approximately, 81% were in extreme poverty (household earnings <$2.10 per day). Median duration on ART was 8 years (IQR 4-13 years).
Following the devaluation, 96% reported increased commodity prices and eroded purchasing power (45%). A total of 12% experienced a reduction in income earned from work, 9% reported failure of household enterprises and 12% stopped receiving routine remittances. 28% of clients attributed missed ART appointments (>28-days late) or failure to seek other needed health services to consequences of devaluation.
To cope, 8% reduced food intake, 12% switched to cheaper (and often less nutritional) food, 8% sold household assets and 12% obtained a loan.
Conclusions: Economic shocks like currency devaluation have a negative effect on use of health services both directly (failed engagement with health services) and indirectly (eroding factors that promote health seeking such as access to food).
Embedding social protection programs within health systems could cushion against these shocks to promote resilient engagement in HIV services.

EP0628

Strategic partnerships and community-level interventions addressing human rights violations in the HIV response

O. Buzovici[1]
[1]*Specialised Paralegals Network, Balti, Moldova, the Republic of*

Background: Key affected populations face not only challenges related to acquired HIV risks but also significant stigma and discrimination. These issues deeply influence societal perceptions, often portraying these groups negatively. Consequently, these populations encounter systemic human rights violations, particularly from healthcare providers, social service systems, and law enforcement agencies.
Legal empowerment for these communities is crucial, as the existing state-guaranteed legal aid system, coordinated by the National Legal Aid Council, has historically been inaccessible to them. Limited coverage of legal services, with paralegals present mainly in rural areas and public lawyers in urban centers influenced by bias, restricts access to justice. This gap affects cases involving discrimination, breaches of confidentiality, and criminalization of certain behaviors.
Description: Since 2018, with the support of National Legal Aid Council, a Specialized Network of Paralegals was created from key population communities. Starting with 15 activists, this network has grown to 29 members: community activists, peers, outreach workers and Harm Reduction Program specialists.
In 2024, 4988 rights violations were reported through national system SIA CNAJGS, with 40% related to healthcare access, 15% to civil and labor rights, and 9% to human rights violations such as discrimination and violence. Additionally, 458 barriers to HIV-related services were reported via REAct-130 resolved.



Lessons learned: Paralegals play a vital role in drafting complaints, mediating disputes, engaging with communities to address systemic challenges, empowering vulnerable populations to claim their rights and improve access to justice.
Community-driven paralegal networks improve legal empowerment, addressing stigma and discrimination, critical barriers to achieving UNAIDS 95-95-95 goals.
Collaborative approaches and tailored interventions ensure equitable access to HIV prevention, treatment, and care.
Conclusions/Next steps: Scale up paralegal networks, enhance rights-based training, and foster partnerships to eliminate legal barriers, improving outcomes across the HIV cascade and to advocate for policy reforms to ensure sustainable access to justice and rights protection.

EP0630

The role of patent oppositions and higher patentability criteria in facing up to monopolies on HIV and TB drugs

P. Sivasubramanian[1], R. Rodrigues[1]
[1]*Third World Network, Penang, Malaysia*

Background: Prolonged monopolies on essential medicines driven by secondary patenting and evergreening strategies, limit access to affordable treatment in low- and middle-income countries. While patent opposition mechanisms are often criticized for delaying drug approvals, they are crucial in preventing unjustified patents that extend monopolies without genuine innovation.
This study examines the effectiveness of India's patent opposition system in challenging weak patents on the HIV drug dolutegravir and the TB drug bedaquiline. It also

explores pharmaceutical evergreening tactics and the legal, technical, and financial considerations involved in patent opposition.

Methods: This study analyzes successful patent oppositions against secondary patents on tenofovir and bedaquiline in India in the period of 2019 to 2024. Data was collected from patent office records, opposition filings, and reports from civil society organizations. The analysis focuses on legal arguments, case outcomes, and the impact on generic drug availability and pricing.

Results: India's patent law provisions, like inventive step requirement and Section 3(d), which restrict patents on minor modifications without significant therapeutic benefits, have demonstrated its importance in promoting public health interest. Patent oppositions in India have effectively blocked weak secondary patents, enabling timely entry of generic alternatives and fostering competition. As a result, national treatment programs have been rolled out with more affordable HIV and TB medicines, increasing access and promoting health system sustainability.

Conclusions: Strengthening patent opposition mechanisms and enforcing rigorous patentability standards are essential to curbing the misuse of patent laws and ensuring equitable access to life-saving medicines. The findings underscore the need for global cooperation and national policy reforms to protect public health. Balancing innovation with the urgency of affordable treatment remains critical to sustainable HIV and TB care.

EP0631

Leveraging mobile phones by peer educators to monitor and report HIV-related human rights violations in the framework of the 47th cycle universal periodic review of DRC

M. Aaron Clevis[1], N. Dieu Merci[1], K. Baeni Jemima[2], A. Chimenesa Grace[3], K. Mwiza Huguette[1]

[1]Repro Justice Congo, Goma, Congo, the Democratic Republic of the, [2]University of Goma, Public Health, Goma, Congo, the Democratic Republic of the, [3]University of Goma, Law, Goma, Congo, the Democratic Republic of the

Background: The purpose of this research was to enhance the visibility of human rights violations faced by LGBTQ+ individuals in the Democratic Republic of Congo (DRC), particularly during the 47th cycle of the Universal Periodic Review (UPR). The objective was to collect, document, and report violations affecting key populations, including LGBTQ+, to ensure their inclusion in human rights discussions. The research also addressed the limited participation of LGBTQ+ groups in the UPR process, highlighting a lack of knowledge and confidence in the process among affected communities. The aim was to bridge these gaps and advocate for inclusive policies.

Methods: With support from the Elton John AIDS Foundation, Repro Justice Congo embarked on the process of monitoring, collecting, and documenting human rights violations faced by the LGBTQ+ community in DRC from September 2023 to February 2024. Peer educators, trained and equipped with mobile phones for real-time reporting, monitored violations. A team of lawyers supported case analysis. The Redcap platform was used to confidentially document eligible cases. This study aimed to enhance the visibility of LGBTQ+ human rights violations and advocate for their protection.

Results: 49 cases of human rights violations against LGBTQ+ persons were reported and documented, with 26 related to access to HIV services. The findings were submitted to the UPR process, with peer educators engaging with the UPR technical working group through virtual meetings. As a result, the issue was included in the stakeholders' summary report, as well as in the UN's compiled report. This led to four recommendations directed at DRC to improve the human rights situation for LGBTQ+ individuals.

Conclusions: The findings highlighted barriers faced by LGBT in accessing HIV services, particularly stigma and discrimination. By documenting these violations and submitting them to the UPR process, the research contributed to the inclusion of LGBTQ+ issues in the broader human rights discourse.

The four recommendations issued to DRC are a significant step towards improving legal protections and healthcare access for LGBTQ+ individuals. In the future, these results can guide policy changes, inform advocacy strategies, and strengthen support networks, ensuring more inclusive and accessible HIV prevention, treatment, and care services for LGBT.

EP0632

The impact of domestic violence and stalking on HIV risk: insights from Title 18 USC Chapter 110A, Section 2261

S. Glass-Broom[1]

[1]N/A, MEMPHIS, United States

Background: This study aims to analyze the increased risk of HIV among people experiencing domestic violence and stalking, as addressed by Title 18 USC Chapter 110A, Section 2261. The hypothesis is that individuals in such situations face higher HIV risks due to coercive sexual activities and limited access to healthcare. According to the CDC, about 41% of women and 26% of men have experienced contact sexual violence, physical violence, or stalking by an intimate partner.

Methods: The study was conducted over a one-year period, focusing on various locations across the United States. It involved a comprehensive review of legal documents, medical literature, and case studies. Data was collected from court records, healthcare reports, and interviews with healthcare professionals and individuals affected by domestic violence and stalking. The analysis aimed to identify patterns of abuse, the prevalence of HIV among these individuals, and barriers to accessing healthcare and prevention resources.

Results: The findings indicate a strong correlation between domestic violence, stalking, and increased HIV risk. People experiencing domestic violence and stalking are often subjected to forced unprotected sex, limiting their ability to negotiate safer sex practices. The isolation and

control tactics used by abusers further restrict access to healthcare and HIV prevention resources. Women who experienced intimate partner violence were over three times more likely to have a diagnosis of HIV/AIDS. The psychological impact of abuse also contributes to risky behaviors and a weakened immune system, increasing susceptibility to HIV.

Conclusions: Title 18 USC Chapter 110A, Section 2261, is crucial for addressing the legal aspects of domestic violence and stalking. However, integrated approaches combining legal protection with healthcare support are needed to mitigate the increased HIV risk among affected individuals. Enhancing access to healthcare, providing comprehensive support services, and raising awareness about the intersection of domestic violence, stalking, and HIV are essential steps in reducing the vulnerability of these individuals. Future policies should focus on creating a supportive environment that empowers people to seek help and access necessary resources without fear of retribution or stigma.

EP0633

PrEP policy in a long acting era: a policy barrier study of 179 countries

M. Kavanagh[1], V. Srivatsan[1], T. Parenti[1], L. Gil Abinader[1], V. Unnikrishnan[1], S. Lynch[1]
[1]Georgetown University, O'Neill Institute for National and Global Health Law, Washington, United States

Background:
Having missed the opportunity to use oral PrEP to reverse the course of the HIV epidemic, Lenacapavir now offers a historical moment to shift this trajectory. To fully capitalize on this, countries must close the gaps in PrEP eligibility policies and regulatory approvals that have now left millions without PrEP, resulting in uptake falling more than 80% below UNAIDS targets for 2024.

Methods: The HIV Policy Lab housed at Georgetown University is a online public data platform that longitudinally tracks 33 key legal and policy indicators critical to the HIV response. The analysis and visualization of national legal and policy environments, and their alignment with global norms are informed through a thorough review of legal and policy documents and comprehensive review of the data collected from global surveys of government officials.

On PrEP, a composite index assesses countries' alignment with World Health Organization guidance on i) population-specific eligibility and ii) regulatory approvals for different PrEP technologies.

Results: An analysis of national policies on PrEP in 179 countries shows policy remains a barrier to access. Sero-discorant couples had the highest eligibility for PrEP, followed by men who have sex with men, sex workers, transgender people and people who inject drugs.

Fewer than 50% of the countries make PrEP eligible for adolescent girls and young women. PrEP eligibility was determined based on either population-specific or general criteria that make PrEP accessible to high-risk individuals as outlined in national PrEP policies.

Among the various available PrEP technologies—oral, injectable, and vaginal ring—nearly three-quarters of the countries had granted regulatory approval for at least one of these options.

Conclusions: While oral PrEP is effective, policy gaps have hindered its full potential. However, Lenacapavir offers a unique opportunity to address these gaps in HIV prevention, particularly for high-risk groups who face issues with adherence or require a more frequent dosing schedule. Expanding PrEP eligibility policies by creating demand for Lencapavir can help accelerate the availability of generics while failing to use this opportunity may lead to governments rationing access to PrEP among vulnerable groups undermining efforts to end AIDS.

EP0634

Addressing misconceptions in clinical services uptake by adolescent girls and young women: debunking harmful social, religious, and cultural norms - insights from six districts in Zimbabwe

G. Mavheneke[1], B. Mukome[1], R. Mundingi[1], E. Nyakanda[1], G. Shumba[1], T. Nyatsanza[1]
[1]FACT Zimbabwe, Mutare, Zimbabwe

Background: Adolescent girls and young women (AGYW) in Zimbabwe and Africa south of the Sahara face significant barriers to accessing clinical services, often rooted in harmful social, religious, and cultural norms. These misconceptions hinder health-seeking behaviors and contribute to adverse health outcomes. Fear of judgment, misinformation about services, and cultural taboos create formidable obstacles. Addressing these misconceptions is crucial for improving health outcomes among this demographic.

This presentation discusses a targeted intervention aimed at debunking these harmful norms and fostering a supportive environment for AGYW to access clinical services in Chipinge, Chivi, Gutu, Makoni, Mutare, and Zaka districts of Zimbabwe.

Description: Our multifaceted approach involved community engagement, leadership involvement, education, and collaborative dialogues. Traditional and religious leaders were trained on the Changing the River's Flow Dialogue Model and supported in conducting six community dialogues each on harmful norms and practices.

These dialogues brought together AGYW, community leaders, healthcare providers, and parents to openly discuss myths surrounding clinical services. The discussions culminated in drafting locally enforceable commitments, such as making clinics the first referral points for abused girls and ensuring timely reporting of gender-based violence cases to law enforcement.

Additionally, we developed educational materials to address misconceptions and highlight the importance of healthcare access.

Lessons learned: Initial assessments revealed that 70% of AGYW felt uncomfortable accessing clinical services due to misconceptions. Post-intervention surveys indicated a substantial shift: awareness of available services increased by 65%, and the number of AGYW willing to seek

clinical care rose by 50%. Participants emphasized the value of community discussions in transforming perceptions and reducing stigma.

Conclusions/Next steps: The successful debunking of harmful norms not only enhanced clinical service uptake among AGYW but also cultivated a supportive community environment. Moving forward, we recommend scaling these interventions, integrating feedback mechanisms to adapt strategies, and collaborating with local leaders to sustain momentum.

We invite stakeholders to commit to creating a more enabling environment for AGYW by prioritizing education and engagement. Together, we can dismantle barriers to health and empower young women to take control of their well-being.

EP0635

The association between social determinants of health and HIV risk behaviors and HIV testing among sexual and gender minority individuals: a national survey study

E. Utaka[1], F. Shi1[2], H. Xia[1], X. Yang[1], Y. Brooks[1], D. Friedman[1], L. Donelle[3], X. Li[1], H. Zhang[2]

[1]University of South Carolina, Department of Health Promotion, Education, and Behavior, Columbia, United States, [2]University of South Carolina, Health Promotion, Education, and Behavior, Columbia, United States, [3]University of South Carolina, Department of Nursing, Columbia, United States

Background: Social determinants of health (SDOH) predispose Sexual and Gender Minority (SGM) individuals to HIV through risky behaviors and less HIV testing. A composite SDOH measure could capture the cumulative impact of interrelated social factors on health outcomes.

Using data from the 2022 Behavioral Risk Factor Surveillance Survey (BRFSS), this study aimed to evaluate the association between composite measures of some SDOH and HIV risk behaviors and HIV testing among the adult SGM population in the US.

Methods: SGM individuals were identified through two questions that asked about respondents' sexual orientation and gender identity. Two primary outcomes of interest were HIV testing behavior and HIV risk behavior, and both were dichotomized as yes/no responses.

Participants who responded "don't know/not sure" or "refused" were excluded from analysis for each outcome, resulting in different sample sizes based on the number of valid responses available for each measure. SDOH was measured by ten items. We summed up the response score of each item to get a composite score, where a higher score indicates a worse social disadvantage.

A logistic regression model was developed to examine the association of SDOH composite score with HIV risk behaviors and HIV testing, adjusting for some other social demographic characteristics as confounders.

Results: In the BRFSS dataset, 10,401 SGM individuals provided yes/no responses to the HIV testing question, with 5,696 (54.76%) reporting lifetime HIV testing. For the HIV risk behavior question, 10,685 SGM individuals responded yes/no, of whom 2,059 (19.27%) reported engaging in HIV risk behaviors. SGMs with more social disadvantages (a high composite SDOH score) were more likely to engage in HIV risk behaviors (Adjusted Odds ratio (AOR) =1.15, 95% Confidence interval (CI) =1.12, 1.19) but also have a high likelihood of HIV testing (AOR=1.09, 95% CI=1.06, 1.12) compared with those with less social disadvantages.

Conclusions: A high composite SDOH score is associated with increased HIV risk behaviors and high HIV testing among socially disadvantaged SGM individuals.

This pattern reflects disparities in risk exposure and underscores the impact of targeted testing among vulnerable groups. Reducing the HIV burden among the SGM population requires addressing structural factors through multifaceted approaches.

EP0636

Unlocking access to long-acting HIV medications: a 194 country study of compulsory licensing

M. Kavanagh[1], L. Gil Abinader[1], V. Srivatsan[1]

[1]Georgetown University, O'Neill Institute for National and Global Health Law, Washington, United States

Background: Long-acting medications could become a significant breakthrough in the prevention of HIV, if globally accessible. In October 2024, Gilead announced a voluntary license authorizing six companies to supply generic lenacapavir in 120 countries.

Middle-income countries excluded from this agreement may expand access with compulsory license - which allow their governments to authorize generic supply without patent holders consent - if national laws permit rapid access.

Methods: The HIV Policy Lab is a global public data platform that longitudinally tracks 33 key legal and policy indicators that shape the course of the HIV epidemic. The analysis, based on an expert review of legal documents and data review of a global survey of government officials, evaluates national legal environments and their alignment with global norms.

Using a novel dataset containing more than 200 intellectual property laws and policies we determined:

1. Which countries excluded from the Gilead voluntary agreement have compulsory licensing laws, and;
2. Whether civil society organizations can formally trigger legal proceedings.

Results: 84 of the 88 countries excluded from the lenacapavir agreement have compulsory licensing laws. National governments can use these provisions as leverage to negotiate greater access conditions or authorize the generic supply of lenacapavir without Gilead's consent.

However, 65 these 84 laws limit participation of civil society organizations in compulsory licensing proceedings.

While a handful of countries excluded from the Gilead agreement allow civil society organizations to formally trigger proceedings, most legislations have *TRIPS plus* provisions requiring compulsory licensing applicants to demonstrate manufacturing or economic capabilities before lodging a petition. These provisions weaken global efforts seeking greater access to lenacapavir.

Conclusions: Compulsory licensing provisions are widely adopted including in 84 of the 88 countries excluded from the Gilead lenacapavir agreement. However, there is a need for short- and medium-term reforms to enable the formal participation of civil society in compulsory licensing processes. Granting the ability to these organisations to formally trigger compulsory licensing proceedings would enhance their ability to enhance their ability to influence national policy agendas and advocate for the expanded access to lenacapavir.

EP0637

Risk of displacement based on neighborhood level socio-economic factors relates to higher intersectional discrimination and trauma exposure among black women living with HIV in Miami, FL, USA

I. Wright[1], M. Wright[2], S.K. Dale[2]
[1]University of Miami, Economics, Miami, United States, [2]University of Miami, Psychology, Miami, United States

Background: Socio-structural factors such as racism, stigma, poverty, unstable housing, and limited access to care play a role in the impact of HIV among Black women in the U.S. Displacement from neighborhoods they reside in may have implications for their health and well-being. Using neighborhood and individual level variables we examined the relationships between risk of displacement, experiences of discrimination, and trauma exposure among Black women living with HIV.
Methods: Among 151 Black cisgender women enrolled in a cohort study in Miami, FL, baseline data was collected (2019-2020) on trauma exposure, discrimination (related to HIV status, race, gender, and sexual orientation), and sociodemographic variables (e.g., income).
Change in zip code level data (2014 – 2019) on poverty level above 150%, bachelor degree, Black individuals, White individuals, renter occupied house, owner occupied house, median gross rent, and Airbnb house and apartment fees were used to assess the risk of displacement (dichotomized [0, 1]).
Spatial analyses and nonlinear regression models were conducted accounting for robust standard errors (controlling for age and crime) to assess risk of displacement on discrimination and trauma exposure using Stata version 18.
Results: Spatial analyses and nonlinear regressions indicated that higher risk of displacement was associated with higher trauma exposure (5.78 [2.78], p<.01) and higher discrimination experiences related to HIV-status (4.22 [4.97], p<.01), race (4.50 [4.41], p<.01), gender (3.46 [4.52], p<.01), and sexual orientation (3.44 [3.34], p<.01).
Conclusions: Our findings echo the need for policy and resources geared at addressing socio-structural factors. Ongoing research is needed to inform multi-level interventions that may be beneficial in minimizing the impacts of displacement and improving the well-being of Black women living with HIV.

Community-engaged/participatory social science-based interventions

EP0638

High prevalence of genital diseases among young female domestic workers in Mali and the role of community-based support in promoting sexual health: the ANRS-0005S 2DM2K project

M. Fiorentino[1], F. Cavaro[1], B. Coulibaly[2], M. Hoyer[1], A. Kamissoko[2], F. Traoré[2], B. Diarra[2], M. Koné[3], S. Dramé[2], M. Cissé[2], B. Dembélé Keita[2], B. Spire[1], S. Fofana[3], L. Sagaon-Teyssier[1]
[1]IRD, Aix Marseille Univ, Inserm, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France, [2]ARCAD Santé PLUS, Centre Intégré de Recherche, de Soins et d'Action Communautaire (CIRSAC), Bamako, Mali, [3]ADDAD Association de Défense des Droits des Aide-ménagères et Domestiques, Bamako, Mali

Background: In Mali, the increasing migration of rural girls to work as domestic workers in cities exposes them to sexual health vulnerabilities due to young age, poverty, sexual violence, exploitation, lack of knowledge, and limited access to adapted care. We aimed to characterize young female domestic workers (YFDW) who tested positive for genital diseases or declined testing during community-based activities.
Methods: As part of the ANRS-0005S 2DM2K project (2023), sessions were held in Bamako neighbourhoods (communes 2,4,6) and in provinces, to inform YFDWs about the integration of a global and sexual health offer, provided by ARCAD-Santé PLUS, into routine community activities organized by the ADDAD association (YFDW peer-based support). Genital diseases testing (GDT) requiring gynaecological sampling was offered to sexually active YFDWs during medical visits.
We used multinomial logistic regression to assess factors associated with i) declining GDT and ii) genital diseases (reference: accepted and all tests negative).
Results: Of 908 YFDW participants to community activities, 746 requested a medical visit, and 222 were eligible to GDT. Among them, 46%(102) declined it, 54%(120) accepted, 30%(66) tested all negative, and 24%(54) tested positive for ≥1 genital condition (*Candidiasis sp.* n=24, *Gardnerella vaginalis* n=19, Human papillomavirus n=15). Compared to YFDW who had all tests negative, YFDW who tested positive and those who declined GDT were less likely to regularly attend ADDAD (aOR: 0.09, 95% CI[0.02–0.49], p=0.005; 0.34[0.12–0.97], p=0.044), and had lower monthly incomes (5500–15,000 FCFA [8-23 USD]: 6.11[1.44–26], p=0.014; 4.52[1.23–16.6], p=0.023; reference:≥15000 FCFA). YFDW who tested positive were younger (0.9[0.82–0.99] per year, p=0.030). Those who declined GDT had a lower contraceptive knowledge score (0.8[0.67–0.95] per point, p=0.011) and were less likely to have accepted pregnancy testing offered during the medical visit (0.19[0.05–0.76], p=0.019).
Conclusions: The prevalence of HPV, *Candidiasis sp* and *Gardnerella vaginalis* diseases was high. Regular attendance at ADDAD increased the acceptability of sexual

health procedures and reduced genital diseases, while socioeconomic vulnerability and low reproductive health knowledge had the opposite effects. Peer-based support and tailored interventions improve sexual healthcare access, but more efforts are needed to reach and engage the most vulnerable YFDWs.

EP0639

Engaging communities in maternal syphilis and HIV co-infection prevention through participatory research: insights from Zambia

M. Chipunza[1], L. Nchimunya[1], P. Haimbe[2]
[1]Clinton Health Access Initiative, Maternal syphilis, Lusaka, Zambia, [2]Clinton Health Access Initiative, Infectious Diseases, Lusaka, Zambia

Background: Maternal syphilis and HIV co-infection pose severe public health risks, including adverse pregnancy outcomes such as stillbirths, neonatal deaths, and congenital infections. In Zambia, limited awareness, socio-cultural barriers, and healthcare misconceptions hinder timely diagnosis and treatment, complicating efforts toward disease elimination.
Methods: A participatory research approach was employed in Lusaka, Copperbelt, and Northwestern provinces, targeting 19 health facilities identified as syphilis and HIV hotspots. Community discussions were conducted with men, women of childbearing age, and elders using a structured interview guide. Health facility staff attended but did not intervene. Responses were anonymized and analyzed for emerging themes on knowledge, beliefs, and healthcare-seeking behavior.
Results: Participants demonstrated limited knowledge of syphilis and HIV co-infection, often confusing syphilis with gonorrhea and attributing infections to unhygienic practices like using public toilets or drinking dirty water. Herbal remedies were frequently cited as more effective than conventional medicine, particularly among men.
Misconceptions about maternal syphilis and HIV transmission, diagnosis, and treatment were widespread. Male involvement in maternal health was minimal, constrained by cultural norms, stigma, and economic barriers.
Conclusions: Developing culturally appropriate IEC materials, engaging traditional and religious leaders, and conducting large-scale community sensitization campaigns are critical. Introducing men's clinics and promoting couple-based antenatal care can strengthen early diagnosis and treatment of syphilis and HIV co-infections.
Participatory research revealed deep-rooted misconceptions about maternal syphilis and HIV co-infection. A community-driven, culturally sensitive approach is essential to design effective interventions that address these knowledge gaps, promote early care-seeking, and improve maternal and neonatal health outcomes in Zambia.

EP0640

Contrasting social media strategies for trial recruitment in the US, South Africa and Thailand

C. Beyrer[1], S. Bock[2], N. Zylberberg[3], S. Kacungira[4], M. Poonsaketwattana[5], HVTN, COVPN and COPE Study Groups
[1]Duke University, Duke Global Health Institute, Durham, United States, [2]HIV Vaccine Trials Network, Seattle, United States, [3]Socialisssima, Austin, United States, [4]BLU Flamingo Africa, Johannesburg, South Africa, [5]APCOM, Bangkok, Thailand

Background: When adapted to the communities it seeks to reach, social media can support study recruitment. Best practices often generalize based on the developed world without examinations across diverse geographies.
Description: Contrasting three social media case studies in diverse locations with differing populations, cultures and digital environments revealed common principals and unique applications.
A 30-month, US social media campaign for HIV vaccine clinical trials focused on BIPOC and LGBTQ+ communities was developed with community input with micro-targeted messages to priority groups EG: Black faith leaders, MSM, LatinX, and Trans communities. Social media influencers including a woman of trans experience, a Latina woman living with HIV, a Black educator/activist, and a gay Black man were engaged to create content on their Instagram, TikTok, Facebook and YouTube channels. The campaign directed users to a study registry and secured nearly 5000 signups.
A South African social media campaign for COVID-19 vaccine studies was produced in 5 languages and featured local people and familiar settings. Data on social media performance was collected in addition to a post-campaign study showing 40.77% of respondents recalled the ad and 44.92% of respondents' reported their perception had shifted to considering participating in a COVID vaccine trial after seeing the ads.
The Thai campaign engaged social media influencers (SMI) to promote short, scenario-based videos developed with MSW-specific content to reach their combined 5 million+ LGBTQ followers. From September 2018 through August 2019 the SMI led to 17,393 website views and 63.3 men/month enrolled in a PrEP study, a marked increase over the prior period. Among later recruits, 36.4% reported learning of the study through social media.
Lessons learned: Social media campaigns reflecting community messages, messengers and culture show positive impacts on the steps towards study participation: awareness, education, consideration and site contact. Consistent data collection across case studies was a challenge due to limits of software and digital platforms, and/or local regulation.
Conclusions/Next steps: Social media is a useful tool for outreach when the content has local relevancy. Due to the digital divide, social media may not reach all communities and non-digital media remains an important tool.

EP0641

The role of community-led monitoring for quality health improvement in Nigeria

F.J. Medayese[1], A. Ibrahim[2], N. Ugbenyen[2], J. Atusue[2], O. Obeten[3], O. Adebayo[4], U. Ugwoke[4]
[1]Network of People Living with HIV/AIDS in Nigeira, Monitoring and Evaluation, Abuja, Nigeria, [2]Network of People Living with HIV/AIDS in Nigeria, Programs, Abuja, Nigeria, [3]Network of People Living with HIV/AIDS in Nigeria, Monitoring and Evaluation, Abuja, Nigeria, [4]Institute of Human Virology, Nigeria, Programs, Abuja, Nigeria

Background: In the pursuit of ending HIV and AIDS by 2030, it has become evident that Communities hold the health systems accountable by empowering community members to monitor service delivery, identify gaps and implement solutions. Community-Led Monitoring (CLM), an intervention under Nigeria's Global Fund GC7 grant and led by the Network of People Living with HIV (NEPWHAN) is being implemented across 13 States in Nigeria. The strategy aims to improve the quality-of-service provision through routine community-level data collection, translate these data into actionable insights, and bring the information to the attention of decision-makers and advocate for changes in policy and practice.
Description: A cross-sectional descriptive study was conducted across the 13 states of Nigeria where community-led monitoring is being implemented from April to June 2024. Quantitative data was collected using the mobile application, community iMonitor, while qualitative data was from focus group discussions. Quantitative data was obtained from the backend of the app, exported and analyzed using IBM SPSS Statistics 23 while qualitative data was analyzed using inductive thematic analysis.
Lessons learned: A total of 8828 responses were recorded from the app and 6 focus group discussion sessions with 6 participants each were conducted across the 13 states. 71.6%, 13% and 9% of the responses were from PLHIV, Key Population; and adolescent and young persons (AYP) respectively.
From the iMonitor, the top three major challenges reported were access to mental health services 47.9%, access to legal services 44.8% and stock-out of condoms and lubricants 5.3%. The qualitative data focused on 4 themes which are barriers to treatment, quality of care, availability of commodities, gender and human rights.
The top three areas of challenges include lack of nutritional support, stock-out of condoms and lubricants, and lack of access to mental health and legal services.
Conclusions/Next steps: Continued monitoring, led by the community is a very important approach to enhancing person-centred care and improve service quality for both the persons living with HIV, the key and vulnerable population.
Addressing the identified issues through targeted interventions and engaging with key policymakers will be crucial in achieving epidemic control and ending AIDS by 2030.

EP0642

Providing psychosocial support through online community-based engagement program to empower the future of youth

S. Wu[1], K. Anggita[1], E. Widiastuti[2], T. Ittihadia[2]
[1]Universitas Katolik Indonesia Atma Jaya, Jakarta, Indonesia, [2]Lentera Anak Pelangi, Jakarta, Indonesia

Background: In 2023, Adolescents and Young Adults (AYA), ages 15-24 years old, accounted for 53.6% of new global infections (WHO, 2023). In Indonesia, AYA accounts for 46.4% of total new infections (Ministry of Health Indonesia, 2023). As of December 2022, Indonesia's achievement toward triple 95s was 81-41-19.
Description: LAP is a non-profit organization supporting Children and Adolescents Living with HIV (CLHIV, ALHIV) in Indonesia. Since 2009, it has served over 250 beneficiaries, with ALHIV comprising 65%. Since 2022, LAP piloted Indonesia's first in-person and online support to foster positivity and improve ART adherence through community engagement.
In 15 years of service, many CLHIV supported by LAP have since reached the age of AYA. LAP's AYA, are critically vulnerable (LAP, August 2024):

1. 70% beneficiaries come from marginal socioeconomic background
2. 64.55% have lost one or both parents
3. Mortality rate is 14.98%; AYA accounts for 60%
4. 73% AYA have progressive AIDS, 30% suffer from disabilities
5. >40% of ALHIV has interruption or discontinuation of ART

Lessons learned:

1. Online community-based programs reach more beneficiaries who are geographically challenged. Within 2 years, the group grew from 8 to 69 participants
2. More than 30% AYA resumed ART, and 60% have improved adherence
3. 50% participated in life-skill education, 20% enrolled in leadership programs for peer group facilitators and influencers

Conclusions/Next steps: LAP's beneficiaries' profiles represent many CLHIV and AYA in Indonesia. Due to resource limited HIV care in Indonesia, coupled with marginal backgrounds, stigma, and discrimination, most AYA do not have adequate access to care and support. Many are unaware that they have HIV.
Virtual-based programs offer a promising solution to fill the blank space in HIV care across Indonesia. Building an online hub allows people to access information, support, and engage with peers conveniently while protecting privacy. LAP's community-based online peer engagement programs have better outreach, are less costly, and effectively enhance mental health and psychosocial support. Thus, peer engagement is an effective approach to fostering positivity and improving ART adherence for better living outcomes.

EP0643

Adapting community case management strategy to improve HIV treatment outcomes outside OVC sites in 2023: lessons learnt from the 'Sungani Bana' initiative in CDC supported provinces in Zambia

C. Muleya[1], B. Mainza[2], P. Sakala[3], S. Mainza[2], C. Muleya[2], T. Zilundu[2], H. Simwala[2], C. Mumbwe[4], M. Phiri[5], V. Manzi[6], B. Wabanza[7], N. Flowers[8], B. Alvarez[8], O. Mwiinde[1], K. Mweebo[1], O. Chituwo[1], A. Mwila[9]

[1]US Centers for Disease Control and Prevention, Division of Global HIV and TB, Lusaka, Zambia, [2]Development Aid from People to People, Lusaka, Zambia, [3]Circle of Hope, Lusaka, Zambia, [4]Ministry of Health, Mongu, Zambia, [5]Center for Infectious Disease Research in Zambia, Kabwe, Zambia, [6]Ministry of Health, Lusaka, Zambia, [7]Ministry of Health, Choma, Zambia, [8]US Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta Giorgia, United States, [9]UNICEF Zambia Country Office, Lusaka, Zambia

Background: Children and adolescents living with HIV (C/ALHIV) in Zambia are disproportionately offtrack from achieving the UNAIDS goals of 95/95/95, with 72.8% of adolescents and young people (AYP) 10-24 years, living with HIV being diagnosed, 71.7% on antiretroviral therapy (ART) and 66.6% being virally suppressed. HIV testing, access to and retention in care for C/ALHIV are largely dependent on their caregivers. Unmet psychosocial and economic needs impact caregivers and subsequently the ability of C/ALHIV to adhere to their treatment.

The United States Centers for Disease Control and Prevention (CDC) Zambia demonstrated improved clinical outcomes of C/ALHIV receiving Orphans Vulnerable Children (OVC) case management. However, the program is only in seven of the 50 CDC supported districts. Therefore, in 2022, CDC Zambia adapted the OVC case management strategy to develop the "Sungani Bana initiative (SBI)". This initiative provides child-centered case management in non-OVC program districts, aiming to minimize barriers for C/ALHIV, and enhance their treatment outcomes. To assess the effectiveness of SBI, we analyzed interruption in treatment (IIT), viral load coverage (VLC), and suppression (VLS) after one year of implementation in 160 SBI sites across 30 districts.

Description: We identified community case workers and trained them in the SBI. Case workers established a trusting relationship with C/ALHIV ages 0-19 years and their families. Each case worker supported up to 20 C/ALHIV, through monthly home visits, appointment reminders, tuberculosis (TB) screening, nutrition assessment, disclosure counselling, adherence counseling, and linkage to other client need-based support services.

After one year of implementation, we analyzed IIT, VLC and VLS in 160 SBI supported sites using PEPFAR Program data for 2022 and 2023.

Lessons learned: Between October 2022 (pre-implementation) and September 2023 (post-implementation), IIT decreased from 3% to 1%, VLC increased from 79% to 84% and VLS increased from 93% to 95% in the 160 implementation sites.

Conclusions/Next steps: Community case management through the SBI yielded improved treatment outcomes for C/ALHIV. CDC Zambia will continue to scale up the model to all non-OVC sites to enhance treatment outcomes among all C/ALHIV.

EP0644

CekUpYuk.id: a community-driven digital tool addressing critical HIV & STI education and prevention gaps among men who have sex with men (MSM) in Indonesia

E. Eril[1], M.A.J. Martins[1], D.P. Rahmawati[2], T.P. Muhamad[1], N. Kawi[3], H. Luis[4], M. Oktaviani[2], A.S. Azwar[5], E. Sukmaningrum[6], S. Wignall[4], E. Sihotang[3], H. Rahman[3], P.P. Januraga[7], R.L. Hamers[2], I. Irwanto[6], K. Gedela[8], on behalf of the INTERACT study group

[1]Yayasan Kasih Suwitno, Jakarta, Indonesia, [2]Oxford University Clinical Research Unit Indonesia, Faculty of Medicine Universitas Indonesia, Jakarta, Indonesia, [3]Klinik Utama Globalindo, Jakarta, Indonesia, [4]Yayasan Bali Peduli, Denpasar, Indonesia, [5]Community Representative, Jakarta, Indonesia, [6]Atma Jaya Catholic University, HIV/AIDS Research Centre, Jakarta, Indonesia, [7]Udayana University, Centre for Public Health Innovation, Denpasar, Indonesia, [8]Chelsea & Westminster Hospital NHS Foundation Trust, 56 Dean Street Sexual Health Service, London, United Kingdom

Background: Indonesia faces a growing HIV epidemic among men who have sex with men (MSM), driven by the lack of basic sex education, societal conservatism, and stigma that hinder access to HIV prevention and care. CekUpYuk.id, developed collaboratively by community and clinical teams, addresses this gap by engaging MSM through personalised digital HIV risk-reduction interventions. The platform directs users to high-serving non-government sexual health clinics in Jakarta and Bali for acute HIV infection (AHI) testing under the Indonesia Intervention Study to Test & Treat People with Acute HIV Infection (INTERACT).

Description: CekUpYuk.id was co-designed by the INTERACT group and Yayasan Kasih Suwitno, a community organisation in Indonesia. We conducted a needs assessment through participatory workshops with MSM community groups in Jakarta and Bali to identify barriers and content preferences.

The digital platform integrates an interactive AHI algorithm for tailored risk assessments, educational modules (HIV testing, ART, PrEP, and STIs), and trust-building content (healthcare worker videos and community stories). CekUpYuk.id was launched in May 2024 and promoted via tailored posts on Instagram, TikTok, and X targeting Jakarta and Bali. We analysed user data, including risk assessments, social media engagement, and Google Analytics metrics.

Lessons learned: Between May-November 2024, CekUpYuk.id had 11,873 unique users and 14,650 sessions recorded, peaking in July (4,629 users and over 20,000 tracked actions). High engagement was recorded on 'STIs and HIV,' 'HIV Testing,' and 'Acute HIV Infection.' 1,680 indi-

vidual users completed the AHI-risk tool [1914 total assessments-752 (39%) among those under 25 years-old]; 80% (1,339) from Jakarta, 11% (185) Bali, and 9% (156) from other provinces. Of the users, 1,172 self-identified as male, 496 as female, 10 as non-binary, and 2 as transwomen. Posts garnered 117,242 TikTok views, 148,251 views on Instagram, and 435,000 impressions on X; reaching a combined Instagram and X following of over 30,000, driving peak user engagement.

Conclusions/Next steps: CekUpYuk.id engaged over 11,000 users and 1,600 individual risk assessments in five months, highlighting the unmet need for tailored digital HIV risk-reduction tools in Indonesia. Combining personalised risk assessments, community-driven education, and strategic social media outreach, the platform effectively addressed critical gaps in HIV/STI prevention and care for at-risk MSM.

EP0645

Catalysts of change: women's organizations driving HIV testing accessibility for pregnant women in remote areas of Lagos State

M. Okeneye[1], A. Adesina[1], O. Durosinmi-Etti[2], O. Ogungbade[3], C. Umeh[4], O. Majekodunmi[5], N. Nsungwara[6]

[1]John Snow Incorporated, Heartland Alliance LTD/GTE; ACE-6 Project (Public-Private Partnership, Lagos, Nigeria, [2]JSI Research & Training Institute, Country Directorate, Abuja, Nigeria, [3]West Africa Centre for Public Health and Development (WACPHD), Implementation Science, Lagos, Nigeria, [4]Heartland Alliance LTD/GTE, Chief of Party, Lagos, Nigeria, [5]Heartland Alliance LTD/GTE, Technical Directorate, Lagos, Nigeria, [6]Heartland Alliance LTD/GTE, Lagos State Program Management, Lagos, Nigeria

Background: Ensuring equitable access to HIV testing and prevention services for pregnant women in underserved communities remains a pressing challenge in Nigeria. The Association of Lady Pharmacists (ALPs), a women-led professional organization, partnered with the USAID-funded Accelerating Control of the HIV Epidemic (ACE-6) project to deliver life-saving interventions to women in Makoko, a densely populated suburb of Lagos State with limited healthcare infrastructure. This study aims to determine the effectiveness of the intervention.

Description: The outreach targeted pregnant and breastfeeding mothers without access to antenatal services. The USAID-funded ACE-6 project, through a public-private partnership approach, provided education on HIV transmission, prevention, and treatment options. With informed consent, the project offered the following services to other stakeholders: HIV testing and linking positive cases to antenatal clinics and PMTCT.

Lessons learned: Key outcomes of this intervention include the identification of four HIV-positive out of the 43 pregnant women tested. ALPs also distributed "Mother Love (Mama)" packs containing essential baby and hospital items to the 43 pregnant women (comprising of young women and girls between the ages of 15 - 24 years and women), promoting preparedness for delivery and encouraging the uptake of maternal care services. The four positive pregnant women in their third trimester were successfully linked to PMTCT services, achieving a 100% linkage rate. They all had safe deliveries, and their babies accessed Nevirapine and Zidovudine suspensions. At the same time, their first exposed infant diagnosis (EID) (the staff at the primary healthcare centre collected samples within 24 hours of birth) was negative.

Subsequently, it necessitated activating HIV service at the primary health centre within walking distance of the community. ALPs paid for a year subscription to the Lagos State Health Insurance Scheme for HIV-positive women to access continued care.

Conclusions/Next steps: This model is a testament to the effectiveness of gender-focused, community-driven solutions in addressing critical health challenges, one woman at a time.

EP0646

Identifying emerging local trends to inform interventions: a qualitative study on condom use behavior among at-risk dancers in Madhesh province, Nepal

A. Sharma[1], S. Kumar[1], A. Katuwal[1], M. Cassell[2], P.K. Thakur[3], S. Lama[1]

[1]FHI 360, EpiC Nepal, Kathmandu, Nepal, [2]FHI 360, HIV Program Optimization and Strategic Growth, Atlanta, United States, [3]FHI 360 Nepal, Strategic Information, Kathmandu, Nepal

Background: In fiscal year 2024, the Meeting Targets and Maintaining Epidemic Control (EpiC) project in Nepal reported sexually transmitted infection (STI) prevalence of 32% among the at-risk population in Madhesh province. An emerging trend was observed where entertainment groups (commonly called DJs) that employ at-risk women dancers were hired for religious and cultural celebrations.

Unprotected sex within and outside these groups may be associated with higher risk of STIs. This abstract outlines EpiC Nepal's study to understand and address the STI risk among at-risk dancers.

Methods: A phenomenological approach was used to explore the knowledge, experiences, and behavioral factors of dancers. Data were collected through 10 focus group discussions (FGDs) with 145 participants from eight districts (dancers: 77, operators: 12, owners: 36, "*malkins*" [at-risk agents who contract dancers to DJ events]: 20). Findings were thematically analyzed to identify common themes and patterns of risk behaviors.

Results: Participants reported moderate to low knowledge of HIV, STIs, and pre-exposure prophylaxis (PrEP). Dancers frequently engaged in unprotected sex with male owners, operators, or audiences. Eight (10%) dancers never used condoms; others used them occasionally. Reasons for low condom use were trust in partner's exclusivity, inconvenience, higher pay for condomless sex, unavailability, alcohol-related disinhibition, removing condoms during sex, and lack of knowledge on condom use for anal/oral sex. In condom demonstrations, only five

out of 15 (33%) randomly selected dancers performed correctly. In response, EpiC Nepal developed a condom negotiation wheel game and planned for creative events to address knowledge gaps.
Ten creative events were organized with the same groups after the FGDs, among which 57 (42%) perceived their HIV risk and were tested, with no positive results. Twenty-one (15%) were treated for STIs, 13 enrolled in PrEP, and five restarted PrEP. EpiC Nepal alerted DJ owners and *malkins* about the risks and arranged for outreach workers to deliver condoms at events.
Conclusions: EpiC Nepal will monitor emerging trends in different districts and at-risk population groups for early intervention against HIV and STIs. Monthly creative events will be restructured to foster regular meetups, enhance knowledge sharing, and facilitate HIV/STI prevention and testing.

EP0647

Revolutionizing HIV care for women: the power of person-centered differentiated models

M. Okeneye[1], A. Adesina[1], O. Durosinmi-Etti[2], O. Ogungbade[3], C. Umeh[4], O. Majekodunmi[5], N. Nsungwara[6]
[1]John Snow Incorporated, Heartland Alliance LTD/GTE, ACE-6 Project (Public-Private Partnership), Lagos, Nigeria, [2]JSI Research & Training Institute, Country Director, Abuja, Nigeria, [3]West Africa Centre for Public Health and Development (WACPHD), Implementation Science, Lagos, Nigeria, [4]Heartland Alliance LTD/GTE, Chief of Party, Lagos, Nigeria, [5]Heartland Alliance LTD/GTE, Technical Director, Lagos, Nigeria, [6]Heartland Alliance LTD/GTE, Lagos State Program Manager, Lagos, Nigeria

Background: Differentiated Service Delivery (DSD) models were developed to address the complexities of HIV care, including overburdened healthcare systems, limited access, and the diverse needs of people living with HIV (PLHIV). These models, endorsed by WHO and UNAIDS, emphasize person-centered care to achieve the UNAIDS 95-95-95 targets and Sustainable Development Goal 3.
This study evaluates the impact of a support group-led Facility ART Refill Group (FARG) and Community ART Refill Group (CARG) on viral suppression, retention in care, and quality of life among women living with HIV in a secondary health facility in South-West Nigeria.
Description: • Assess viral load suppression and retention in care among women engaged in FARG and CARG.
• Examine participants' experiences, focusing on benefits and challenges.
A mixed-methods approach was employed:
1. Quantitative Analysis: Retrospective review of patient records (TX_CURR, 2022) to assess viral suppression and retention.
2. Onsite Assessment: Vital signs (e.g., weight, BMI, blood pressure, blood sugar) and clinical indicators (e.g., viral load results, pill count) were measured during bi-annual refills and compared to baseline values.
Lessons learned: Outcomes from three service delivery models highlight the superiority of differentiated care:
• Community ART Refill Groups (CARG): 98% sample collection, 98% coverage, 97% viral suppression.
• Facility ART Refill Groups (FARG): 98% sample collection, 98% coverage, 98% viral suppression.
• No DSD: 82% sample collection, 76% coverage, 83% viral suppression.
FARG and CARG models demonstrated improved retention and viral suppression, showcasing the effectiveness of person-centered, community-linked interventions.
The onsite assessment showed that 99% of the women in CARG and FARG looked healthier and had better clinical outcomes than other women not assigned to a DSD model.
Conclusions/Next steps: This study affirms the transformative potential of DSD models in improving health outcomes for women living with HIV. Tailored care approaches achieved superior viral suppression (up to 98%) and retention rates (97–98%), fostering sustainable and patient-centered health systems. Scaling these models is essential for improving the quality of life for women living with HIV and their families, particularly in underserved settings.

EP0648

Perspectives on analytical treatment interruptions and prospects of an HIV cure amongst people living with HIV in Singapore

C.Y. Choy[1,2], Y. Hao[3,4], M.P.H.S. Toh[3], S. Archuleta[5], Y.E. Teh[6], E.C.Y. Sng[7], PA. Kumar[1], C.S. Wong[1,2,8], P.H. Lee[1], Z. Ferdous[1], Z.H. Tan[1], T. Le[5], T.C.P. Chia[5], L. Binte Hamid[6], S.K.L. Lee[6], A. Lee[7]
[1]National Centre for Infectious Diseases, Infectious Diseases, Singapore, Singapore, [2]Tan Tock Seng Hospital, Infectious Diseases, Singapore, Singapore, [3]National Centre for Infectious Diseases, National Public Health and Epidemiology Unit, Singapore, Singapore, [4]National University Hospital, National Public Health and Epidemiology Unit, Singapore, Singapore, [5]National University Hospital, Infectious Diseases, Singapore, Singapore, [6]Singapore General Hospital, Infectious Diseases, Singapore, Singapore, [7]Changi General Hospital, Infectious Diseases, Singapore, Singapore, [8]Yong Loo Lin School of Medicine, Medicine, Singapore, Singapore

Background: Singapore has yet to conduct an HIV cure trial, and studies involving analytical treatment interruption (ATI) may face scepticism from the community. This study aims to understand the perspectives of people living with HIV in Singapore regarding participation in functional cure research with ATI.
Methods: Participants were recruited from an HIV care facility in Singapore through study advertisements at study sites. The self administered survey collected demographic information, participants' views on ATI and HIV cure, their acceptability of ATI, and tolerance for CD4 decline and viral load fluctuations during ATI. Descriptive analysis, univariate analysis, and multivariable logistic models were performed to identify barriers and motivational factors influencing cure study participation.

Results: Of the 200 participants, 116 (58%) indicated they were likely to participate in a cure trial, while 84 (42%) were not. A majority, 94.5% (189/200), had never participated in an HIV clinical study previously. No significant differences in age, gender, sexuality, or duration of HIV diagnosis were observed between those likely to participate and those unlikely to do so. Key factors predicting participation included having at least a tertiary education (aOR 2.99, 95% CI 1.33-7.06) and identifying altruistic motivations, such as advancing research or benefiting others and oneself (aOR 2, 95% CI 1.57-2.61).
Participants less tolerant of potential increases in viral load or decreases in CD4 count during an ATI study were 23% less likely to participate (aOR 0.77, 95% CI 0.67-0.87).
The frequency of monitoring, availability of self-testing, and home visits did not significantly influence the likelihood of participation. The primary concern among participants was the risk of HIV transmission during an ATI study, with 82.5% (165/200) expressing concern.
Conclusions: Those more likely to participate in a cure trial involving ATI tend to have higher education, altruistic motivations, and fewer concerns about viral load or CD4 count outcomes. Increased outreach and education are vital to engage the community, build trust, and foster support for future ATI studies and HIV cure research.

EP0649

Applying community-led monitoring to community engagement: a person-centered approach to improving HIV service delivery and quality of care across 21 African countries

P. Murugan[1], N. Rafif[1], B. Killingo[1], N. Peerun[1], S. Perez[1], S. Baptiste[1], C.A.N. (Can)[1]
[1]ITPC, Build Resilient Communities, Johannesburg, South Africa

Background: Applying Community – Led Monitoring (CLM) to Community Engagement (CE) improves both the quality and efficiency of Differentiated Service Delivery (DSD) HIV services. Community Engagement (CE) is central to the success of DSD as it is a people-centered approach. However, there is a lack of rigorous and robust tools to monitor meaningful engagement of Recipients of Care (RoC), highlighting the need for CE monitoring tools to track meaningful engagement.
Description: The 18-indicator quantitative excel based CE tool was rolled-out across 21 Community Advocacy Network (CAN) country partners. CE was monitored retrospectively for the period 1 June 2022 to 31 May 2023 across the policy, program, and community levels of engagement as well as across the design, implementation, monitoring and evaluation areas of engagement. The level of engagement was assessed using a six – color coding system ranging from dark green (81-100%) to grey (0%).
Lessons learned: CE scores have progressed from 57% to 69% between 2022 and 2023 equivalent to a 21% increase. Levels of CE have risen by 70% in countries tracking CE since 2022. In 2023, 69% of CE scores were satisfactory or meaningful engagement (61%-100% achievement rate) as compared to a 49% satisfactory or meaningful engagement rate in 2022. Uganda, Burundi, Cameroon, Malawi and Senegal progressed by more than 40% in 2023 within the no current engagement domain (red: 0-40%).
Five countries (Rwanda, Liberia, Zimbabwe, South Africa, and DRC) scored meaningful engagement in 2023 (dark green 81-100%) as compared to only one country (Liberia) in 2022. A 35% increase in the policy level in 2023 was a result of meaningful engagement during the design of DSD policies, while the 18% increase in 2023 within the programme level was due to the implementation of the CQUIN Capability Maturity Model self-assessments. Meaningful CE in DSD across thematic working groups and demand creation contributed to a 10% increase across the community level in 2023.
Conclusions/Next steps: CLM serves as a crucial baseline for meaningful CE and quality DSD programs. Using CLM to monitor CE improves the relevance, acceptability, and effectiveness of DSD programs for sustained demand creation.

EP0650

Bridging gaps between communities and science – Lessons from Uganda's Cross-CAB Networking Forum

R. Serunkuuma[1,2,3], R.(. Wasswa Ssaku[4], D. Kalinzi[5], R. Tibakanya[6,7], P. Mudiima[8]
[1]Positive Men's Union (POMU), Advocacy and Networking, Kampala, Uganda, [2]UVRI-IAVI HIV Vaccine Program, Social Sciences Dept. / Community Advisory Board (CAB), Entebbe, Uganda, [3]Cross-CAB Networking Forum, Social Sciences, Kampala, Uganda, [4]Cross-CAB Networking Forum, Entebbe, Uganda, [5]Rakai Health Sciences Program (RHSP), Social Sciences / Community Engagement Dept., Kyotera, Uganda, [6]Africa Medical & Behavioural Sciences Organization (AMBSO), Community Liason Office, Hoima, Uganda, [7]Hoima District Forum of PLHIV Networks, Hoima, Uganda, [8]Makerere University - John Hopkins University (MU-JHU) Research Collaboration, Community Dept., Kampala, Uganda

Background: The annual Cross-CAB Networking Forum has since 2005 brought together at least 130 Community Advisory Board (CAB) members from eleven HIV research institutions in Uganda i.e. *Africa Medical & Behavioral Sciences Organization (AMBSO), Makerere University-Walter Reed Project (MU-WRP), Makerere University-John Hopkins University (MU-JHU), UVRI-IAVI HIV Vaccine Research Program, Infectious Diseases Institute (IDI), Rakai Health Sciences Program (RHSP), Joint Clinical Research Centre (JCRC), Baylor-Uganda, Mildmay-Uganda, The AIDS Support Organization (TASO) and MRC/UVRI & LSHTM Uganda Research Unit* for information sharing, networking, capacity building, advocacy and community mobilization. Stakeholders from relevant bodies including Uganda National Council of Science & Technology, ministry of health, National Drug Authority and AVAC have always attended the yearly event. Forum business is spearheaded by the Steering Committee of 11 CAB Liaisons and the Executive Committee composed of 11 CAB members drawn from the participating institutions.

Description: The Forum is hosted rotationally allowing each member institution to host an event preferably in their area of operations. While the Forum agenda is 70% generated by CAB members, the Institutions put together a basket-fund to meet accommodation, meals and other expenses. Participants include PLHIV, key populations, priority populations, former research participants and community gatekeepers including political and religious leaders. CABs present on areas such as community mobilization strategies, defining research terms, best practices and myths/misconceptions from communities.

Lessons learned: The Forum has helped in not only mitigating prospective research-related barriers but also in designing and informing research priorities for the country. It has also played key roles in building/strengthening collaboration between scientists and communities; making it a critical enabler for community participation in research. Furthermore, the basket-fund is an illustration that research implementers can fund their own programs and challenges before looking elsewhere.

Conclusions/Next steps: The Cross-CAB Networking Forum remains crucial in building research-competent communities in the country. It also provides both formal and informal opportunities of learning, networking, capacity building and advocacy which are key fostering and accelerating country-based approvals for proven products.

EP0651

Assessment of HIV treatment knowledge among People Living with HIV (PLHIV) in South-South Nigeria

B.C. Okoh[1,2,3], I. Elechi2[4], E. Odima1[2], O. Toyo[2], O. Onyedinachi[5], A. Adegboye[2], E. Etiemana I[2], J. Umana[2], S. Idowu[2], B. Jong[2], O. Esosuakpo[2], C. Obi[2], N. Mbaba[2], M. Echi[2], A. Eyo[2], N. Ibah[6], S. Nwakuba[2], S. Effiong[6], A. Azeez[2], I. Udo[2], K. Odey[2]

[1]University of Port Harcourt, Public Health, Portharcoult, Nigeria, [2]Excellence Community Education Welfare Scheme (ECEWS), Monitoring and Evaluation, Uyo, Nigeria, [3]Office of HIV and TB, United States Agency for International Development, Monitoring and Evaluation, Abuja, Nigeria, [4]Achieving Health Nigeria Initiative (AHNi), SI, Uyo, Nigeria, [5]Excellence Community Education Welfare Scheme (ECEWS), Program Management, Abuja, Nigeria, [6]Achieving Health Nigeria Initiative (AHNi), Monitoring and Evaluation, Uyo, Nigeria

Background: HIV treatment literacy among people living with HIV (PLHIV) is associated with optimal antiretroviral therapy (ART) adherence and treatment outcomes. However, there is limited data on HIV treatment knowledge among PLHIV receiving ART in Southern Nigeria.

This study assesses HIV treatment knowledge among PLHIV receiving ART in Akwa Ibom and Cross River States, Southern Nigeria.

Methods: This cross-sectional study included PLHIV (≥18 years) receiving ART at 53 high-volume PEPFAR/USAID-supported health facilities in Akwa Ibom and Cross River. Data was collected in February 2024 using a 4-question short-answer questionnaire that assessed client knowledge of HIV viral suppression, undetectable viral load, differentiated service delivery (DSD) models, and antiretroviral resistance. Respondents' data included age (18-24, 25-49, ≥50), sex, education (none, primary, secondary, or tertiary), occupation (unemployed, student, or employed), DSD model (Facility-based, Community-based, or none) and ART duration in years (<5, 5-9, 10-14, ≥15). Clients were adjudged to have good knowledge if they answered two questions (50%) correctly (ie stated key terms in the standard definition). Descriptive statistics summarised client characteristics, and associations between knowledge levels and demographic variables were tested using Chi-square.

Results: In total, 1,995 clients (60.7% [1,212/1,995] female) with a mean age of 38.3 (SD±11) years were assessed. Majority (52.1% [1040/1995]) were on ART for >4 years, 57.1%, (1140/1995) were on Facility-based DSD, 59.0% (1178/1195) had secondary education level, and 64.0% (1276/1995) were employed.

Overall, 97.2% (1940/1955) of clients had good knowledge; the highest and lowest proportion of correct responses were for defining "HIV viral suppression" (97.3% [1941/1995]) and "Antiretroviral resistance" (67.9% [1355/1995]) respectively. Good knowledge was higher among those with tertiary education (99.1%, p<0.01) or who were in DSD (97.6%, p<0.01), lower among those aged ≥50 years (94.4%, p<0.01), but comparable by sex (Females: 96.9% vs Males: 97.7%, p=0.32), duration on ART (<5 years:97.2%, 5-9 years:97.1%, 10-14 years:97.1%, ≥15 years:100%, p=0.54), and occupation (Unemployed:96.5%, student:98.2%, employed:97.4%, p=0.41).

Conclusions: Most PLHIV receiving ART in this setting had good knowledge of HIV treatment, particularly those with tertiary education or who were on DSD. Client-centered interventions to improve knowledge, especially on antiretroviral resistance and among elderly clients, are recommended.

EP0652

Exploring pay-it-forward initiatives for HIV care and retention among adolescent and young adults living with HIV (AYAH) in Kenya

H.F. Adhiambo[1], E. Akama[2], J. Lewis-Kulzer[3], G. Ontuga[4], E. Nyandieka[4], N. Sang[4], E. Nyagesoa[4], A. Muhinji[4], J. Osoro[4], I. Orenyo[4], E. Bukusi[4], L. Abuogi[5], E. Geng[6], Z. Kwena[7], D. Mangale[6]
[1]University of Washington, Child, Family and Population Health Nursing, Seattle, United States, [2]University of Washington, Global Health, Seattle, United States, [3]University of California San Francisco, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States, [4]Kenya Medical Research Institute, Centre for Microbiology Research, Kisumu, Kenya, [5]University of Colorado, Medicine, Denver, United States, [6]Washington Unversity in St Louis, Medicine, St Louis, United States, [7]Kenya Medical Research Institute, Center for Microbiology Research, Kisumu, Kenya

Background: Adolescents and young adults living with HIV (AYAH) face significant barriers that limit their engagement in HIV care services. Pay-it-forward (PIF) is a social practice where a community makes a donation to cover the opportunity costs of using a health service, and thereafter, the recipient is asked to donate to others in their community. Although this approach has demonstrated effectiveness in promoting behaviours people value but often defer (e.g. cervical cancer screening), the potential for PIF to enhance engagement in HIV services among young people in Kenya is not known.
Methods: In-depth interviews were conducted between March and November 2023 among participants enrolled in the Adaptive Strategy for Prevention and Treatment of Lapses in Retention in Adolescent HIV Care (A4A) study. We purposively selected 20 AYAH aged 14-24 receiving conditional cash transfers (CCT) due to poor engagement in care. Semi-structured interview guides were used to explore participant perspectives on PIF initiatives, including preferred modes of support, contribution amounts and participation determinants. The interviews were audio-recorded and transcribed verbatim into English and analyzed using thematic analysis.
Results: 57% of the participants were female, 47% were <18 years and a majority (87%) had at least a high school education. Three main themes emerged: motivation to participate in PIF initiatives, PIF mechanisms and PIF preferences for intervention delivery. AYAH were motivated by their commitment to prescribe to sociocultural norms that embrace kindness, generosity, and reciprocity, along with their desire to create and inspire positive change. Lack of employment was a significant barrier to participation in PIF initiatives.
Nonetheless, those without money or jobs were willing to offer their time or items such as clothing and food. Two implementation approaches were identified: monetary and non-monetary, with monetary contributions being preferred.
Conclusions: Pay-it-forward mechanisms are feasible and promising for advancing HIV services among young people. Constraints related to regular income sources exist, but the challenging access to resources may augment the social effects of generosity. Empirical testing of PIF mechanisms for HIV prevention and care are urgently needed, particularly among AYAH in Africa.

EP0653

Mock parliament as a tool for policy stimulation in comprehensive sexuality education (CSE) advocacy: experience from young people's program (YPP) in Sierra Leone

V.O. Popoola[1], E. Teh-Kamara[2], D. Tibesigwa[3], M. Jkaisamba[4], O. Gbadamosi[3], L. Buzaalirwa[5], N. Dube[6], T. Popoola[7], P. Iutung[8]
[1]AIDS Healthcare Foundation, Medical Unit, Freetown, Sierra Leone, [2]AIDS Healthcare Foundation Sierra Leone, Prevention and Advocacy, Freetown, Sierra Leone, [3]AIDS Healthcare Foundation Africa Bureau, Policy and Advocacy, Kampala, Uganda, [4]AIDS Healthcare Foundation Sierra Leone, Freetown, Sierra Leone, [5]AIDS Healthcare Foundation Africa Bureau, Quality, Kampala, Uganda, [6]AIDS Healthcare Foundation Africa Bureau, Quality, Manzini, Eswatini, [7]University of Newcastle, Nursing and Midwifery, Newcastle, Australia, [8]AIDS Healthcare Foundation Africa Bureau, Kampala, Uganda

Background: Although sexual and reproductive health is crucial to our overall well-being, discussions around sexual matters and related information are often treated as taboo or spoken about in hushed tones in many parts of Africa, including Sierra Leone. The secrecy around information regarding sexual matters not only allows the spread of false information but also increases vulnerabilities among young people. Only a quarter of schools in Sierra Leone offer CSE, prompting this advocacy intervention to raise awareness and empower young people to speak for themselves.
Description: Sierra Leone has been recording high HIV incidence among young people and this reality calls for a deliberate action to provide age-appropriate, culturally sensitive, scientifically accurate and non-judgmental information about sex and relationships. As part of this effort, AIDS Healthcare Foundation (AHF) through her young people's program have been championing access to CSE and organized a mock parliament in 2024 on the floor of the parliament where about 160 young persons divided across 2 groups debated on the motion of whether to continue to have CSE incorporated into 7 subjects or have it as an examinable standalone subject. The session was overseen by the Deputy Speaker, televised across major stations and have in attendance several members of the parliament.
Lessons learned: Despite the inclusion of CSE in the curriculum, the feedback from young people was that not all schools are currently implementing it, and it has also not been effective in the current model of incorporating it into several subjects. The debate by the young people prompted the parliament to write the ministry of education to consider having CSE as a standalone subject. This request was subsequently approved and CSE should now become an examinable standalone subject. This mock

parliament gave the young persons an opportunity to appreciate policy processes and parliamentary proceedings while also enabling them to directly address issues affecting them by advocating for a policy change regarding how CSE is being taught in schools.

Conclusions/Next steps: Providing young people with platforms such as the mock parliament can be an effective tool for young people to advocate for policy changes that affect their wellbeing.

EP0654

Breaking the silence: PLHIV at the same time TB survivors' experiences and the critical need for enhanced psychosocial support

A.P. Baguma[1]

[1]Support On AIDS & Life Through Telephone Helpline (SALT), Counseling Department, Kampala, Uganda

Background: HIV) remains a major public health concern, affecting millions of people worldwide. Beyond access to Ant Retroviral therapy People Living with HIV (PLHIV) face significant psychosocial challenges including, stigma, anxiety, depression and social isolation. It is from the same that they experience offer valuable insights into addressing these challenges.

Objective: To Explore PLHI who are TB survivors and their psychosocial experiences, identify gaps in support and inform effective strategies to improve their quality of life.

Methods: A mixed-methods approach combined surveys, focus groups, and in-depth interviews with 200 PLHIV who were TB survivors and 100 family members in the 11 Regional Referral Hospitals and 1 National Referral Hospital in Uganda and Data were analyzed using thematic analysis.

Results: Findings revealed:

1. High levels of Stigma, anxiety, and depression among PLHIV who have TB
2. Stigma, Anxiety and depression persisting beyond treatment completion.
3. Social isolation and loneliness exacerbated by TB-related stigma.
4. Limited access to psychosocial support services.
5. Need for culturally and Religious sensitive support interventions.

Conclusions: PLHIV who have been diagnosed with TB TB survivors' and families require comprehensive psychosocial support to cope with the disease

Recommendations include:

1. Integrating psychosocial support into TB care services.
2. Encourage formation of community-based support groups for TB survivors.
3. Training healthcare providers in psychosocial care and support.
4. Public awareness campaigns to reduce stigma.

Implications:

Enhancing psychosocial support for TB survivors can improve long-term health outcomes, well-being, and reintegration into society.

EP0655

Strengthening community education in HIV cure research: insights from Latin America and the Caribbean

G. Devisich[1], L. Kamel[2], G. Turk[3,4], F. Valiente-Echeverria[5], M.I. Figueroa[1], P. Cahn[1], C.P. Cortes[6,7], O. Sued[8], B. Crabtree-Ramírez[9], I. Cassetti[10], N. Laufer[3,4]

[1]Fundación Huésped, Research Department, Ciudad Autónoma de Buenos Aires, Argentina, [2]Instituto Nacional de Infectologia Evandro Chagas-Fiocruz, Rio de Janeiro, Brazil, [3]CONICET – Universidad de Buenos Aires. Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Buenos Aires, Argentina, [4]Universidad de Buenos Aires, Facultad de Medicina - Departamento de Microbiología, Parasitología e Inmunología, Buenos Aires, Argentina, [5]HIV/AIDS Workgroup (CHAIR), Instituto de Ciencias Biomédicas (ICBM), Universidad de Chile, Facultad de Medicina, Santiago, Chile, [6]Fundación Arriarán, Santiago, Chile, [7]HIV/AIDS Workgroup (CHAIR), Instituto de Ciencias Biomédicas (ICBM), Universidad de Chile, Facultad de Medicina, Santiago de Chile, Chile, [8]Pan American Health Organization, Washington DC, United States, [9]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Departamento de Infectología, Mexico City, Mexico, [10]Helios Salud, Buenos Aires, Argentina

Background: Lessons from HIV prevention research underscore the importance of early community education to support study implementation. With large-scale HIV cure trials yet to be conducted in Latin America and the Caribbean (LAC), this study explored HIV cure research and advocacy needs among civil society (CS) in the region.

Methods: A one-time web-based survey was made available in Spanish, English, Portuguese and French between March and April 2024. Conducted by LAC-Cura, the Latin America and the Caribbean HIV Cure Consortium, the instrument screened for CS perceptions of HIV cure research knowledge, facilitators and barriers to trial participation, and educational preferences.

Data was summarized using descriptive statistics. Percentages were calculated based on valid responses to each question.

Results: A total of 365 responses from CS members across 24 LAC territories were received. Most participants reported low knowledge about HIV cure related-issues: funding (n=271; 80.6%), community engagement modalities (n=246; 74.4%), ongoing studies (n=242; 72.4%), new cases (n=228; 69.1%), research challenges (n=223; 61.4%) and strategies (n=198; 57.6%).

Low knowledge was attributed primarily to lack of visibility of HIV cure, (n=262; 71.8%), limited training opportunities (n=243; 66.6%), and low relevance of HIV cure on current agendas (n=204; 55.9%).

Key factors discouraging for trial participation included analytical treatment interruptions (n=240; 70.8%), logistical inconveniences (n=220; 67.2%), and fear of side effects or intervention invasiveness (n=218; 66.2%). Encouraging factors included receiving detailed information (n=246; 73.2%), contributing to the advancement of science (n=232; 70.5%) and benefiting the community (n=229; 70.1%).

Primary sources of information on HIV cure were social media (n=240; 65.8%), websites of HIV-related organizations (n=215; 58.9%), and participation in HIV-related networks and communities (n=197; 54.0%).

Conclusions: Findings underscore the need to strengthen community education on HIV cure research across LAC. Addressing knowledge gaps, mitigating barriers and amplifying facilitators for trial participation are critical steps. LAC-Cura should prioritize partnerships with CS organizations to strategically disseminate information online, fostering community engagement and preparing for future trial implementation in the region.

EP0656

Community-engaged approaches to strengthen Advanced HIV Disease (AHD) care: lessons from THRIVE

J. Wambui[1], K. Sikwese[2], J. Akai[3], D. Chihenyo[4], D. Adaga[5], F. Nwankwo[6], N. Laeokane[7], N. Kubai[8], J. Lule[9], R. Ninsiima[9], C. Bonzo[10], A. Tonderai[10], B. Caldwell[11], S. Pease[12]

[1]Afrocab Treatment Access Partnership, HIV and TB, Kilifi, Kenya, [2]Afrocab Treatment Access Partnership, HIV, Lusaka, Zambia, [3]Afrocab Treatment Access Partnership, HIV, Nairobi, Kenya, [4]Afrocab Treatment Access Partnership, HIV, Mombasa, Kenya, [5]Afrocab Treatment Access Partnership, HIV, Lagos, Nigeria, [6]Afrocab Treatment Access Partnership, HIV, Abuja, Nigeria, [7]Afrocab Treatment Access Partnership, HIV, Johannesburg, South Africa, [8]Afrocab Treatment Access Partnership, HIV and TB, Johannesburg, South Africa, [9]Afrocab Treatment Access Partnership, HIV, Kampala, Uganda, [10]Afrocab Treatment Access Partnership, HIV, Harare, Zimbabwe, [11]Clinton Health, HIV, Ontario, Canada, [12]Clinton Health, HIV, Boston, United States

Background: Advanced HIV Disease (AHD) remains a significant challenge in addressing the HIV pandemic, especially in low-resource settings. AHD-related mortality is prevented by timely diagnosis, treatment and supportive care. To enhance AHD awareness and improve care, community engagement is critical. The Unitaid-funded, CHAI-led THRIVE Consortium project, with AFROCAB leading the community component, implemented a participatory approach to sensitize communities and strengthen AHD care in five countries, leveraging the expertise of THRIVE Community Advisory Board (CAB) members and partnerships with Ministries of Health.

Description: THRIVE CAB members in five THRIVE countries facilitated a series of community-centered trainings focused on AHD. These trainings targeted networks of people living with HIV (PLHIV) including caregivers, healthcare workers and other stakeholders, emphasizing knowledge dissemination, advocacy and capacity building.

Through participatory methodologies, community members were brought up to speed on AHD care, including key aspects of prevention, early diagnosis and treatment regimens. Collaboration with Ministries of Health ensured alignment with national HIV strategies and sustainability. The trainings utilized an interactive model, engaging the lived experiences of PLHIV to inform session content and increase mutual confidence. Participants engaged in activities and discussions promoting shared learning and a deeper understanding of AHD-related challenges and solutions.

Lessons learned:

1. Enhanced Community Capacity: Communities reported increased confidence in addressing AHD issues, advocating for better care and supporting peers.
2. Strengthened Health Systems: Health facilities demonstrated improved readiness to provide AHD care, including availability of diagnostic and treatment commodities.
3. Collaborative Success: Partnerships with Ministries of Health and active community involvement ensured broader acceptance and impact of the initiative.
4. Barriers Persist: Gaps and resources in infrastructure highlighted the need for sustained advocacy and investment.

Conclusions/Next steps: The participatory approach employed by the THRIVE CAB members demonstrated the potential for change in community engagement addressing AHD. Building capacity of PLHIV networks and healthcare systems created a foundation for improved AHD care. Moving forward, there is a need to scale up efforts to address systemic barriers and monitor long-term outcomes to ensure comprehensive AHD management and reduce preventable AHD-related deaths.

EP0657

Characterising key concerns from communities on upcoming HIV prevention products: the case of the Dual Prevention Pill in Zambia

R. Msiska[1]

[1]Copper Rose Zambia, Advocacy and Health Promotions, Lusaka, Zambia

Background: In recent years, the Zambian government has shown commitment to expanding choice for HIV prevention to the people by prioritising the introduction of new prevention tools like the Dual Prevention Pill (DPP) - which simultaneously prevents HIV acquisition and pregnancy. However, limited community awareness and engagement often leads to myths and misconceptions that may hinder product uptake. Early and inclusive community engagement is critical to address concerns, enhance understanding, and ensure successful product uptake once available.

Methods: Between July and December 2024, a series of consultation meetings were held to gather insights and concerns about the DPP. Participants included 67 healthcare workers, 71 adolescents and young people, 37 community health workers and 39 female sex workers in Kitwe and Lusaka. Discussions were analysed using a narrative analysis approach to identify concerns regarding the DPP.

Results: Key concerns raised across the groups included: how quickly the product will be available; side effects; missed pills; access platforms; availability for adolescents under 16; STI protection; time to effectiveness; post-discontinuation conception; suitability for breastfeeding

mothers; and stock sustainability in health facilities. These concerns are integral to ongoing policy discussions with government decision-makers, shaping strategies for the effective implementation of the DPP in Zambia.

Conclusions: Findings reinforce the importance of early and broad community engagement in the introduction of new HIV prevention products. Addressing these concerns is important not only for understanding and acceptance but also for ensuring that products like the DPP can be effectively adopted and sustained in Zambia.

EP0658

AIDS or advanced HIV disease? Results from a multi-stakeholder global DELPHI process to gain consensus on terminology

Y. Dunkley[1,2], D. Lawrence[1,2], A. Piñeirúa-Menéndez[3], K. Mupeli[4], P. Ochieng[5], J. Wambui[6], A. Aggarwal[2], A. Rangaraj[7], N. Ford[7], J.N. Jarvis[1,2]

[1]Botswana Harvard Health Partnership, Gaborone, Botswana, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]CISIDAT, Cuernavaca, Mexico, [4]Centre for Youth of Hope (CEYOHO), Gaborone, Botswana, [5]DACASA (Dandora Community AIDS Support Association), Nairobi, Kenya, [6]Afrocab Treatment Access Partnership, Nairobi, Kenya, [7]World Health Organisation, Department of Global HIV, Hepatitis and Sexually Transmitted Infections Programmes, Geneva, Switzerland

Background: "Advanced HIV Disease" (AHD) was defined in 2017 to distinguish between those established on antiretroviral therapy – and those with additional care needs. The global HIV community have asked for clarity on the use of AHD and AIDS in World Health Organization and other global guidelines. This study aimed to investigate global consensus on the use of both terms.

Methods: A landscape analysis was presented at *AIDS2024* to workshop statements for a two-round Delphi process. 22 statements were developed, divided into sections corresponding to feelings associated with each term, overall usage and scenarios for usage. Surveys were conducted in English, Spanish, French and Portuguese. Round-one recruitment was purposive and open (Oct 24-Nov 24), targeting community-sector and geographic regions with greatest HIV burden. Round-two (Dec 24-Jan 25) was restricted to round-one participants.

Participants ranked levels of agreement with statements (1-7 Likert). Predefined consensus thresholds were ≥75% participant agreement; statements with <25% agreement were rejected. Remaining statements were re-ranked in round-two. Explanatory qualitative analysis was conducted after consensus assessment.

Results: There were 646 eligible responses in round-one; round-two participation-rate was 45% (292/646). African-region participation was greatest (47%, 288/618), followed by Americas (29%, 179/618), with primarily Spanish speakers from this region (60%, 107/179). Half (48%, 303/636) worked in civil society or as frontline workers. Almost half (44%, 287/646) identified as people living with HIV (PLWHIV).

Six statements reached consensus and two were dropped. Consensus was reached for use of AHD to: differentiate levels of care (83%); communicate to PLWHIV about disease (78%) and stage of diagnosis (81%); inform and educate the public (77%); and monitor HIV-programme success (77%). There was borderline consensus that AIDS is always stigmatising (75%). No consensus was reached on scenarios for use of AIDS or outright rejection of the term. More respondents agreed AIDS (65%) was a useful term for advocacy than AHD (56%). Qualitative analysis identified AIDS as intrinsically stigmatising, associated with death and trauma, yet this stigma communicated urgency of action.

Conclusions: There is sufficient consensus to support the use of AHD in clinical guidelines; there was no consensus on continuing or discontinuing use of the term AIDS.

EP0659

Adolescent-driven podcasting for HIV prevention: engaging communities to address barriers in sexual health education

O. Mlanzeli[1], A. Ononiwu[2], S. Ndimbira[1]

[1]Africa REACH, Cape Town, South Africa, [2]Technology for Inspiration Initiative-InspireIT, Abuja, Nigeria

Background: Adolescents in Nigeria face significant barriers to accessing comprehensive sexual education (CSE), exacerbated by stigma and cultural taboos. These challenges are particularly pressing for adolescent girls, limiting their knowledge of sexual and reproductive health (SRH) and HIV prevention. InspireIT, an Africa REACH grantee, responded to these gaps by developing an adolescent-owned podcast, created in collaboration with the Ministry of Health in Imo State, Nigeria.

The podcast aimed to dismantle stigma, foster community dialogue, and empower adolescents with life-saving information.

Description: Using a participatory approach, InspireIT conducted semi-structured interviews with adolescent girls to identify gaps in knowledge and barriers to accessing SRH education. This input guided the design of podcast episodes, focusing on relatable narratives and evidence-based information about HIV acquisition, sexually transmitted infections (STIs), and teenage pregnancy.

Community members and stakeholders were engaged throughout the process, ensuring cultural relevance and broad acceptance. Data collection included podcast analytics, user feedback, and follow-up interviews with participants to assess impact.

Lessons learned: The participatory methodology contributed to the success of the initiative, as adolescents felt ownership of the content and actively engaged with the material. The podcast increased awareness of HIV prevention and other SRH topics, reduced stigma, and created a space for open dialogue within communities. Stakeholders, including educators and parents, noted the value of integrating community-driven approaches to CSE, particularly in regions where traditional systems fall short.

Conclusions/Next steps: InspireIT's adolescent-driven podcast demonstrates the transformative power of participatory approaches in addressing barriers to SRH education. Through fostering community engagement and empowering young people as co-creators, this initiative not only enhanced knowledge and awareness but also inspired the development of Red Ribbon, a digital health platform offering comprehensive SRH resources to adolescents.

EP0660

Enhancing community engagement in HIV prevention clinical trial design: insights from CASPR's Clinical Trial Design Academy

G. Kumwenda[1], N. Sikwana[2], D. Ouya[3], D. Nhamo[4], N. Yola[5], S. Hannah[6], M. Warren[7]
[1]AVAC, Research Engagement, Blantyre, Malawi, [2]AVAC, Research Engagement, Johannesburg, South Africa, [3]AVAC, Research Engagement, Nairobi, Kenya, [4]Pangea Zimbabwe, Harare, Zimbabwe, [5]Desmond Tutu Health Foundation, Cape Town, South Africa, [6]AVAC, Atlanta, United States, [7]AVAC, New York, United States

Background: Community Engagement (CE) has been instrumental in shaping HIV prevention research, but its influence on clinical trial design remains underexplored. To address this gap, the Clinical Trial Design Academy, supported by Coalition to Accelerate & Support Prevention Research (CASPR), aims to empower African-based advocates with the knowledge and skills to more vigorously shape next-generation clinical trial designs.
Description: CASPR identified 20 advocates from nine African countries based on their interest in clinical trial design. The program began with three foundational virtual workshops focusing on
1. Fundamentals of HIV prevention clinical trials,
2. Innovative trial designs in the PrEP era, and;
3. Regulatory guidance for externally controlled trials.
An in-person workshop followed, where participants consolidated learnings and priorities. Participants engaged with researchers, statisticians, and scientists, exploring new trial design approaches, such as identifying and using appropriate active controls, and use of hypothetical placebo measures such as background HIV incidence data, recency assays, registrational cohorts, and biomarkers. Participants also deliberated on the implications of conducting prevention trials in the context of choice of existing, effective HIV prevention products.
Lessons learned: The Academy identified key community priorities for the design and conduct of future HIV prevention trials;

- Novel trial designs must meet rigorous scientific validity standards while addressing critical factors, including drug-drug interactions, and gathering data on pregnancy and lactation. Pharmacokinetic studies should explore protection onset, forgiveness, and drug tail effects.
- Trials must represent diverse geographies and populations, including people who inject drugs , and assess acceptability, choice, and persistence.
- Trials should reflect the principle of choice, offering product options in different phases of research including during, and after trials.
- HIV prevention trials must prioritize access, equity, and community relevance. No product should start efficacy trials without a clear plan for post-trial manufacturing, pricing, and equitable access.

Conclusions/Next steps: The Academy demonstrated the potential of CE in HIV prevention clinical trial design. By equipping advocates with tools to meaningfully contribute to research, the Academy fostered collaboration between communities, researchers, and regulators. In 2025, the Academy will launch an online resource hub to provide advocates with real-time information and tools for continued engagement and advocacy.

EP0661

Clinical outcomes associated with the "Newly Admitted Care Program" (NACP) applied to people living with HIV in a Clinic in Mexico City

R.C. Iquize Condori[1], J. Mejía Castrejón[1], H.O. Rivera Villegas[1], Y. Caro Vega[1], A. López Iñiguez[1], J.G. Sierra Madero[1], B.E. Crabtree Ramírez[1]
[1]Instituto Nacional de Ciencias Médicas y Nutricion Salvador Zubirán, Infectious Diseases, Mexico City, Mexico

Background: Antiretroviral therapy (ART) improves life expectancy and decreases the incidence of advanced disease in people living with HIV (PWH). However, important challenges remain for successful long term HIV care. The *Newly Admitted Care Program* (NACP) was implemented and offered to all newly enrolled individuals into the INCMNSZ HIV clinic since 2015 as a local client-centered care initiative. Individuals participated in NACP by choice, providing initial psychosocial and mental health assessment with a psychoeducation session.
We aimed to evaluate clinical outcomes (HIV-related hospitalization, loss to follow-up (LTFU), treatment suspension (TS), virologic failure (VF) and mortality) among PWH who participated in NACP and those who did not (non-NACP).
Methods: We performed a retrospective cohort study in PWH from a single center in Mexico City from 2015 to 2023, including all individuals in both groups from their enrollment up to their last available visit. Clinical and laboratory outcomes were evaluated. Adjusted models were performed to identify factors associated with LTFU and mortality.
Results: We included 758 participants: 387 (51.1%) in the NACP group and 371 (48.9%) in the non-NACP. NACP individuals have a median follow-up of 58 months vs. 31 in non-NACP (RIQ 58-104 vs. 7-67; p<0.001). NACP participants were younger (mean age 32 vs. 37 years, p=0.001), were more likely to be MSM (78% vs. 70.1%, p=0.042), and had a higher educational level (34.1% vs. 25.3%, p=0.014).
There were no differences between groups regarding proportion of male sex (p=0.126), median CD4 count (p=0.37) or AIDS-defining events (p=0.084) at enrollment. No differences were found in TS and VF between groups. The NACP group experienced significantly lower frequency of hos-

pitalization (21.9% vs. 32.6%, p=0.01), LTFU (10.9% vs. 27.8%, p<0.001), and mortality (3.4% vs. 8.9%, p<0.001). Adjusted analysis found an independent association for NACP participation with reduced risk of mortality (OR=0.40 [95% CI=0.20-0.80]) and LTFU (OR=0.32 [95% CI=0.22-0.49]).

Conclusions: Despite similar virological and immunological characteristics at baseline, those who participated in NACP experienced fewer unfavorable outcomes, highlighting the importance of client-centered care programs in improving health outcomes for PWH.

EP0662

Operationalizing sexuality education in Uganda: lessons learned from Peer To Peer Uganda's implementation

B. Moses[1]

[1]*Peer To Peer Uganda, Public Health, Kampala, Uganda*

Background: In response to gaps in sexuality education, Peer To Peer Uganda (PEERU) has been at the forefront of operationalizing the National Sexuality Education Framework (NSEF) in Uganda. The initiative seeks to equip adolescents, and young people with knowledge and skills to make informed decisions about their sexual and reproductive health (SRH), reduce stigma surrounding HIV, and foster a supportive environment for HIV prevention, treatment, and care. The program targets schools and communities, emphasizing inclusivity and youth-led advocacy to address cultural sensitivities and systemic barriers.

Description: Since 2022, PEERU has implemented this initiative in rural and peri-urban schools across Uganda. The program focuses on capacity building for teachers, parents, and local leaders, integrating the National Sexuality Education Framework (NSEF) into school curriculums, and addressing SRH topics such as HIV prevention, menstrual health management, and gender-based violence. Over 79 schools, 500 teachers, and 1,200 parents have been engaged through training, community dialogues, and sensitization meetings like the Parents and Teachers Associations (PTA) . Activities include the development of culturally sensitive teaching materials, interactive sessions with students, and advocacy campaigns targeting policy alignment.

Lessons learned:

- Community engagement is critical to addressing misconceptions and fostering acceptance of sexuality education.
- Parental involvement through Parents-Teachers Association (PTA) meetings strengthens the program's sustainability and builds a supportive home environment for students.
- Teachers require continuous capacity building and support to confidently deliver age-appropriate sexuality education.
- Aligning program content with national policies ensures institutional backing, reducing resistance at the implementation level.
- Monitoring and evaluation tools tailored to track attitudinal and behavioral changes among students and stakeholders are essential for demonstrating impact.

Conclusions/Next steps: Operationalizing sexuality education in Uganda has highlighted the potential for school-based programs to drive informed decision-making and reduce vulnerabilities to HIV among adolescents. Moving forward, PEERU plans to scale up the initiative to more schools and districts, integrate digital learning tools for wider reach, and strengthen partnerships with government bodies and civil society.

The insights gained contribute to global efforts in achieving better HIV prevention and SRH outcomes for young people, especially in resource-constrained settings.

EP0663

Enhancing PrEP literacy through AI-assisted visuals: a cost-effective approach for community engagement

S. Muhammad Soomar[1]

[1]*Aga Khan University & Humraz Male Health Society, Karachi, Pakistan*

Background: Pre-exposure prophylaxis (PrEP) is a proven method for preventing HIV transmission, yet its uptake is hindered by gaps in awareness and accessibility, especially among marginalized populations, such as people living with HIV, gender-diverse individuals, and men who have sex with men (MSM).

AI-assisted visuals offer a novel and cost-effective approach to enhance public education and knowledge retention about PrEP. This project aimed to address gaps in awareness and accessibility of PrEP.

Description: Conducted in a community setting, this advocacy project engaged 65 participants, including people living with HIV, gender-diverse individuals, MSM, and community stakeholders working on HIV/AIDS prevention. The project employed AI-assisted visuals to convey key messages about PrEP. These visuals were designed to be visually appealing, easily understandable, and accessible. Participants were exposed to these visuals during the project period, and their ability to recall and verbalize information was assessed.

Responses were categorized into three groups: those recalling all three aspects (access, importance & use), those recalling two aspects (access & importance), and those recalling only access-related information.

Lessons learned: The immediate outcome was monitored through recall and verbalization of information which demonstrated that AI-assisted visuals are effective in enhancing knowledge retention. We were able to see that:

- 48 participants (73.84%) were able to recall and verbalize all three aspects.
- 13 participants (20%) recalled information about access and importance.
- 4 participants (6.15%) recalled only access-related information.

These insights highlight the potential of AI-assisted visuals as a cost-effective and impactful tool for public education in marginalized communities. The visually engaging format facilitated information retention and accessibility, making it a best practice for improving health

literacy in similar contexts. The major lesson we learnt is that health literacy tools with growing and advancing technology can become much easier to create, are becoming less time consuming and much more cost effective than ever.

Conclusions/Next steps: The project underscores the importance of leveraging AI-assisted visuals to enhance awareness and accessibility of PrEP. This innovative approach can significantly contribute to HIV prevention efforts by improving knowledge retention and empowering marginalized populations to access preventive healthcare services.

EP0664

Words matter: co-producing the PORADA HIV disclosure decision aid for older adults in Ukraine

I. Pykalo[1], V. Earnshaw[2], O. Zeziulin[1], I. Zaviriukha[1], S. Shenoi[3], A. Deac[4], J. Rozanova[3]
[1]European Institute of Public Health Policy, Kyiv, Ukraine, [2]University of Delaware, Newark, United States, [3]Yale University, New Haven, United States, [4]University of East London, Institute for Connected Communities, London, United Kingdom

Background: Older people with HIV (OPWH) in Ukraine face unique challenges in disclosing their HIV status due to pervasive stigma and intersecting vulnerabilities, such as substance use disorders (SUD). The humanitarian crisis caused by the ongoing war further exacerbates these challenges.

In response, the PORADA intervention (Pursuing Optimal Results over Aging via Decision Aid) was developed as a structured, culturally tailored tool to support informed decision-making about disclosure. This intervention considers the complex realities of a war-torn country and aims to reduce decisional conflict while promoting client-centered disclosure aligned with personal values and goals.

Description: Using the ADAPT-ITT framework, the intervention was co-produced with OPWH (as peer consultants), HIV physicians, social workers, and psychologists. Initial development incorporated qualitative findings and feedback from four focus groups (two with OPWH and two with HIV clinicians) to ensure relevance and usability. A pilot of four sessions was conducted with two facilitators to assess PORADA's feasibility and acceptability.

The paper-based Decision Aid includes tools for systematically weighing the pros and cons of disclosure, guided exercises for planning disclosure conversations, real-life examples tailored to Ukrainian OPWH experiences, and techniques for addressing challenges such as stigma and building supportive networks.

Implementation will be supported by a detailed facilitators guide, ensuring confidentiality and consistency in delivering the intervention by social workers and OPWH peers to participants.

Lessons learned: The co-production process underscored the critical role of language and terminology in creating a culturally sensitive tool. For example, while "status disclosure" is neutral in English, Ukrainian participants perceived it as coercive, requiring careful adjustments to convey neutrality. Refining phrasing to resonate with the audience fostered trust and engagement, ensuring the tool was empowering rather than directive.

Conclusions/Next steps: The PORADA intervention underscores the value of participatory design in developing tailored decision aids. The next step involves implementing the intervention for OPWH at Kyiv City Clinical Hospital No. 5 by integrating the Decision Aid into routine care and gathering data on its effectiveness to inform further broader adaptation of the approach for similar settings, addressing the unique challenges faced by aging OPWH.

EP0665

Re-engaging lost to follow-up to antiretroviral (ARVs) care: a community-driven tracking initiative to improve continuity of care in Rwanda

P. Mutesi[1], J.B. Tugirimana[1], D. Mutambuka[1], G. Mbaraga[2], O. Nyiramucyo[1], B. Sebujangwe[1], G. Rwibasira[3]
[1]Rwanda Network of People Living with HIV/AIDS (RRP+), Kigali City, Rwanda, [2]AIDS Healthcare Foundation (AHF), Kigali City, Rwanda, [3]Rwanda Biomedical Center (RBC), Kigali City, Rwanda

Background: Despite Rwanda maintaining an HIV prevalence rate below 3% (RPHIA, 2020) and achieving a 97.5% antiretroviral therapy (ART) coverage rate, a small yet significant proportion (2.5%) of individuals have discontinued ART, posing challenges to achieving UNAIDS' 95-95-95 targets. The "Back to Care Project," launched in June 2024 by the AIDS Healthcare Foundation (AHF) in collaboration with the Rwanda Network of People Living with HIV (RRP+), aimed to re-engage individuals lost to follow-up (LTFU) and improve ART adherence.

Description: This one-year project, conducted between October and December 2024, targeted four health facilities in Kigali city—Remera, Kagugu, Kacyiru, and Kinyinya, with LTFU cases totaling 275 (99, 70, 59, and 47, respectively).

The initiative involved:

1. Training 4 ARV service social workers, 4 facility heads, and 121 peer educators (PEs) on LTFU tracking methods,
2. Facilitating regular follow-ups and coaching for PEs, and;
3. Fostering trust-building interactions between PEs, health workers, and LTFU people living with HIV to address systemic barriers such as stigma and financial constraints.

Lessons learned: By integrating online tools and SMS reminders, the tracking program in Kigali serves as a great example of how to successfully re-engage individuals who have been lost to follow-up on ARVs, improving medication adherence and continuity of care. Data safety is given top priority in this community-centered approach through confidentiality, secure storage, and access controls based on roles.

Training for staff as well as regular safety reviews help to ensure that sensitive data is handled ethically. The approach has effectively re-engaged 17 people living with HIV within three months including 8 women and 9 men

through integrating social health workers, peer educators and support groups, and developing long-lasting connections.

Conclusions/Next steps: Through efficiently re-engaging individuals who were lost to ARV follow-up, back to care project in Rwanda has improved adherence, resolved treatment gaps, and improved health outcomes, the program has created a scalable and sustainable model by combining specific data and community-driven approaches. The program's potential for wider replication and long-lasting impact is highlighted by its emphasis on forming partnerships and introducing techniques into national HIV programs.

EP0666

Enhancing HIV treatment continuity, overcoming urban mobility challenges through community cadres in the Zingane_OVC Project, a case of Bulawayo

D. Jumbe[1], M. Tshuma[1]
[1]Bantwana Zimbabwe, Harare, Zimbabwe

Background: In Zimbabwe although the HIV epidemic is pre-dominantly in rural areas there is an influx to cities in search of better economic prospects. In urban areas people are highly mobile, the mobility is influenced by job opportunities, housing affordability, educational needs, lifestyle choices, and changes in family circumstances. Migrants face greater stigma related to HIV in new environments.

This paper describes how the Zingane_OVC project is promoting treatment continuity for the highly mobile urbanites in Bulawayo.

Description: The project tracked 2,846 PLHIV in Bulawayo using 124 community cadres which each cadre having a defined cohort. The project applies a socioecological lens to understand and address the factors affecting PLHIV. The project uses Community Childcare Workers, Community Health Workers, youth peer facilitators, and mentor mothers as providers of frontline care to PLHIV.

These cadres are an increasingly essential bridge between clinic and community systems, they identify any new members of their communities as well as bi-directional referrals with other cadres. Their role involves assisting with appointment monitoring and follow-ups, ensuring referral completion and treatment continuity for children and caregivers, maintaining a community service directory, providing psychosocial support and ensuring proper identification of index cases. Each community cadre has an assigned cohort, which offers a structured and efficient way to monitor and support PLHIV.

Lessons learned: The use of the cadre-participant cohort system has improved viral load suppression in the children being monitored to 95% which is above the national average, 100% being retained on treatment while 91% being met physically within the community by the cadre. The system improves the maximum use of Differentiated Service Delivery (DSD) Models through a human centered design approach. The cohort system improves communication, enhances participant tracking, enables timely interventions, optimizes resource allocation, and promotes accountability in healthcare, PLHIV stay engaged in the treatment process.

Conclusions/Next steps: DSD models require a clear understanding of patient preferences which can help in designing services that ensure optimal utilization and improve the efficiency of care. Community cadres play a pivotal role in linking communities to the health facilities supporting the overstretched health care workers, however, investing in motivating these individuals is essential.

EP0667

(Re)producing HIV Care for Ukrainian refugees in Germany and Poland: trans-local community-based support in action

D. Kashnitsky[1], M. Vyatchina[2], K. Rivera[3]
[1]Paris Cité, Cermes3 Laboratory, Paris, France, [2]Tartu University, Tartu, Estonia, [3]100% Life, Communications, Kyiv, Ukraine

Background: Following the 2022 Russian invasion of Ukraine, millions were displaced across Europe, creating unique challenges for healthcare access among refugees living with HIV. This study examines the role of community-based organizations (CBOs) in Germany and Poland in overcoming barriers to HIV care for displaced Ukrainian populations, with an emphasis on gender-sensitive and community-led approaches.

Methods: A participatory action research design was employed, involving Ukrainian HIV activists, community members, healthcare professionals, and social workers (46 participants interviewed in 2023-2024). Data collection included semi-structured interviews and ethnographic observations in Germany and Poland. Reflexive thematic analysis identified key barriers and enablers to HIV care linkage and retention, focusing on gender dimensions, stigma, and the integration of community-led interventions.

Results: This study identifies systemic, structural, and individual barriers to HIV care for displaced Ukrainian refugees in Germany and Poland. Systemic hurdles include Germany's decentralized healthcare and Poland's insurance-based model, delaying access to antiretroviral therapy (ART). Structural challenges involve language barriers, limited mobility, and a shortage of trained social workers, while individual obstacles include stigma, fear of disclosure, and war-related trauma.

CBOs like HelpNowHUB in Poland and PlusUkrDe in Germany bridged these gaps, offering peer counseling, translation, cross-border ART transportation, and advocacy for migrant-sensitive care. Women, the majority among displaced populations, faced compounded challenges yet played a pivotal role in sustaining these networks. Their contributions ensured continuity of care, addressed gender-specific needs, and fostered inclusive, empowering spaces for mutual aid.

Conclusions: This research underscores the transformative potential of community-driven interventions in ensuring equitable HIV care for displaced populations. Recognizing and supporting CBOs as key stakeholders in pub-

lic health responses is essential to overcoming systemic barriers and addressing the complex needs of Ukrainian refugees in European countries. The findings advocate for policy shifts toward integrated, migrant-sensitive, gender-responsive healthcare and greater agency of migrants groups in health policy and budget advocacy to enhance HIV prevention and care for vulnerable groups in host countries. Community-based migrant organisations must be supported and encouraged to play a structural role in planning and implementing national HIV programs across EU countries.

EP0668

Empower-HER: igniting the potential of adolescent girls and young women in HIV and SRH leadership

M. Idifonce[1], E. Mwemutsi[1], DARE TEAM
[1]DARE Organization, Dar es salaam, Tanzania, the United Republic of

Background: Over the past decades, HIV prevalence, incidence, and burden have consistently decreased across WCA, indicating a controlled epidemic. Nevertheless, significant variations continue to exist.
Description: The project conducted a mapping exercise to assess the involvement of youth in Council Multisectoral AIDS Committees (CMACs) and Regional Multisectoral AIDS Committees (RMACs) in five regions of Tanzania. The mapping evaluated CMAC/RMAC activeness, youth participation in decision-making platforms, and resource availability for meetings.
Additionally, mapping was conducted in three other regions (Kilimanjaro, Manyara, and Mwanza) to gain a broader understanding of youth representation.
Lessons learned: The mapping exercise revealed key insights into the challenges and opportunities for youth involvement in HIV and SRH decision-making in Tanzania. Findings highlighted the need for strategies to improve youth representation, strengthen communication channels between youth and decision-making bodies, and increase resource allocation for youth-led initiatives.
These findings will inform the development of targeted interventions to enhance youth engagement and improve the effectiveness of HIV and SRH programs in Tanzania.
Conclusions/Next steps: The EMPOWER-HER project highlights the transformative power of investing in adolescent girls and young women (AGYW) as leaders in the HIV response. By equipping over 300 AGYW with leadership and advocacy skills. By addressing the identified gaps in youth engagement, the project ensures that the voices and needs of young people, particularly AGYW, are fully integrated into the national HIV response.
This approach contributes to more effective and equitable HIV prevention, treatment, care, and support services for young people in Tanzania. Moving forward, expanding mentorship programs, strengthening partnerships with local stakeholders, and increasing resource allocation will be critical. Future initiatives must build on these successes, prioritizing AGYW to create sustainable, community-driven solutions in the HIV response.

EP0669

Perceptions of long-term survivors of HIV on cure research in the United States

A. Ahmed[1], J. Taylor[2,3,4], S.D. Diunugala[1], R. Lau[1], J.C.-J. Lai[1], M. Louella[3,4,5], J. Berry[6,7], T.H. Burdo[8,9], M.J. Peluso[10,11], L. Dee[4,12], K. Dube[1]
[1]University of California San Diego, Division of Infectious Diseases and Global Public Health, School of Medicine, San Diego, United States, [2]HIV + Aging Research Project – Palm Springs (HARP-PS), Palm Spring, United States, [3]Reversing Immune Dysfunction for HIV-1 (RID-HIV) Eradication Martin Delaney Collaboratory Community Engagement Coordination and Community Advisory Board, San Diego, United States, [4]Delaney AIDS Research Enterprise (DARE) Martin Delaney Collaboratory Community Advisory Board and Community Engagement Coordination, San Francisco, United States, [5]University of Washington Center for AIDS Research (CFAR), Seattle, United States, [6]CRISPR for Cure Martin Delaney Collaboratory Community Advisory Board, Philadelphia, United States, [7]The Reunion Project, Calabases, United States, [8]CRISPR for Cure Martin Delaney Collaboratory, Philadelphia, United States, [9]Rutgers Institute for Translational Medicine and Science, Robert Wood Johnson Medical School, New Brunswick, United States, [10]Delaney AIDS Research Enterprise (DARE) Martin Delaney Collaboratory, San Francisco, United States, [11]University of California San Francisco, Division of HIV, Infectious Diseases and Global Medicine, Department of Medicine, San Francisco, United States, [12]AIDS Action Baltimore, Baltimore, United States

Background: Efforts to find a cure for HIV have intensified. Long-term survivors (LTS) of HIV, including those who were diagnosed with HIV before the advent of effective antiretroviral therapy, can provide critical insights for HIV cure trials. As over half of people with HIV (PWH) in the United States (U.S.) are now over 50, with projections reaching 70% by 2030, it is vital to understand the perceptions, willingness, and barriers to participation in cure trials among this aging population, who face elevated risks of co-morbidities and psychosocial challenges.
Methods: We conducted a qualitative study with LTS aged 60 and older, recruiting participants through community-based organizations and research networks. Semi-structured interviews explored their views on HIV cure research, focusing on motivations, concerns, and barriers to participation. We anonymized transcripts and analyzed the data using conventional content analysis, achieving thematic saturation through independent coding. All participants provided verbal informed consent, and the University of California San Diego IRB (#808882) approved the study.
Results: We enrolled 32 participants (mean age 66.6, range 60–82), including 53.1% cisgender female, 50.0% cisgender male, and 3.1% transgender female. The sample included 53.1% White and 37.5% Black participants from various U.S. regions. LTS expressed strong motivation to join cure research, driven by a sense of responsibility and hope for future generations. Many viewed trial participation as a way to access innovative treatments and improve their health.

However, participants highlighted significant barriers, including age-based exclusions, logistical challenges like transportation and clinic accessibility, and considerations related to analytical treatment interruptions such as viral rebound and HIV transmission risk. Some voiced skepticism because of past research disappointments, while others stressed the need for transparent communication, clear informed consent, and flexible research designs. Invasive procedures, such as lumbar punctures, also deterred participation for some.

Conclusions: Engaging LTS of HIV in cure research requires careful consideration of their unique experiences and needs. It is essential to address barriers to participation, such as age-based exclusion and logistical challenges, while fostering trust through clear, straightforward communication. Meaningfully engaging LTS in future HIV cure trials will help enrich the research landscape and lead to more inclusive HIV cure approaches.

EP0670

How community engagement enables researchers to obtain funding and implement grants successfully

L. Scruggs[1], V. Johnson[1], M. Karris[2]
[1]Ribbon-A Center of Excellence, Largo, United States, [2]University of California San Diego, San Diego, United States

Background: Community Advisory Boards (CABs) are essential to ethical and participatory research practices. CAB involvement throughout the research process enhances the relevance and applicability of findings, ensures the research resonates with community needs, fosters culturally relevant and practical study designs, proactively addresses potential ethical issues, and improves recruitment and retention of study participants.

Description: In preparation for submitting an Ending the HIV Epidemic (EHE) grant, researchers and community members (e.g., Ribbon-A Center of Excellence, Christie's Place, and Older Women Embracing Life) co-developed a proposal to implement a program addressing Substance (Ab)use, Violence, and the AIDS/HIV syndemic in women. Additional activities included developing an independently led CAB for the Women-focused Encounters for Resilience, Independence, Strength, and Eudaimonia (WE RISE) study.

Lessons learned: Employment of community-based participatory research principles such as deliberate, early, mutually respectful, transparent, and active engagement with community members enabled WE RISE to:

1. Develop an acceptable and feasible intervention to be implemented in community-based organizations (CBOs) across the U.S.,
2. Identified CBOs to partner with in EHE jurisdictions,
3. Assisted in the decision-making around inclusion/exclusion criteria,
4. Selected CAB representatives with complementary experiences,
5. Co-developed processes to ensure CAB and researcher equity, and;
6. Provided recommendations to encourage study recruitment and retention (Table 1).

These efforts led to research processes and decisions contributing to successful NIH funding and active, enthusiastic, and rapid implementation of WE RISE within CBOs. CAB members also ensured that study decisions prioritize research equity and are consistent with individual CBO missions.

1. Active engagement through ALL phases
2. Foster trust through consistent engagement
3. Ensure adherence to ethical standards
4. Build capacity to optimize contribution
5. Implement shared decision-making
6. Provide resources and support
7. Co-develop ground rules
8. Maintain confidentiality
9. Evaluate effectiveness

Table 1: Essential Community Engagement Principles

Conclusions/Next steps: Engaging the community cultivates trust and transparency, ensures ethical research conduct, honors the needs and values of all participants, and optimizes research performance, particularly for underrepresented persons. Ongoing CAB activities and outcomes will continue to be evaluated through study implementation and dissemination.

Engaging the community cultivates trust and transparency, ensures ethical research conduct, honors the needs and values of all participants, and optimizes research performance, particularly for underrepresented persons. Ongoing CAB activities and outcomes will continue to be evaluated through study implementation and dissemination.

EP0671

Providers' perspectives towards integration of hepatitis C test-and-treat strategies into key population-led HIV clinics in Thailand: a qualitative study using the theory of planned behavior

A. Wongsa[1], R. Janamnuaysook[1], K. Sinchai[1], S. Janyam[2], P. Patpeerapong[3], S. Saiwaew[4], S. Sittikarn[5], S. Mills[6], N. Phanuphak[1], R.A. Ramautarsing[1]
[1]Institute of HIV Research and Innovation, Bangkok, Thailand, [2]Service Worker in Group Foundation, Bangkok, Thailand, [3]MPLUS Foundation, Chiang Mai, Thailand, [4]Rainbow Sky Association of Thailand, Bangkok, Thailand, [5]Caremat Foundation, Chiang Mai, Thailand, [6]FHI360 and USAID EpiC Project, Bangkok, Thailand

Background: The integration of key population (KP)-led hepatitis C virus (HCV) test and treat in KP-led health clinics aims to address the high prevalence of HCV and barriers to care among key populations in Thailand. Understanding KP-lay providers' perspectives is crucial to design strategies to ensure successful implementation. We assessed the perspectives of these lay providers on delivering HCV test and treat services during the pre-implementation phase.

Methods: We conducted a cross-sectional study among KP-lay providers using survey developed based on the Theory of Planned Behavior (TPB), which included demographics and basic constructs of TPB: intentions, attitudes, perceived behavioral control, and subjective norms regarding the HCV test and treat intervention and its integration in their routine service.
Multiple regression was conducted to identify demographic variables influencing KP-lay providers' perspectives on implementation. Prediction level was evaluated utilizing Structural Equation Modeling (SEM).
Results: Between June-December 2024, 101 KP-lay providers from nine KP-led HIV clinics who had a minimum of six-month work experience responded to the survey. The median age (interquartile range, IQR) was 32 (28-36) years, median (IQR) working years in clinic was 4.8 (2.3-6.9). Mean scores (standard deviation, SD) for intentions, attitudes, perceived behavioral control, and subjective norms were 4.48 (0.57), 3.98 (0.85), 3.91 (0.64), and 3.89 (0.28), respectively. Experience in providing HIV and HCV care was significantly linked to attitudes (p=0.029).
SEM demonstrated excellent model fit (χ^2=68.36, CFI=0.97, RMSEA=0.065). Perceived behavioral control was a strong predictor of service provision intentions (β=0.774, p<0.001). Covariances showed significant relationships between attitudes and subjective norms (0.343, p=0.001), attitudes and perceived behavioral control (0.275, p=0.017), and subjective norms and perceived behavioral control (0.619, p<0.001).
Conclusions: KP-lay providers in KP-led HIV clinics showed a favourable perspective on implementing the HCV test and treat intervention. Direct experience with clients with HCV shaped perceptions. Perceived behavioral control strongly predicted intentions to provide services, with attitudes and subjective norms influencing intentions indirectly through perceived behavioral control. Tailored strategies, such as knowledge-building or confidence-building for KP-lay providers, are needed to ensure high intention and successful implementation of KP-led HCV test and treat intervention, potentially leading to HCV elimination among key populations in Thailand.

EP0672

Parental, spousal, peer spaces of influence on adolescent girls and young women's participation in HIV prevention research among fishing communities along lake Victoria, Uganda

M. Namuleme[1], M. Wambuzi[1], G. Nanyonjo[1], J. Nanyondo[2], A. Ssetaala[1], A. Nanvubya[1], J. Mpendo[1], B. Okech[1], S. C Francis[3], M. Price[3,4], P. Maenteje[5], M. Kuteesa[3]
[1]UVRI-IAVI HIV Vaccine Program, Entebbe, Uganda, [2]IAVI, Nairobi, Kenya, [3]IAVI, New york, United States, [4]UCSF, San Francisco, United States, [5]Aurum, Rustenburg, South Africa

Background: Adolescent girls and young women (AGYW) in sub-Saharan Africa contribute 30% of new HIV/AIDS infections. Newer prevention strategies that attend to maturing immune systems and inequities faced by AGYW are vital in ending HIV/AIDS by 2030. Clinical research to test new prevention strategies is vital but challenged by vast parental, spousal and peer spheres of influence as significant social barriers across the research processes. The UVRI – IAVI HIV Vaccine Program implemented a preparedness study among AGYW to inform future HIV vaccines and BnABs as new HIV prevention options.
We explored the social influence that parents, spouses and peers play in impacting AGYW participation in HIV prevention research.
Methods: The Good Participatory Practices framework of engagement highlighted broader stakeholders for involvement in the AGYW recruitment and retention. These included; local government policy makers, Community gate keepers, health services providers, Village Health Team structures.
Consultative meetings with the above stakeholders highlighted the role of parents, spouses and peers in the research processes. Research and study specific literacy platforms were established for AGYW parents and spouses to facilitate the consenting processes and recruitment. Parents were involved in obtaining potential participants identification as a prerequisite for recruitment. Parents were constituted into Focus Group Discussions and In-depth Interviews to provide insights into the Social Behavioral Research component of the study with outcomes highlighting demystifying on mucosal sampling. Parental and spousal targeted meetings were conducted to address retention challenges. Formal Peer advisory and engagement mechanisms were established to facilitate co-creation and support. These included; Youth CAB and Community based retention committees.
Results: Although 805 AGYW expressed willingness to participate in the study, 193 (23.9%) were negatively influenced by parents, spouses and peers at pre-screening, 155 (38.8%) minors received parental consent to enroll into the study while 165(41.2%) sought for spousal permission. Peer networks have greatly influenced retention efforts through peer education and support.
Parental, spousal and peer predictors of influence included; perceived benefits like free treatment and risks, perceived HIV risk, knowledge on health research, myths and misconceptions.
Conclusions: Engagement of parents, spouses and peers remains critical in shaping AGYW participation in HIV prevention research.

EP0673

Leveraging digital platforms to address social determinants of health and promote behaviour change among South African youth

K. Mangam[1]
[1]Reach Digital Health, MERL, Johannesburg, South Africa

Background: South Africa faces significant sexual and reproductive health (SRH) and mental health challenges among young people, exacerbated by social determinants such as poverty, stigma, and limited access to youth-friendly services. The Young Africa Live (YAL) platform integrates these determinants into its tailored digital health interventions, focusing on strengthening user persistence and behavior change.

Description: The YAL platform employs a multipronged digital approach via WhatsApp and Facebook, offering SRH and mental health education, self-assessment tools, and linkage to services. Tailored interventions are informed by baseline assessments of users' mental health, locus of control, and social connectedness, guiding personalised content delivery.
The study conducted a mixed-method evaluation using baseline and endline surveys, program monitoring data, and focus group discussions to measure changes in knowledge, attitudes, and behaviors
Lessons learned: Analysis of platform data revealed a significant decrease in depression and anxiety among users, accompanied by an increase in locus of control and improved feelings of connectedness. These psychological improvements strongly correlated with positive changes in SRH behaviors, such as increased condom usage and STI testing. Endline results showed that users who demonstrated the greatest improvements in psychological resilience were more likely to sustain desired behaviors, underscoring the importance of persistence in achieving long-term impact. Furthermore, YAL's targeted interventions effectively engaged marginalised youth, addressing disparities in SRH and mental health outcomes.
Conclusions/Next steps: The findings highlight the potential of integrating social determinants into digital health interventions to drive sustained behavior change. By addressing mental health and connectedness, YAL fosters a supportive environment for users to adopt and maintain positive health behaviors. Future phases will prioritise scalability and incorporate advanced data-driven approaches to further tailor interventions. By enhancing access to adolescent-friendly services, particularly for underserved populations, it bridges critical gaps in HIV prevention and treatment. This scalable, data-driven model offers a replicable framework for tackling global health challenges in resource-limited settings.

EP0674

Human-centered HIV risk self-assessment for HIV prevention study eligibility and participation among adolescent girls and young women in fishing communities-Entebbe, Uganda

M. Wambuzi[1], G. Nanyonjo[1], M. Namuleme[1], P. Mulungi[1], T. Wambi[1], A. Nanvubya[1], A. Ssetaala[1], J. Mpendo[1], B. Okech[1]
[1]UVRI-IAVI HIV Vaccine Program, Community, Entebbe, Uganda

Background: AGYW in fishing communities in Uganda face disproportionate HIV risk, making them key candidates for future HIV prevention trials. Newer prevention strategies that attend to maturing immune systems and inequities faced by AGYW are vital in ending HIV/AIDS by 2030.
UVRI-IAVI HIV Vaccine program implemented human centered engagement and pre-screening activities to identify potential participants for HIV prevention trials. The engagements were premised on a Good Participatory Practice framework that aimed to involve communities in more meaningful research partnerships.
We engaged communities with high burden of HIV across the trial processes using GPP models that elicit mobilization, self-risk evaluation, recruitment, retention and support for new HIV improved interventions.
Methods: Approved GPP plans were implemented to engage research communities and high-risk females in conversations that generate self-assessments to support mobilization, recruitment and retention of female participants aged between 18-49years.
Pre-screening meetings were organized for AGYW to discuss key risk drivers in their communities. Manilla charts, markers were used by female participants to make visual pictures of a female while marking parts of the body that indicate points of risk translated in form of need for monies from men who can afford to provide.
We demonstrated HIV risk in relation to body parts cosmetics. Keys notables make up areas included Hair, lips, nails, foot ware, clothing, under pants, facial make up, bras, food and child support.
The more parts on the female body required for make – up, the more resources are required to maintain and ultimately the more sexual partners hence HIV risk.
Results: Involving AGYW participants in HIV risk assessment has greatly supported processes for defining risk in the context of HIV. Promoted self-evaluation of the risk and informed consent to participate in studies.
The conversation around self-evaluation and assessments has promoted meaningful relationships between researchers and communities with the later feeling involved rather than exploited. Communities have gained more understanding on the need for female participation in health research.
Conclusions: Involving communities in HIV risk self-assessment empowers communities to be active partners in the research processes while complimenting conventional risk assessment tools and addressing vulnerability drivers.

EP0675

Co-creation to encourage youth engagement in health and wellness services in South Africa

W. van Eyck[1], C. Osborne[2], M. Jones[2], J. Pienaar[2], N.E. Fologwe[2]
[1]Believ Content Agency, Gqeberha, South Africa, [2]Project Last Mile, Arlington, United States

Background: This study explores the application of co-creation as a participatory methodology to engage youth in health and wellness services, particularly in HIV prevention, in underserved South African communities. The project aimed to improve healthcare engagement among young people, especially males aged 18-30, in Khayelitsha and Mitchell's Plain.
While not solely focused on HIV prevention, the project utilized a community-engaged approach to develop health communication campaigns with youth, local organizations, and role models. Believ Contact Agency was the creative agency contracted by Project Last Mile for the Western Cape Department of Health, with funding from USAID and PEPFAR.

Description: Running from mid-2023 to December 2023, the project used a co-creation process involving six youth organizations to design health communications and wellness events. Through co-creation workshops, young people, community leaders, and health professionals collaboratively developed campaign materials and identified key health priorities, including HIV prevention. Health services, including HIV screenings, were integrated into the wellness events, which aimed to engage youth in a safe, relatable environment.
The intervention reached over 779 young people, delivering 1,333 health services. The process was documented, and the co-creation methodology is available for other organizations to replicate interventions.
Lessons learned: The project demonstrated that co-creation significantly enhances youth engagement in health services by fostering a sense of ownership and trust. Youth role models played a critical role in the success, with 85% of attendees hearing about the events through these role models. Trust in healthcare providers increased by 5%, and trust in role models grew by 20%. The participatory approach created a safe space for discussing health issues, including HIV, and allowed for integrated health services to be delivered in a non-judgmental environment, improving health literacy and encouraging positive behaviors.
Conclusions/Next steps: This co-created model provides a replicable framework for HIV-related interventions, particularly for engaging hard-to-reach youth populations. The documented process offers a valuable tool for scaling similar initiatives and integrating mental health services into future youth health programs, fostering holistic, community-driven solutions to public health challenges.

EP0676

Ahoundjouê, a key lever for HIV prevention and strengthening parent-child bonds in the DREAMS Initiative in Côte d'Ivoire

M.E.A. Kouassi[1], P. Kouassi[1], V. Gnanhe[1], M. Ahoussi[1]
[1]OGRADIE, Abidjan, Côte d'Ivoire

Background: In Côte d'Ivoire, Adolescents Girls and Young Women (AGYW) aged 15 to 24 are particularly vulnerable to HIV, with a prevalence rate of 3.2% in 2012[2]. They face challenges such as early pregnancies, forced marriages, and gender-based violence, which increase their exposure to HIV. The DREAMS[3] Soungourou Farima program, supported by USAID/PEPFAR since 2018, aims to prevent HIV by strengthening the relationships between parents and young girls.
The positive parenting program Ahoundjouê, implemented in Cocody-Bingerville, has been a key tool in improving communication and raising awareness within families about HIV issues.
Description: The Ahoundjouê (we are at peace) program consists of 14 sessions focused on three main areas: defining the program's goals and expectations, encouraging quality time between parents and young girls to strengthen their bonds, and providing tools to resolve family conflicts while promoting healthy family budgeting. These weekly sessions take place in secure spaces at intervention sites, using an interactive and participatory methodology that fully engages all participants for better family skills development.
Lessons learned: To date, 21,690 people have participated in Ahoundjouê sessions, including 10,845 parents (3,317 men and 7,528 women) and 10,845 AGYW (5,596 aged 10-14, 5,249 aged 15-19). Feedback indicates a significant improvement in family relationships, with better communication around reproductive health and HIV issues.
Both young girls and their parents are now actively engaged in discussions on HIV prevention and risks, contributing to a reduction in the vulnerability of adolescents.
Conclusions/Next steps: The Ahoundjouê program has strengthened family relationships and parental skills in HIV prevention. Its collaborative approach has facilitated the acquisition of essential skills for combating HIV.
To sustain these results, it is crucial to integrate these initiatives into national HIV response policies, ensuring that family relationships remain central to prevention strategies.

EP0677

An AGYW-led HIV prevention research agenda: shaping inclusive and responsive strategies

N. Sikwana[1], C. Kasanda[2], G. Kumwenda[3], L. Somnono[4], M. Mhaka[5], S. Gaika[6], S. Hannah[7]
[1]AVAC, Klerksdorp, South Africa, [2]Treatment Advocacy and Literacy Campaign (TALC), Lusaka, Zambia, [3]AVAC, Blantyre, Malawi, [4]Sex Workers Education and Advocacy Task Force (SWEAT), East London, South Africa, [5]WACI Health, Bindura, Zimbabwe, [6]Advocacy for Prevention of HIV and AIDS (APHA), Port Elizabeth, South Africa, [7]AVAC, Antlanta, United States

Background: Adolescent girls and young women (AGYW) in sub-Saharan Africa remain disproportionately affected by HIV, yet their voices are often underrepresented in prevention research and implementation. In 2024, the Young Women's HIV Prevention Council (YWHPC), through the Coalition to Accelerate and Support Prevention Research (CASPR), launched a multi-country initiative across 8 African countries to define AGYW priorities across the HIV prevention R&D pipeline.
The resulting AGYW-led research agenda promotes equitable access, culturally relevant solutions, and a more inclusive approach that positions AGYW as leaders and partners in combating HIV.
Description: The YWHPC research agenda was developed through a multifaceted approach, April-July 2024: online survey, in-person and virtual convenings, and targeted discussions across YWHPC countries, Key data collection categories included research priorities of AGYW on HIV prevention, product preferences, and how best to engage AGYW from research to roll out. The YWHPC survey data was analyzed using qualitative methods.
Meeting notes were transcribed and synthesized for further analysis. Thematic analysis identified common themes and insights. The insights were validated in October 2024 among AGYW and other stakeholders.

Lessons learned: The research agenda called for decision-makers across the research enterprise to:

- Prioritize discreet, long-acting, user-friendly prevention tools, drawing inspiration from innovative industries;
- Integrate clear, early access strategies into efficacy trial programs;
- Address systemic barriers like stigma and gender inequality; e.g., through cultural and gender-sensitive approaches to community and facility-based services;
- Address vaccine hesitancy through transparent, AGYW-focused communication;
- Integrate HIV prevention with broader sexual and reproductive health (SRH) services, leveraging digital platforms to improve education and outreach;
- Align prevention efforts with AGYW's lived realities by creating meaningful mechanisms for culturally sensitive input.

Conclusions/Next steps: The AGYW-led research agenda demonstrates the importance of inclusive and participatory approaches in HIV prevention. It offers actionable insights to improve prevention research, policy, and advocacy through AGYW leadership.

The agenda will be instrumental in guiding future research, policy, product development, and advocacy efforts to ensure HIV prevention efforts optimal for AGYW. This model serves as a blueprint for similar interventions that address the unique needs of AGYW to accelerate progress toward ending the HIV epidemic.

EP0678

An innovative community engagement model for improving HIV prevention: The LISTEN Process in Eswatini

B. Shaw[1], B. Okiya[2], S. Ojoo[2]

[1]Georgetown University, Center for Global Health Practice and Impact, Washington, United States, [2]Georgetown University, Center for Global Health Practice and Impact, Nairobi, Kenya

Background: Long-term solutions addressing barriers and utilization of HIV prevention and treatment services require community participation, ownership, and programs integrated with local priorities. Yet, communities are rarely engaged in designing and delivering of HIV prevention interventions, and their innovations are seldom identified or scaled.

The LISTEN process (Local Initiatives Scaled Through Enterprise Networks) offers a structured approach—through enhanced communities of practice (CoP), linked to decision-makers, using human-centered design (HCD) and data support—to leverage local knowledge and innovation so communities are empowered to develop and own solutions.

We hypothesized that LISTEN would improve HIV prevention outcomes for vulnerable and key populations through LISTEN's innovative community engagement processes.

Methods: We conducted a quasi-experimental, mixed-methods evaluation on HIV prevention outcomes — i.e., utilization of condoms, HIV testing, PrEP, and VMMC — after four years of implementation in two Regions of Eswatini. We developed a comparison population of existing CoP, matching them to LISTEN CoP (e.g., youth, savings groups) at endline. A two-stage sampling was conducted, first purposively selecting CoP, then random selection of members (n = 439).

We analyzed data using matched analysis owing to limitations in constructing a suitable comparison. We conducted 30 in-depth interviews with LISTEN CoP members, analyzing qualitative data with thematic analysis.

Results: LISTEN CoP members were significantly more likely to report using condoms, initiating PrEP, and circumcision than comparison CoP members. There was a difference comparing the proportion of HIV+ individuals in LISTEN (16.8%) versus comparison CoP (20.6%), but this was not significant after matching.

We found significant improvements in individual attitudes, behavioral control, and norms relating to HIV prevention behaviors, particularly among males. Qualitative interviews with LISTEN CoP members highlighted extensive participation of priority populations, "empowered CoP" with dense links to communities and decision-makers, and an appreciation of LISTEN's participatory nature and use of HCD to organize problem solving with CoP and communities "at the center."

Conclusions: The LISTEN process, through its innovative engagement and solutioning to community problems, is a promising model for improving access to HIV prevention opportunities. We believe that these efforts lead to improved collective efficacy, buy-in, and development of contextually appropriate and sustainable solutioning.

EP0679

Strengthening health systems through community engagement and demand generation: lessons from COVID-19, HIV/AIDS, and TB interventions at Efut Anantigha PHC, Calabar South Cross River State Nigeria

F. Ngwu[1], G. Akpan[2], J.I. Odey[3]

[1]Center for Healthworks, Development and Research Initiative, Health, Calabar, Nigeria, [2]Center for Healthworks, Development and Research Initiative, Programs Office, Calabar, Nigeria, [3]Centre for Healthworks, Development and Research Initiative, Program, Calabar, Nigeria

Background: The Centre for Healthworks, Development, and Research Initiative (CHEDRES), in collaboration with the Global Funds and the TB Network, implemented the COVID-19 Response Mechanism (C19RM) and Resilient and Sustainable Systems for Health (RSSH) programs at Efut Anantigha Primary Healthcare Centre in Calabar South. The initiative sought to strengthen health systems, improve healthcare outcomes, and actively involve communities in the design, delivery, and evaluation of health services.

Its objectives was to mitigate the effects of COVID-19 while enabling testing and treatment of HIV/AIDS and tuberculosis, with strong emphasis on raising awareness and fostering community engagement.

Description: The project focused on vulnerable populations, including individuals with pre-existing conditions, women of reproductive age (16–40 years), the elderly, and underserved communities in Calabar South. It used community-led participatory approaches including recruiting and training a Community-Led Monitoring Team (CLMT),Hosting monthly coordination meetings to track progress and gather feedback, Organizing demand-generation initiatives to raise awareness and boost the use of health services having 1194 general clients, 144 Antenatal care clients and 184 OPD clients from May to September 2024

Lessons learned: The project revealed several critical insights showing that Demand Generation Drives Service Uptake creating awareness campaigns and community sensitization were pivotal in increasing the use of COVID-19 RM, HIV/AIDS, and TB services. Also, Community Participation Enhances Effectiveness, foster trust, ownership, and sustainability for the interventions.

Additionally, Flexible Implementation Expands Access through Outreach initiatives and extended clinic hours made healthcare more accessible for vulnerable populations. The use of Data-Driven Adaptation Improves Outcomes enhanced participatory tools like FGDs and KIIs provided actionable insights, enabling real-time adjustments to address service gaps.

Conclusions/Next steps: The success of the C19RM and RSSH interventions at Efut Anantigha PHC demonstrates the transformative impact of demand generation and community engagement in strengthening health systems. These findings underscore the importance of integrating participatory approaches and sustained sensitization efforts to boost the uptake of COVID-19 RM, HIV/AIDS, and TB services.

Future efforts will focus on expanding this model to other facilities in Calabar South and incorporating community-led monitoring into national health policies. Building the capacity of local stakeholders will remain essential for sustaining these achievements and advancing healthcare outcomes.

EP0680

Youth leadership and engagement in HIV strategy and policy development: a case study from the UNICEF/WHO/UNAIDS Blueprint Collaborative

D. Ho[1], T. Hlatshwako[1], K. Chima[2], Y. Tao[3], J.D. Tucker[4]
[1]University of North Carolina at Chapel Hill, Department of Health Policy and Management, Chapel Hill, United States, [2]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, [3]University of North Carolina-Project China, Guangzhou, China, [4]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States

Background: Adolescents and young adults (AYAs) face worse outcomes along the HIV prevention and care continuum compared to adults. Despite global commitments to youth engagement, AYAs are often excluded from research, programs, and policy, with few opportunities for youth leadership. We present a case study of young people (10–30 years) shaping adolescent HIV strategy through the 2023 Blueprint Collaborative, co-sponsored by UNICEF, WHO, and UNAIDS.

Description: The Blueprint Collaborative compiled research evidence and crowdsourced ideas to guide UNICEF's strategic planning for adolescent HIV programming in high-burden settings. The initiative included a youth-led rapid evidence synthesis on adolescent HIV interventions and a global open call organized by youth co-leads and judged by a majority-youth jury, which received 107 ideas from young people on improving adolescent HIV outcomes.

Lessons learned: We applied the RIGHTS framework by Olivera et al. (2018) to assess the strengths and limitations of youth engagement in the Blueprint Collaborative (Table 1). A major strength was the degree of youth engagement, moving beyond youth consultations to youth leadership. Youth were 'substantially engaged' as lead researchers, organizers, and open-call judges, sharing decision-making authority with adults (Asuquo et al., 2021). Youth not only informed but directed research which affected them. Lived experience with sexual health services enabled open-call participants to innovate creative solutions and judges to assess relevance. Through a 'learning by doing' approach, youth gained skills in research and multidisciplinary collaboration. Outputs were impactful, being presented to senior leadership, incorporated into UNICEF strategy, and disseminated through publications and global youth networks. As for limitations, youth organizers and participants were generally older (20–30). Youth reach and engagement were further limited by the digital nature of activities.

Criterion	Explanation	Rapid evidence synthesis	Open call
Resourced	What remuneration, financial or otherwise, is provided?	Honoraria and mentorship provided for co-leads	Cash prizes for finalists ($1500) and runners-up ($500); honoraria for co-leads, organizing committee members, and judges; mentorship provided for organizers and participants
Impactful	How are results used?	Results reviewed by UNICEF, WHO, and UNAIDS decision-makers; published in eClinicalMedicine; disseminated via social media (X, BlueSky, LinkedIn) and UNICEF/IAS global youth networks	Winning submissions presented to senior UNICEF, WHO, and UNAIDS leadership, manuscript submitted for publication
Genuine	Is engagement voluntary and participatory?	Participants volunteered to be involved and took on review tasks as time and skillset allowed	Participants were aware of open-call rules and voluntarily participated, independently forming teams, generating ideas, and crafting pitches
Harmless	Are there harms of participation?	No obvious harm from participation	No obvious harm from participation
Teen-friendly	Adapted as, Are activities age-appropriate?	Tasks at an appropriate level of research literacy and competency for team members, with input and supervision from senior researchers	Opportunities to leverage lived experience as youths in submissions; judging criteria cognizant of age and considered novelty and relevance, not just technical competencies; shared decision-making authority with adults
Skill-building	What skills or competencies are learned or practiced by participating?	All team members gained training in systematic review methods, including searching, screening, data extraction, quality assessment, and confidence assessment; co-leads enhanced their project management skills	Participants practiced teamwork, creativity, and presentation skills; judges honed evaluation for public health potential; co-leads and organizing committee practiced project management and qualitative research methods

Table 1. RIGHTS framework.

Conclusions/Next steps: Youth are eager to drive HIV strategy and policy, but more opportunities for youth leadership are needed.
Policymakers should enable youth leadership in policy planning to align programming with youth priorities and build research and advocacy skills.

EP0681

Early engagement of communities in HIV cure research: insights from the Makerere University Walter Reed Program (MUWRP)

S. Mugamba[1], G. Mirembe[1], R. Babirye[2], M. Ssekitoleko[1], J. Nawatti[1], R. Mayanja[1], B. Raymond Kihumuro[1], P. Defechereux[3], R. Furler O'Brien[3], S. Norman[3], P. Naluyima[1], H. Kibuuka[1], B. Mwesigwa[1]
[1]Makerere University Walter Reed Program, Kampala, Uganda, [2]MUWRP Community Advisory Board (CAB), Kampala, Uganda, [3]Gladstone Institute of Virology, Gladstone Institutes, San Francisco, United States

Background: The HIV pandemic has greatly impacted Uganda, with approximately 1.4 million people living with the virus, and prevalence rates reaching up to 9.9% in a localized epidemic distribution. This calls for innovative HIV cure research initiatives whose progress is partly dependent on community acceptance. The Makerere University Walter Reed Program (MUWRP) in Uganda, implemented innovative community engagement activities to advance HIV cure research. We highlight the lessons learned to inform future HIV cure research initiatives in Uganda and similar settings.
Description: The HOPE Collaboratory under the Martin Delaney Collaboratories for HIV Cure Research, aims to accelerate HIV cure research through multidisciplinary collaboration. Between October 2023 and September 2024, MUWRP, as part of the Collaboratory, conducted community dialogues in Uganda, reaching 227 individuals, including persons of diverse sexual orientation and gender identities and people living with HIV (PLWH). These dialogues focused on inclusivity, stigma, fears, and opportunities related to HIV cure research.
Additionally, a roundtable dialogue involving scientists, Community Advisory Boards (CABs), civil society organizations, key populations, HIV cure research advocates, and health journalists was held. Data were documented through interactions and analyzed thematically.
Lessons learned: The Community Engagement initiatives highlighted 5 key areas;
(1) Legal and social barriers; where stigma and discrimination were cited to deter key populations from participating in research and access services,
(2) Confidentiality; where participants underscored the need for their information to remain private to avoid any backlash from the community,
(3) The burden of daily antiretroviral therapy (ART); as being exhausting and affecting the daily lives of persons living with HIV, thus the need for HIV cure discovery,
(4) Engaging policymakers; engage the Ministry of Health in Uganda and research regulators to create supportive policies that facilitate HIV cure research,
(5) Developing less burdensome HIV cure regimens; that is easier to manage and less intrusive.
Conclusions/Next steps: The findings suggest inclusive community engagement efforts to address legal, social, and confidentiality concerns, and foster supportive policies to advance HIV cure research.
The organization looks to disseminate these findings with key players to improve the feasibility and acceptability of HIV cure research in Uganda and similar settings.

EP0682

Using storytelling to address HIV stigma in Tanzania through co-created tools

Y. Kruger[1], S. Pincus[2], C. Marona[1], R. van de Ven[3], P. Faustine[4], Z. Masunga[4], S. Shoko[4], S. Kwilasa[4]
[1]Matchboxology, Directorate, Cape Town, South Africa, [2]Matchboxology, HCD, Cape Town, South Africa, [3]Elizabeth Glaser Pediatric AIDS Foundation, Deputy Chief of Party, Dar es Salaam, Tanzania, the United Republic of, [4]Ministry of Health, National AIDS Control Program, Dodoma, Tanzania, the United Republic of

Background: In Tanzania, stigma presents a persistent barrier to HIV care and treatment adherence. The USAID Afya Yangu (My Health) Northern project adopted a human-centered design (HCD) approach to develop social behavioral tools. These tools aimed to promote empathy, reduce stigma, and encourage open communication about HIV within families and communities.
Description: The project began with extensive evidence gathering and immersion interviews with 70 participants, including people living with HIV (PLHIV) and healthcare providers. Two co-creation workshops engaging 40 stakeholders led to the development of two key storytelling tools:
Tara Atabasamu Tena Storybook: A child-friendly narrative featuring Tara, a personified river, designed to explain HIV and antiretroviral therapy (ART) adherence through relatable characters, vibrant illustrations, and story.
Njoo Tusemezane Game: A family-oriented game designed to facilitate conversations about HIV stigma and cultural practices, fostering mutual understanding and openness.
These tools were tested with children, families, and healthcare providers across rural and urban settings, to iterate them further for cultural context.
Lessons learned: The Tara storybook was pre-tested in a workshop setting and feedback indicated that using culturally resonant narratives and interactive elements like songs to simplify complex HIV concepts engaged children and adults alike.
However, implementation challenges, such as unsuitable healthcare settings for interactive sessions, underscored the need for community-centered venues and flexible scheduling.
The Njoo Tusemezane game was pre-tested and feedback indicated that the game encouraged families to discuss difficult topics, breaking down stigma and fostering inclusiveness. Families reported that the game not only strengthened communication but also inspired reflection

on cultural practices and behaviors. Initial difficulties in understanding the game format highlighted the importance of facilitation during early rollout.
These interventions highlighted storytelling's ability to create inclusive, empathetic spaces for dialogue, leveraging cultural traditions to address sensitive topics and empower participants.
Conclusions/Next steps: By integrating cultural narratives and interactive elements, storytelling tools promote inclusiveness and openness in HIV communication. Future implementations should focus on context-specific adaptations and support mechanisms to sustain engagement and dialogue across diverse settings.

EP0683

Harnessing digital innovation to combat HIV: lessons learned from Sex Talks Podcast in transforming SRHR education for Namibian youth

S.N. Iyambo[1]
[1]Sex Talks Podcast, Windhoek, Namibia

Background: In Namibia, youth make up 71.1% of the population, but accessing comprehensive Sexual Reproductive Health and Rights (SRHR) education is challenging due to cultural taboos, stigma, and limited resources. This results in low contraceptive use (24%) and high unmet family planning needs (11.7%), which increase the risks of unintended pregnancies, STIs, and HIV. To address these challenges, innovative solutions are needed to engage youth and provide accessible, stigma-free SRHR and HIV education.
Description: Sex Talks Podcast is an award-winning digital platform aimed at improving SRHR education for Namibian youth aged 10-35. Covering topics like HIV, gender-based violence, mental health, and consent, the podcast offers a safe space for open discussions. With 19 episodes and over 6,000 listeners across platforms like Spotify and Apple Podcasts, the podcast also hosts community listening sessions, live events and is developing a chatbot as part of their podcast website. By combining expert interviews and youth-driven storytelling, the podcast challenges misconceptions and provides accurate information about HIV and SRHR, particularly reaching youth in remote areas.
Lessons learned: Sex Talks Podcast has successfully engaged Namibian youth through digital media, helping to reduce stigma and increase HIV prevention awareness. Key lessons include:

- **Youth-Led engagement:** Empowering young people to share their stories fosters relatable content and breaks down stigma.
- **Digital accessibility:** Reaching youth online has overcome geographical barriers to education and discrimination that comes with in person conversations.
- **Stigma reduction:** Open discussions challenge societal taboos and encourage youth to seek HIV testing and prevention.
- **Community impact:** Live sessions and community listening events build a sense of shared learning and local engagement.

These lessons underscore the effectiveness of digital innovation in providing accessible and impactful education to youth.
Conclusions/Next steps: Sex Talks Podcast shows how digital platforms can transform SRHR education and HIV prevention for youth. Moving forward, we aim to scale the podcast and develop a chatbot to reach more young people, continue fostering stigma-free conversations, and encourage greater engagement with HIV testing and prevention. This initiative aligns with the global goal of ending HIV by 2030 through youth empowerment, accessible education, and stigma reduction.

EP0684

Analysis of the Accelerating Progress in Pediatrics and PMTCT (AP3) Programme in Uganda

K. Mwehonge[1], B. Ajonye[2], E. Lankiewicz[3], A. Kayongo[4], A. Sharp[5], A. Nsubuga[6], J. Kilande[1]
[1]Coalition for Health Promotion and Social Development (HEPS Uganda), Kampala, Uganda, [2]International Community of Women Living with HIV - Eastern Africa (ICWEA, Kampala, Uganda, [3]amfAR, Washington, United States, [4]Georgetown University, O'Neill Institute for National and Global Health Law, Washington, United States, Washington, United States, [5]Georgetown University, Washington, United States, School of Public Health, Washington, United States, [6]Sexual Minorities Uganda (SMUG), Kampala, Uganda

Background: In Uganda, 37% of all new infections happen among children and adolescents, but despite progress in the country's HIV response, over 12,000 (0 – 19 years) children and adolescents living with HIV remain unidentified. The Accelerating Progress in Pediatrics and PMTCT (AP3) program, launched under COP22 by PEPFAR/CDC, seeks to address persistent gaps in pediatric and PMTCT HIV care in Uganda. To strengthen AP3 work, we use community-led monitoring (CLM) data to assess community perspectives on barriers and enablers to PMTCT and Pediatric HIV/TB services in Uganda.
Description: We conducted qualitative data collection under the CLM program through purposively sampled adolescents, and pregnant or breastfeeding girls and women. Focus group discussion and individual interviews were used at both the facility and community level. A total of 30 interviews and 10 FGD were conducted in November – December 2024. Data were analyzed thematically, with a focus on barriers and enablers.
Lessons learned: Respondents reported improvements in accessibility and quality of PMTCT and pediatric HIV services during the early implementation of AP3. However, key barriers were also identified that could strengthen programming. In particular, respondents reported inefficiencies in the implementation of differentiated service delivery (DSD) in schools which is contributing to the non-suppression rates andchallenges with pediatric medication, particularly bitter pills. Respondents also shared challenges with bringing their children for HIV PCR testing and reported low health literacy levels in relation to mixed feeding practice after child birth.

Conclusions/Next steps: This data points to progress achieved under the AP3 program, but also reveals clear areas that can be further strengthened. In particular, there is a need to create school-specific DSDM protocols, enhance community sensitization on pediatric formulations and literacy on mixed feeding, improve data collection systems in schools to strengthen HIV service delivery and outcomes for vulnerable populations. These data additionally point to the critical role of continuing to engage service users voices to improve program implementation.

EP0685

Effects of peer-education intervention on adolescents' utilization of HIV/AIDS prevention services at Adolescent and Youth Friendly Health Facilities, Makurdi, Nigeria

S. Ngobua[1], O. Olaleye[2], I. Ieren[3]
[1]University of Benin, Department of Public Health and Community Medicine, Benin, Nigeria, [2]University of Ibadan, Department of Health Promotion and Education, College of Medicine, Ibadan, Nigeria, [3]Population Health Branch, Saskatchewan Ministry of Health, Saskatchewan, Canada

Background: Adolescents constitute a significant proportion of Nigeria's population. They face heightened vulnerabilities to HIV and other sexual reproductive health challenges majorly due to their limited access to sexual and reproductive health information and services. Despite establishing Adolescent Youth Friendly Health Facilities (AYFHF) to address this gap in Makurdi, Benue State, Nigeria, service uptake has remained low.
This study was, therefore, designed to examine the effects of peer-education intervention on the adolescent's utilization of HIV prevention services at AYFHF.
Methods: The quasi-experimental study was conducted among in-school and out-of-school adolescents aged 10 to 19 in Makurdi. Baseline data was collected using a pre-tested questionnaire among 837 and 890 adolescents selected using multistage sampling technique in the intervention and control groups (CG) respectively which explored their socio-demographic information and utilization of AYFHF in the last five months. A 3-day workshop and educational training were carried out for 12 selected peer-educators who in turn carried out peer-education on basic information about HIV and AIDS, HIV transmission and prevention, youth-friendly facilities, location, and types of services provided among their peers for five months.
After this, post-intervention data was collected using the same questionnaire used at the baseline. Ten questions were used to assess the level of AYFHF services utilization. Each service utilized and not utilized was scored ‚10' and ‚0', marks respectively. Scores≥50 and <50 were graded as high and low utilization respectively. Data were analysed using frequency, and chi-square at p<0.05.
Results: The mean age of the participants was 16±2.3 and 15±2.4, 37.0% and 41.0% were males in the intervention and CG respectively. At the baseline, there was no significant difference in the utilization of HIV prevention services among participants in the intervention and CG (p>0.05). Only 2.7% and 2.0% had high utilization in the intervention and CG respectively. At the endline, 14.5% and 4.1% have high utilization in intervention and CG respectively (p<0.001).
Conclusions: Peer-education has helped to increase utilization of AYFHF among the target population. The government and other stakeholders should design and implement sustainable peer-education interventions to increase the utilization of HIV prevention services among adolescents.

EP0686

Health-seeking behavior among key populations in Rwanda: Persistent stigma and discrimination

J.P. Ayingoma[1], N. Kabanyana[1], S. Murindanyi[1], L. Ngabonzima[1], D. Ndagijimana[1], B. Ikuzo[2], G. Rwibasira[2]
[1]Rwanda NGOs Forum on HIV/AIDS & Health Promotion (RNGOF on HIV/AIDS & HP), Kigali, Rwanda, [2]Rwanda Biomedical Centre, Kigali, Rwanda

Background: Despite improvements in HIV prevention programs, engagement with healthcare services is still low in Female Sex Workers (FSWs) and Men who have Sex with Men (MSMs). This impedes the overall effectiveness of HIV interventions.
This study investigates the factors influencing health-seeking behavior among FSWs and MSMs, with a focus on stigma, discrimination, and accessibility of services.
Methods: A cross-sectional study was conducted using respondent-driven sampling (RDS) to recruit 2,560 FSWs in 2023 and 3,757 MSMs in 2024, who were receiving HIV prevention and care services from RNGOF. Participants were recruited from high-risk hotspots across Rwanda. Data were analyzed using advanced regression models to examine the relationships between stigma, discrimination, and health-seeking behavior while adjusting for socio-demographic variables and service accessibility.
Results: Among the 6,317 participants, 40.5% of FSWs and 59.5% of MSMs reported avoiding healthcare services due to fear of stigma or mistreatment, highlighting the importance of addressing these barriers. Regression analysis revealed significant associations between stigma (β = 0.42, p <0.001) and gender-based violence (β = 0.35, p <0.01) with reduced health-seeking behavior.
Furthermore, peer education and community support were positively associated with health-seeking behavior, increasing service utilization by 25%. HIV prevalence among FSWs decreased from 50.8% in 2010 to 35.5% in 2024, suggesting a positive trend in HIV prevention efforts.
Conclusions: Stigma, discrimination, and gender-based violence continue to be major barriers to health-seeking behavior among FSWs and MSMs in Rwanda, despite the progress in HIV prevention. Addressing these socio-cultural barriers through targeted interventions, such as advocacy for the rights of key populations and strengthening peer education, is essential for improving healthcare access and reducing HIV prevalence.
Future efforts must prioritize eliminating these barriers to enhance the effectiveness of HIV prevention and treatment programs.

EP0687

Youth advisory boards in adolescent HIV research in LMICs: literature review and reflections from youth advisors

P.K. Chima[1,2], J.R. Durham[3], C. Mazonde[4], E. Kyalo[5], R. Mtei[6], S.N. Owino[7], A. Goi[8], S. Vorkoper[3]
[1]University of Oxford, Nuffield department of Medicine, Oxford, United Kingdom, [2]University of Nigeria, Faculty of Medical Sciences, Nsukka, Nigeria, [3]National Institutes of Health, Fogarty International Center, Maryland, United States, [4]The Health Research Unit, Zimbabwe, Pangea, Zimbabwe, [5]Catholic University of America, Washington, D.C, United States, [6]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, the United Republic of, [7]Impact Research and Development Organisation, Kisumu, Kenya, [8]Kilimanjaro Christian Medical University College, Moshi, Tanzania, the United Republic of

Background: The Adolescent HIV Implementation Science Alliance (AHISA) youth advisory group, composed of youth HIV advocates and researchers primarily from low- and middle-income countries (LMICs), conducted a literature review and provided reflections on the use of youth advisory boards (YAB) in HIV research. The aim was to describe how and to what extent YABs are being engaged in adolescent HIV research in LMICs.
Methods: We searched seven literature databases for articles that had a designated YAB as part of youth HIV research (10-24 years). Peer-reviewed articles were included if they had a YAB, were conducted exclusively in an LMIC, and were published between 2014-2024 in English. We characterize how YABs are engaged, their composition, activities, and role in the research study. Then, as youth actively engaged in different YABs, we reflect on the findings and their alignment with our own experiences.
Results: Among 248 unique citations, only 10 articles from five countries—Kenya, South Africa, Nigeria, Lesotho, and Kazakhstan—met the inclusion criteria. They primarily targeted HIV prevention. Their additional focus areas included PreP uptake, stigma, gender-based violence, and mental health. YAB activities in the literature typically included providing early feedback on intervention and implementation activities.
However, AHISA youth reported that they were usually involved throughout the research process, co-designing research components and engaged in dissemination. Both the literature and AHISA youth found that YABs were designed for the specific study with members reflecting the study population. Explicit changes based on YAB involvement were only stated in 30% of studies.
In contrast, the AHISA youth reported that their YABs impacted the final research design, better reflecting the community in which the research was taking place and making the research more acceptable and youth-centered.
Conclusions: Description of YAB composition, engagement, activities, and impact on adolescent HIV research in LMICs in the literature is limited, not well described, and may not reflect how YABs actually operate. Addressing this gap would help to ensure that through formal engagement of youth, adolescent HIV research is responsive to the community in which it sits, and that youth input is integrated, impactful, reported, and recognized.

EP0688

"Sisters Influencing Sisters:" developing a community-engaged, social media-based, influencer-led intervention to increase PrEP awareness, knowledge, and uptake among transgender women in the United States

S. Zamudio-Haas[1], J. Johnson[2], K. Singley[3], E.A. Freedman[3], C. Lane[3], S. Scott[2], V.V. Patel[4], J.M. Sevelius[5], S.B. Bass[3]
[1]University of California, San Francisco, Medicine, San Francisco, United States, [2]University of California, San Francisco, San Francisco, United States, [3]Temple University, Philadelphia, United States, [4]Albert Einstein College of Medicine, New York, United States, [5]Columbia University, Psychiatry, New York, United States

Background: Transgender women (TW) have a disproportionate burden of new HIV diagnosis globally, yet are less likely to use PrEP, due to intersectional social and structural barriers to accessing services. TW utilize social media to share health information and foster community, yet few interventions have harnessed these platforms for education or linkage-to-care. We partnered with TW Influencers and engaged a Community Advisory Board (CAB) to develop content to refine an evidence-informed intervention to increase PrEP awareness and use, among TW through peer education and referral to vetted service providers.
Methods: Community activists and healthcare providers were recruited to join the CAB, who attended meetings (3), completed surveys, and in-depth interviews. Formative information was gathered on (1) social media use patterns; (2) recommendations on platforms, Influencers, and strategies; (3) preferences on health communication products.
We also established paid partnerships with TW Influencers, representing diverse cultural backgrounds, who had public accounts and minimum 1,000 followers. We designed and conducted an online training to prepare Influencers to be peer educators and to finalize intervention content.
Results: CAB members (8 TW; 1 cisgender woman) recommended TW-specific infographics and storylines and provided feedback on images, colors, and message preferences. They offered input on training needs and suggested influencers. We conducted a review of online accounts, looking at reach, follower demographics, and content, and recruited and partnered with TW Influencers (8).
Influencers participated in a 10-hour training over five days, on PrEP education, research training, and co-design of intervention content and implementation. Final intervention materials addressed common concerns, such as interference with hormone therapy and how to talk with partners about PrEP; provided education on HIV; and featured PrEP navigators. Graphic templates included a range of styles that Influencers adapted to align with their brand.

Conclusions: We co-designed and developed an intervention with our CAB and TW-influencers, resulting in the "SIS" intervention to increase access to PrEP information, foster dialogue around PrEP within community online spaces, and provide linkage to trans competent and gender affirming prevention services.
Partnering with community was essential to designing an online intervention that met the specific needs of TW to increase PreP knowledge and access.

EP0689

Gathering feedback on the delivery of HIV prevention services or interventions from orphaned and vulnerable children and adolescent girls and young women in Eswatini: beneficiary surveys

M. Maseko[1], H. Mkhatshwa[2], H. Nxumalo[3], M. Dlamini[1]
[1]World Vision Eswatini, Strategic Information, Mbabane, Eswatini, [2]World Vision Eswatini, Health and Nutrition, Mbabane, Eswatini, [3]World Vision Eswatini, Program Development Evidence & Impact, Mbabane, Eswatini

Background: World Vision Eswatini (WVE) implements several HIV prevention programs targeting orphaned and vulnerable children, adolescent girls and young women, adolescent boys and young men, and caregivers. The effective rollout of these HIV prevention interventions requires the input and voice of different target populations. World Vision Eswatini conducts an annual beneficiary satisfaction survey aimed at determining the views of program participants on the different HIV prevention interventions and selected program areas and to facilitate engagements on suggested improvements and changes in delivery of these HIV prevention programs.
Description: World Vision Eswatini uses a mixed methods approach in that both qualitative and quantitative methods are applied. Face-to-face interviews and focus group discussions are conducted to allow probing.
Respondents rate the relevance of provided HIV interventions, where 98% stated that the interventions were relevant, 93% mentioned improved health education, and 99% were extremely satisfied with these interventions.
Respondents also reflect on knowledge improvements in their lives as a result of HIV prevention interventions provided through WVE programs, and 94% (1615/1719) indicated significant improvements.
Lessons learned: Partnering with communities is essential in designing relevant HIV prevention programs. Feedback from beneficiaries enables HIV prevention programs to meet target populations at their point of need and minimize the risk of new HIV infections.
Feedback from this survey also enabled WVE to identify gaps such as stigma associated with family planning which hinders service uptake and also built trust as target populations engage with WVE staff.
The beneficiary survey provides substantive qualitative insights that complement quantitative data, offering a full picture of HIV prevention program outcomes.
Conclusions/Next steps: Beneficiary satisfaction surveys ensure that HIV prevention interventions are sustainable, impactful and inclusive. They also enable programs to effectively allocate resources and help normalize discussions about HIV prevention, reducing stigma in the different communities. This survey enables WVE to come up with community-driven solutions, ensuring sustainability of rolled out HIV prevention interventions.

EP0690

Addressing advanced HIV disease (AHD) within the HIV sector through community-based screening initiatives in Zimbabwe

L. Murembo[1], T. Makoni[1], S. Mukungwa[1], C. Mademutsa[1], W. Mukuwapasi[1], P. Gonorashe[1], S. Mlauzi[1], M. Chananuka[1]
[1]Zimbabwe National Network of People living with HIV, Harare, Zimbabwe

Background: AHD represents a critical challenge in the global fight against HIV/AIDS. Despite progress in antiretroviral therapy (ART), late diagnosis of HIV is still common in marginalized rural communities in Zimbabwe. AHD requires a comprehensive approach focused on accessibility, education, and support for timely interventions. Community-based screening is essential for early identification and connection to care.
Methods: In December 2024, under the Global Network of People living with HIV (GNP+) grant, we trained 30 AHD champions from 30 rural health facilities in Mutasa, Hwange, and Mazowe districts, Zimbabwe. These champions pre-screened and facilitated referrals for potential AHD cases using a digital screening tool in CommCare. They used electronic tablets to record screenings, referrals, and follow-ups, collecting data on various health indicators, including viral load, CD4 count, clinical management, and ART adherence. Referrals included necessary tests for viral load, CD4 count, and opportunistic infections(OI). The AHD Champions served as vital links for referrals, appointment scheduling, and follow-up care in CommCare.
Results: A total of 210 clients were screened, with specific attention given to those at risk of AHD. The screening process Among the screened clients, 3 had not undergone a viral load test in over a year, and 2 had never been tested. Additionally, 9 clients had not had a CD4 test in more than a year, while 11 had never been tested. Notably, 2 clients had stopped ART, with only 1 returning to treatment. Following these screenings, referrals for viral load testing and CD4 count assessments were made, alongside referrals for clients returning to treatment. Subsequent follow-ups revealed that 4 clients had AHD, indicated by viral load results exceeding 1000 copies.
Conclusions: ZNNP+ has made significant strides in reducing AHD through targeted community efforts in the three districts. The proactive screening and referral processes facilitated by AHD Champions have not only identified at-risk individuals but also enhanced their access to essential health services. Continued follow-up, counseling sessions, and education on adherence are crucial for sustaining these gains and improving health outcomes for individuals living with HIV.

EP0691

Co-creating HIV prevention campaigns with communities: lessons from the Time Up HIV Campaign in Uganda

E. Kagguma Kakooza[1], L. Bufumbo[1]
[1]Johns Hopkins University/ Center for Communication Programs, Center for Communication Programs, Kampala, Uganda

Background: Uganda has made progress in HIV prevention, yet challenges like message fatigue, fragmented communication, and stigma persist, undermining efforts to achieve the UNAIDS 95-95-95 targets. Small, disconnected campaigns dilute impact, and stigma—especially around interventions like PrEP—remains a barrier.

The *Time Up HIV* campaign introduced an umbrella platform to streamline messaging, enhance collaboration, and mobilize communities through gatekeepers, aligning efforts with Uganda's national HIV priorities.

Description: The campaign involved participatory collaboration with the Ministry of Health, USG Implementing Partners, CSOs, private sector players, and community representatives. A review of existing communication materials evaluated their relevance and effectiveness, while human-centered design workshops refined messaging for interventions such as VMMC, PrEP, cervical cancer screening, and HIV self-testing. This process prioritized inclusivity and cultural relevance, aligning the campaign with Uganda's health goals.

Lessons learned: The campaign achieved impactful results. Fidelity in implementation ensured effectiveness, while advanced audience segmentation allowed tailored messaging for diverse populations, including youth. Technical assistance strengthened stakeholders' capacity, and integration across thematic areas minimized fragmentation and optimized resources. Digital media innovations expanded reach, especially among Uganda's young people.

Conclusions/Next steps: Scaling the umbrella platform will streamline messaging and reduce fatigue. Strengthening collaboration among stakeholders will enhance integrated service delivery.

Digital innovations should continue targeting youth, while quality improvement practices like the iDARE methodology ensure adaptability. Inclusive community engagement will reduce stigma and foster ownership, driving Uganda closer to achieving its HIV goals.

EP0692

Healthy Happy Human (HHH) show: a youth-led initiative for health education through digital platforms

L. Fana-Granville[1], V. Adasi[1], J. Nwosu[1,2]
[1]Healthy Happy Human Limited, Department of Sexual and Reproductive Health, Port-Harcourt, Nigeria, [2]Birmingham City University, Birmingham, United Kingdom

Background: The widespread adoption of digital media has revolutionized the way health information is consumed, particularly among Nigerian youth. However, this digital landscape is marred by fraudulent health information, misinformation, and misconceptions that disproportionately target young people, exacerbating the HIV epidemic and other health challenges.

To address this growing concern, the Healthy Happy Human (HHH) show was launched as a targeted intervention aimed at combating health misinformation, providing accurate health information, and enhancing health awareness among Nigerian youth, with a special focus on HIV prevention, treatment, and management.

This initiative seeks to leverage digital media to promote health literacy, informed decision-making, and behaviors that reduce the risk of HIV transmission and improve overall health outcomes among young people in Nigeria.

Description: Healthy Happy Human (HHH) employs a multi-faceted approach to achieve its HIV-focused objectives. The show features expert-led discussions in the form of one-on-one talk shows with young medical professionals, who educate audiences on HIV prevention, treatment, and management.

Additionally, informal HIV-focused dialogues (vox-pops) are conducted with young individuals in urban hotspots and university settings, aimed at exploring HIV-related misconceptions and providing corrective HIV education. These engagements are recorded and disseminated via digital media and social platforms, amplifying the show's reach and impact. HHH encourages active involvement of young participants in its production and dissemination processes, promoting a sense of ownership and community in the fight against HIV.

Lessons learned: The HHH show has reached over a hundred thousand people, results form surveys, focus groups and digital metrics demonstrate improved health literacy, awareness, and community engagement.

Culturally relevant content and interactive elements are key to sustaining interest, while popular digital platforms, social media and strategic partnerships with organizations are crucial for program sustainability and amplifying health education initiatives.

Conclusions/Next steps: The surge of HIV-related misconceptions and misinformation online necessitates a trusted source of health information.

Our initiative, Healthy Happy Human (HHH), bridges this gap by providing accurate HIV education, engaging people, and fostering partnerships with NGOs and organizations to establish a forefront for reliable HIV and health information dissemination to young people in Nigeria.

EP0693

Harmonized community led monitoring strategy – a critical tool in identifying gaps in service delivery and advocating for improved programme outcomes in Sierra Leone

E. Okey-Uchendu[1], G. Egesimba[2], M. Ellie[3], J. Yankay[4]
[1]National Agency for the control of AIDS, Community prevention and care services, FCT, Nigeria, [2]World Vision International Sierra Leone, Freetown, Sierra Leone, [3]Network of People Living with HIV in Sierra Leone, Freetown, Sierra Leone, [4]Sierra Leone Consultant, Freetown, Sierra Leone

Background: Community-led monitoring is a collaborative approach to tracking and evaluating services and programs, primarily led by affected communities. Community participation in designing, planning, implementing, and monitoring of health programmes is critical for achieving universal health coverage. In 2024, a harmonized Community-led monitoring strategy covering HIV, TB, malaria, hepatitis, mental health, human rights and pandemic preparedness was developed for Sierra Leone and country one of the first to have an integrated CLM strategy.

Description: Community-led monitoring (CLM) has emerged as an effective tool to strengthen community leadership and contribute to the quality and accessibility of care. CLM is a process in which communities, especially people who use health services, take the initiative to identify and regularly monitor the issues that matter to them. Communities define indicators to track priority issues, receive training to collect data and analyze results, and engage with a broader group of stakeholders to share insights from the data to co-create solutions.CLM programs are accountability mechanisms designed, led, and implemented by local community organizations run by the communities themselves, using structured platforms and rigorously trained peer monitors to collect quantitative and qualitative data. World Vision International Sierra Leone (WVISL) the Principal Recipient (PR) for implementing the HIV/AIDS component of the Global Fund for HIV/AIDS, TB, and Malaria under the Grant Cycle Seven (GC7) will work with NETHIPS to implement Community-Led Monitoring (CLM) in Sierra Leone. Part of the work includes development of a CLM strategy for Sierra Leone.

Lessons learned: Community members when involved from the onset of any activity are willing to ensure that the aims and objectives are met. The development of this strategy was carried out through a review of already existing documents at national and international levels and a participatory and multisectoral approach with national stakeholders in Sierra Leone. This process took place in four stages: Desk review, Strategy development Consultative meetings with community members, Key Informant interviews (KII), Strategy validation workshop and Trainings

Conclusions/Next steps: CLM is a great accountability mechanism. Strengthening the implementation of CLM in Sierra Leone requires creating community ownership and ensuring robust coordination that puts service recipients are at the center for smooth implementation.

EP0694

Participatory methodologies: lessons learned from a youth-led social accountability approach to improving HIV/AIDS and SRHR services in Shibuyunji, Mumbwa and Luwingu Districts of Zambia

F. Chinyimba[1], N.C. Musonda[1], S. Christensen[1], N.S. Kaoma[1], M. Chituma[1], F.K. Kabeleka[1]
[1]Copper Rose Zambia, Lusaka, Zambia

Background: According to the 2024 Zambia Demographic and Health Survey, only 42% of young women and 43% of young men aged 15–24 reported having knowledge of HIV prevention, implying that more than half of the population have no adequate knowledge on HIV prevention. Additionally, Zambia's teenage pregnancy prevalence stands at 28% despite the various efforts to equip adolescents and young people with knowledge on HIV/AIDS and sexual reproductive health.

Description: Copper Rose Zambia collaborating with USAID MCGL,is implementing the Youth-led social accountability activity in selected districts of Northern and Central provinces. The aim is to empower adolescents and young people with skills to hold public officials and service providers accountable for the provision of quality, equitable, and accessible healthcare and health education in sexual reproductive health, including HIV/AIDS to adolescents and young people. In the baseline assessment, a participatory approach using a community scorecard was employed, utilizing net mapping to identify and visualize key stakeholders, their influence and to gather structured youth feedback on service quality, fostering dialogue with providers. Bi-monthly review meetings are being conducted to review implementation of action points, address challenges and refine strategies. An endline assessment will be done and a technical brief with all the findings documented.

Lessons learned: Youth-led advocacy demonstrated its effectiveness in improving HIV/AIDS service delivery by addressing barriers such as underrepresentation, stigma, insufficient privacy, and staff shortages. Engaging and training healthcare providers and community gatekeepers created a shared accountability framework, improving trust and responsiveness in addressing youth access to family planning, HIV testing and treatment.
Adaptive management achieved through after action reviews ensures emerging gaps are addressed in real time, fostering a more supportive environment for adolescents and young people seeking SRHR services. The trained youth champions lead the advocacy efforts, ensuring continuity and long-term impact.

Conclusions/Next steps: The adolescents and young people developed trackable indicators and action points to address the identified gaps in provision of quality, equitable, and accessible healthcare and health education in sexual reproductive health, including HIV/AIDS, ensuring that youth voices and priorities are heard.

EP0695

HIV prevention, testing and treatment through the eyes of Zimbabwean social media influencers: a digital ethnography study of content posted between 2020 and 2023

K. Masunda[1], O. Mpofu[1], N. Ndlovu[1], G. Katsamba[1], V. Guvava[1]
[1]*JF Kapnek Zimbabwe, Health, Harare, Zimbabwe*

Background: Misconceptions about HIV/AIDS contribute to the spread of HIV and constrain uptake of preventive services. Social media platforms are being used increasingly as part of HIV prevention and treatment efforts, hence, with the increasing usage, their influence can impact on HIV services. Social media influencers tend to have broader reach.
This study investigates content on HIV prevention, treatment, and care that was generated by Zimbabwean social media influencers with over 100,000 followers.
Methods: A retrospective digital ethnographic approach was used. Framing analysis was used to analyse qualitative data for posts from Facebook, Tik Tok and Twitter. Posts included videos, text content, pictures made between January 2020 and June 2023. Analysis was done on original content by the influencers.
Results: From the 59 posts analysed by 36 influencers, 4 posts were sponsored by partners and government agencies in the HIV implementation space. Many of the posts focus on spreading awareness about HIV and AIDS, discussing prevention methods like condom use, taking PrEP (Pre-Exposure Prophylaxis), and adhering to antiretroviral therapy (ART).
Influencers living with HIV shared personal experiences of individuals living with HIV, discussing challenges they face, coping mechanisms, and the importance of seeking support and not letting their condition define their identity. Sponsored posts covered HIV prevention, ARV adherence and condom promotion. One post on PrEP violated regulations in the Medicines and Allied Substances Act.
Conclusions: Social media influencers are generating content on HIV prevention, treatment, and care. Although the information shared by influencers has a wide reach, some of the information shared is not scientifically plausible and in one instance, illegal influence.
Considering forming ongoing partnerships with influencers to maintain consistent HIV awareness efforts over time. Long-term engagement can have a more lasting impact on the audience and reinforce key messages.
Collaborating with influencers who have credibility and authenticity when discussing health-related topics. Influencers with personal experiences related to HIV, or those who are knowledgeable in the field, can establish trust and credibility among their followers, making the information more relatable and impactful.

EP0696

Hagamos Comunidad, a strategy of differentiated services for key populations in social vulnerability in Mexico City

S. Jiménez Fragoso[1]
[1]*Inspira Cambio, A.C., Ciudad de México, Mexico*

Background: The living conditions for some key populations in the center of CDMX, such as sex workers or homeless people, hinder access to health services, which is why strategies are needed to involve these populations in accessing their right to health. The Inspira Cambio A.C. Community Center is located in one of the neuralgic points of impact for these populations, however, those who practice sex work did not respond to our invitation to sexual health services. In view of this, we decided to implement a strategy of differentiated services in situ.
Description: Seven community sexual health days were held in two sex work sites in the Cuauhtémoc district of CDMX, four in Tabacalera (sex work for cis women and trans women) and three in the Ciudadela (sex work for men who have sex with men).
Counseling, STD Testing (HIV, Syphilis, HCV), PrEP (pre-exposure prophylaxis) and PEP (post-exposure prophylaxis) services were provided.
Prevention supplies: condoms and lubricants. Food and clothing. People were given the option of deciding which services and supplies to access without conditions.
Lessons learned: A total of 165 people were reached. 53.94% (89 people) agreed to be tested. Eighty-two individuals were tested for HIV (4 reactive results), 85 were tested for syphilis (2 reactive results) and 22 individuals reported substance use and agreed to be tested for HCV (3 reactive results). The reactive cases were concentrated in two of the populations reached: trans women and MSM. And currently 5 people are already on PrEP treatment in the organization.
Conclusions/Next steps: With the results obtained, we observed that the direct approach in the field can build a relationship of trust with the populations: they know us, they locate us and thus we can generate more and more security for them to also come to Inspira and receive continuous care. And the opportunity to establish community ties where key sex workers serve as a link and support for their self-care. This strategy led to a community mobilization of care and mutual accompaniment.

EP0697

Bridging gaps in HIV awareness and adolescent health: perspectives of faith-based leaders in Keffi and surrounding rural communities

C. Peter[1,2,3], V.O. Onwuemene[1]

[1]AYA Health Watch, Keffi, Nigeria, [2]Person-Centred HIV Research Team (PeCHIVReT)), Nsukka, Nigeria, [3]Federal Medical Centre, Anti-RetroViral Therapy, Keffi, Nigeria

Background: Religious leaders play a pivotal role in shaping community health attitudes, yet their involvement in HIV prevention and adolescent health remains underexplored. This study investigates the awareness, knowledge, and engagement of ordained pastors in Keffi and its rural suburbs regarding HIV testing options and adolescent health.

Methods: A total of 65 pastors participated in an enlightenment program, which included surveys and discussions aimed at assessing their familiarity with HIV testing, particularly HIV self-testing, and their role in promoting health among their congregants.

Results: The findings revealed significant gaps in knowledge: only 12 pastors (18.5%) were aware of the OraQuick HIV self-testing kit, 3 pastors (4.6%) had seen it, and none had used it or understood its application. Despite being familiar with blood-based HIV testing, pastors were less aware of alternative testing methods.

Regarding health discussions, only 29 pastors (45%) had addressed general health issues with their congregants in the past year, and only 13 pastors (20%) included HIV-related topics.

More concerning, none of the pastors had initiated any programs focused on adolescents' and young people's health, despite 49 pastors (75%) acknowledging they were aware of the HIV statuses of some members of their congregation. This neglect of adolescent health, despite the high vulnerability of this group, underscores a significant gap in religious and health education.

Conclusions: The study highlights the urgent need for training and empowering faith-based leaders with accurate health information and resources to address HIV prevention, adolescent health, and the promotion of HIV self-testing in their communities.

By integrating health education into church programs and fostering collaboration between faith-based organizations and health institutions, this research proposes an effective strategy to enhance HIV awareness, improve health outcomes, and reduce stigma in rural and underserved populations.

Key populations and other vulnerable populations: Behavioural, social, cultural, structural and multilevel issues, contexts and interventions

EP0698

Cultural perspectives on aging well with HIV among Two-Spirit and Indigenous LGBTQ+ people living with HIV

C. Bryer[1]

[1]Brown University, Behavioral and Social Health Sciences, Providence, United States

Background: Despite their vital roles in preserving knowledge and traditions, Two-Spirit and Indigenous LGBTQ+ (2S/LGBTQ+) people face disproportionately high rates of HIV/AIDS compared to their white counterparts. Over the past 30 years, advancements in treatment have increased the number of Indigenous 2S/LGBTQ+ people living with HIV (PLWH) in the U.S. and Canada, a trend expected to continue as 70% of PLWH will be over age 50 by the end of the decade. Yet, their perspectives remain largely ignored in social and behavioral research, which often prioritizes prevention over addressing the challenges of aging with HIV.

This qualitative study explored diverse aging trajectories and meanings of aging well with HIV among Indigenous 2S/LGBTQ+ PLWH.

Methods: This study, led by an Indigenous doctoral student, employed a Two-Eyed Seeing approach to integrate Indigenous and Western research methods, ensuring cultural sensitivity throughout the process. In-depth life review interviews were conducted with 15 Indigenous Two-Spirit and LGBTQ+ individuals living with HIV, aged 35 and older, using both in-person and Zoom formats.

Narrative analysis methods were employed to better understand intersectional health disparities, and to understand how participants make sense of their experiences and the world by interpreting the stories they tell.

Results: Numerous themes emerged across participant narratives. First, culture served as a mediator for acceptance of participants' HIV diagnoses and adherence to antiretroviral medication (ART), promoting healthy aging with HIV. Second, Indigenous cultural generativity, passing down cultural knowledge to younger generations, played an important role in aging well with HIV.

Finally, HIV served as a "gift" or "messenger" in the lives of participants, allowing them to alter their life trajectories, "get on the right path", and become connected to their life's purpose, which often included Two-Spirit community activism and HIV advocacy.

Conclusions: These findings highlight the importance of leveraging cultural connectedness and Indigenous cultural generativity to inform culturally tailored HIV care and support strategies to address intersectional health disparities and promote wellness among Indigenous 2S/LGBTQ+ PLWH across the lifespan.

EP0699

A systematic review of intimate partner violence among sexual minority men in sub-Saharan Africa: implications for HIV prevention and care

C. Hong[1], O. Adeagbo[2], O. Badru[2], S. Bonett[3], P. Muro[1]
[1]University of Connecticut, School of Social Work, Hartford, United States, [2]University of Iowa, Department of Community and Behavioral Health, Iowa City, United States, [3]University of Pennsylvania, School of Nursing, Philadelphia, United States

Background: Sexual minority men (SMM) in sub-Saharan Africa (SSA) are particularly vulnerable to intimate partner violence (IPV) due to social stigma, entrenched societal discrimination, and insufficient access to affirming support systems. Despite this heightened vulnerability, there is limited evidence synthesizing the scope and drivers of IPV, and its associations with HIV prevention and care outcomes among SMM in the region.
This systematic review aims to examine the prevalence and patterns of IPV, identify the social, structural, and behavioral factors associated with IPV, and describe the associations between IPV and HIV risk, prevention, and care outcomes in SMM in this region.
Methods: A systematic review was conducted following the PRISMA guidelines, including published studies on IPV among SMM in SSA. Data extraction was performed to collect information on study characteristics, IPV prevalence, associated factors, and health-related outcomes, including engagement in HIV prevention and care services. A thematic analysis was used to synthesize evidence on patterns and themes related to the experiences of IPV and its relationship with HIV prevention and care outcomes.
Results: Seventeen out of 121 records met the inclusion criteria, including five conducted in South Africa, two in Kenya, two in Nigeria, one in Zimbabwe, one in Namibia, and six multi-country analyses. The reported prevalence of IPV victimization ranged from 7.3% to 69.2%, with only one study reporting a perpetration rate of 10.2%. Key factors influencing IPV included relationship dynamics, internalized homophobia, childhood abuse, and social discrimination. IPV was associated with behaviors increasing HIV risk, such as condomless anal sex and engagement in transactional sex.
Notably, none of the studies examined the associations between IPV and HIV testing, PrEP utilization, or the impact of IPV on antiretroviral therapy adherence.
Conclusions: This systematic review highlights a limited but critical body of literature on IPV among SMM in SSA, demonstrating its association with adverse health outcomes, including increased HIV risk and vulnerability. Significant gaps remain regarding the integration of strategies to address IPV into HIV prevention and care.
These findings underscore the urgency of integrating IPV considerations into HIV prevention and care policies and practices to improve the health and well-being of SMM in SSA.

EP0701

COVID-19 vaccine uptake, barriers and facilitators among key populations living with HIV/AIDS in Rivers State: a cross-sectional quantitative study

U. Korfii[1,2], G. Owhonda[3], R.B. Kanee[4], I.A. Wali[5], S.V. Amakuro[6], E. Aigbogun[7], M.E. Neenwi[8], D. Akpona[9], N. Ajaero[10], A. Ade-Dosumu[11], F. Sanusi[7], D. Bashorun[7], E.I. Uchechukwu[12]
[1]Miva Open University, Abuja, Nigeria, [2]Study Plus Hub LTD, Port Harcourt, Nigeria, [3]Rivers State Ministry of Health, Public Health and Disease Control, Port Harcourt, Nigeria, [4]Clinton Health Access Initiative, Abuja, Nigeria, [5]Rivers State University, Community Medicine, Port Harcourt, Nigeria, [6]University of the Western Cape, Statistics and Population Studies, Cape Town, South Africa, [7]Solina Centre for International Development and Research (SCIDaR), Abuja, Nigeria, [8]Rivers State University, Haematology and Blood Transfusion Science, Port Harcourt, Nigeria, [9]Centre for Population Health Initiatives, Port Harcourt, Nigeria, [10]Institute of Human Virology, Nigeria, Abuja, Nigeria, [11]Diadem Consults, Port Harcourt, Nigeria, [12]Evolving Women Foundation, Port Harcourt, Nigeria

Background: HIV/AIDS and COVID-19 disproportionately impact key populations, including men who have sex with men (MSM), female sex workers (FSW), and people who inject drugs (PWID). This study evaluates COVID-19 vaccine uptake and the barriers and facilitators influencing COVID-19 vaccine uptake among key populations living with HIV/AIDS in Rivers State, Nigeria.
Methods: A key population-based cross-sectional study employed purposive sampling to recruit 458 participants from one-stop shops between April – June 2024. The study was carried out among key populations (MSM, FSW and PWID) living with HIV/AIDS in Rivers State, Nigeria. Data collection tools were integrated into a Kobo database. SPSS version 27 (IBM, Armonk, USA) for descriptive and inferential statistics (Chi-square and bivariate logistic regression) analysed vaccine uptake and associated factors, with significance determined at $p < 0.05$.
Results: The study population comprised 26.6% FSW, 40.8% MSM, and 32.5% PWID. The COVID-19 vaccine uptake was moderate at 54.1%, with Pfizer-BioNTech (43.5%) and Moderna (22.2%) being the most administered vaccines. However, only 25.4% received two doses, and 21.8% had booster doses. Key barriers included lack of information (90%), vaccine side effects concerns (91.4%), and distrust in vaccine safety (95.2%). Concerns about vaccine compatibility with HIV/AIDS treatment were cited by 94.1% of MSM, 80.3% of FSW, and 79.2% of PWID.
Facilitators included informational campaigns (97.4%) and enhanced healthcare access (96.8%). Younger participants, those with shorter ART durations, single individuals, and unemployed participants showed significantly lower vaccine uptake (χ^2 = 48.266, 37.689, 28.131, and 62.136; $p < 0.001$). Barriers such as stigma, cultural beliefs, and religious concerns significantly influenced vaccine hesitancy.
Conclusions: Moderate vaccine uptake highlights gaps in COVID-19 vaccination among key populations. To improve vaccine confidence and uptake, tailored interventions addressing stigma, misinformation, and access barriers

are recommended. Leveraging community leaders and integrating vaccines into HIV/AIDS care programs can enhance acceptance and delivery.

EP0702

Success rate of discreet HIV intervention for key populations through virtual health platforms: the Centre for Population Health Initiatives experience, Nigeria

E. Shoyemi[1], K. Okeke[1], D. Uganden[2], G. Dikio[1]
[1]Centre for Population Health Initiatives, Lagos, Nigeria, [2]Henry Jackson Foundation Medical Research international, Abuja, Nigeria

Background: Key Populations (KPs) in Nigeria, including men who have sex with men (MSM), people who inject drugs (PWID), and female sex workers (FSW), face disproportionately higher HIV prevalence rates compared to the general population. Criminalization, stigma, and limited access to key population-friendly centers with comprehensive HIV prevention and treatment services exacerbate these challenges.
The Centre for Population Health Initiatives (CPHI) implemented innovative virtual health platforms to address these barriers and ensure discreet, inclusive, and comprehensive care for KPs.
Methods: With support from the Henry Jackson Foundation Medical Research International, Nigeria, and funding from the US President's Emergency Plan for AIDS Relief, CPHI launched its web portal – "cphinigeria," in October 2020 to facilitate virtual consultations, behavior change communication, and linkage to care to its one-stop-shop center managed by health care workers trained to provide culturally sensitive services to key populations in Lagos, Nigeria.
Complementary social media tools such as Instagram X, Facebook, TikTok, Zoom, Google Business Workspace, WhatsApp, and Telegram were employed for peer-led support groups, direct communication, and ongoing client follow-up with trained peer educators and healthcare workers,
Results: Between October 2020 and September 2024, 12,700 KPs utilized these platforms. Among those counseled, tested, and who received HIV results, 98% were aged 16–35 years. HIV positivity rates were 9.4% among MSM, 8.2% among FSW, and 1.0% among PWID.
Of the 1,242 seropositive clients identified, 100% were initiated on treatment and are currently on antiretroviral therapy (ART), and over 48% actively participate in virtual support groups hosted on the CPHI virtual platforms.
Conclusions: The integration of CPHI's virtual spaces and web portals has significantly increased service utilization among KPs, demonstrating the potential of virtual health models to overcome barriers and enhance HIV care. This success instills confidence in the effectiveness of virtual health platforms and reassures us of their potential to achieve the UNAIDS 95-95-95 targets and halt the spread of HIV.

EP0703

Opportunistic infections affecting men who have sex with other men in Kenya and are living with HIV/AIDS

E.P. Mwore[1], J. Zech[2], J. Walimbwa[1], S. Wambua[3]
[1]Ishtar, Research, Nairobi, Kenya, [2]ICAP University of Columbia, Research, New York, United States, [3]Key Populations Consortium, Research, Nairobi, Kenya

Background: Men who have sex with other men (MSM) in Kenya represent a key population disproportionately affected by HIV/AIDS. Due to higher rates of HIV acquisition and inadequate access to timely medical care, MSM living with HIV are at increased risk of opportunistic infections (OIs). These infections, which are a major cause of morbidity and mortality among individuals with compromised immune systems, remain a significant public health concern in Kenya. However, limited data exists on the specific burden of OIs among MSM with HIV in major Kenyan cities, including Mombasa, Nairobi, Nakuru, and Kisumu.
This study aimed to assess the prevalence and types of opportunistic infections affecting MSM living with HIV in these urban centers, and to identify associated factors that may inform prevention and treatment strategies.
Methods: A cross-sectional study was conducted in Mombasa, Nairobi, Nakuru, and Kisumu between January and July 2024. A total of 400 HIV-positive MSM participants, aged 18-45 years, were recruited from HIV clinics, community health centers, and MSM support organizations. Data were collected through structured questionnaires on demographics, HIV treatment adherence, sexual behavior, and history of opportunistic infections.
Clinical examination and laboratory tests were conducted to identify the presence of OIs, including tuberculosis, candidiasis, pneumocystis pneumonia, cryptococcal meningitis, and toxoplasmosis.
Results: Among the 400 MSM participants, 56% were diagnosed with at least one opportunistic infection. The most common OIs included candidiasis (28%), tuberculosis (22%), pneumocystis pneumonia (15%), and cryptococcal meningitis (12%). Factors such as low CD4 count, inconsistent HIV treatment adherence, and late HIV diagnosis were significantly associated with a higher risk of OIs. MSM who reported higher rates of unprotected anal intercourse and multiple sexual partners had a 40% higher likelihood of presenting with OIs. Urban centers like Nairobi and Mombasa had higher rates of OIs compared to Nakuru and Kisumu, likely due to better access to HIV testing and healthcare services.
Conclusions: The study highlighted the need for enhanced HIV care and prevention programs that address both the medical and social needs of MSM.
Key interventions should focus on improving HIV treatment adherence, regular health check-ups, and early detection of OIs.

EP0704

Breaking the cycle: tackling HIV vulnerability among refugee women and girls in South Western Uganda

U. Muhumuza[1], E.S. Abay[2], Z. Nahumuza[3]
[1]Africa CDC, Kampala, Uganda, [2]Africa CDC, Addis Ababa, Ethiopia, [3]International University of Africa, Khartoum, Sudan, the

Background: Refugee populations in South Western Uganda face unique vulnerabilities to HIV acquisition, especially among women and adolescent girls. Despite ongoing HIV prevention and care efforts, these groups experience heightened risks driven by entrenched gender inequalities, stigma, limited healthcare access, and economic hardship. Existing research in refugee settings often lacks a focused understanding of the interplay between social and structural drivers specific to women and girls, leaving critical gaps in targeted intervention strategies.

This study addresses these gaps by analyzing how social norms, structural barriers, and systemic inequities contribute to HIV vulnerability and identifies actionable, community-driven solutions to mitigate these risks.

Methods: Between January 2023 and June 2024, a cross-sectional mixed-methods study was conducted in Nakivale Refugee Settlement, South Western Uganda. The study involved 600 participants, including 400 women (ages 15–49) and 200 adolescent girls (ages 10–19). Quantitative data was collected through structured surveys assessing HIV knowledge, healthcare access, and risk behaviors, while qualitative data were gathered via focus group discussions and interviews with healthcare workers, community leaders, and refugee women.

Quantitative data was analyzed using descriptive and inferential statistics, and qualitative data underwent thematic analysis to explore recurring patterns.

Results: The study revealed stark gaps in HIV prevention knowledge, with 67% of women and 53% of girls lacking comprehensive understanding. Structural barriers, including long distances to healthcare facilities (72%) and economic challenges (81%), were significant obstacles to HIV testing and treatment. Social drivers, such as stigma, gender-based violence, and early marriages, compounded risks, with 43% of adolescent girls reporting forced or early sexual experiences. HIV prevalence stood at 11% among adult women and 6% among adolescent girls, with fear of stigma and cultural taboos cited as primary deterrents to seeking testing/care.

Conclusions: This research underscores the critical need for tailored, gender-responsive interventions to address HIV vulnerability among refugee women and girls. Key recommendations include improving healthcare accessibility, empowering women economically, reducing stigma through community-based education, and integrating culturally sensitive approaches into HIV programming.

Addressing these structural and social drivers not only reduce HIV-related risks but also promote behavior change and inform sustainable policies for equitable HIV outcomes in refugee contexts.

EP0705

Improved PrEP uptake among adolescent girls and young women through focused site support: lessons learnt from Matabeleland North Province in Zimbabwe from October 2023 to September 2024

J. Ncube[1], P. Moyo[2], E. Molande[1], S. Nyakuwa[1], J. Murungu[1], I. Mahaka[3], L. Sibanda[4], G. Ncube[5], T. Mharadze[6], A.K. Korn[7]
[1]Pangaea Zimbabwe, DREAMS, Harare, Zimbabwe, [2]Precious Moyo, DREAMS, Harare, Zimbabwe, [3]Pangea Zimbabwe, DREAMS, Harare, Zimbabwe, [4]Zimbabwe Technical Assistance Training and Education Center for Health, DREAMS, Harare, Zimbabwe, [5]Ministry of Health and Child Care, TB and AIDS Unit, Harare, Zimbabwe, [6]Division of Global HIV & TB (DGHT), U.S.Centers for Disease Control and Prevention, Division of Global HIV & TB (DGHT), U.S. Centers for Disease Control and Prevention, Harare, Zimbabwe, [7]International Training and Education Center for Health, University of Washington, Seattle, United States

Background: Adolescent girls and young women (AGYW) are at high risk of HIV, yet uptake of pre-exposure prophylaxis (PrEP) remains low in the four Determined Resilient Aids-free Mentored Safe (DREAMS) districts in Matabeleland North, Zimbabwe. PrEP access was hindered by stockouts, poor documentation and inadequate use of electronic Logic-Management-Information-Systems (eLMIS), and community stigma.

Despite Health care workers (HCW) efforts to mobilize AGYW for PrEP, uptake remained suboptimal highlighting the need for expert support from district teams.

Description: From October 2023 through September 2024, district officers from Pangaea Zimbabwe and Ministry of Health and Child Care conducted support visits to fifty facilities. Experts in pharmacy and community health provided training for HCW on eLMIS to address supply-chain issues. Capacity-building for HCW focused on clinical-community-linkages and service-delivery; experienced clinicians provided mentorship through one-on-one coaching and quality improvement initiatives.

Lessons learned: In Quarter1 monthly AGYW PrEP new users increased from 4 to 350, sustained throughout year by community education and public campaigns to boost knowledge. Support led to significant service improvements: Integrating PrEP services into existing health programs (immunizations, family-planning, antenatal and postnatal care), repackaging PrEP into more user-friendly formats such as drug envelopes, door-to-door deliveries for clients who missed appointments or were not due for testing, and conducting community awareness sessions to reduce stigma and increase support for PrEP improved PrEP uptake. Monthly quality-improvement visits, performance reviews, and use of evidence-based-strategy adjustments allowed for continuous improvement. Improved eLMS utilization led to improved stock status, continuous quality-improvement, streamlined PrEP ordering, stock management and documentation facilitated open communication supporting higher uptake among AGYW. Addressing supply chain issues, expanding PrEP service delivery points, and providing ongoing mentorship to HCW assisted with sustaining progress.

Conclusions/Next steps: Use of person-centered-care models and a robust supply chain improved continued PrEP uptake. For long term success, the program can maintain external support to enhance outcomes. PrEP literacy sessions can be used to reduce stigma and gaining support from husbands and in-laws, contributing to greater uptake and improved social acceptance. The program in Matabeleland North plans to continue with community engagement and public awareness campaigns to reduce stigma among AGYW

EP0706

Challenges and facilitators to safe sexual and reproductive health practices among adolescents living with HIV in Mandalay, Myanmar

S.K.K. Zaw[1], K.K. Aye[2], P.P.N. Win[2], K. Cherry[2], T.T. Aung[1], E.E. Chaw[1]

[1]Spectrum PLHIV network, Mandalay, Myanmar, [2]I-search Myanmar, Mandalay, Myanmar

Background: Adolescents living with HIV have many challenges concerning sexual and reproductive health (SRH) due to stigma, knowledge gaps, and limited access to supportive healthcare services. This study aimed to identify the key barriers and facilitators to safe SRH practices among adolescents living with HIV, focusing on individual, social, and systemic factors that influence their SRH behaviors.

Methods: A qualitative cross-sectional design was done. There were 45 adolescents living with HIV in the study from different HIV clinics. Semi-structured interviews and focus group discussion were carried out. Thematic analysis was conducted to identify recurring patterns and insights from the data.

Results: Challenges to safe SRH practices consisted of stigma, fear of disclosure, poor SRH knowledge, lack of adolescent-friendly healthcare services, peer pressure and issues of mental health. Factors that aid in overcoming these challenges included strong relationships with healthcare providers, peer support networks, family engagement, and access to SRH counseling and educational resources.

Additionally, gender and age differences underscored distinct challenges and priorities among adolescents.

Conclusions: The study highlighted the requirement of policies and programs that provide SRH into user-friendly services for adolescents living with HIV in Myanmar. Comprehensive interventions addressing stigma, poor knowledge and healthcare access, will improve SRH outcomes.

EP0707

Assessing factors associated with antiretroviral treatment discontinuation among female sex workers in 12 drop-in centers, Malawi

J. Gondwe[1], T. Mnenula[1], M. Kamtimaleka[1], A. Chimderenji[1], A. Chabaluka[1], E. Mkandawire[1], P. Lizibowa[1], B. Jambo[1], S. Sibuni[1], E. Mkwala[1], C. Chimzimu[1], M. Mbwewe[1], D. Njuzi[1], S. Kaunda[1], T. Chavula[1], P. Nkhonjera[1], W. Phiri[1], C. Kamba[1], S. Sikwese[1], O. Kumwenda[2]

[1]Pakachere Institute of Health and Development Communication, Strategic Information, Blantyre, Malawi, [2]United States Agency for International Development, Malawi, HIV, Lilongwe, Malawi

Background: Despite a 91% in ART coverage in Malawi. High viral load among key populations is still being registered due to poor adherence to antiretroviral therapy (ART). This study aims to assess the factors influencing ART discontinuation amongst female sex workers enrolled on ART.

Methods: Retrospective cohort study was conducted using data from a total of 256 female sex workers and clients of female sex workers who were on Intensive adherence counseling between 2019 and 2024. Data was collected during Intensive adherence counseling sessions conducted by Clinicians through qualitative interview.

The study was carried out among Female sex workers and their clients on ART who registered a high viral load of more than 1000 copies/ml and on Intensive adherence counseling. Purposive sampling was used to select a defaulter from 12 drop-in centers Malawi. Chi-square was used to assess frequency distribution in R software.

Results: Results showed that there were 245 female sex workers and 11 clients of female sex workers. Out of those the age group of 26-35 had (125, 49%), followed by 16-25 (68, 27%), then 36-45(51, 20%) and 46-65 (12, 5%).

A chi-squared test revealed significant differences among the factors ($\chi 2(df) = 337.91$, $p<0.001$) and these were mobility (87, 34%), non-disclosure of HIV-positive serostatus to partners (NDHPSS) (55, 21%), alcohol and substance abuse (50,20%), forgetting (28,11%), fear of side effects (16,6%), lack of food (10, 4%), lost medication (6, 2%) and pill burden (4, 2%).

Conclusions: Mobility, NDHPSS and alcohol abuse are the main factors contributing to ART discontinuation among female sex workers, suggesting more interventions to tackling adherence. There is need to intensify ART multi-month dispensation and incentivizing female sex workers to join support groups with interventions on Alcohol and drug rehabilitation.

EP0708

Spatial and structural determinants of HIV prevalence among adolescent mothers in Eswatini

L. Gebrekristos[1], A. Groves[1], A. Ezeh[1], M. Stoner[2], L. Robinson[1], F. Le-Scherban[1]
[1]Drexel University, Philadelphia, United States, [2]RTI International, Berkeley, United States

Background: In Eswatini, 85% of adolescent HIV diagnoses occur among girls (and risk of diagnoses is higher among mothers). There is significant subnational spatial variation in where these diagnoses occur. Structural determinants influence subnational-level HIV prevalence, and yet studies have not spatially linked structural determinants to subnational level HIV prevalence in this vulnerable population.

To understand spatial determinants of HIV prevalence which can guide tailored prevention strategies for AM, this study uses Bayesian spatial smoothing to map HIV prevalence and examine the associations between structural factors and HIV prevalence among adolescent mothers (AM) in Eswatini at the subdistrict-level, the second-level administration unit.

Methods: Data are drawn from the Population-based HIV Impact Assessment (PHIA) (2016-2017), comprising a sample of 135 AM (aged 15–19) across 55 subdistricts. Subdistrict-level factors included gender disparity in education (percentage-based ratio of male to female high school graduates among 18-24 year-olds), gender disparity in workforce (percentage-based ratio of male to female workforce participation among 18-24 year-olds), percent of households in poverty, mean travel time to a healthcare facility, male circumcision rate, percent of people who ever tested for HIV, percent of people living with HIV who were virally suppressed, and an interaction term between education disparity and percent of viral suppression. We used global Moran's I statistics to assess spatial autocorrelation of HIV prevalence. Associations were examined using spatial conditional autoregressive binomial models.

Results: Significant spatial clustering of HIV prevalence was detected (p-value=0.01). Among structural determinants, the main effects for education (ϐ=1.03; 95% credible interval (CI): 0.24,1.84) and gender disparities in workforce participation (ϐ=0.5; 95% CI: 0.001,1.004) were positively associated with HIV prevalence. An interaction between education and viral suppression effects was observed, suggesting that the positive association weakens in subdistricts with higher levels of viral suppression.

Conclusions: Results highlight the spatial heterogeneity of HIV prevalence among AM in Eswatini. Further, areas with higher gender inequities in education and workforce participation had higher HIV prevalence among AM. Interventions that address these structural inequities may reduce HIV prevalence among AM in Eswatini.

Further, structural-level interventions may be particularly important in areas with low levels of viral suppression.

EP0709

Impact of Anti-LGBTQ campaigns on STI incidence among MSM and transgender persons in Mombasa, Kenya: a case study of ICRHK

S. Mwangi[1], D. Muchiri[1], A. Mokua[1], M. Ochieng[1], A. Vose[1], P. Samia[1], S. Ontiri[1], D. Ouma[1]
[1]International Centre for Reproductive Health, Health Department, Nairobi, Kenya

Background: The Supreme Court ruling in March 2023, which granted the LGBTQIA+ community the right to associate, sparked a wave of homophobic protests and anti-LGBTQIA+ agitation in Mombasa, Kenya. These protests led to the profiling of MSM and TG individuals, forcing many into hiding and creating barriers to accessing HIV prevention and sexual reproductive health services.

The objective of this case study is to examine the association between anti-LGBTQ campaigns and the incidence of STIs among MSM and TG individuals in Kenya.

Methods: ICRHK conducted a retrospective review and analysis of clinical data collected between January 2023 and April 2024 from three key population Drop in Centers in Mombasa to identify the effects of anti-LGBTQ campaigns on STI and gender-based violence (GBV) prevalence among MSMs.

We compared trends before and during the anti-LGBTQ campaigns. We examined the number of STIs screened, diagnosed, and treated during this period.

Results: The findings revealed a significant increase in STI incidence among men who have sex with men (MSM), rising from 1.1% (9/799) to a peak of 4.4% (39/880) in September 2023, with the highest recorded incidence at 5.5% (24/435) in December 2023, coinciding with the peak of anti-LGBT protests and campaigns in Mombasa.

For transgender individuals, STI incidence increased from 0.7% (2/277) in January to 3.2% (11/34) in September, peaking at 3.7% (7/189) in April 2024.

Following ICRHK's intervention to establish a gender-based violence (GBV) response mechanism, the prevalence decreased to 2.1% (18/866) by September 2024.

Conclusions: The significant increase in STI incidence among MSM and transgender individuals during periods of heightened anti-LGBT sentiment indicates a strong correlation between social and political factors and health outcomes. The peak incidences during anti-LGBT protests suggest that stigma, discrimination, and violence can lead to increased vulnerability to STIs due to limited access to reproductive health services including STI/HIV prevention services.

EP0710

Developing an Unconditional Cash Transfer to Improve Post-Partum HIV Outcomes in Rural Haiti

A. Richterman[1], S. Desire[1], E. Derose[2], W. Blaise[2], M. Alexis[2], L. Ward[2], C. Millien[2], H. Thirumurthy[1], F. Momplaisir[1], L. Ivers[3]

[1]University of Pennsylvania, Philadelphia, United States, [2]St. Boniface Hospital, Health Equity International, Fond-des-Blancs, Haiti, [3]Massachusetts General Hospital, Boston, United States

Background: Improving perinatal engagement in HIV care is crucial to prevent disease progression and transmission. Poverty contributes to poor perinatal outcomes globally, including in Haiti, and cash transfers are a promising intervention that alleviates poverty and may improve perinatal HIV outcomes through economic and psychological pathways.

Methods: We conducted semi-structured interviews of pregnant and postpartum people with HIV at St. Boniface Hospital in rural Haiti. We developed an interview guide with open-ended questions about barriers and facilitators to post-partum HIV care, and preferred characteristics of an unconditional cash transfer prototype for pregnant people with HIV.

We transcribed and translated the interviews from Haitian Creole to English. Transcripts were coded using a codebook developed through a combination of deductive and inductive coding, with 20% of transcripts coded by two investigators, to identify major themes.

Results: We interviewed 20 pregnant or postpartum women with HIV between 12/2023 and 5/2024 (50% pregnant, median age 24 years). Reported barriers to postpartum engagement in HIV care included ART side effects (particularly when not having food), interpersonal stigma from people in their neighborhood, poverty (e.g., difficulty coming to clinic), and food insecurity. (e.g., needing to focus on finding food).

Reported facilitators included motivation to protect the child's health, understanding the benefits of antiretroviral therapy, material support from the hospital, and social/family support.

Regarding the hypothetical cash transfer intervention, participants reported they would use it for immediate needs (particularly related to their children) or for small household business activities. Most participants were hesitant to provide an exact figure for the preferred total size of the cash transfer, but ultimately reported a median of $190, ranging from $19-$1000.

Some participants preferred to receive cash through a mobile phone payment method, whereas others preferred coming to the hospital cashier to pick up the cash, reflecting confidentiality concerns about other people becoming aware of their HIV status or being a cash recipient.

Conclusions: In a high poverty setting, pregnant and postpartum people with HIV reported a variety of barriers post-partum engagement in HIV care that could be addressed using unconditional cash transfers, particularly when linked to child needs.

EP0711

Preferences for on-demand/intermittent/event-driven and long-acting injectable (LAI) HIV pre-exposure prophylaxis (PrEP) among HIV-negative Black gay, bisexual, and other sexual minority men in the United States: a qualitative study

A. Ogunbajo[1], A. Euceda[1], R. Ekundayo[1], J. Smith[1], T. Oke[1], D. Hickson[1]

[1]Us Helping Us, People into Living Inc, Washington DC, United States

Background: Black sexual minority men (SMM) are disproportionately affected by HIV and pre-exposure prophylaxis (PrEP) use reduces the risk of HIV acquisition. There is a gap in our understanding on the acceptability of and preference for on-demand and LAI-PrEP among PrEP-eligible Black SMM.

This study aimed to explore preference for on-demand and LAI-PrEP and reasons for those preferences among HIV-negative Black SMM of different PrEP use profiles.

Methods: Between March 2022 and April 2023, we conducted 17 focus group discussions with a total of 58 HIV-negative (current PrEP users, non-PrEP users, and PrEP discontinuers) Black SMM in the Washington D.C. metropolitan area. We explored acceptability and interest in on-demand and LAI-PrEP and anticipated barriers and facilitators to uptake.

Results: Most participants expressed a lack of interest in on-demand PrEP for various reasons. These sentiments were expressed after the moderators provided a brief overview of on-demand PrEP and the dosing strategy currently recommended by the CDC.

The reasons for lack of interest were:

1. Inability to accurately anticipate and plan for sexual activity in advance,
2. Uncertainty about effectiveness of on-demand PrEP, and;
3. Potential for unnecessary medication use, especially when anticipated sexual activity doesn't occur.

Most participants found LAI-PrEP to be highly acceptable and this can be attributable to:

1. LAI-PrEP being convenient, and;
2. LAI-PrEP being a potential solution to suboptimal adherence to daily oral PrEP due to forgetfulness.

However, there were still concerns around LAI-PrEP specifically around the fear of needles and novelty of this new PrEP modality.

Conclusions: While daily oral PrEP is the most utilized PrEP modality, some SMM—who might not be acceptable to oral PrEP—are capable of accurately identifying specific periods and circumstances of heightened risk for HIV infection. It is important that healthcare providers present on-demand PrEP as an option to individuals who fall into these categories. Programs to increase awareness and knowledge of LAI-PrEP among Black SMM and HCP that serve them are needed. It is imperative that HCP who provide PrEP services receive proper training on the administration of LAI-PrEP and that there is dedicated staff to help clients navigate the insurance process.

EP0712

Perceptions, acceptability, and utilization of HIV self-testing kits among young people in urban slums in Kampala: a mixed methods study

M. Segawa[1], A. Namiiro[1], B. Natuhwera[1], P. Ahereza[1], I. Pitua[1], M. Kirya[1], D. Kiberu[1], M. Najjuka[1], R. Olum[2]
[1]Makerere University College of Health Sciences, Kampala, Uganda, [2]Makerere University School of Public Health, Kampala, Uganda

Background: Globally, 14% of people with HIV are unaware of their status. HIV prevalence in African slums is reportedly double that of non-slum areas. HIV self-testing (HIVST) could help bridge testing gaps in these high-risk settings. This study assessed perceptions, acceptability, and use of HIVST kits among young people in Kampala's urban slums.
Methods: A mixed-methods cross-sectional study was conducted from February to May 2024 in Katanga Slum, Kampala, involving young people aged 15 to 24 who had resided there for at least six months. Simple random sampling was used. Quantitative data were collected using semi-structured questionnaires and analyzed with descriptive statistics and logistic regression.
Qualitative data from focus group discussions were analyzed using thematic content analysis. Written informed consent was obtained from all participants.
Results: Of the 267 participants (mean age 20.05 years, SD = 2.60), 62.9% were male. The willingness to use HIVST kits was 87.6%, and 43.1% had used them. Participants viewed the kits as accurate, and convenient, and valued their confidentiality, privacy, and stigma reduction.
Education level (OR = 2.02, 95% CI: [1.04, 3.94], p = 0.039), marital status (OR = 0.13, 95% CI: [0.02, 0.97], p = 0.046), prior HIVST awareness (OR = 3.42, 95% CI: [1.41, 8.28], p = 0.007), and family support (OR = 3.23, 95% CI: [1.40, 7.46], p = 0.006) significantly influenced willingness to use HIVST kits. Peer discussions (OR = 3.34, 95% CI: [1.81, 6.14], p < 0.001), kit availability (OR = 1.82, 95% CI: [1.02, 3.24], p = 0.040), and barriers to traditional testing (OR = 1.96, 95% CI: [1.09, 3.50], p = 0.023) influenced HIVST utilization. Qualitatively, privacy, confidentiality, convenience, cost, availability, accuracy, and trust in results were crucial for acceptability and use.
Conclusions: Strengthening education, improving kit availability, and fostering family and peer support are essential for increasing HIVST uptake among young people in urban slums. Addressing traditional testing barriers can further enhance HIV prevention efforts in these high-risk communities.

EP0713

Healthcare provider's experiences and perceptions caring for LGBTQ+ clients at a sexual and reproductive clinic in Uganda

S.J. Nalubega[1], P. A. Muwanguzi[2], R. Nabunya[1], T. Ngabirano[2], G. Nalwadda[3]
[1]African Centre for Health Equity Research and Innovation, Research, Kampala, Uganda, [2]Makerere University, School of Nursing, Kampala, Uganda, [3]Luziibangi International Health School, Mityana, Uganda

Background: LGBTQ individuals often encounter negative experiences when seeking medical assistance, resulting in unmet healthcare needs and negative health outcomes. Research in other countries has shown that healthcare providers have varying experiences when attending to LGBTQ clients seeking healthcare, with a predominance of negative experiences characterized by a lack of knowledge on LGBTQ health issues and related care, resulting in ineffective interactions and poor healthcare services. Research about the experiences of healthcare providers in Uganda offering services to LGBTQ individuals is limited, creating a gap in understanding their perceptions and experiences when providing care.
This study therefore explored healthcare providers' experiences and perceptions while caring for LGBTQ clients at a sexual and reproductive healthcare clinic in Uganda.
Methods: An explorative qualitative study was conducted between May and June 2024 at a sexual and reproductive healthcare clinic in Uganda. A purposive sampling technique was used to enrol 12 healthcare providers, including doctors (4), nurses (2) and counsellors (6).
We utilised a semi-structured in-depth interview guide for data collection. The interviews were conducted in English, transcribed verbatim and analysed thematically.
Results: Four main themes emerged regarding healthcare providers' perceptions of LGBTQ healthcare including professional healthcare, stigmatized populations, vulnerability to HIV and STI acquisition, and LGBTQ-specific health needs.
Healthcare providers reported having both negative and positive experiences. The positive experiences included the provision of quality healthcare, personal satisfaction and fulfilment, and continuous professional development. The negative experiences were characterized by inappropriate and disruptive client behaviour, challenges in healthcare communication and engagement, bias and prejudice, and gender non-inclusive language.
Conclusions: Healthcare providers should undergo training focused on LGBTQ issues, including cultural competence, sensitivity, and awareness to create a safe and welcoming environment for their clients. This encourages LGBTQ individuals to seek necessary health services, including HIV prevention and treatment.
Such a proactive approach not only improves individual client outcomes but also contributes to broader public health goals by controlling the spread of HIV within this high-risk population.

EP0714

Scaling up good practices in Nigeria's key population HIV programme: lessons learned

O. Oshagbami[1], F. Agbo[2], T. Ilori[3]
[1]United Nations Office on Drug and Crime, HIV, Abuja, Nigeria, [2]National Agency for the Control of AIDS (NACA), Research, Monitoring and Evalaution, Abuja, Nigeria, [3]National Agency for the Control of AIDS (NACA), Director General Office, Abuja, Nigeria

Background: Scaling proven interventions is critical to addressing service gaps and improving health outcomes for key populations (KPs) in Nigeria, including Female Sex Workers (FSWs), Men who have Sex with Men (MSM), People Who Inject Drugs (PWID), and Transgender People (TG).
This study documents best practices from the national KP HIV programme, focusing on strategies that demonstrated measurable impact and scalability in underserved regions.
Methods: Using the Prevention Self-Assessment Tool Lite (PSAT Lite), polling booth surveys (PBS), and stakeholder interviews, successful interventions were identified and assessed for scalability. Key practices such as One-Stop Shop (OSS) models, peer-led outreach, and integrated HIV prevention services were evaluated. Desk reviews were conducted to analyze implementation data and identify operational gaps.
Results: Peer-led outreach was a standout strategy, achieving a 20% higher HIV testing uptake among MSM engaged in peer networks compared to those reached through conventional methods. OSS facilities demonstrated high impact, with 90% of enrolled clients achieving ART adherence.
Community engagement strategies were instrumental in increasing service uptake and reducing stigma among FSWs and PWID. However, only 65% of TG-focused programmes reached their target populations, highlighting inequities in service delivery.
Scalability assessments indicated that replicating these interventions in underserved regions could significantly enhance programme reach.
Conclusions: Nigeria's KP HIV programme offers scalable models that can improve health outcomes if replicated nationwide. Peer-led outreach and OSS models should be prioritized for expansion, with additional investment in TG-focused programmes to ensure equitable coverage. Sustained funding, training, and community involvement are essential for effective scale-up.
These lessons underscore the importance of leveraging successful practices to bridge gaps and achieve HIV epidemic control among KPs.

EP0715

Integration of mpox Surveillance at Bugiri Municipal Drop-in Center (DIC) supporting key populations in Bugiri District, Uganda

S. Malende[1]
[1]Makerere University Joint AIDS Program, Monitoring and Evaluation, Kampala, Uganda

Background: Mpox, a re-emerging zoonotic disease, presents significant public health challenges, particularly in high-risk and resource-limited settings. This study highlights the integration of mpox screening and management services at a drop-in center in Bugiri district, Uganda, after three suspected cases were identified at the center. The drop-in center serves key populations, including men who have sex with men (MSM), female sex workers, people who inject themselves with drugs and other priority populations.
Given the overlapping service populations and the heightened risk, urgent interventions were implemented to mitigate potential transmission and safeguard public health within this vulnerable community.
Description: The center established an integrated surveillance system to respond to the emerging mpox threat, focusing on the detection, management, and prevention of its spread among vulnerable populations.
The program's key components included continuous medical education to build healthcare workers' capacity, enhanced screening protocols to identify cases early, targeted health education to raise awareness, and the provision of handwashing materials to promote hygiene.
A robust referral system was put in place to ensure timely treatment of suspected cases, while ongoing data collection and monitoring using the community Mpox tracking tool allowed for trend tracking and informed decision-making to adapt the response as needed.
Lessons learned: During the initial 30 days of intensified mpox surveillance at the Bugiri Municipal Drop-in Center (DIC), 77 clients were screened, with no suspected cases identified. This outcome emphasized the effectiveness of enhanced screening protocols, healthcare worker training, and active community engagement in fostering timely health-seeking behaviors. The availability of sanitation supplies played a critical role in reducing transmission risks.
Continuous data collection facilitated timely interventions, underscoring the value of robust surveillance systems, efficient referral mechanisms, and preparedness in addressing emerging health threats among vulnerable populations.
Conclusions/Next steps: This initiative has shown the importance of integrating comprehensive surveillance systems in community-based centers to address emerging health threats like mpox.
Through effective screening, community engagement, and timely response, the DIC effectively mitigated the risk of further transmission and demonstrated the essential role of preparedness in managing public health emergencies.

EP0716

The crafting and implementation of HIV prevention program for people who inject drugs in Malawi

N. Madidi[1], B. Magomero[1], T. Chatepa[1], R. Luhanga[1], G. Phombeya[1], P. Gunda[1], T. Kamanga[1], D. Gondwe[2], C. Mabulekisi[2], A. Mwansambo[2], B. Afirima[2], R. Nyirenda[3], W. Ozitingotsauka[4], E. Mlanga[5], C. Akolo[6], A. Gotlieb[6], T. Lillie[6], J. Arney[6], E. Ecard[6], M. Kiriuki[6], D. Chilongozi[1]
[1]FHI 360, EpiC Malawi Project, Lilongwe, Malawi, [2]Government of Malawi, National AIDS Commission, Lilongwe, Malawi, [3]Ministry of Health, Department of HIV, STI and Hepatitis, Lilongwe, Malawi, [4]Ministry of Health, Department of HIV/AIDS, Lilongwe, Malawi, [5]UNAIDS, HIV Program, Geneva, Switzerland, [6]FHI 360, Global Health Programs, Washington, DC, United States

Background: The 2022 Malawi National HIV Spectrum data estimated 27% HIV prevalence among people who inject drugs (PWID), the second highest rate after at-risk women (49%), but Malawi did not have specific HIV interventions for PWID.
In 2022, the government of Malawi, through the National AIDS Commission (NAC), requested that the FHI 360-led Meeting Targets and Maintaining Epidemic Control (EpiC) project guide the introduction of HIV interventions for PWID. EpiC outlined the steps involved in introducing these interventions for PWID in Malawi.
Description: By July 2023, FHI 360 conceptualized and executed a PWID program design premised on the health system pillars of the World Health Organization: governance and coordination, community engagement, capacity building, service delivery, data systems, policy, and the legal environment. Various activities, guided by these pillars, were implemented.
At a national level, activities included the facilitated establishment of a multisectoral PWID National Steering Committee (NSC) to oversee the introduction and rollout of the PWID program; a sponsored South-to-South learning tour to South Africa to prepare NSC members for their new role; and the development of guidelines, standard operating procedures, and a core package of services for use by health care workers. At community and facility levels, activities included PWID network mapping and community awareness on the safer use of needles.
By leveraging existing health service delivery points, 2,342 PWID were reached; 1,503 were tested for HIV, of whom 92 (6%) were newly diagnosed, and all 92 (100%) initiated antiretroviral therapy. Of the 1,411 who tested negative, 571 were offered pre-exposure prophylaxis (PrEP) and 384 initiated PrEP while awaiting the government rollout of a harm-reduction package.
Lessons learned: Government departments, including the NAC, were instrumental in making evidence-based decisions to introduce the PWID program. Implementing partners were an essential resource for the government in introducing the PWID program for HIV prevention.
Conclusions/Next steps: Innovations call for the government's commitment to initiate additional evidence-based HIV prevention interventions, such as the PWID program in Malawi. With technical assistance from FHI 360, the government is scaling up PWID interventions, including the introduction of the harm-reduction package of services.

EP0717

Back in care campaign to address interruption in treatment among people living with HIV in a Nomadic community, in Turkana County, Kenya: a quality improvement project

L. Mwambingu[1], K. Osman[1], E. Ekuwom[1], W. Chebon[2], O. Mito[3], J. Kwatampora[4], S. Kinyanjui[5]
[1]Lodwar County Referral Hospital, Comprehensive Care Clinic, Lodwar, Kenya, [2]Lodwar County Referral Hospital, Lodwar County Referral Hospital, Lodwar, Kenya, [3]AIDS HealthCare Foundation, Care and Treatment, Homabay, Kenya, [4]AIDS HealthCare Foundation, AHF-Kenya Medical Director, Nairobi, Kenya, [5]AIDS HealthCare Foundation, AHF-Kenya Country Program Director, Nairobi, Kenya

Background: Continuity in HIV care is critical to ensure prompt treatment initiation, viral suppression, reduced transmission, and mortality prevention. Lodwar County Hospital serves 2,151 People Living with HIV (PLHIV), out of whom 74% had kept their last clinic appointment as of July 2024 which was below the recommended 95% target. We implemented a quality improvement project aimed at addressing the Interruption in Treatment (IIT) among the PLHIV.
Description: Using fishbone analysis, we identified low enrollment in Differentiated Service Delivery Models (DSDM), social-cultural barriers, poverty, and stigma as gaps. In July 2024, we implemented a quality improvement project with the following interventions: a back in care campaign (BIC) with activities including daily pre and post calling clients for their appointments, same day follow up of those who missed appointments including physical tracing.
Additionally, the client flow was reorganized to accommodate different DSDM which included scaling up of community antiretroviral groups (CAG) to capture cross-border migration, and smart scheduling to avoid cultural events. A health worker (HW) managed each of the CAG. The appointment management rate (AMR) was then reviewed after 6 months.

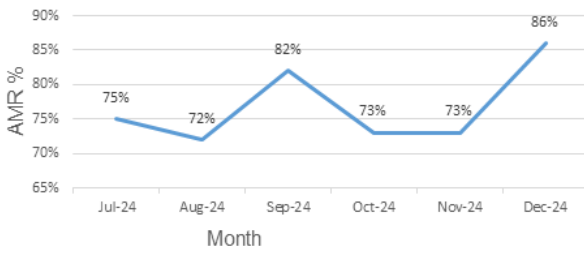


Figure 1. Proportion of clients keeping appointment per month.

Lessons learned: AMR improved from 74% to 86%. DSDM uptake of CAG and Fast track models improved from 34% to 39%. Among those who returned to care, 59% were female and 41% male. The reported attrition reasons were:

39% cited distance, 35% lacked transport, 15% feared disclosure, 9% long waiting time and 2% scared of HW rebuke. CAG reduced the clinic workload, however the cost implication to cover transport of the HW managing the CAG was significant due to region's vastness.

Conclusions/Next steps: Distance, poverty, stigma, and nomadism continue to hinder continuity in care. Training peers and community health workers to manage the CAG may reduce the transport costs. The project highlighted the importance of BIC strategies which were successful in reducing IIT.

EP0718

Exploring homelessness among LGBTQI+ persons in Nigeria

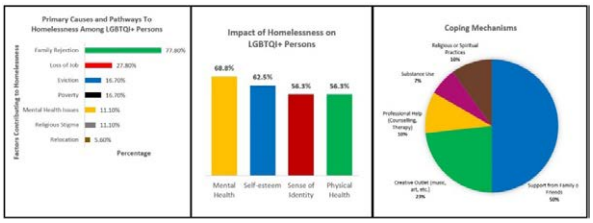
O. Oludipe[1], O.J. Okolie[1], M. Nwaokolo[2], O. Ebelubhuhi[2], E. Suru[1], O.D. Ajowele[1], G.I. Nkasi[1]

[1]Improved Sexual Health & Rights Advocacy Initiative (ISHRAI), Lagos, Nigeria, [2]NGỌỌ Consultants, Abuja, Nigeria

Background: Homelessness stands as a pervasive global issue and a violation of human rights. Within the Nigerian context, LGBTQI+ persons are vulnerable to homelessness which is compounded by the intricate interplay of socio-cultural dynamics and legal frameworks.

This research aims to identify the primary causes and pathways leading to homelessness, the impact of homelessness on LGBTQI+ persons in Nigeria and coping mechanisms.

Methods: This research utilized a mixed-method approach of quantitative online surveys and qualitative focus group discussions (FGDs) and key informant interviews (KIIs) with a total of 48 LGBTQI+ persons aged 16-45 years in Nigeria. Quantitative data were analyzed using descriptive and inferential statistics that included t-tests, while thematic analysis was used for qualitative data. Findings were triangulated to explore different factors impacting homelessness. To protect the privacy and dignity of participants, ethical guidelines such as informed consent, confidentiality and cultural sensitivity were adhered to throughout the research process.



Results: Findings from the study revealed that 88.9% of LGBTQI+ participants experienced homelessness, with 77.8% identifying family rejection as the primary cause. Most participants (72.2%) aged were with low incomes (77.7% earning under ₦650,000/year) and unstable employment. Homelessness significantly impacted participants' sense of identity (56.3%), self-esteem (62.5%), and mental health (68.8%), as shown by statistical analysis ($p < 0.05$). Coping mechanisms included support from either family or friends (50%), creative outlets such as music and art (17%), professional help (10%), religion (10%), and substance use (6.7%). However, access to social and healthcare services was inadequate, with 100% dissatisfaction among participants.

Conclusions: The findings from this research reinforce that homelessness among LGBTQI+ persons in Nigeria is deeply intertwined with societal misconceptions about their sexual orientation. Highlighting the need for public education, policy reforms, and the establishment of supportive institutions and community-based programs to address the systemic barriers to LGBTQI+ homelessness.

EP0719

Types, perpetrators and prevalence of violence experienced by Female Bar Workers in Dar es Salaam

H. Goymann[1], W. Akyoo[2], V.K. Nguyen[1], D. Kamori[3], I. Mosha[2], A. Jahn[1], R. Mpembeni[4], T. Bärnighausen[1,5,6], G. Harling[7,6,8]

[1]Heidelberg University, Institute of Global Health, Heidelberg, Germany, [2]Muhimbili University of Health and Allied Sciences, School of Public Health and Social Sciences, Department of Behavioural Sciences, Dar es Salaam, Tanzania, the United Republic of, [3]Muhimbili University of Health and Allied Sciences, Department of Microbiology and Immunology, Dar es Salaam, Tanzania, the United Republic of, [4]Muhimbili University of Health and Allied Sciences, School of Public Health and Social Sciences, Department of Epidemiology and Biostatistics, Dar es Salaam, Tanzania, the United Republic of, [5]Harvard University, Harvard T. H. Chan School of Public Health, Boston, United States, [6]Africa Health Research Institute, KwaZulu-Nata, South Africa, [7]University College London, Institute for Global Health, London, United Kingdom, [8]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Science, Johannesburg, South Africa

Background: Violence against women (VAW) is a major health challenge worldwide, and is directly and indirectly linked to HIV acquisition, especially in key populations. Moreover, violence limits women's access to HIV prevention, testing and care services. Stigma and criminalization make women who have transactional sex particularly vulnerable to violence from intimate partners, clients, pimps and authorities. In sub-Saharan Africa, female bar workers (FBWs) frequently engage in sex work and face stigma as a result, putting them at higher risk for acquiring HIV. We therefore assessed the experience of violence against FBWs and its association to sex work in Ubungo district, Dar es Salaam, Tanzania.

Methods: We analyzed baseline self-reported data from a randomized controlled trial of service delivery models to increase initiation and retention of FBWs on oral HIV Pre-Exposure Prophylaxis in 2023-24. We calculated the prevalence of violence by type and perpetrator and tested whether engagement in transactional sex was associated with experiencing sexual or physical violence using Chi-square tests.

Results: Of 782 participants 55% reported being verbally abused, 29% reported physical abuse (mainly perpetrated by parents (51%) and non-client intimate partners (17%)) and 7% reported sexual abuse (primarily by male friends (46%) and non-client intimate partners (15%)) since age 15.
277 FBWs (35%) reported having had sex with a client from the bar with 72% receiving money, 11% gifts and 21% receiving neither. Those who had had sex with bar clients were no more likely to have experienced physical violence (32% vs 27%, $\chi^2 = 2.8$, p=0.09) but were more likely to have experienced sexual violence (10% vs 5%, $\chi^2 = 5.5$, p=0.02).
Conclusions: Female bar workers in Dar es Salaam do not appear to be at greatly elevated risk of violence compared to non-FBWs, despite almost one-third of them reporting transactional sex. The locus of violence experienced appears to be more in their home and social spaces than at their workplace, suggesting the need for multifocal interventions to reduce both VAW and HIV risk among FBWs.

EP0720

Facilitating transgender participation in efficacy trials – mixed methods study at HVTN clinical research sites in Peru conducting the Antibody Mediated Prevention Study (AMP)

H. Sánchez Sarmiento[1,2], L. Oseso[3], J. Andriesen[4], G. Broder[3], P. Andrew[5], J. Davis[6], J. Lucas[7], F. Rentas[3], J. Gallardo-Cartagena[1], K. Mayer[8,9,10], S. Karuna[3], M. Andrasik[3,11]
[1]Centro de Investigaciones Tecnológicas, Biomédicas y Medioambientales, Universidad Nacional Mayor de San Marcos, Lima, Peru, [2]Epicentro, Lima, Peru, [3]HIV Vaccine Trials Network (HVTN), Fred Hutchinson Cancer Center, Seattle, United States, [4]HIV Vaccine Trials Network (HVTN), Fred Hutchinson Cancer Center, Statistical and Data Management Center Operations, Seattle, United States, [5]HIV Prevention Trials Network (HPTN), FHI 360, Durham, United States, [6]North Carolina Central University, Durham, United States, [7]HIV Prevention Trials Network (HPTN), FHI 360, Durham, United States, [8]The Fenway Institute, Fenway Health, Boston, United States, [9]Division of Infectious Diseases, Beth Israel Deaconess Medical Center, Boston, United States, [10]Harvard Medical School, Department of Medicine, Boston, United States, [11]University of Washington, Department of Global Health, Seattle, United States

Background: Transgender women (TGW) in Peru bear the highest burden of HIV across all populations with a prevalence of 30%. Peruvian TGW experience higher rates of violence, fewer employment opportunities, and lack of access to health services and opportunities to participate in clinical studies. The Antibody Mediated Prevention (AMP) Study (HVTN 704/HPTN 085), a post-hoc analysis showed that a broadly neutralizing antibody against HIV did not protect against HIV acquisition, unless the HIV was sensitive to the antibody.
In this research, we sought to understand the experiences of clinical research sites (CRSs) working to engage TGW in Peru during AMP Study and the facilitators and barriers to trial participation they observed.
Methods: We conducted a mixed methods study administering 10-20-minute online surveys and 45–60-minute one-on-one semi-structured interviews with total of 9 Community Advisory Board (CAB) members, community educators/recruiters (CERs), and clinic coordinators at 2 sites in Lima and 1 site in Iquitos, Peru between November 2018 and February 2019. We assessed general knowledge regarding transgender health and services; bnAbs and PrEP; site resources and procedures for the recruitment and retention of transgender participants; capacity building needs; and additional information needed to inform work with transgender participants.
The Higher Enrolling (HE) site (n=1) had enrollment of transgender participants ³11%. Lower Enrolling (LE) sites (n=2) had enrollment of transgender participants ≤7%.
Results: Site staff across HE and LE sites perceived their sites as successful in recruiting and retaining transgender participants and also identified challenges. Across all sites, 2 key facilitators emerged: staff members created a welcoming environment and provided support. The top barriers experienced by TGW across the sites were stigma, transphobia, homophobia and discrimination; and lengthy study visits conflicted with work. Lack of legal protection for transgender people was identified at LE sites. At the HE site, transience of TGW was the most cited barrier.
Conclusions: It is necessary to continue researching best practices for engaging transgender populations in order to improve facilitators and address barriers. Due to the presence of stigma and discrimination against this community, continued efforts are needed to find optimal strategies that support meaningful integration of TGW in clinical trials

EP0721

Exploring HIV care disparities among foreigners in Taiwan: insights from a multicenter study (2017–2023)

S.-H. Huang[1], S.-Y. Chang[2], P.-H. Liou[3], C.-Y. Shih[4], P.-Y. Wu[5], M.-H. Lee[6], C.-Y. Lin[7], M.-S. Tsai[4], C.-J. Yang[4], C.-Y. Cheng[2], S.-H. Cheng[2], C.-C. Hung[7,5], Taiwan HIV Study Group
[1]National Taiwan University Hospital Hsin-Chu Branch, Hsinchu City, Taiwan, Province of China, [2]Tao-Yuan General Hospital, Taoyuan, Taiwan, Province of China, [3]Mackay Memorial Hospital Hsinchu Branch, Hsinchu City, Taiwan, Province of China, [4]Far-Eastern Memorial Hospital, New Taipei City, Taiwan, Province of China, [5]National Taiwan University Hospital, Taipei, Taiwan, Province of China, [6]Shuang Ho Hospital, New Taipei City, Taiwan, Province of China, [7]National Taiwan University Hospital Yunlin Branch, Yunlin County, Taiwan, Province of China

Background: Restrictions on the entry and stay of foreigners with HIV (FWH) in Taiwan were lifted in 2015, however, barriers to HIV care remained, including a high cost of antiretroviral therapy (ART) and laboratory testing in the first 2 years when it was not covered by National Health Insurance. In this study, we aimed to investigate the quality indices of HIV care among FWH in Taiwan to explore the potential disparities.

Methods: FWH who first sought HIV care at 7 Taiwanese hospitals between 2017 and 2023 were included. The rates of ART initiation, retention in HIV care at 1 year, and virological suppression were calculated. Factors associated with discontinuation of HIV care within 1 year were analyzed with Cox proportional hazards model.

Results: We included 123 FWH with a median age of 32 years and a male-to-female ratio of 3:1. The majority (77%) were originated from Southeastern Asian countries. Among 79 ART-naïve FWH, the median CD4 at presentation was 273 cells/μL, 45.6% had AIDS, 86.1% started ART, and 48.1% remained in HIV care at 1 year with 84.2% of those remaining in care achieving plasma HIV RNA <50 copies/ml. Among the 44 ART-experienced FWH, only 76.3% had achieved virological suppression at the time of enrollment, while 72.7% remained in care at 1 year.

In the Cox proportional hazards model, having opportunistic illnesses was associated with earlier HIV care discontinuation (hazard ratio 1.80, 95% CI 1.13 – 2.86) while ART initiation was associated with retention in care (hazard ratio 0.14, 95% CI 0.07 – 0.30).

Variable		N	Hazard ratio		p
Age		123		0.99 (0.97, 1.01)	0.48
Sex	F	29		Reference	
	M	94		0.91 (0.58, 1.44)	0.69
Country	LMIC	52		Reference	
	UMIC	62		1.27 (0.87, 1.85)	0.22
	HIC	9		0.88 (0.39, 2.01)	0.76
Occupation	white collar	30		Reference	
	student/family/traveller	29		1.17 (0.68, 2.02)	0.57
	blue collar or unemployed	64		1.35 (0.83, 2.18)	0.22
Opportunistic infections	no OIs	98		Reference	
	With OIs	25		1.80 (1.13, 2.86)	0.01
ART initiation	0	11		Reference	
	1	112		0.14 (0.07, 0.30)	<0.001

0.1 0.2 0.5 1 2

Conclusions: Late HIV diagnoses were common and substantial gaps in both ART initiation and retention in care were observed among FWH in Taiwan. More investigations are warranted to better understand the barriers to access to HIV testing and care to improve the quality of client-centered HIV care in this vulnerable population.

EP0722

What transgender communities need out of a person-centered care model integrating HIV: qualitative findings from India

R.P. Kaptchuk[1], K. Pawar[2], S. Rao[3], T. Kshatriya[3], M. Ahmad[3], P.M. Ramien[2], Y.A. Reddy[2], A. Singh[2], J. Thakker[2], S.S. Solomon[2]

[1]The Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]The Johns Hopkins University School of Medicine, Baltimore, United States, [3]YRG CARE, Chennai, India

Background: India's transgender and gender diverse (TGD) populations vary considerably across socioeconomic status, cultural groups, living environments, and health needs. TGD communities continue to bear an HIV burden (3.8% prevalence) about 19 times higher than the general population, yet public HIV services do not align with community needs. Person-centered care delivered in a welcoming environment may improve service engagement but the blueprint of such a model remains unclear.

Methods: This study partners with three USAID-supported person-centered TGD health clinics in Maharashtra and Telangana, India, called Mitr clinics, offering HIV services and linkage to gender-affirming services. To explore priorities and factors influencing access-to-care among TGD individuals, Indian researchers fluent in local languages conducted in-depth interviews with TGD respondents in Maharashtra and Telangana, India. Clinic staff supported purposive sampling for diversity across clinic engagement, age, gender identity, and HIV status.

We conducted iterative data analysis with interviewers through discussions, memo-writing, and thematic analysis of transcripts.

Results: We conducted 28 interviews from September 2024-January 2025 (25 in Telangana, three in Maharashtra). Among respondents, ages ranged from 21-51 years; 21 identified as women or transgender women, six as men or transgender men, and one as gender diverse. Five were living with HIV and seven had never been to Mitr clinics. Participants sought care because they wanted cosmetic, hormone, and surgical services, emphasizing the need for improved information and affordability. Other priorities included mental health counseling, HIV awareness-building, and HIV comorbidity management when aging. Participants shared narratives of isolation and increasing violence and vocalized the need for accessible housing, self-defense/self-advocacy training, visibility for transgender men, ways to build community, and support to navigate family dynamics. Individuals returned to Mitr clinics because they felt open talking about their bodies with providers and it felt like a welcoming, proud space.

Conclusions: Findings emphasize the role that individualized sociostructural factors play in determining healthcare access and how they can be important entry points for HIV and other healthcare. Interviews are ongoing to expand findings. Learnings can inform TGD healthcare policy and resource allocation to optimize person-centered models, ensuring they align with TGD community priorities and overcome multilevel barriers to care access.

EP0723

Prevalence and predisposing factors of comprehensive knowledge about HIV among MSM in Rwanda

I. Tuyishime Ntaganda[1], J.C. Kwizera[1], T.T. Adegboyega[2]

[1]Rwanda Biomedical Centre, Kigali, Rwanda, [2]University of Rwanda, Huye, Rwanda

Background: Limited comprehensive knowledge of HIV among men who have sex with men (MSM) contributes to an increased risk of HIV acquisition and limits access to testing, prevention, and treatment services. However, the factors that predispose MSM to have low HIV knowledge remain poorly understood. This study aims to identify the prevalence and factors associated with comprehensive HIV knowledge among MSM in Rwanda.

Methods: This cross-sectional study used data from a 2024 Respondent Driven Sampling (RDS) survey conducted among 3,757 MSM, aged 18 years and older, who had engaged in sex with men in the past year. Participants

were recruited using valid coupons and provided informed consent. Data were collected through structured interviews and health tests, including HIV status and knowledge of HIV prevention and treatment. The study was conducted from January to March 2024. Data were analyzed using Stata. Descriptive statistics and adjusted prevalence ratios (aOR) with 95% confidence intervals were used to identify factors associated with comprehensive HIV knowledge.

Results: Among the 3,757 MSM, the median age was 25 years (IQR: 22–31). The majority had completed secondary education (55.8%), were unemployed or had irregular jobs (53.5%), and 61.2% had received HIV/AIDS information in the past six months. The prevalence of comprehensive HIV knowledge was 55.2%. HIV knowledge was significantly higher among MSM with higher education (aOR: 1.9, 95% CI: 1.2–3.6), those exposed to HIV/AIDS messages (aOR: 1.4, 95% CI: 1.1–1.8), and those who paid for sex (aOR: 1.4, 95% CI: 1.1–1.9).

Conclusions: Addressing HIV-related issues among MSM requires a comprehensive approach that includes education, stigma reduction, and improved access to healthcare. The findings underscore the importance of targeting younger MSM, those with lower education levels, and those with limited access to HIV/AIDS messages to reduce HIV transmission and improve their quality of life.

Future interventions should focus on integrating HIV education with services that address stigma and ensure equitable access to healthcare for all MSM, especially in resource-limited settings.

EP0724

Peer support in action: LGBTIQ Community-Led psycho-social support, sexual reproductive health and HIV care services in Angola

P. Matyanga[1], T. Zvirawa[1], M. Mawodzeke[1], A. Mutsinze[1], N. Willis[1], E. Mbwende[2], E. Tchilala[2]

[1]Zvandiri, Programs, Harare, Zimbabwe, [2]ADPP, Programs, Luanda, Angola

Background: Four decades into the HIV pandemic, children, adolescents and young adults living with HIV (CAYAHIV) have challenges in retention, viral suppression, and mortality. Lesbian, Gay, Bi-sexual, Transgender, Queer, Intersex (LGBTQI+) youth living with HIV face double stigma and discrimination because of their HIV status and their sexual orientation, limiting access to care. Despite supportive policies in Angola, stigma in communities and healthcare persists restricting access to sexual and reproductive health services. The World Health Organization recommends peer-provider models as a key strategy to address these challenges and support the goal of ending paediatric AIDS by 2030.

Description: Leveraging extensive experience in Zimbabwe and regional partnerships, Zvandiri developed peer model to ensure adolescents with HIV survive and thrive. Adapted in Angola the Community Adolescents Treatment Supporters initiative, and in collaboration with Angola Ministry of Health trained peer providers from the LGBTQI+ community, in Benguela and Luanda in Angola, across five clinics. The Peer Providers play a crucial role in supporting their peers by providing counselling, sexual and reproductive health rights (SRHR) information, disclosure support, assistance in coping with stigma and retention in care. Peer to peer information is disseminated through clinics, support groups, home visits, and digital platforms.

Lessons learned: Peer Providers supports clients facing discrimination in accessing HIV services and in navigating clinic settings. They bridge the gap between clients and healthcare workers, improving service delivery and fostering positive attitudes. Their shared experiences and empathetic care help reduce the stigma of living with HIV and being part of a key population. They assist parents and caregivers in accepting the young people in their care. By handling counselling needs, they alleviate healthcare worker's workload, allowing clinical personnel to focus on medication provision. This support has started to demonstrate reduction in their viral load results after three months of support.

Conclusions/Next steps: Peer providers play a critical role in delivering psychosocial support, sexual reproductive health information, and HIV care to CAYAHIV. By leveraging peer support, the program demonstrates improves retention and viral suppression rates, underscoring the need to scale and sustain peer-provider models to address the unique challenges faced by young people in the LGBTQI+ community.

EP0725

Exploratory qualitative analysis of the acceptability of HIV prevention methods among pregnant and lactating women interviewed during the randomized blinded phase of PURPOSE 1

A.M. Nyamaizi[1], I. Hawley[1], L. Isidoro[2], H. Makkan[2], B.L. Dlamini[3], C. Milford[3], K. Gill[4], T. Nkosi[4], N. Mosery[5], J. Smit[5], K. Reddy[6], P. Sibiya[6], T. McClure[7], C.C. Carter[8], A. Kintu[8], M. Das[8], E.T. Montgomery[1]

[1]RTI International, Oakland, United States, [2]The Aurum Institute, Rustenburg Clinical Research Centre, Rustenburg, South Africa, [3]Centre for the AIDS Programme of Research in South Africa, Vulindlela, South Africa, [4]The Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [5]WMRU (Wits MatCH Research Unit), School of Obstetrics and Gynecology, Faculty of Health Sciences, University of the Witwatersrand, Durban, South Africa, [6]Wits RHI, University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [7]FHI 360, Durham, United States, [8]Gilead Sciences, Inc., Foster City, United States

Background: PURPOSE 1 (NCT04994509) was the first pre-exposure prophylaxis (PrEP) trial to support inclusion of pregnant and lactating people (PLP) and demonstrated safety and 100% efficacy of lenacapavir for PrEP among cisgender young women, including PLP. We are conducting a qualitative substudy exploring the acceptability of twice-yearly injections and daily oral PrEP among select PURPOSE 1 subgroups. This analysis focuses on PLP attitudes during the randomized blinded phase.

Methods: Contraception was provided for free but was not required. Participants who became pregnant were counseled about the benefit/risk and reconsented to continue on study drug. At 5 of 25 South African substudy sites, PLP were purposively enrolled to explore acceptability of study products.

We conducted 16 in-depth interviews with 13 participants prior to release of data on efficacy and safety of lenacapavir. Three participants were interviewed during both pregnancy and lactation, and one during lactation alone. Interviews used a semi-structured guide, were translated and transcribed in English, and were analyzed thematically.

Results: Participants were generally satisfied with both the injection and oral pills for HIV prevention. They appreciated the convenience and reliability of a long-acting injectable that obviated daily adherence. Some described initial injection-related pain and discomfort but they felt consistently protected.

Some expressed concerns about the unknown safety of the injections during pregnancy and lactation, including concern about administration of the subcutaneous injection in the abdomen, or that infants might be exposed to study drug via lactation.

These concerns led some to indicate a preference for oral PrEP, despite side effects and daily adherence challenges, noting its established safety, familiarity, and alignment with prenatal medications.

However, others awaiting their next injection expressed a willingness to continue, citing availability of an alternative injection site (thigh) as a motivating factor.

Conclusions: Among this subsample of 13 PLP, participants shared concerns about the use of investigational study drugs while pregnant or lactating; while also noting benefits for consistent HIV protection and appreciating the option for an alternative injection site in the thighs.

These findings underscore the value of education and counseling about the efficacy, safety, tolerability, and pharmacokinetics for successful PrEP implementation among PLP.

EP0726

Ethical considerations for research involving pregnant women living with HIV and their children

M.S. McHenry[1,2], E.R. Masese[3], D. Kinyanjui[4], E. Were[5], J.G. Carlucci[1,2], J. Humphrey[6,2], E. Wahome[2], D. Munyoro[2], G. White[1], A. Nafiseh[1], K. Cunningham[1], M. Cory[1], M. Nyalumbe[2], R.A. Ombitsa[2], M.A. Ott[7], C. Halverson[8]

[1]Indiana University School of Medicine, Pediatrics, Indianapolis, United States, [2]Academic Model Providing Access to Healthcare (AMPATH) Kenya, Eldoret, Kenya, [3]Moi University, Sociology, Psychology, and Anthropology, Eldoret, Kenya, [4]Moi University School of Medicine, Mental Health and Behavioral Sciences, Eldoret, Kenya, [5]Moi University School of Medicine, Reproductive Health, Eldoret, Kenya, [6]Indiana University School of Medicine, Medicine, Indianapolis, United States, [7]Icahn School of Medicine at Mount Sinai, Arnhold Institute for Global Health, New York City, United States, [8]Indiana University School of Medicine, Center for Bioethics, Indianapolis, United States

Background: Pregnant and post-partum women living with HIV (PWLHIV) and their children have historically been excluded from certain research in the name of protection. This may, however, inadvertently exacerbate health disparities. While calls for their inclusion have increased, practical guidance on achieving this goal is lacking.

This project developed practical recommendations for enabling PWLHIV and their children to participate ethically in research.

Description: To inform this project, we performed 75 one-on-one qualitative interviews, primarily with PWLHIV and controls without HIV with history of prior research participation at Moi Teaching and Referral Hospital in Eldoret, Kenya, using a person-centered approach to gather insights on factors influencing research participation.

Additionally, two participatory workshops (n=40) were held to further interpret these factors with key stakeholders (e.g. community leaders, partners, ethic committee members.)

A multi-disciplinary team of U.S. and Kenyan research, ethics, and clinical professionals analyzed data to generate recommendations, and 12 additional PWLHIV reviewed their conclusions to ensure value and perspective alignment.

Lessons learned: PWLHIV were most concerned about methods by which participant confidentiality would be protected, specially related to their HIV status. Tailored strategies were required. Traditional prioritization of autonomy by international research ethics often conflicted with the communitarian values held in contexts with high HIV-prevalence, where decisions are influenced by close and community relationships.

Concerns were raised about therapeutic misconceptions. However, participants did report enhanced care, such as careful physical exam or access to providers for a child with disabilities, reflecting the challenges of conducting studies in settings with limited healthcare infrastructure and research literacy.

Study participants and community members emphasized their desire to be actively involved at multiple stages of the research process.

Additionally, dual ethical review – both local and from sponsoring institutions – was highlighted as crucial, alongside the need for increased support and infrastructure within host countries to optimize oversight and include community and cultural perspectives.

Conclusions/Next steps: We identified critical considerations in implementing processes protecting confidentiality, promoting agency, respecting their personhood, engaging communities, and providing appropriate oversight. The resulting guidance will be disseminated widely to inform future research practices, with significant implications for advancing ethical and inclusive research involving PWLHIV and their children.

EP0727

Prevalence of HIV and related behaviors among MSM in Albania. Integrated bio-behavioral surveillance

E. Gjebrea Hoxha[1], R. Bani[2]
[1]Albanian Center for Population and Developement, Research and Policy, Tirana, Albania, [2]Institute of Public Health, Epidemiology and Control of Infectious Diseases, Tirana, Albania

Background: Although Albania remains a low HIV prevalence country, the prevalence among MSM is increasing. MSM are the most hidden population in Albania, and their activities are not visible owing the stigma and discrimination experienced by this population. In 2024, a study was conducted among MSM by ACPD (Albanian Center for Population and Development) supported by Global Fund, Albania aiming at estimating the prevalence of HIV and exploring its associated risk factors.

Methods: Using standard methods of respondent driven sampling (RDS), 554 MSM were recruited MSM in three larger cities in Albania. RDS-adjusted population estimates were calculated to estimate prevalence of HIV and risky behavior.

Results: The median age of 28 years reflects the predominance of young to middle-aged adults in the MSM community. Almost half of MSM (48%) reported having sex with non-regular, non-commercial partners in the last six months, indicating a common practice among this population.

The high number of casual partners and the varying roles during sexual encounters suggest a dynamic sexual network that could facilitate the spread of HIV and other STIs if not adequately managed. The study highlights a concerning perception among MSM regarding their risk of HIV acquisition of HIV.

Almost half (43%) of MSM believed they were at no risk of HIV acquisition of HIV. The study reveals that 13% avoid healthcare due to stigma, and 14% avoiding it because of fear that someone might discover their sexual orientation. These rates are higher than those reported in previous studies, indicating a negative trend in healthcare avoidance due to stigma and fear of exposure.

The prevalence of HIV is still low at 3.3%, but higher than in 2019 (2.0%). The Syphilis prevalence was 4.8%, more than twice the prevalence of 2019 (1.9%).

Conclusions: The combination of HIV related risky behaviors among MSM population makes it imperative this group to be targeted as part of any HIV prevention strategy. The relatively high rates stigma underscore the hostile environment that MSM navigate daily. These experiences can lead to increased mental health issues, reluctance to seek healthcare, and reduced willingness to engage in preventive behaviors such as regular HIV testing.

EP0728

Prevalence of chemsex and associated factors among gay, bisexual, and other men who have sex with men in Nepal: findings from an online national survey

K. Paudel[1], K. Gautam[1], J.A. Wickersham[2], R. Shrestha[1]
[1]University of Connecticut, Storrs Mansfield, United States, [2]Yale University, New Haven, United States

Background: Chemsex typically involves the use of psychoactive substances such as crystal methamphetamine, mephedrone, gamma-hydroxybutyrate, or gamma-butyrolactone (GHB/GBL) before or during sex to enhance sexual activity. The increase in the chemsex phenomenon among gay, bisexual, and other men who have sex with men (GBMSM) is alarming, as it is associated with risky sexual behaviors, including condomless sex and multiple sex partners. Despite increasing concerns, there is non-existent research on chemsex among GBMSM in Nepal. Therefore, this current study aimed to identify the prevalence and factors associated with engagement in chemsex among GBMSM in Nepal.

Methods: A cross-sectional online survey of 842 Nepali GBMSM was conducted between March and May 2024. Participants completed a self-administered assessment of their demographic characteristics, psychosocial factors and behaviors, recent sexual and health-related behaviors, and their chemsex engagement in the last 12 months. Multivariable logistic regression was used to identify factors associated with recent chemsex engagement (within the past 12 months).

Results: Among 842 participants (mean age 27.6 ± 7.1 years), 24.7% reported ever engaging in chemsex, and 19.1% did so in the past 12 months. GBMSM who were high school graduates were less likely to have engaged in chemsex in the past 12 months (aOR: 0.5; 95% CI: 0.3-0.8). However, GBMSM who reported having multiple sex partners (aOR: 9.6; 95% CI: 1.3-71.4), being involved in party/group sex in the past 12 months (aOR: 2.5; 95% CI: 1.5-3.9), and with depressive symptoms (aOR: 2.0; 95% CI: 1.3-3.0) were more likely to have engaged in chemsex in the past 12 months.

Conclusions: Chemsex engagement among GBMSM in Nepal is relatively higher compared to rates observed in other countries, heightening vulnerability to HIV and other sexually transmitted infections. An integrated approach is urgently needed, encompassing awareness raising, drug use support, sexual health services, and mental health care. This approach should prioritize harm reduction strategies specifically tailored for GBMSM engaged in chemsex practices.

EP0729

Men on the move: coping with HIV and mobility in Johannesburg, South Africa

M. Nardell[1], J.J. Lee[2], S. Mngadi-Ncube[3], B. Ram[4], C. Govathson[3], L. Long[5], M. Lurie[6], L. Butler[7], S. Pascoe[3], I. Katz[1]

[1]Brigham and Women's Hospital, Medicine, Boston, United States, [2]Ewha Womans University, Department of Data Science, Seoul, Korea, the Republic of, [3]Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [4]Harvard Kennedy School, Cambridge, United States, [5]Boston University School of Public Health, Global Health, Boston, United States, [6]Brown University School of Public Health, Providence, United States, [7]Queen's University, Department of Public Health Sciences, Kingston, Canada

Background: Johannesburg is home to ~5.5 million people who have relocated from elsewhere, the majority of whom are men. Mobility is a risk factor for acquiring HIV, and people who move across provincial and country borders are more than twice as likely as others to forgo testing and health services. Positive coping skills are critical for effective healthcare decision-making, but little is known about how men's HIV status and mobility-related stressors affect their coping strategies.

Methods: From February-April 2024, we recruited 200 mobile men (living in Johannesburg for ≤5 years) at community sites (e.g., taxi ranks, workplaces, parks). We administered a socio-demographic survey, including HIV status and the Soweto Coping Scale, which has two domains of coping. We defined problem-focused/emotional (score range 5-45 points) and religious (score range 5-25 points) coping scores as the sums of their respective scale responses. We fitted multivariate linear regression models to assess associations between these coping scores with HIV status and mobility variables, adjusting for mobility-related (legal status, nights away from home, any nights with hunger) and demographic (age, education, employment) variables.

Results: Participants had a mean age of 33 years, 25% reported living with HIV, and 77% reported having legal residence status. The religious coping score was higher among men with HIV versus men with negative/unknown status (2.18 points higher, 95% CI=[0.28,4.08]; p=0.025). The religious (2.24 points higher, 95% CI=[0.25,4.23]; p=0.028) and problem-focused/emotional (2.74 points higher, 95% CI=[0.35, 5.19]; p=0.28) scores were higher among men with legal status versus those without.

Conclusions: South African mobile men are significantly more likely to use religious coping in response to stressors in their lives. Prior research has shown that strong religious beliefs in conjunction with psychosocial support promotes good clinical outcomes, including higher rates of antiretroviral therapy adherence. Men without legal status may struggle with coping in the face of challenges such as seeking jobs and healthcare while fearing deportation and may benefit from clinical care provided with social and/or legal services. Further research is needed to understand how religious beliefs impact clinical outcomes among South African mobile men living with HIV to inform treatment interventions for this population.

EP0730

Fisting and HIV correlates among gay, bisexual, and other men who have sex with men

T. Carpino[1,2], M. McCormack[3], L. Wignall[4]

[1]Johns Hopkins University, Epidemiology, Baltimore, United States, [2]Duke University Global Health Institute, Durham, United States, [3]Aston University, Birmingham, United Kingdom, [4]University of Brighton, Brighton, United Kingdom

Background: Fisting is the sexual practice of inserting a hand into the anus/vagina. Despite its popularity within kink subcultures, it remains understudied in relation to sexual health; despite potential significant implications for HIV and other STI prevention and care.

This study explores the knowledge, experiences, and practices of anal fisting among gay, bisexual, and other men who have sex with men (GBMSM) and compares these characteristics to non-fisters to inform targeted public health education efforts and interventions.

Methods: From July 4-14, 2024, users of Recon, a kink socio-sexual networking site for GBMSM, were invited to complete the Kink Health, Wellbeing and Orientation survey. Alongside sociodemographic factors, the survey assessed the 1,012 respondents' experience with fisting and sexual health practices. Bivariate analyses were conducted between participants who engage in fisting and non-fisters to explore HIV and other STI prevalence, incidence, and prevention uptake.

Results: Past-year fisting engagement was 33.5% (n=339) of GBMSM in the past year. HIV prevalence was 22.1% (n=75) among fisters and 8.5% (n=57) among non-fisters; HIV incidence was 5.4% (n=15) among fisters compared to 2.7% (n=17) among non-fisters. Healthcare engagement also varied; 64.2% (n=167) of HIV-negative fisters used PrEP in the past 12 months, compared to 31.3% (n=189) of non-fisters. Additionally, past-year STI testing was significantly more common among people who fist (p<0.01). Fisters were more likely to use DoxyPEP (22.1% vs. 7.1%, p < 0.01) and expressed greater interest in future DoxyPEP utilization (70.2% vs. 61.2%, p < 0.01).

	GBMSM Non-Fisting n (col %)	GBMSM Fisting n (col %)	Pearson χ^2 value
Total	673 (100.0)	339 (100.0)	-
Health, overall			0.13
Excellent	101 (15.0)	53 (15.6)	
Very good	295 (43.8)	173 (51.0)	
Good	199 (29.6)	83 (24.5)	
Fair	68 (10.1)	28 (8.3)	
Poor	10 (1.5)	2 (0.6)

*HIV PrEP use row tabulated among people who reported current HIV-negative serostatus.

+STIs reported in our sample includes gonorrhea, chlamydia, HPV, syphilis, Hep A, Hep C, mpox, shigella, herpes, mycoplasma, giardiasis, genital warts, and meningitis

Conclusions: This study highlights significant differences in HIV prevalence and incidence, PrEP use, STI testing, and DoxyPEP engagement, suggesting fisters may be more connected to prevention and care services yet simultaneously be at higher risk for HIV acquisition.
Public health prevention and education efforts should recognize fisting as a high impact activity which can influence syndemics of HIV and other STIs.

EP0731

Bridging barriers: key populations revolutionizing HIV prevention and local development through human-centered design in Liberia

L. Nagbe[1], J. Toomey Garbo[1], S.M. Kpadeh[1], A. Christensen[2], L.T. Gbe-Fully[1], E.C. Charles[2]
[1]Jhpiego Liberia, Monrovia, Liberia, [2]Jhpiego Reginoal, Dar es Salaam, Tanzania, the United Republic of

Background: Community offering of HIV Pre- Exposure Prophylaxis (PrEP) has been offered in Liberia since June 15, 2023, using general educational messaging, but uptake and continuation was lagging below targets.
In August 2023, a human-centered-design (HCD) approach was used to co-design PrEP demand generation messaging with key populations (KP). From October 2023 to September 2024, the co-designed promotion strategies were rolled out, reaching 5,080 KPs, with 4,961 (98%) eligible for PrEP and 4,724 (95%) enrolled on PrEP, representing a significant increase when compared to the pre-intervention uptake and continuation trends.
Description: A workshop for KPs using a HCD approach was conducted in June and August of 2023. The creative workshop engaged a total of 12 Female Sex Workers; 6 Men who have Sex Men; 5 Transgender; 5 People Who Inject Drugs and 18 Non KP as co-leads and participants.
Insights were gathered through interviews and focus group meetings, followed by creative sessions to develop resonant messages, e.g. "Flex with PrEP," "I glow with PrEP," and identify powerful messengers such as Mammy Queens (Respected female leaders within the sex worker community). Subsequently, posters, stickers, and flyers were designed iteratively, shaped and refined by feedback from KPs.
Co-designed interventions using both emotional and functional messages were rolled out through Mammy Queens and Peer Educators, resulting in significant increases in both uptake and continuation, exceeding donor targets for HIV testing and PrEP from 253 (2023) to 2,186(2024).
Lessons learned: HCD offers an effective approach to engaging KPs in co-designing tailored messaging and promotional strategies that resonate and inspire change. HCD's participatory and creative exercises and iterative approach to materials development can be completed in a short timeframe. KPs are effective co-facilitators.
Fact-based medical messaging alone is less motivating than a combination of emotional and functional appeals. Collaboration with CSOs was essential for smooth implementation and scaling-up.

Conclusions/Next steps: The HCD approach has been transformative in improving uptake of PrEP among KPs in Liberia. By engaging them in co-creating communication solutions, the initiative not only surpassed donor targets for testing and PrEP enrollment but also demonstrated the power of community-driven interventions in overcoming barriers and achieving impactful outcomes.

EP0732

Impact of violence on HIV prevalence and cascade of care in men who have sex with men and transgender women: a global systematic review and meta-analysis

S.A. Khan[1], K. Mazhar[1], J. Dawe[1], J. Ambia[1], G.M. Kassa[1], V. Bendaud[2], K. Sabin[2], A. Artenie[1], P. Vickerman[1], J. Stone[1]
[1]University of Bristol, Bristol Medical School, Bristol, United Kingdom, [2]The Joint United Nations Program on HIV/AIDS (UNAIDS), Data for Impact, Geneva, Switzerland

Background: Violence towards men-who-have-sex-with-men (MSM) and transgender women (TGW) may detrimentally affect HIV risk and treatment outcomes and hinder progress towards the 2030 AIDS elimination targets. We synthesised global evidence on the impact of violence on HIV outcomes among MSM and TGW.
Methods: We searched MEDLINE, Embase, and PsycINFO databases for studies published between January 2010 and 2024, assessing associations between any violence and at least one HIV outcome (HIV prevalence, incidence, ART uptake/adherence, and viral suppression) among MSM and TGW.
We pooled associations (adjusted estimates when available) from the included studies and also used multilevel random-effect analysis to account for multiple estimates from studies with different exposure types.
Results: From 12,895 publications, we reviewed 228 full-texts selecting 46 studies as eligible and retrieving 42 estimates from MSM-only studies, 20 from TGW-only studies, and 9 from MSM and TGW studies. Most estimates covered the American (24%) and African (27%) regions. Experiences of any form of violence were associated with greater odds of incident (HR: 2.14; 95% CI: 1.18-3.91) and prevalent (OR: 1.61; 95%CI: 1.23-2.10) HIV infection among MSM and TGW. Subgroup analyses found strong associations between recent (OR: 2.23; 95%CI: 1.03-5.21) or lifetime experiences of sexual violence (OR: 1.48; 95%CI: 1.17-1.89) and prevalence HIV infection but there was weaker evidence for the effects of recent (OR: 2.86; 95%CI: 0.44-18.47) or lifetime experiences of intimate partner violence (OR: 1.60 95% CI:0.93-2.75). Experience of violence was associated with lower viral suppression levels (OR: 0.54; 95%CI: 0.38-0.75) but was not associated with ART uptake/adherence among MSM and TGW.
Conclusions: Experiences of violence among MSM and TGW are associated with an increased risk of prevalent and incident HIV, and lower levels of viral suppression. Integration of violence reduction interventions in policies and programs may help in achieving 2030 HIV/AIDS targets.

EP0733

Assessing a syndemic of discrimination, stigma, material insecurity, depression, substance use, and intimate partner violence among sexual and gender minorities in Nigeria

R. Turpin[1], M. Mansfield[2], T. Dyer[3], A. Mitchell[2], C. John[4], R. Adebiyi[4], U. Ononaku[4], C. Katu[4], J. Aigoro[4], A. Aka-Bashorun[5], S. Adebajo[4], M. Charurat[2], R. Sullivan Robinson[6]

[1]George Mason University, School of Public Health, Global and Community Health, Fairfax, United States, [2]Institute of Human Virology, University of Maryland, School of Medicine, Baltimore, United States, [3]University of Maryland, School of Public Health, Epidemiology and Biostatistics, College Park, United States, [4]Institute of Human Virology, Abuja, Nigeria, [5]International Centre for Advocacy and Right to Health, Abuja, Nigeria, [6]American University, School of International Service, Washington, United States

Background: Sexual and gender minority people (SGM) in Nigeria experience disproportionate HIV burden, with an HIV prevalence four to ten times higher than the national average. Gaining a better understanding of factors that create HIV vulnerability in this population is important for designing effective interventions, particularly in a context largely hostile to SGM.

Methods: We assessed a conceptual model describing a syndemic of experienced discrimination, stigma, material insecurity, depression, substance use, and intimate partner violence among SGM in Nigeria. As part of a larger, longitudinal study examining noncommunicable disease outcomes among this population, we conducted a mixed method analysis using both quantitative intake data (n=515) as well as data from three focus groups (n=36) collected in 2023-24.

We tested for intercorrelations among syndemic factors, and associations between a cumulative syndemic index and HIV status using modified Poisson regression. We also conducted a convergent qualitative assessment of the conceptual model in three focus group discussions.

Finally, we examined the co-prevalence of syndemic factors highlighted in our qualitative findings.

Results: There were consistent intercorrelations among syndemic components, supporting the presence of a syndemic. After adjustment for sociodemographic factors, every quartile-unit increase in the syndemic index was associated with an 18% increase in prevalence of HIV (aPR=1.18, 95% CI 1.07, 1.29).

Additionally, our qualitative findings highlighted relationships between discrimination, material insecurity, and depression as especially relevant among this population. Examining syndemic factors identified as particularly salient in our qualitative analyses, nearly every single co-prevalence in our quantitative data was significantly greater than expected.

Conclusions: We found strong evidence of a syndemic of experienced discrimination, stigma, material insecurity, depression, substance use, and intimate partner violence among SGM in Nigeria in both our quantitative and qualitative data. Participants described discrimination, material insecurity, and depression as especially salient to the HIV-related outcomes of SGM in Nigeria. Overall, our findings highlight the presence of a syndemic that must be addressed not simply at the individual level, but through larger scale social and structural change efforts.

EP0734

Individual-level factors associated with self-reported PrEP use among MSM sex workers (MSMSW) advertising services in California

K. Jackson[1], E. Arnold[2]

[1]University of Massachusetts Dartmouth, College of Nursing & Health Sciences, North Dartmouth, United States, [2]University of California San Francisco, Center for AIDS Prevention Studies, San Francisco, United States

Background: California, long-considered a safe-haven for sexual and gender minorities, offers male sex workers both economic opportunity and abundant sexual health services, including low-cost HIV testing and PrEP. However, misperceptions that PrEP is exclusively for gay men hinder uptake among populactions at risk for HIV infection, including MSMSW who are non-gay identified (NGI).

This study explores individual-level factors associated with advertising PrEP use among HIV-negative, cisgender, male-identifying sex workers who have sex with men (MSMSW) advertising commercial sex work services in California for the purposes of informing uptake strategies.

Methods: Following IRB approval, we web-scraped profile data from July-October 2024 at biweekly intervals from MSMSW advertising services in California on a global, Internet-based MSMSW-oriented advertising platform.

Multivariate logistic regression was applied to assess the association between sociodemographic characteristics (age, race/ethnicity, sexual orientation), physical traits (body hair, body type, circumcision status), sexual preferences (position, condom use), and advertised PrEP use.

Results: Of 2436 unique MSMSW advertisements, 61.5% (n=1498) described PrEP use, 21.7% (n=529) reported being HIV-negative, and 16.8% (n=409) did not disclose their serostatus nor PrEP use.

Among HIV-negative MSMSW with complete profile data (N=1693), MSMSW identifying as bisexual (aOR=0.58, 95% CI: 0.42-0.81), straight (aOR=0.34, 95% CI: 0.19-0.62), or "ask me" (aOR=0.52, 95% CI: 0.32-0.82) were less likely to advertise PrEP compared to gay-identifying MSMSW. MSMSW advertising anal sex were more likely to report PrEP use (aOR=2.13, 95% CI: 1.36-3.33) than those who did not.

MSMSW advertising condomless anal intercourse, such as those indicating "ask me" (aOR=4.14, 95% CI: 2.91-5.89) or "anything goes" (aOR=4.61, 95% CI: 3.04-7.00), to potential clients were more likely to advertise PrEP use than their peers who required condom use during client encounters.

Notably, Black (aOR=0.52, 95% CI: 0.33-0.83) and Native American (aOR=0.05, 95% CI: 0.01-0.28) MSMSW were less likely to advertise PrEP use than their White peers.

Conclusions: Our findings demonstrate how PrEP use may not align with socially-defined masculine identities constructed to appeal to consumers of MSMSW services across California. Some MSMSW populations may require

more tailored approaches to promote PrEP uptake that challenge societal definitions of masculinity, particularly among NGI Black and Native American MSMSW.

EP0735

Colorado empire: exploring drug use, stigma, and ART adherence among GBTQ sex workers living with HIV in Nigeria

O. Olajubu[1], R. Oyeniyi[1], V. Thompson[1], M. David[2], D. Emmanuel[3], B. Bassey[3]
[1]The Momentum Support Initiative, Lagos, Nigeria, [2]The Rainbow Alive Hub Initiative, Strategic Learning and Development, Lagos, Nigeria, [3]The Momentum Support Initiative, Community Engagement, Lagos, Nigeria

Background: Drug use and abuse as a coping mechanism is a rising concern for Gay, Bisexual, Transgender, and Queer (GBTQ) sex workers living with HIV in Lagos due to compounded stigma, discrimination, and the criminalization of the intersectionality of their identities. The widespread drug use among this population has potential impacts on ART adherence, healthcare access, and safe sex practices.
This study, which is the first of its kind in Nigeria, investigated the patterns of drug use, its influence on the health behaviors of GBTQ sex workers living with HIV, and the systemic barriers that exacerbate these challenges.
Methods: A cross-sectional survey was designed to explore drug use, ART adherence, and stigma among GBTQ sex workers living with HIV in Lagos State, Nigeria. A total of 264 GBTQ sex workers living with HIV were recruited through peer networks and snowball sampling.
Data collection focused on drug use frequency, types of substances consumed, ART adherence behaviors, and barriers to healthcare access. Respondents also provided qualitative feedback on their experiences with stigma, and discrimination, and recommendations for improved care.
Results: 78.1% of respondents reported drug use within the last six months (prescription drugs eg tramadol, codeine (51.6%), cannabis (21.9%), and methamphetamine (15.5%)). Among users, 28.1% reported daily use, correlating with respondents with ART adherence challenges (27.5%). 17.2% identified drug use as a barrier to adherence, citing forgetfulness, disrupted timing, and physical side effects as primary reasons. 21.9% admitted drug use impaired their ability to use protection consistently, with only 37.5% always practicing safe sex.
While 57.2% of respondents felt supported by healthcare providers, 42.8% reported service-provision gaps, including stigma, lack of trauma-informed care, and insufficient harm reduction services.
Conclusions: This study highlights significant trends in drug use and its interplay with ART adherence, healthcare access, and safe sex practices among GBTQ sex workers living with HIV.
Findings from the study emphasize the need for integrated harm reduction programs, ART delivery services, and mental health support tailored to diverse GBTQ identities. Future programs should prioritize intersectionality, ensuring that services address the unique vulnerabilities of this population while fostering a stigma-free, supportive environment for long-term health engagement.

EP0736

Addressing HIV care disparities among LBQ women in Southwest Nigeria

G.J. Samuel[1], O. Olajubu[1], P. Bennett[1], H. Adegbite[1], G. Ekpo[1]
[1]The Rainbow Alive Hub Initiative (TRAHI), Lagos, Nigeria

Background: Lesbian, bisexual, and queer (LBQ) women in Southwest Nigeria face significant barriers to accessing HIV-related healthcare services due to pervasive stigma, discriminatory practices, and restrictive legal frameworks. These systemic challenges discourage disclosure of sexual orientation and limit engagement with HIV prevention, treatment, and care services. Despite global efforts to address HIV disparities, the unique vulnerabilities of LBQ women living with or at risk for HIV remain critically underexplored in Nigeria.
This study, conducted in Lagos and Ogun States, seeks to uncover these barriers and propose actionable solutions.
Methods: A mixed-methods approach was utilized in 2024, including focus group discussions, key informant interviews, and structured online surveys with 209 participants. These included LBQ women, healthcare providers, and other stakeholders. Data collection tools were designed to explore access to HIV care, barriers faced, and service utilization. Triangulation was applied to validate findings, ensuring depth and reliability of emerging themes.
Results: The study highlighted significant barriers faced by LBQ women in accessing HIV care. Among respondents, 68% reported experiencing discrimination from public healthcare providers, discouraging disclosure of sexual orientation and leading to avoidance of essential services such as HIV testing, PrEP access, and ART adherence support.
While 42% relied on private clinics or One-Stop Shops (OSS) to avoid stigma, 31% reported the high cost of transportation to access these services as a major barrier. Alarmingly, 29% resorted to self-medication for managing HIV symptoms, increasing the risk of adverse health outcomes.
Additionally, 74% of participants reported the absence of safe, non-judgmental mechanisms for addressing mistreatment or receiving guidance on navigating HIV care.
These findings reveal systemic neglect and the urgent need for inclusive, targeted interventions to improve health outcomes for LBQ women.
Conclusions: Targeted systemic reforms are essential to close HIV care gaps for LBQ women in Nigeria. Expanding KP-friendly services, such as OSS, anti-stigma initiatives, and cultural competence training for healthcare providers, can significantly enhance HIV prevention, treatment, and care for this marginalized group.
This study underscores the urgency of inclusive policies that respect the rights and health needs of LBQ women, advancing efforts to eliminate HIV disparities by 2030.

EP0737

Breaking the barriers: enhancing treatment cascade among key populations receiving HIV care in complex sociocultural settings

O. Fajemisin[1], I. Jahun[2], U. Omo-Emmanuel[3], A. Bashorun[4], F. Agbo[5], A. Salihu[1], O. Idogho[1], O. Oyelaran[3]
[1]Society for Family Health, Abuja, Nigeria, [2]University of Mannitoba, Rady Faculty of Health Sciences, Winnipeg, Canada, [3]United States Agency for International Development, Abuja, Nigeria, [4]Federal Ministry of Health, National HIV and AIDS Control Program, Abuja, Nigeria, [5]National Agency for the Control of AIDS, Research, Monitoring and Evaluation Department, Abuja, Nigeria

Background: Key populations (KPs) deserve special attention in attaining the UNAIDS 95:95:95 targets. Pervasive stigma and discrimination against KPs perpetuated by political, sociocultural and religious beliefs are the major barriers that complicate service provision in northern Nigeria. To overcome these barriers, Society for Family Health Nigeria (SFH), a nongovernmental organization implementing multifaceted public health interventions with focus on KP programs, deployed an innovative package of interventions that enabled access and provision of quality care to the population. This study reports on the outcomes of the interventions.
Methods: In the third quarter of 2022, in five Northern Nigeria states, SFH conducted enhanced awareness creation among policy, religious and community leaders and engaged social media influencers to minimize misconceptions thereby creating an enabling environment to reach KPs with quality HIV services. There was deployment of differentiated service delivery (DSD) models with the use of KP community members as case managers to optimize retention, treatment adherence and timely viral load (VL) testing. Similarly, program data was used to consistently review progress, performance and address gaps. A retrospective cohort analysis to evaluate treatment cascade among KP who initiated treatment between January – February 2023 was carried out.
Results: Between January and February 2023, 1,025 KPs were screened positive for HIV (indicating 3-fold increase in case identification when compared to prior performances) of whom people who inject drugs (PWIDS), female sex workers (FSW), men who have sex with men (MSM), people in prison and enclosed settings (PIPES) constituted 46.6%, 34.4%, 18.3% and 0.6% respectively.
All the 1,025 were initiated on treatment and 1,009 (98%) retained on treatment at 12 months (FSW = 348 [99%]; MSM= 187 [99%]; PWID= 470 [98%]) and PIPES=4 [67%]). Of the 1,025 KPs, 959 (93.6%) had a viral load test done of whom 957 (FSW = 328 [100%]; MSM= 179 [99%]; PWID= 446 [100%]) were virally suppressed.
Conclusions: The package of interventions deployed by SFH to reach KPs in the five northern states in Nigeria yielded unprecedented results and have proven to be highly effective. Therefore, provision of quality KPs program in complex sociocultural settings is possible using community participatory approaches as described in this study.

EP0738

Enhancing communication strategies to promote HIV self-testing through social media: an exploratory study of the 'A Hora é Agora' project in five Brazilian Municipalities, 2024

V.L. Cota[1], P. Nery[2], M. Paiva[3], A. Silva[4], L. Rosso[5], D. Raenck da Silva[6], L. Colles[6], C. Schweitzer[7], R. Zonta[7], R. Miranda[1], M. Cruz[1]
[1]Sergio Arouca National School of Public Health (ENSP/Fiocruz), Rio de Janeiro, Brazil, [2]Unodesign, Belo Horizonte, Brazil, [3]Fortaleza Municipal Health Secretariat, Fortaleza, Brazil, [4]Campo Grande Municipal Health Secretariat, Campo Grande, Brazil, [5]Curitiba Municipal Health Secretariat, Curitiba, Brazil, [6]Porto Alegre Municipal Health Secretariat, Porto Alegre, Brazil, [7]Florianopolis Municipal Health Secretariat, Florianopolis, Brazil

Background: Despite Brazil's universal access to free antiretroviral therapy since 1996, socioeconomic inequalities and cultural barriers hinder early diagnosis and treatment. Research indicates that individuals with lower educational levels are significantly more likely to start treatment late, with delays increasing by up to 89% and worsening health conditions rising by 2.5 times (Rodrigues et al., 2021). Effective educational campaigns targeting key populations are essential to overcoming stigma and fear of judgment.
Description: The project A Hora é Agora, implemented by Fiocruz and funded by PEPFAR, supports Campo Grande/MS, Curitiba/PR, Florianopolis/SC, Fortaleza/CE, and Porto Alegre/RS. It focuses on tailored communication efforts for key populations, raising awareness about their rights, and providing information on HIV testing and treatment. The initiative collaborates with local civil society organizations (CSOs) and municipal health departments to promote combined prevention and address opportunistic diseases.
Lessons learned: Partnering with CSOs enhances our connection with KPs due to their credibility in municipalities. We held a photoshoot with community members and KP representatives for print and online materials. We utilized social media to promote received actions (PR Unboxing), featuring local influencers who also represent the KP and vulnerable groups to publicize the home delivery of HIV self-tests (HIVST), reaching 161,861 people and having 1,642 shares (Figure 1).

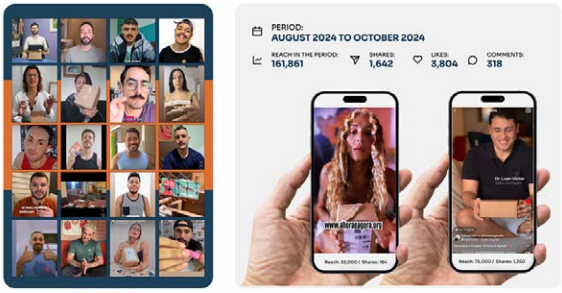

Figure 1. Campaign self-tests PR Unboxing.

Additionally, we established a partnership with Grindr, resulting in an over 60% increase in HIVST requests compared to the previous month in two municipalities par-

ticipating in the campaign, along with direct outreach efforts in social venues for KPs to promote combined HIV prevention services.

Conclusions/Next steps: Effective communication is vital in the response to HIV, as it promotes equitable healthcare access, reduces new acquisitions, and enhances the quality of life for vulnerable populations.

Engaging key populations and marginalized individuals remains a challenge. Despite a decade of progress, many who need public services are still unaware of them.

EP0739

Acceptance of female condoms among Brothel-Based Female Sex Workers (BBFSW) and their clients in Brothels in Lagos

E. Shoyemi[1], K. Okeke[1], M. Bassey[2]
[1]Centre for Population Health Initiatives, Lagos, Nigeria, [2]Lagos State University, Lagos, Nigeria

Background: Unprotected heterosexual intercourse remains the predominant mode of HIV transmission in Nigeria, accounting for approximately 80% of new infections. While the national HIV prevalence among the general population aged 15–49 is estimated at 1.3%, key populations, particularly female sex workers (FSWs), bear a disproportionately higher burden.

Notably, HIV prevalence among brothel-based female sex workers (BBFSWs) in Nigeria is reported at 19.4%. In Lagos, earlier studies indicated a prevalence of 12% among BBFSWs, though more recent data is needed to assess current trends.

This study investigates the acceptance and utilization of female condoms as a strategy for negotiating safer sex practices among BBFSWs and their clients in Lagos.

Methods: A cohort of 130 BBFSWs received comprehensive training on female condom usage, negotiation techniques, and data reporting methods.

Over four weeks, these sex workers documented their interactions with clients using structured survey questionnaires. Key variables assessed included types of sexual partners, willingness to use condoms, negotiation efficacy, and baseline knowledge of HIV transmission and prevention.

Results: The participating BBFSWs reported 757 client interactions during the study period. The mean age of the sex workers was 22 years, while that of their clients was 29 years. Notably, 80% of the BBFSWs had regular partners, referred to as "special boyfriends," with whom they intended to pursue long-term relationships.

Following sensitization efforts, 72% of clients accepted the use of female condoms. Conversely, 19% preferred male condoms, citing unfamiliarity and misconceptions about female condoms.

Additionally, 9% of clients offered increased payment for unprotected sex; however, the BBFSWs did not disclose whether these offers were accepted. Among the special boyfriends, 53% accepted female condom use, while 34% insisted on unprotected sex, expressing willingness to assume responsibility in case of pregnancy. Overall, 96% of all clients demonstrated basic HIV knowledge of HIV.

Conclusions: Enhancing awareness and education about female condoms is crucial to correct prevalent misconceptions and promote their acceptance. Also, access to female condoms can empower women, including sex workers, to effectively negotiate safer sex practices, ensuring the reduced risk of HIV transmission.

EP0740

Assessing the relevance of ethical positive parenting on the quality of HIV care & treatment services for adolescents living with HIV in Malawi: report on the 2024 Peer Supporters Training

H. Nasona[1], L. Phiri[1], K. Mwitiwa[1], I. Mataya[1], S. Solom[1], S. Ndege[1], A. Ngambi[2], P. Mbulaje[1], P. Damiano[3], C. Udedi[1]
[1]Malawi AIDS Counselling and Resource Organisation, Programs, Lilongwe, Malawi, [2]Malawi AIDS Counselling and Resource Organisation, Programs, Blantyre, Malawi, [3]Malawi AIDS Counselling and Resource Organisation, Monitoring and Evaluation - Biostatistics, Lilongwe, Malawi

Background: Adolescents living with HIV (ALHIV) in Malawi face significant challenges, including mental health issues, stigma and discrimination and non-adherence to Antiretroviral Therapy (ART). Despite being vital to ALHIV Support, caregivers often lack ethical parenting skills necessary to address these challenges. Discussions on sexuality and HIV-related care are further impeded by cultural norms, which lead to gaps in psychosocial care, adherence support, and disclosure. Ethical and positive parenting advocacy within communities has the potential to bridge these gaps and strengthen outcomes across the UNAIDS 95:95:95 cascade.

Description: In 2024, a training program was conducted for 50 participants, including 16 healthcare professionals, 26 peer supporters, and 8 young mentor mothers. The training program addressed critical areas such as disclosure, adherence, and community attitudes as it examined the role of caregivers in supporting ALHIV. Pre and post training assessments evaluated participants' knowledge, attitudes, and experiences with ethical parenting. Focus Group Discussions were used to collectr qualitative data (FGDs).

Lessons learned: Training highlighted crucial areas that needed intervention about the difficulties faced by ALHIV and their caregivers. Key Findings Include

69% of ALHIV with treatment interruptions lacked stable caregiver support, 50% of ALHIV reported caregivers' inability to practice ethical positive parenting, and 67% experienced stigma and discrimination, leading to poor mental health and ART adherence.

Post-test findings showed increased awareness of gaps in caregiver support:

95% of participants noted caregivers lacked truth-telling practices; 87% reported verbal insults as a disciplinary method; and 70% identified poor caregiver involvement in ART uptake.

FGDs further identified cultural norms, stigma, and illiteracy as significant impediments to effective caregiver support.

Conclusions/Next steps: Ethical and positive parenting is essential for improving HIV care outcomes for ALHIV. The findings underscore the importance of community advocacy to address cultural and systemic barriers. Future initiatives should focus on empowering caregivers and communities to adopt ethical parenting practices, thereby contributing to epidemic control and sustainable HIV care outcomes.

EP0741

Assessment of accessibility and inclusivity features for people with hearing disability in YouTube videos addressing HIV prevention

M. Adesina[1], R. Oladele[1], I. Olufadewa[1], T. Shokoya[1], R. Bowe[1], A. Mohammed[1], P. Taiwo[1]
[1]Slum and Rural Health Initiative, Ibadan, Nigeria

Background: YouTube is widely used to share health information on HIV prevention and services to millions of users. About 20% of the world's population live with hearing disability and thus requires disability-friendly services to access health information. Therefore, this study assessed the accessibility and inclusivity features present in YouTube videos related to HIV prevention, specifically focusing on their suitability for individuals with hearing disabilities.

Methods: We systematically searched YouTube using the keyword 'HIV prevention'. The search results were filtered to include videos that were 4 minutes or less in duration, posted within the past five years, and available in the English language. Subsequently, the identified videos were ranked based on the number of views, and the top fifty videos were selected for inclusion in the analysis. These videos were accessed using a checklist created from guidelines from the British Broadcasting Corporation, Imperial College London and other sources as well as academic literature. The checklist was made up of 17 items and accessed the videos based on closed captions and styling, language and clarity, speaker identification plus sound descriptions and quality.

Results: Almost all the videos (92%) had consistent volume levels throughout the videos and 86% were clear and free from background noise. Most (74%) had closed captions provided for all spoken content and 72% of the video's captions accurately represented the spoken words and relevant sounds. Furthermore, the majority of the videos (70%) had captions that were synchronized properly with the audio and 82% had text large enough and with sufficient contrast for easy readability. However, speakers were identified in only 12% of the videos and one-fifth (20%) had consistent methods for identifying speakers throughout the video. Additionally, only about a quarter (24%) described relevant sounds (such as laughter) in the captions.

Conclusions: The study findings revealed gaps in the inclusivity of the most-viewed videos on HIV prevention for people with hearing disability. Addressing these shortcomings will foster a more inclusive digital environment and ensure equitable access to HIV prevention information for individuals with hearing disabilities.

EP0742

Intersecting Stigma: the triple burden of HIV and cancer in LGBTQI+ identifying adolescents, a Botswana Baylor experience

S.S. Sosome[1], T. Nkone[2], B. Maloge[3], T. Batsile[3], O. Phoi[4], J. Farirai[5], B. Ditshekiso[6], M. Pono[6], R. Kgaswane[7], M. Matshaba[8]
[1]Botswana Baylor Childrens Clinical Centre of Excellence, Clinical Social Work, Letlapeng, Botswana, [2]Botswana Baylor Childrens Clinical Centre of Excellence, Patient Navigator, Gaborone, Botswana, [3]Botswana Baylor Childrens Clinical Centre of Excellence, Social Work, Gaborone, Botswana, [4]Botswana Baylor Childrens Clinical Centre of Excellence, Clinical Psychologist, Gaborone, Botswana, [5]Botswana Baylor Childrens Clinical Centre of Excellence, Associate Director, Gaborone, Botswana, [6]Botswana Baylor Childrens Clinical Centre of Excellence, Monitoring and Evaluation, Gaborone, Botswana, [7]Botswana Baylor Childrens Clinical Centre of Excellence, Systems Engineer, Gaborone, Botswana, [8]Botswana Baylor Childrens Clinical Centre of Excellence, Executive Director, Gaborone, Botswana

Background: Botswana-Baylor Children's Clinical Centre of Excellence (Botswana-Baylor Trust) is a national general care and treatment facility providing paediatric infectious disease and oncology services. Adolescents with a cancer diagnosis, HIV, and LGBTQI identities face a unique and compounded stigma that deeply impacts their care, making them feel marginalized across multiple dimensions. The intersection of these identities often leads to a lack of understanding or empathy from healthcare providers.

There is a need to balance cancer treatments with HIV management, while also navigating the complexities of LGBTQI-specific health concerns in environments that may not be affirming and exacerbate mental health challenges.

Description: Counseling sessions explored the experiences of five HIV-positive adolescents, aged between 16 and 23, who were diagnosed with cancer and identified as LGBTQI, they illustrated the unique challenges they faced due to triple stigma. These patients, each at one time experienced a high viral load, indicating poor adherence possibly due to anxieties and low self-esteem associated with HIV and their sexual identity. These adolescents not only dealt with physical health challenges but also faced significant mental health struggles, including depression, anxiety, and trauma, amplified by societal rejection and fear of discrimination from both healthcare providers and peers.

The lack of specialized support tools further complicated their mental health to help them navigate their identities, as many reported feeling either invisible or misunderstood by both their medical teams and social circles.

Lessons learned:

- Complex Treatment Regimens
- Mental Health Struggles
- Lack of Identity-Support Tools
- The Need for Holistic Healthcare Models

Conclusions/Next steps: There are medical, psychological, and social needs of adolescents facing triple stigma. It emphasizes the importance of developing LGBTQI-affirming healthcare environments that provide tailored support for managing chronic conditions like HIV and cancer.
Next Steps:
1. Training healthcare providers in cultural competency and intersectionality.
2. Development and adjustment of assessment tools in self-identification.
3. Interventions that support systemic changes to meet the multifaceted challenges they face.

EP0743

Mental health disparities among transgender women living with HIV: a scoping review of prevalence and challenges

D.R.A. Coelho[1], R.d.S. Sanglard[2], W.F. Vieira[3,4], C.G. Wade[5], A.S. Keuroghlian[1,6]
[1]Massachusetts General Hospital, Harvard Medical School, Boston, United States, [2]Federal University of Rio de Janeiro, Department of Medicine, Institute of Medical Science, Macaé, Brazil, [3]University of São Paulo, Department of Anatomy, Institute of Biomedical Sciences, São Paulo, Brazil, [4]Instituto e Centro de Pesquisas São Leopoldo Mandic, Faculdade São Leopoldo Mandic, Laboratory of Neuroimmune Interface of Pain Research, Campinas, Brazil, [5]Harvard Medical School, Countway Library, Boston, United States, [6]The Fenway Institute, Fenway Health, Boston, United States

Background: Transgender women living with HIV experience significant mental health disparities due to intersecting vulnerabilities, including stigma, discrimination, and systemic inequities. This scoping review aimed to synthesize the global prevalence of mental health outcomes among transgender women living with HIV.
Methods: A comprehensive search was conducted across six databases (Embase, Medline, Web of Science, PsycINFO, CINAHL, Cochrane CENTRAL) on September 7, 2023, using terms related to transgender women, HIV, and mental health outcomes. Eligible studies reported quantitative data on transgender women and transfeminine people (e.g., hijra, travesti) living with HIV.
Exclusion criteria included studies not in English, qualitative studies, non-peer-reviewed articles, protocols, studies with mixed populations where outcomes of transgender women could not be extracted separately (e.g., cisgender women, cisgender men who have sex with men, transgender men, nonbinary people), and studies not reporting outcomes by HIV status.
Results: A total of 5,489 records were identified, deduplicated, and screened by two independent reviewers for eligibility. Following the screening process, 51 studies met the inclusion criteria, encompassing 6,110 transgender women living with HIV across 13 countries.
The ranges of mental health prevalences were:
1. depression: 16.04%-62.60%;
2. suicidal ideation: 15.60%-48.96%;
3. Ssuicide attempts: 7.80%-38.30%;
4. anxiety: 32.26%-51.22%;
5. post-traumatic stress disorder: 39.58%-40.00%;
6. tobacco use: 32.67%-68.34%;
7. hazardous alcohol use or at-risk alcohol use: 6.35%-77.00%;
8. binge drinking: 18.22%-43.00%;
9. substance use (any): 13.11%-73.17%;
10. marijuana: 18.87%-63.53%;
11. cocaine: 6.19%-82.75%;
12. crack cocaine: 5.66%-85.71%;
13. amphetamines and other stimulants: 2.87%-58.49%;
14. opioids: 2.60%-28.57%;
15. injectable drug use: 0%-47.82%;
16. other substances (e.g., poppers, LSD, ecstasy, sedatives, ketamine, PCP, barbiturates): 0.94%-44.60%;
17. polysubstance use: 22.53%-25.97%;
18. chemsex: 8.27%-55.84%; and 19) stigma/discrimination: 21%-93.54%.
Conclusions: This review highlights the disproportionate burden of mental health challenges faced by transgender women living with HIV, emphasizing the critical need for tailored interventions. The findings underscore the importance of integrating culturally tailored, trauma-informed, and stigma-reducing strategies into HIV care.
Addressing these disparities requires implementing policies to reduce structural inequities and scaling up focused interventions to improve mental health and HIV outcomes for transgender women.

EP0744

Quality of HIV services offered to GBTQ persons in differentiated One-Stop-Shop (OSS) clinics in Lagos State, Nigeria

G. Ekpo[1]
[1]The Rainbow Alive Hub Initiative, Programmes, Ifako-Ijaiye, Nigeria

Background: The study assesses the quality of HIV services for GBTQ individuals in Lagos OSS clinics, identifying gaps, biases, and service deficiencies. Objectives include evaluating service accessibility, effectiveness, and satisfaction while providing recommendations for improvement. Hypotheses test service quality, disparities, and biases affecting specific demographic groups.
Methods: This mixed-method study in Lagos State focused on GBTQ individuals attending OSS clinics. Data was collected via Google forms and focus group discussions, using snowball sampling. Analysis involved descriptive statistics and SPSS. The study explored service utilization, quality, gaps, and biases, providing recommendations for service improvement.
Results: The study involved 215 respondents accessing HIV services at One-Stop-Shop (OSS) clinics in Lagos State, Nigeria. Most respondents (46.5%) were aged 21–25, and 51.6% identified as cis-male. Regarding sexual orientation, 52.1% identified as gay and 41.4% as bisexual. A majority (55.8%) had tertiary education, while 37.2% were employed. Income levels showed 44.2% earned below ₦50,000.

HIV services were utilized by 85.2% of respondents, with HIV testing (64.7%), information (60%), and condom/lubricant distribution (59.1%) being the most accessed. Quality assessments found 54% agreed services were accessible, 45.1% found scheduling efficient, and 28.8% rated care at 4/5.

Identified challenges included delays in services (19.1%), lack of GBTQ-specific knowledge (40%), and staff shortages (34.9%). Respondents recommended hiring more staff, improving service friendliness, and expanding clinic access to address biases and enhance service delivery.

Conclusions: This study highlights key insights into the accessibility, utilization, and quality of HIV services for GBTQ individuals in Lagos State. While OSS clinics play a vital role, challenges persist, including accessibility issues, service inefficiencies, and stigma. Improved staffing, extended service hours, and cultural competency training are recommended to enhance care delivery.

EP0745

Key findings and lessons learned from a pre-exposure prophylaxis (PrEP) demonstration project among people who use drugs (PWUDs) in Johannesburg

N.G. Zuma[1], A.E. Manyuchi[1], M. Mabitsi[2]

[1]Anova Health Institute, PWUD Program, Johannesburg, South Africa, [2]Anova Health Institute, Chief Executive Officers, Johannesburg, South Africa

Background: Rolling out pre-exposure prophylaxis (PrEP) as part of HIV prevention in South Africa's harm reduction programs is a new approach, with limited research available. Uptake and sustained use of PrEP among people who use drugs (PWUDs) face barriers such as skepticism, misinformation, and a lack of tailored information. However, PrEP remains a critical prevention option for this high-risk group.

Description: The Anova Health Institute implemented a tailored PrEP demonstration project for PWUDs through its existing harm reduction program, JabSmart. The project aimed to improve PrEP literacy, uptake, and adherence. Peer educators provided basic PrEP information at PWUD sites and referred eligible clients to the psychosocial support (PSS) team for comprehensive counseling, readiness assessments, and identifying social barriers to retention. The PSS team worked with clients to create personalized support plans and evaluate family reunification opportunities. After PSS sessions, eligible clients were referred to professional nurses for clinical counseling and PrEP initiation.

Lessons learned: From September to October 2024, 53 clients (37 males and 10 females) were initiated PrEP. A PrEP retention review in January 2025 showed that 52 out of 53 clients remained on PrEP. One client discontinued due to pill fatigue, and another one was treated for an STI. The PSS team addressed social and mental health challenges among 53 PWUDs. The pilot project revealed a knowledge gap about PrEP among PWUDs and showed that traditional methods like posters and pamphlets in healthcare facilities do not effectively reach this group. Instead, using harm reduction program networks for PrEP education proved more effective in reaching PWUD communities in their hotspots. This suggests that PrEP education should be integrated into trusted, accessible community channels to improve engagement and retention. The data above indicates that PWUD clients can be retained on PrEP when appropriate support is provided.

Conclusions/Next steps: Targeted PrEP education through existing PWUD interventions is essential. Integrating PrEP into harm reduction programs is a highly effective strategy to reach diverse PWUD communities. Additionally, PSS teams must be integrated with clinical teams to assist in addressing mental health and PrEP engagement and adherence.

EP0746

Understanding benefit-burden acceptability thresholds for HIV prevention vaccines among key and vulnerable populations: insights from a choice experiment in Uganda, South Africa and India

P. Saha[1], J. Mukherjee[1], V. Chakrapani[2], H. Makkan[3], M. Atujuna[4], M. Wallace[4], R. Kawuma[5], A.K. Srikrishnan[6], K. Ondeng'e[7], Y.W. Machira[7], S. ul Hadi[1]

[1]IAVI, Gurugram, India, [2]Centre for Sexuality and Health Research and Policy, Chennai, India, [3]The Aurum Institute, Rustenburg Clinical Research Centre, Rustenburg, South Africa, [4]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [5]MRC-UVRI-LSHTM Uganda, Entebbe, Uganda, [6]Y R Gaitonde Centre for AIDS Research and Education, Chennai, India, [7]IAVI, Nairobi, Kenya

Background: As novel HIV vaccine strategies are being pioneered and tested globally, it is essential to understand the unique value these next generation of vaccines hold for end-users, especially within the context of a rapidly expanding HIV prevention toolbox.

This study explored the key drivers of product choice that shape demand and value perception of HIV vaccine among currently reached and emerging risk networks, proliferating on digital platforms.

Methods: Employing threshold technique of preference elicitation to identify critical benefit-burden tradeoffs (Hauber et al 2021, Parikh et al 2023), an end-user choice experiment was conducted during September-December 2024, among 970 individuals including sex workers, men who have sex with men, transgender women, fisherfolks, adolescent boys and girls and long-haul truck drivers from India, Uganda and South Africa. Six scenarios faced off varying levels (high, moderate, low) of benefits including degree and duration of protection against burdens including multiple vaccination shots and side effects.

Participants were subjected to a scenario-based choice path starting from minimum levels of benefits and burdens to quantify maximum level of risk accepted for desired benefit.

Results: The choice experiment data across all populations and regions revealed an overarching tolerability of higher burdens to achieve desired benefit, however, there are consequential attributes that shape the product choice. Some key findings include:

- 89% respondents were willing to opt for a vaccine with multiple vaccination shots (6-8 injections over 2.5 years) as their **maximum acceptable risk/burdens** to achieve various benefits. 60% accepted this burden for **minimal acceptable benefits** of moderate degree (40-60%) and longer duration of protection (2-7 years) than available options.
- 21% were **consistently willing** to tolerate severe and rare side effects for various levels of both degree and duration of protection, while other 19% were **consistently averse** to any side effects for even highest degree (>80%) or longest duration (>8 years) of protection.
- Duration of protection and side effects emerge to be important decision factors driving nuanced preference trade-offs.

Conclusions: These data provide critical insights into potential HIV vaccine attributes that significantly influence acceptability, aiding in the strategic positioning of HIV vaccines and informing product design in its early development phase.

EP0747

HIV among key populations: addressing the cultural deficiencies of Afghan female refugees in Pakistan

A. Rubab[1], B. Rani[1]
[1]*BAHAM Foundation, Program, Lahore, Pakistan*

Background: Afghan female refugees in Pakistan, particularly those residing in camps, face unique challenges that heighten their vulnerability to HIV and limit access to prevention, care, and treatment services. Isolated from the broader society, these women encounter severe social exclusion and linguistic barriers that prevent them from engaging with the local population and accessing vital healthcare services. Many Afghan women in refugee camps resort to sex work for survival, where they face difficulties in negotiating safer sex practices, such as condom use, and fair wages with network operators due to their inability to communicate effectively. These compounded issues increase their risk of HIV and other sexually transmitted diseases. Tailored interventions are necessary to address the socio-economic, linguistic, and cultural barriers.
Methods: This qualitative study conducted 10 in-depth interviews and a focus group discussion with Afghan Female Refugees, focusing on those involved in sex work. Participants were selected based on their migrant status, sex work involvement, and HIV vulnerability. The study explored barriers to accessing HIV prevention and care services, particularly in the context of language, social isolation, and limited healthcare access due to language barrier and cultural diversity. Thematic analysis identified key challenges and care gaps.
Results: The study revealed that Afghan women face significant barriers to HIV care. Language was the primary barrier preventing effective communication with healthcare providers and clients, making it difficult to negotiate condom use and fair wages. Social isolation, fear of discrimination, and lack of knowledge about HIV prevention and sexual health further exacerbate their risks. Overcrowded and unsanitary camp conditions increase susceptibility to other health problems, while a lack of education leaves many women vulnerable to both HIV and violence.
Conclusions: Addressing the needs of Afghan female refugees requires a multifaceted approach, including culturally appropriate healthcare services with language support, mobile health clinics, and peer networks. Legal protections against exploitation and gender-based violence, along with public health campaigns, are essential. International support for refugee-inclusive HIV programs is critical to improving outcomes for this vulnerable group.

EP0748

Stigma, discrimination and other factors are associated with the decision to migrate among Jamaican MSM living with and at-risk for HIV

K. Walton-Levermore[1], J. Brown-Tomlinson[1], H. Hall[1], X. Biggs[1]
[1]*Jamaica AIDS Support for Life, Kingston, Jamaica*

Background: Stigma and discrimination significantly impact the lives of men who have sex with men (MSM) living with or affected by HIV in Jamaica, influencing their access to healthcare, employment, and housing. This environment contributes to high levels of social exclusion and drives the desire to migrate in search of safer, more accepting conditions. Despite public health interventions, MSM in Jamaica face pervasive discrimination, which is compounded by legislative barriers such as the "buggery" law.
This study aims to examine the association between stigma and discrimination and the migration decisions of MSM, highlighting socio-economic, cultural, and political factors.
Methods: A mixed-methods, cross-sectional observational study was conducted between August and October 2023. Data were collected via surveys from 317 MSM clients accessing HIV prevention and treatment services in four high-burden parishes, desk reviews of 85 medical dockets from MSM who migrated, and 15 key informant interviews with MSM who had already left Jamaica. Quantitative data were analyzed using descriptive statistics and chi-square tests, while qualitative data from interviews provided deeper insights into lived experiences.
Results: The findings indicate that 81.4% of respondents experienced discrimination, with verbal abuse (75.7%) and physical violence (22.7%) being the most common forms. Approximately 85.5% of participants expressed a desire to migrate, citing reasons such as personal safety (48.3%), freedom to express their identity (65%), and employment opportunities (64%). Desk reviews showed that 89.3% of MSM remained adherent to HIV treatment until migration, with 88.9% achieving viral suppression. Interview respondents highlighted experiences of discrimination in workplaces, housing, and social settings, with many feeling unsafe in public spaces.

Conclusions: Stigma and discrimination are significant push factors driving MSM to leave Jamaica. The study highlights the need for policy reforms, including the repeal of discriminatory laws, implementation of anti-discrimination legislation, and greater public education to foster inclusion. Enhancing safe spaces and mental health support services is crucial to improving the quality of life for MSM and reducing the need for migration. Addressing these issues aligns with Jamaica's Vision 2030 goals and can contribute to social and economic development.

EP0749

Engaging displaced girls as leaders in HIV conversations and Sexual and Reproductive Health and Rights (SRHR): a case study from Adamawa State, Nigeria

A. Bassey[1], W.K. Markus[2], S.G. Michael[1]
[1]University of Calabar, Public Health, Calabar, Nigeria, [2]Modibbo Adama University, Department of Tropical Health, Adamawa, Nigeria

Background: According to Humanitarian Need Response Plan (HNRP) report, conflict and insurgencies (like Boko Haram) have led to over two million internally displaced persons (IDPs) as of January 2025 in North-Eastern Nigeria. Around 7.8 million people urgently need aid, with young women and girls disproportionately affected, undermining their Sexual and Reproductive Health and Rights (SRHR) and increasing their vulnerability to HIV and other STDs. Displacement exacerbates misinformation, stigma, restricted access to essential services, unplanned pregnancies, and heightened STD risks.
Recognizing these challenges, the Today for Tomorrow Initiative developed a project to equip displaced girls from three Adamawa State IDP camps with vital SRHR and HIV education, along with leadership skills.
Description: Implemented from July 2021 to October 2024, this project trained 740 girls (185 yearly), aged 15–24, focusing on HIV prevention, leadership development, and SMART advocacy. After their intensive training, these girls facilitated weekly peer sessions in both IDP camps and host communities, establishing safe spaces for open dialogue on SRHR. Monthly healthcare professional visits and mentorship ensured consistent support, while local radio programs run by the girls reached broader audiences.
Lessons learned: Social and behavioral change can be achieved using a Target Right Holders approach, where direct engagement and co-implementation by beneficiaries fosters ownership. Through this strategy, 740 girls reached 7,401 peers affected by displacement.
A post-monitoring approach at mid-year intervals demonstrated a 76% improvement in knowledge of SRHR and HIV prevention. HIV testing increased by 37%, and 40% of married young women adopted family planning methods, reversing the trend of high birth rates among younger mothers.
One participant advanced to a National Diploma program in Sexual Reproductive Health and intends to become an expert, illustrating the broader impact on personal development.
Conclusions/Next steps: This rights-holder inclusion initiative highlights the transformative potential of engaging displaced girls and young women as leaders in SRHR and HIV education in conflict settings. Beyond imparting knowledge, nurturing leadership creates sustainable advocacy and community-driven progress.
Scaling this model to other conflict-prone areas and IDP camps is imperative. By involving them in advocacy, these programs foster not only immediate health gains but also sustainable community involvement.

EP0750

PrEP4Her: a gynecology clinic-based multi-level intervention to increase PrEP prescriptions among women in the southern United States

A. Mahone[1], G. Watson[2], B. Johnson[3], L. Matthews[3], M.-C. Kempf[4], A. Williams[3], J. Cleveland[3], M. Mugavero[3], L. Elopre[3]
[1]University of Alabama at Birmingham, Center for Outcomes and Effectivness Research and Education, Birmingham,, United States, [2]University of Alabama at Birmingham, Birmingham, United States, [3]University of Alabama at Birmingham, School of Medicine, Birmingham, United States, [4]University of Alabama at Birmingham, Schools of Nursing, Public Health and Medicine, Birmingham, United States

Background: In the Southern United States, HIV racial disparities among women remain consistent despite the availability of effective biomedical interventions. Studies indicate that women prefer to receive PrEP in non-HIV settings, like gynecology (GYN) clinics. However, few studies have developed effective interventions for GYN clinics.
We developed and pilot-tested a multi-level, GYN clinic-based intervention (PrEP4Her) over 6-months, including the evaluation of PrEP prescription increases, and feasibility and acceptability of the intervention.
Methods: The multi-level PrEP intervention implemented between January-August 2024 included: asynchronous clinic-wide trainings, pocket clinical care guides, client brochures, a PrEP order set in the electronic health record (EHR), a client and provider PrEP informational website, and a PrEP champion consultant.
Data including demographics, sexual health history, health behaviors and clinic-based PrEP engagement were collected during clients' routine care visit to the GYN clinic. EHR data captured the number of PrEP prescriptions prescribed throughout the study period. SAS statistical software, version 9.4, was used for demographic tables and frequency distributions.
Results: In total 311 consented to participate, 258 had fewer than 18 missing responses and were included, resulting in a sample size of n=258. Most women (69%) identified as Black/African American and reported less than a college education (80%). Most respondents, 79%, were Medicaid enrolled with annual household incomes less than $30,000 (67%).
When surveyed about sexual behaviors, 82% of women reported having vaginal or anal sex within the past six months and 52% indicated they never used condoms

when having any type of sex. Preliminary results show more than half of respondents saw HIV prevention or PrEP materials in the clinic (58%) and 45% spoke with her provider about PrEP. Thirty-one women (12%) self-reported being prescribed PrEP during their clinic visit. Among them, 20 PrEP prescriptions were verified in the EHR.
Following discussions about PrEP with their provider, women felt comfortable talking about PrEP (84%), understood PrEP side effects (83%), and discussed paying for PrEP (77%).
Conclusions: Multi-level interventions address barriers to PrEP prescriptions and ultimately have the potential to decrease HIV rates among marginalized populations, like Southern, Black women in the United States.

EP0751

Clarifying AIDS-related mortality: exploring the causes of death among PLHIV in Jamaica accessing care at Jamaica AIDS Support for Life (JASL)

J. Brown-Tomlinson[1], X. Biggs[1], K. Walton-Levermore[1]
[1]Jamaica AIDS Support for Life, Kingston, Jamaica

Background: AIDS-related mortality in Jamaica is currently assessed by including all deaths among people living with HIV (PLHIV), regardless of the actual cause. This broad approach impacts the perceived effectiveness of HIV treatment programs and may obscure critical healthcare gaps. Differentiating between AIDS-related and non-AIDS-related deaths is essential for accurately evaluating the impact of antiretroviral therapy (ART), identifying service delivery shortcomings, and designing targeted interventions to reduce preventable deaths.
Jamaica AIDS Support for Life (JASL), a community-based organization with retention rates exceeding 90%, provides a robust dataset for such an analysis and contributes significantly to the national HIV response.
Methods: A retrospective desk review was conducted on all PLHIV on the JASL register reported deceased between January 1, 2018, and December 31, 2022. Data collection involved three key methods: case identification through the Treatment Services Information System (TSIS), validation with the National Death Registry via the Registrar General's Department, and verification through consultations with immediate family and friends when official records were unavailable.
Results: A total of 52 death records were identified, consisting of 21 females and 31 males, with 16 self-identifying as men who have sex with men (MSM). Among these, the cause of death was determined for 45 cases. Verification sources indicated that 56% of deaths were confirmed through the Registrar General's Department, 31% through family and medical staff, while 12% remained unknown. The primary causes of death included advanced HIV disease (25%), co-morbid conditions including cancer (46%), violent deaths, including murder and suicide (19%), and motor vehicle accidents (2%).
Conclusions: While HIV continues to contribute to adverse health outcomes, a considerable number of deaths are linked to non-HIV-related conditions. However, the interplay between HIV and co-morbidities should not be overlooked. The high number of violence-related deaths, particularly among MSM(9 of 10 cases), underscores the urgent need for targeted violence prevention strategies within HIV programming. A holistic approach is necessary, integrating ART education, retention efforts, and comprehensive co-morbidity management to improve survival outcomes.
Further exploration of the socio-cultural context of MSM in Jamaica is critical to addressing underlying factors contributing to violence and stigma within this vulnerable population.

EP0752

Transforming HIV prevention & care: tailored solutions through prioritizing sociodemographic profile of PWIDs through integrated One Stop Centre Intervention Project funded by GFATM in India

K. Biswas[1], B. Borah[1], R. Rana[2], M. Asif[2]
[1]Plan International (India Chapter), Monitoring & Evaluation- GF, Delhi, India, [2]Plan International (India Chapter), Programme, Delhi, India

Background: Though the overall adult HIV prevalence remains low in India, HSS 2021, HIV prevalence was estimated to be at 9.03% among PWID. Complementing Govt. of India's effort to end AIDS by 2030, Plan India is implementing innovative One Stop service project for PWID through community led One Stop Centre project funded by The Global Fund.
Description: The project is guided by three strategic objectives:
1. To reach out to and identify new & unreached PWID population through expanding service coverage beyond HIV prevention,
2. To provide enabling environment to the PWID community and thus, reduce Stigma & Discrimination,
3. Empowerment of the PWID communities through generating awareness and linking them with several social welfare and entitlement programme.
Project reached to more than 13,700 PWID during October,22 to December, 24. The data has been analysed using SPSS 26.
Lessons learned: More than 13,700 PWID has been reached through this intervention. Around 86% of the registered clients were aged less than 34 years with a mean age of 27 years. 44% (n=13759) have completed secondary education, and 15% have completed higher secondary education while 18% are illiterate.
Mostly (58%) are dependent on daily wage earnings, while 21% are unemployed. While overall positivity remained at 5.4%, Positivity is marginally higher in the age group less than 34, compared to more (OR=1.73; CI: 1.334 – 2.240).
Positivity remained higher among the illiterate & secondary educated group (OR=1.334; CI: 1.08 – 1.636), compared to those with higher education. 60% of the client received general physical check-up and provided with blood pressure and blood sugar screening. 15% of the client provided with overdose prevention and management orientation.

Conclusions/Next steps: Integration of general health services beyond HIV testing is a vital strategy to respond to the unmet needs of PWID population with varied sociodemographic profile. While, Plan India's OSC project demonstrates a one stop solution for medical and additional services for the communities most vulnerable, it suggests that the service delivery needs to be prioritized based on sociodemographic profile of the client. Differentiated HIV testing and services be prioritized based on the profile of the client.

EP0753

Expanding PrEP preference: the introduction of ED PrEP in South Africa through POP INN clinics

S. Chipangura[1], V. Ncube[1], L. Mathibe[1], J. Pienaar[1]
[1]The Aurum Institute, Health Systems Division: Key Populations, Johannesburg, South Africa

Background: Access to pre-exposure prophylaxis (PrEP) for key populations, such as men who have sex with men (MSM) plays a crucial role in reducing HIV acquisition rates . The use of PrEP is a personal journey with regimen preferences needing to be prioritised. The Aurum Institute, servicing MSM was the first to implement ED PrEP in South Africa with the aim to influence policy and guideline change and offer a suitable and safe alternative of PrEP regimen to MSM. Regimen choice is very important as risk profiles fluctuate and this necessitates the offering of regimes that take this into account.

Methods: From April 2022 to December 2024, all clients presenting at the Aurum clinics servicing MSM across five districts completed a PrEP risk assessment and were screened for eligibility of Event-driven PrEP. Clients that were eligible were given a diary to track their pill intake and medication to assist them to adhere to the 2+1+1 regimen.

Results: From April 2022 to December 2024, a total of 30,805 clients were offered Event-Driven (ED) PrEP to MSM across five districts in SA. Of these, 29,901 were screened, 11,298 were found eligible, and 5,291 subsequently initiated on ED PrEP. The eligibility rate for ED PrEP was 38%, with an initiation rate of 47%. Throughout the five districts under study, 216 clients transitioned from daily PrEP to ED PrEP, while 35 moved from ED PrEP to daily PrEP.

Conclusions: The introduction of the ED PrEP regimen has proven effective in expanding preferences and uptake of PrEP. Clients have autonomy over their PrEP usage. Daily PrEP also produces a pill burden that is not necessarily required, should the individual be at low risk or have infrequent condomless sex.

Event Driven-PrEP presents a safe alternative solution to MSM and TGW for HIV prevention, enabling them to take PrEP on demand based on high-risk sex acts and fluctuating risk profiles. The regimen has been well understood and adopted by the target population.

EP0754

"A life changer, miraculous thing": PrEP awareness, access, and use among trans women in Ghana

A.O. Gyamerah[1], P.K. Ayeh[2], N. Bawa[3], A.B. Tawiah[3], S. Boakye[2], P. Agbai[2], B. Boateng[2], A. Bello[4], P. Affum[2], P. Sowah[2], V. Opata[2], N.A. Vanderpuye[2]
[1]University at Buffalo, Community Health and Health Behavior, Buffalo, United States, [2]West Africa AIDS Foundation, Accra, Ghana, [3]Independent Scholar, Accra, Ghana, [4]University at Buffalo, Buffalo, United States

Background: Transgender women in Ghana have the highest HIV prevalence at 48.1%, yet little is known about their knowledge and use of pre-exposure prophylaxis (PrEP). Our study examined PrEP awareness and use among trans women and their experiences and needs regarding PrEP.

Methods: This cross-sectional qualitative study examined transgender health needs in Accra, Ghana. Between June-July 2024, we conducted two focus group discussions (FGDs) with seronegative trans women (n=15) and three FGDs with trans women living with HIV (TGW LWH;n=18) using purposive sampling. Eligibility criteria were ≥18 years; identify as trans female; seropositive/seronegative; and live in Accra. Interviews were transcribed and analyzed using thematic analysis.

Results: Mean age of participants was 25.9 years. Among seronegative trans women, most had heard of PrEP and 60.0% (n=9) had enrolled on it at some point. Many TGW LWH were also aware of PrEP; 50.0% (n=9) reported that their current/recent sexual partners used PrEP with them, 27.8% (n=5) did not use PrEP, and 16.7%(n=3) did not know their partner's PrEP status.

Many trans women considered PrEP as useful/helpful, "a life changer, miraculous thing". Some took PrEP regularly while others engaged in event-driven dosing. Factors causing participants to stop taking PrEP included medication side effects, size of pills, stigma, and busy schedules. Some engaged in risk compensation, such as condomless sex while using PrEP. Many felt that PrEP services were not trans-friendly or trans-specific.

TGWLWH reported that they never took PrEP prior to seroconversion because of lack of availability or knowledge of it. A few were previously enrolled. Many shared that they wished they knew of PrEP while they were seronegative.

A few trans women encouraged their sexual partners to use PrEP or have partners who use it to reduce transmission risk.

Despite living with HIV, a few people shared that they use PrEP, indicating a misunderstanding of how PrEP works.

Conclusions: Trans women in Ghana are aware of PrEP, with varying levels/histories of use and multilevel barriers impacting access and adherence. PrEP programming tailored to the unique needs of trans women will be key to improving PrEP knowledge/use among seronegative trans women and partners of TGW LWH.

EP0755

HIV and STI prevention experiences of transgender women in Accra, Ghana

A. Bello[1], N. Bawa[2], M. Afrooz[3], A.B. Tawiah[2], S. Boakye[4], P. Agbai[4], B. Boateng[4], P.K. Ayeh[4], V. Opata[4], N.A. Vanderpuye[4], A.O. Gyamerah[3]
[1]University at Buffalo, Buffalo, United States, [2]Independent Scholar, Accra, Ghana, [3]University at Buffalo, Community Health and Health Behavior, Buffalo, United States, [4]West Africa AIDS Foundation, Accra, Ghana

Background: Transgender women in Ghana have an HIV prevalence of 48.1%, indicating a high need for tailored HIV prevention programming. Yet little is understood about their unique HIV prevention needs. Our study examined trans Ghanaian women's experiences with HIV prevention services and factors shaping their access and use of these services.

Methods: This was a cross-sectional qualitative study in the Accra, Ghana. Using purposive sampling, we conducted two focus group discussions (FGDs) between June-July 2024 with HIV-negative trans women(n=15) about their experiences with HIV prevention services. Eligibility criteria were: identify as trans female; ≥18 years; HIV-negative; and live in Accra. FGD transcripts were analyzed using thematic analysis.

Results: Mean age of participants was 25.8 years. About 66.7% had tested for HIV ≤1 year, while 46.7% had tested for an STI≤1 year. Nearly 60.0% had a history of PrEP enrollment, with many sharing that accessibility, medication side effects, and stigma were barriers to enrollment/adherence. Many participants shared that they get HIV prevention services from peer educators and key population-friendly clinics. They lamented that most HIV prevention programs/services targeted gay, bisexual, and other MSM, often forcing trans individuals to identify as MSM to access services. Participants commonly faced gender identity-based stigma/discrimination when accessing clinic-based STI/HIV prevention services, causing them to avoid services. Additional barriers to services included a lack of professional care that is gender-affirming at clinics; inadequate trans staff at clinics; unaffordability of non-free services; and judgmental attitudes of healthcare workers rooted in religious beliefs and transphobia. Some participants reported being questioned/denied service by pharmacies when they go to purchase certain STI/HIV prevention products due to their gender identity/presentation. Many thus relied on peer educators for delivery of products such as condoms/lubricants and PrEP due to such stigma/discrimination and transportation access/cost, underscoring the need for diverse service delivery programming. Participants emphasized the urgent need for dedicated trans-friendly and trans-staffed facilities that are gender affirming to address these challenges.

Conclusions: Trans women in Ghana face significant socio-structural barriers, including transphobic stigma/discrimination and inadequate gender-affirming HIV prevention services. Tailored, accessible, trans-affirming services and peer-led interventions are essential to addressing unmet needs and improve HIV outcomes.

EP0756

Violence, housing and mother-child co-habitation among female sex workers living with HIV in Durban, South Africa

K.A. Voet[1], K. Rucinski[2], M. Mcingana[3], A. Rao[1], C. Comins[1], J. Steingo[3], H. Hausler[3], S. Baral[1], S. Schwartz[1]
[1]Johns Hopkins School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Johns Hopkins School of Public Health, Department of International Health, Baltimore, United States, [3]TB HIV Care, Cape Town, South Africa

Background: Female sex workers (FSW) in South Africa experience a high burden of physical and sexual violence that affects their overall health and wellbeing. The majority of FSW in South Africa are also mothers.

While sex work is often a means to provide for families, FSW have reported not living with their children, in part to shield their children from potential violence associated with sex work.

Methods: This analysis used data from the *Siyaphambili* study in Durban, South Africa, a randomized intervention implemented among adult FSW living with HIV aimed at improving antiretroviral therapy outcomes. Modified Poisson regression with robust variance estimation was used to quantify the association between experiencing physical and/or sexual violence ≤6 months and whether mothers lived with their children.

Other covariates of interest included age, education, current homelessness, ability to meet financial needs, drug use in the past month, and heavy drinking.

Results: 1,021/1,373 FSW in this study were mothers and included in this analysis (median age:32, IQR:28–38), of which 740/1,021 (72.5%) reported not living with their children. 59.8% (610/1,021) of mothers reported at least one recent experience of violence, with FSW who did not live with their children being more likely to experience this violence than those who did (63.8% vs. 49.1%, p<0.01).

Current homelessness was reported by 25.2% (257/1,021) of mothers, including 31.1% who did not live with their children and 9.6% who did (p<0.01).

Having had a recent experience of violence and homelessness were associated with a lower prevalence of living with children (aPR:0.82, 95%CI:0.67–1.01 and aPR:0.31, 95%CI:0.21–0.46, respectively).

Conclusions: This analysis highlights disparities in family structure, violence experiences, and housing instability among FSW living with HIV in South Africa. While FSW may not live with their children for myriad reasons, unsafe living conditions can further catalyze the separation of mothers and children and negatively impact both physical and mental health.

In the context of pervasive HIV and sex work-related stigmas, strategies and interventions that support the prevention and mitigation of physical and sexual violence, along with access to safe living spaces, should be explored to further address barriers to mother-child co-habitation among FSW.

EP0757

Assessing HIV epidemic control variables among key and general populations in Northern Nigeria

J. Ashivor[1], C. Odima[2], U. James[3], O. Rose[4], O. Olupitan[5], U. Ugwuoke[6], J. Anyanti[7], Y. Maikenti[8], M. Zamsu[9], W. Nibretie[9], O. Farinu[10], C. Ndife[10], C. Idoko[11], K. Ukueku[12], S. Makka[12], Q. Akewusola[1], O. Omede[1], S. Alabi[13], D. Mohammed[14], S. Mohammed[15], R.O. Muhammed[16]

[1]Society for Family Health (SFH)/ N-THRIP, Global Fund Project, care and treatment, Abuja, Nigeria, [2]Society for Family Health (SFH)/ N-THRIP, Global Fund Project, Care and treatment, Abuja, Nigeria, [3]University of Calabar, Public Health, Calabar, Nigeria, [4]Society for Family Health (SFH)/ N-THRIP, Global Fund Project, care and treatment, Gombe, Nigeria, [5]Institute of Human Virology Nigeria (IHVN), Programs, Abuja, Nigeria, [6]Institute of Human Virology Nigeria (IHVN), Research, Abuja, Nigeria, [7]Society for Family Health (SFH)/ N-THRIP, Global Fund Project, Programs, Abuja, Nigeria, [8]Society for Family Health (SFH)/ N-THRIP, Global Fund Project, Gombe, Nigeria, [9]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Switzerland, [10]Society for Family Health (SFH)/ N-THRIP, Global Fund Project, Ilorin, Nigeria, [11]Society for Family Health (SFH)/ N-THRIP, Global Fund Project, Abuja, Nigeria, [12]Society for Family Health (SFH)/ N-THRIP, Global Fund Project, M&E, Abuja, Nigeria, [13]Kwara State Agency for the Control of AIDS, Kwara, Nigeria, [14]Gombe State Agency for the Control of AIDS, Gombe, Nigeria, [15]Gombe state AIDS, STI, Viral Hepatitis control program, Gombe, Nigeria, [16]Kwara state AIDS, STI and Viral Hepatitis control program, Kwara, Nigeria

Background: The UNAIDS 95-95-95 target aims to diagnose 95% of HIV-positive individuals, provide ART for 95% of those diagnosed, and achieve viral suppression for 95% of those treated by 2030. The Society for Family Health, in collaboration with the Nigerian government and the Institute of Human Virology Global Fund Nigeria TB/HIV Reach and Impact Project, supports efforts to meet these goals through targeted case-finding, retention in care, and viral suppression.

This study investigates the epidemic control variables of 95-95-95 among key and general populations in health facilities across Northern Nigeria.

Methods: A retrospective, descriptive cross-sectional study was conducted using RADET data from January to December 2024. Data covered OSS clinics and supportive health facilities in Kwara and Gombe states, with one year of review for key populations and six months for the general population (Jan–December 2024).

Results: In Kwara state, 757 clients (260 males, 497 females) tested positive and were linked to treatment, with 302 deaths (121 males, 181 females). Among key populations, 358 individuals (121 males, 237 females) tested positive, with three deaths (all female). Gombe state recorded 1,030 clients (401 males, 629 females) testing positive, with 327 deaths (162 males, 183 females). Among key populations, 189 individuals (97 males, 92 females) tested positive, with 12 deaths (8 males, 4 females). Retention rates were 99% in Gombe and 97.33% in Kwara, with viral suppression rates of 95% and 94.2%, respectively.

Age significantly predicted both new HIV cases (β = 24.333; t = 3.48; p = .002) and deaths (β = 9.48; t = 2.595; p = .015), with most cases occurring among those aged 25–49 years. Gender was not a significant predictor for either outcome.

Conclusions: While progress toward epidemic control is evident among the general population, rising new cases among key populations emphasize the need for differentiated care and enhanced adherence strategies to improve outcomes and reduce mortality, particularly in high-risk age groups.

EP0758

Patient-provider relationship and engagement in HIV care: perspectives of Black men who have sex with men (BMSM) in the NNHIV cohort study

M. Walcott[1], V. Frye[2], N. Echavarria[2], A. Rodriguez[3], M. Bianco[4], V. Nandi[4], H.-V. Tieu[5]

[1]University at Albany, Rensselaer, United States, [2]Columbia University, New York, United States, [3]City University of New York (CUNY), New York, United States, [4]New York Blood Center, New York, United States, [5]New York Blood Center,, New York, United States

Background: BMSM are disproportionately affected by the HIV epidemic in the U.S., experiencing lower rates of viral suppression and higher morbidity and mortality. We examined how patient-provider relationships influence BMSM's ability to manage HIV infection.

Methods: We conducted in-depth interviews (IDIs) with 31 BMSM enrolled in the Neighborhoods, Networks and HIV Care among Men Who Have Sex with Men (NNHIV) longitudinal study.

Eligibility criteria included:

1. At least 16 years old;
2. Self-reported male sex at birth;
3. Living with HIV;
4. Reported anal sex with a man in the past 6 months, and;
5. Resided in New York City.

Data (CASI and blood draw) were collected every 6 months. The IDIs were transcribed verbatim, coded using NVivo, and analyzed using a thematic approach.

Results: Of the 31 BMSM (mean age 44.7 ± 11.9; and years since HIV diagnosis 14.4±9.3). All participants were retained in HIV care, and 54.8% were virally suppressed (<20 copies/mL). Most participants reported that their relationship with their provider positively influenced their HIV health outcome, such as viral suppression and medication adherence.

However, some felt it had no effect, while others believed it had a negative effect. Dissatisfaction with care included feelings of being rushed, poor communication, high provider turnover, and not being understood, with one participant sharing, "I've been treated like a docket."

A trusting, collaborative relation with open communication and consistency from both parties was considered essential for engagement in HIV care, with one participant stating, "This is my body. It is not the doctor's body. I am going tell the doctor what I think, and the doctor is

going to give me advice. I am going to make the final decision." Provider characteristics seen as facilitators included being patient-centered, knowledgeable, non-judgmental, capable of offering constructive feedback, and actively involving patients in managing their care. Patient characteristics viewed as facilitators included self-management, a strong desire to live, and active involvement in accessing care.

Conclusions: The findings provide recommendations for strengthening patient-provider relationships, including building trust, providing patient-centered care, and enhancing patient self-management, with an aim to improve engagement in HIV care among BMSM.

Mental health and well-being interventions, programmes and models

EP0759

Mental health status among female sex workers in Nepal

R.K. K C[1]
[1]*Jagriti Mahila Maha Sangh, Human Rights and Health Right of Female Sex Workers, Kathmandu, Nepal*

Background: Female sex workers (FSWs) in Nepal face significant mental health challenges due to pervasive stigma, discrimination, and socio-economic marginalization. These factors contribute to high rates of depression, anxiety, and trauma, yet mental health services tailored to their needs remain limited. This study explores the mental health status of FSWs, highlighting the impact of societal exclusion and gaps in support systems.

Methods: A mixed-method approach was used, combining quantitative and qualitative data collection. Semi-structured interviews, focus group discussions (FGDs), and key informant interviews were conducted with 80 FSWs across six provinces: Bagmati, Gandaki, Madhesh, Lumbini, Sudurpaschim, and Koshi. Data analysis focused on identifying common mental health issues, coping mechanisms, and access to services.

Results: The study revealed that 67% of participants reported symptoms of depression and 54% experienced severe anxiety. Many cited societal stigma and economic insecurity as primary stressors. FSWs frequently faced emotional isolation, exacerbated by fear of legal repercussions and social exclusion. Only 23% had accessed any form of mental health support, largely due to a lack of tailored services and fear of discrimination. Participants emphasized the need for community-based mental health programs integrated with existing sexual and reproductive health services.

Conclusions: Mental health challenges among FSWs in Nepal are profound and closely linked to stigma, discrimination, and economic vulnerabilities. Addressing these issues requires comprehensive, stigma-free mental health services integrated into broader health initiatives. Community-based support networks and targeted interventions are essential to improving the well-being and resilience of FSWs. Reducing societal stigma and ensuring accessible mental health care are critical steps toward enhancing their overall quality of life.

EP0760

Promoting adolescent access to mental health support and sexual and reproductive health services through safe desks in rural clinics of Choma District, Zambia

A.C. Chitonka[1]
[1]*Dynamic health institute Zambia/ Lifeline/Childline Zambia, Healthcare/ Child protection programs, Lusaka, Zambia*

Background: Adolescents in rural Zambia face barriers to accessing sexual and reproductive health (SRH) services, including stigma, lack of privacy, and limited youth-friendly facilities. Adolescents living with HIV encounter additional challenges related to mental health stigma and inadequate support. Data from Lifeline/Childline Zambia shows that over 40% of adolescent callers seek counseling on HIV prevention and SRH. This highlights the need for tailored interventions.

This project aimed to increase access to SRH services and mental health support through adolescent safe desks in Choma District, Zambia.

Description: The 12-month intervention established adolescent safe desks in rural clinics, providing confidential SRH counseling, HIV testing, mental health screenings, psycho-social support, and referrals. The desks were managed by trained peer educators and healthcare providers. Key activities included community sensitization, school outreaches, and awareness campaigns to reduce stigma and encourage service uptake. The target population was adolescents aged 10–19, particularly those living with HIV. Lifeline/Childline Zambia's data informed the identification of health needs, ensuring the intervention was tailored to the adolescents' specific needs.

Lessons learned: Community engagement, including sensitization and school outreach, helped reduce stigma and built trust in the healthcare system, resulting in a 35% increase in clinic visits and a 20% rise in HIV testing uptake. Peer educators played a vital role in creating a supportive environment, fostering trust among adolescents. The integration of mental health support with SRH services proved effective, addressing both physical and psychological needs. Preliminary feedback showed improved mental well-being among adolescents living with HIV.

Conclusions/Next steps: The findings indicate that integrating SRH and mental health services is critical to improving adolescent health outcomes, particularly for those living with HIV. Future steps include expanding the model to other rural districts, enhancing data collection, and strengthening local partnerships to ensure sustainability. This integrated care model can be adapted for other regions to contribute to broader HIV prevention and mental health strategies for adolescents in sub-Saharan Africa.

EP0761

Understanding suicidality among young people living with and affected by HIV: a systematic review

K.M. Sievwright[1,2], B.X.J. Chan[3], M. Tan[1,2], M. Ciambrone[4], V.F. Byron[5], M. Barrenechea[6], J. Knox[2,7], L. Sherr[8], C.A. Mellins[1,2], P. Kreniske[6]

[1]Columbia University, Department of Psychiatry, New York, United States, [2]New York State Psychiatric Institute, New York, United States, [3]City University of New York (CUNY), Institute for Implementation Science in Population Health (ISPH), New York, United States, [4]Wake Forest University, Winston Salem, United States, [5]Columbia University Vagelos College of Physicians and Surgeons, Department of Pediatrics, Division of Child and Adolescent Health, New York, United States, [6]CUNY, Department of Community Health and Social Sciences, New York, United States, [7]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, United States, [8]University College London, Department of Infection & Population Health, London, United Kingdom

Background: Suicide is a leading cause of death among young people (10-24 years) and suicidality a major driver of concern. For young people, living with or having family affected by HIV may increase vulnerability to suicidality, yet few evidence-based mental health interventions for this population exist.

To inform future research and intervention among this vulnerable population, this systematic review sought to identify prevalence and determinants of suicidality among young people.

Methods: Using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines, a systematic review of four online databases from January 1, 2008, to August 14, 2023 was completed.

English-language, peer-reviewed studies of any design that satisfied all of the following criteria were included:

1. Data primarily collected from 2008 onwards;
2. Study sample with mean or median age between 10 and 24 years, and;
3. Findings reported on suicidality of young people living with or affected by HIV.

Results: Among 3,737 articles identified, 54 met the above criteria. These studies took place across 19 countries, 17 included a specific study aim focused on suicidality, and only 6 studies presented data from young people affected by HIV. Regarding suicidality prevalence data: 23 studies reported on suicidal ideation (range: 0-36.4%); 13 reported on suicide attempts (range: 0.2-30.4%), and 2 reported on death by suicide (0.17 and 2.8%).

Twelve studies identified demographic, clinical, and psychosocial factors significantly associated with suicidality; depression was most consistently associated with increased likelihood of suicidality.

Conclusions: This review identified a wide prevalence range of suicidal ideation and suicide attempts among young people living with or affected by HIV. Yet, few of these studies were explicitly focused on suicidality or assessed factors associated with suicidality. Depression was the factor most frequently associated with suicidality, indicating a need for tailored mental health interventions. To close research gaps, we recommend purposely: moving beyond cross-sectional study designs, assessing protective factors, and recruiting outside health care settings and young people affected by HIV.

In settings with limited mental health services, clear and practical guidelines for the responsible conduct of research on sensitive topics such as suicidality are needed to facilitate future studies in this critical area.

EP0762

Association between quality of life and survival in HIV-associated lymphoma in Soweto, South Africa

K. Hlongwane[1,2], K. Otwombe[1,2], G. Laudin[3], N. Tshabalala[1], V. Philip[3], N.A. Martinson[1], S.L. Vogt[4]

[1]University of Witwatersrand, Perinatal HIV Research Unit (PHRU), Johannesburg, South Africa, [2]University of Witwatersrand, School of Public Health, Johannesburg, South Africa, [3]University of Witwatersrand, Chris Hani Baragwanath Academic Hospital and Faculty of Health Sciences, Johannesburg, South Africa, [4]Johns Hopkins University, School of Medicine, Baltimore, United States

Background: HIV is associated with an increased risk of lymphoma. In South Africa (SA), real-world treatment outcomes suggest that people living with HIV (PLWH) with aggressive lymphoma have a markedly poor survival. In HIV-negative lymphoma patients, quality of life (QoL) has been shown to predict survival.

This study evaluates whether QoL at time of lymphoma diagnosis can predict survival in PLWH in SA.

Methods: We enrolled an observational cohort of PLWH ≥18 years diagnosed with aggressive lymphoma at Chris Hani Baragwanath Academic Hospital between March 2022 - July 2023 in Soweto, SA. QoL was assessed using the FACT-Lym scale. All participants were followed for up to 12 months. Consent for medical record review including demographics, measures of HIV control, performance status (PS) and clinical course was obtained. Categorical data were compared by Chi-Square and survival by Kaplan-Meier.

Results: Seventy-four PLWH were enrolled, including 46 males (62%) with a median age of 44.5 years (Interquartile range; IQR: 37-50). The median CD4 count was 198.5 (IQR: 93-352) and most were on antiretroviral therapy (89%). At enrolment, 46 (62%) had a PS ≥2, 49 (66%) were diagnosed with non-Hodgkin lymphoma (NHL) and 25 (34%) with Hodgkin (HL). PLWH were followed for a median of 253 days (IQR: 41-377) and 42 (57%) PLWH died. Median FACT-G and FACT-Lym scores at enrolment were 62.5 (IQR: 49-72) and 93.5 (IQR: 76-111), respectively. Mortality was associated with lower CD4 count (118 vs 263.5, p=0.002), lymphoma subtype (65% NHL vs 40% HL, p=0.038), PS ≥2 (81% vs 38%, p<0.001) and lower FACT-Lym score at enrolment (87 vs 102, p=0.043). Despite the higher mortality for participants with NHL, there was no difference in FACT-Lym scores between participants with NHL and HL. FACT-Lym scores did correlate with PS, a known predictor of mortality, as a PS ≥2 was associated with a lower FACT-Lym score (85.5 vs 107, p<0.001).

Conclusions: QoL at time of lymphoma diagnosis in PLWH is associated with mortality, as measured using the FACT-Lym scale. This represents an important tool to help identify high-risk PLWH for close monitoring and early palliative care intervention to improve outcomes.

EP0763

Mental health and well-being interventions for youth living with HIV in Africa: a systematic review

R. M. Kilonzo[1], R. Mutua Kilonzo[1], B. Roger L.[1], L. Kizza[2], O. Norbert Bichene[1], E. Mupakile[3], S. Nalugo[4], M. Mitembo[5]
[1]East Tennessee State University, Community and Behavioral Health, Johnson City, United States, [2]Makerere University Joints AIDS Program, Adolescent and Youth, Kampala, Uganda, [3]Kabangwe Creative Initiative Association, Adolescent and Youth, Lusaka, Zambia, [4]ISC Member, Chapter for Young Women, Adolescents and Girls, Toronto, Canada, [5]Institute St Joseph's College of Maine Graduate School Department, Nursing: Masters of Psychiatric-Mental Health Nurse, Durham, United States

Background: Youths aged 15–24 living with HIV in Africa face significant mental health challenges, including stigma, depression, and anxiety. These issues adversely affect their adherence to antiretroviral therapy (ART) and overall quality of life. This systematic review consolidates evidence on interventions to improve this population's mental health and well-being.
Methods: A systematic search of databases, including PubMed, PsycINFO, and African Journals Online, was conducted for studies published between 2000 and 2024. Eligible studies examined integrated HIV and mental health care, psychosocial support, and cognitive-behavioral therapy (CBT) targeting young people with HIV in African contexts. Data collection and analysis followed PRISMA guidelines, utilizing thematic synthesis for qualitative findings and meta-analysis for quantitative data.
Results: The review of 10 studies involving 3,800 participants across Africa revealed significant improvements in ART adherence, mental health outcomes, and resilience, with reductions in anxiety and depression. Peer-led initiatives like Zimbabwe's CATS program and integrated care models such as the Friendship Bench in South Africa and Zimbabwe were highly effective. Digital platforms like WhatsApp counseling in Kenya reduced stigma and offered scalable solutions. CBT in Uganda and stigma reduction campaigns in Malawi proved context-specific and impactful. Psychosocial support in Zambia and integrated HIV-mental health approaches in Nigeria enhanced resilience and ART adherence. Outcomes varied by age and gender, highlighting the need for culturally tailored and region-specific strategies.
Conclusions: Integrating mental health services into HIV programs is critical to addressing the multifaceted needs of young people living with HIV in Africa. Culturally tailored, community-driven, and scalable interventions are key to maximizing impact. Addressing gender-specific vulnerabilities and expanding access to evidence-based solutions are vital for improving mental health and ART adherence. Future research should focus on longitudinal studies to assess sustainability and scalability, particularly in low-resource settings where digital technologies hold substantial potential. These findings offer actionable insights for advancing HIV care and mental health support policies and practices across the continent.

EP0764

Empowering women through community-led peer support networks for improved mental health and HIV care in Morogoro, Tanzania

E. Mshiu[1]
[1]Women Rise Foundation, HIV Support Programs, Morogoro, Tanzania, the United Republic of

Background:
The Women Rise Foundation's peer support program, launched in 2024 in Morogoro, Tanzania, supports women living with HIV. It aims to reduce stigma, improve mental health, and enhance treatment adherence through safe spaces, counseling, and education. The program has engaged 150 women, offering 500+ counseling sessions and 1,000 informational materials.
Description: The Women Rise Foundation's peer support program, launched in January 2024 in Morogoro, Tanzania, targets women aged 18-45 living with HIV. It operates in urban and rural areas with high HIV prevalence and limited mental health services. The program includes 10 peer support groups led by trained women living with HIV. Key interventions include biweekly group meetings, one-on-one counseling, mental health education, and referrals to mental health professionals. Over 500 counseling sessions and workshops have reached 150 women, with more than 1,000 women receiving informational materials. The program fosters resilience and empowerment while improving HIV treatment adherence.
Lessons learned: The Women Rise Foundation's peer support program improved ART adherence and reduced stigma among women living with HIV, with 78% reporting improved adherence and 85% feeling less isolated. Key lessons included the value of culturally tailored approaches, such as using local language and traditions, and the importance of ongoing peer leader training. Community involvement, partnerships with health facilities, and engaging local leaders reduced stigma and ensured sustainability.
Challenges like transportation for rural participants were addressed through resource mobilization. Best practices, including biweekly support meetings and mental health education integration, provide a scalable model for enhancing HIV care outcomes globally.
Conclusions/Next steps: The Women Rise Foundation's peer support program highlights the significant impact of addressing mental health in women living with HIV, improving ART adherence and reducing stigma. This approach underscores the importance of integrating mental health into HIV care to enhance treatment outcomes. Expanding the program to underserved rural areas, strengthening collaborations with health facilities and policymakers, and refining peer support models through ongoing evaluations will ensure sustainability.

Advocacy for mental health prioritization in HIV care and capacity building for peer leaders are critical next steps. This program provides a replicable model for improving health outcomes in the global HIV response.

EP0765

Predictors of internalising mental disorders among Ugandan children and adolescents living with HIV: a machine learning approach

I. Okello Opio[1], D. Jjingo[2], E. Katagirya[1], D. Akena[3], S. Fatumo[4,5], E. Kinyanda[3], A. Kalungi[5,6]
[1]Makerere University, Department of Immunology and Molecular Biology, Kampala, Uganda, [2]Makerere University, African Center of Excellence in Bioinformatics, Kampala, Uganda, [3]Makerere University, Department of Psychiatry, Kampala, Uganda, [4]Queen Mary University, Precision Health Care University Research Institute, London, United Kingdom, [5]MRC/UVRI & LSHTM Uganda Research Unit, Entebbe, Uganda, [6]London School of Hygiene & Tropical Medicine, Non-communicable Disease Epidemiology, Entebbe, Uganda

Background: In Uganda, 12-27% of children and adolescents living with HIV (CA-HIV) are affected by prevalent internalizing mental disorders (IMDs). These disorders do not only contribute to impaired quality of life but also to accelerated HIV disease progression, increased healthcare utilization, poor adherence to medical care, and risky sexual behaviors.
There is need for tools to identify at risk youth for IMDs in order to implement early interventions to prevent the associated morbidity. Machine learning (ML) algorithms with their ability to handle large and complex data offer promise as possible predictive tools. This study evaluated ML models to predict prevalent IMDs among Ugandan CA-HIV.
Methods: Data from 736 Ugandan CA-HIV participants (368 IMD cases, 368 controls) from the MRC CHAKA Study (2014-2017) on mental health among HIV-infected children and adolescents in Kampala and Masaka, Uganda was analyzed. The dataset was split into training (70%), validation (10%), and testing (20%) subsets.
Supervised machine learning models were developed using the Scikit-learn library in Python (version 3.11.5) to predict prevalent IMDs, with performance evaluated via F1-score metrics.
Results: Psychosocial predictors alone yielded an F1 score of 82.76%, with key predictors being education level, age, gender, and psychosocial stress. Biological predictors achieved F1 score of 80.85%, driven by baseline and 12-month telomere lengths. Genetic predictors achieved F1 score of 80.85%, with *TPH2 rs1386494* and *TPH2 rs1843809* polymorphisms as key predictors of prevalent IMDs.
Combining all predictors resulted in an F1 score of 78.41%, with significant factors including baseline telomere length, religion, gender, 5-HTTLPR polymorphism, and stress.
Conclusions: This study demonstrates that psychosocial, biological, and genetic predictors play significant roles in prevalent IMDs among CA-HIV. Psychosocial predictors, like education, age, gender, and stress, were the strongest predictors, achieving the highest model performance. There is need for larger and more diverse datasets to Improve ML performance.

EP0766

Exploring the impact of social anxiety and mental health literacy on depression symptoms among young People Living with HIV based on a quantile regression model

H. Zhang[1], J. Han[1], Y. Su[1], J. Shi[1], H. Zhao[2]
[1]Beijing Ditan Hospital, WHO Collaborating Centre for Comprehensive Management of HIV Treatment and Care, Beijing, China, [2]Beijing Ditan Hospital, HIV/AIDS Clinical Center, Beijing, China

Background: Poor mental health can lead to adverse outcomes, including reduced immune function and faster disease progression. In China, the increasing number of young people living with HIV (PLWH) underscores the importance of understanding their mental health and related factors to design effective psychological interventions.
Methods: This cross-sectional study was conducted at a designated medical institution providing outpatient antiretroviral therapy. Established psychological scales were used to assess depression symptoms, mental health literacy and social anxiety among young PLWH. Quantile regression analysis was used to establish regression model curves at the 25th, 50th, and 75th percentiles, with different dimensions of social anxiety and mental health literacy as independent variables and depressive symptoms as the dependent variable. All scales demonstrated good reliability and validity (Cronbach's alpha > 0.85), with significance set at α = 0.05.
Results: The study collected data from 184 young people living with HIV receiving treatment at the outpatient clinic from October 2023 to July 2024, of whom 99% (183/184) were male; one female participant was excluded from the analysis. Among the 183 male participants, the median age was 25.60 years (IQR: 23.38–27.62), 53.55% had a bachelor's degree or higher, and 96.17% were single. The median PHQ-9 score was 9.0 (IQR: 3.5–14.5), with 68.85% experiencing mild or higher depressive symptoms.

Variables		Quantile percentages		
		q=25	q=50	q=75
Different dimensions of Mental health literacy	Knowledge	-0.002(-0.562,0.245)	-0.012(-0.428,0.142)	0.008(-0.437,0.346)
	Recognition	0.345(0.018,0.898)	0.431(0.258,1.004)	0.782(0.643,0.894)
	Attitude	-0.599(-0.819, -0.31)	-0.748(-0.903, -0.388)	-0.486(-0.625, -0.313)
	Behavior	-0.492(-0.895,0.119)	-0.305(-0.627,0.091)	-0.361(-0.745,0.008)
Different dimensions of social anxiety	Social recognition anxiety	0.176(0.018,0.429)	0.226(0.161,0.415)	0.339(0.062,0.43)
	Privacy concern anxiety	0.092(-0.131,0.337)	0.171(-0.012,0.356)	0.216(0.006,0.486)
	Interaction anxiety	0.315(0.137,0.436)	0.37(0.187,0.498)	0.283(0.22,0.566)

Mental health literacy dimensions "recognition" and "attitude" significantly influenced depressive symptoms, with "recognition" positively associated with depression and

"attitude" negatively associated. The strongest effect of "attitude" was observed at the 50th percentile. Social anxiety dimensions "social recognition anxiety" and "interaction anxiety" significantly affected depressive symptoms, while "privacy concern anxiety" was significant only in severe cases. "Social recognition anxiety" had a stronger effect at higher depressive levels, while "interaction anxiety" peaked at the 50th percentile.

Conclusions: Tailored interventions targeting these factors at different levels of depression may enhance the effectiveness of psychological support for young PLWH.

EP0767

Integrating mental health and psychosocial support to improve maternal health outcomes for adolescent and young mothers (aged 10-24 years) in Hatcliffe, Zimbabwe

R. Shumba[1], S. Marunda[2], J. Matenga[2]
[1]Midlands State University, Psychology, Harare, Zimbabwe, [2]REPSSI, Programmes, Harare, Zimbabwe

Background: Adolescent and young mothers in Zimbabwe, face significant mental health challenges such as depression and anxiety due to high levels of poverty, stigma and discrimination, GBV, HIV and limited access to healthcare services. These challenges, compounded by early motherhood, increase their vulnerability to common mental health disorders such as depression, negatively impacting maternal outcomes.

Recognizing this, REPSSI developed and tested a model that integrates mental health and psychosocial support with SRHR services to improve wellbeing of this population.

Description: The intervention was designed based on a psychosocial understanding of the interplay between mental well-being, socio-economic determinants, and nurturing capabilities. It incorporated a range of strategies such as economic strengthening initiatives and engagements with community leaders to promote empowerment of young mothers and create an enabling environment for their mental well-being. The intervention focused on providing accessible and culturally sensitive peer led mental health services. This included individual support, group therapy, and education sessions. These activities provided a safe space for them to address their psychological challenges faced such as parental stress, isolation, suicide ideation, and depression.

Lessons learned: The 2023 Endline Report showed an improvement in adherence to treatment and mental health outcomes, with suicidal ideation decreasing from 32% at baseline to 9% at endline. Anxiety levels significantly decreased, with average scores dropping from 40.1 to 18.6. The intervention led to a 27% increase in young mothers reporting independent income illustrating the important role played by economic independence for young mothers, contributing to reduced parental stress. Additionally, the community engagement and creation of safe spaces led to increased feelings of safety, with respondents reporting a rise in community support and emotional and financial support from their partners.

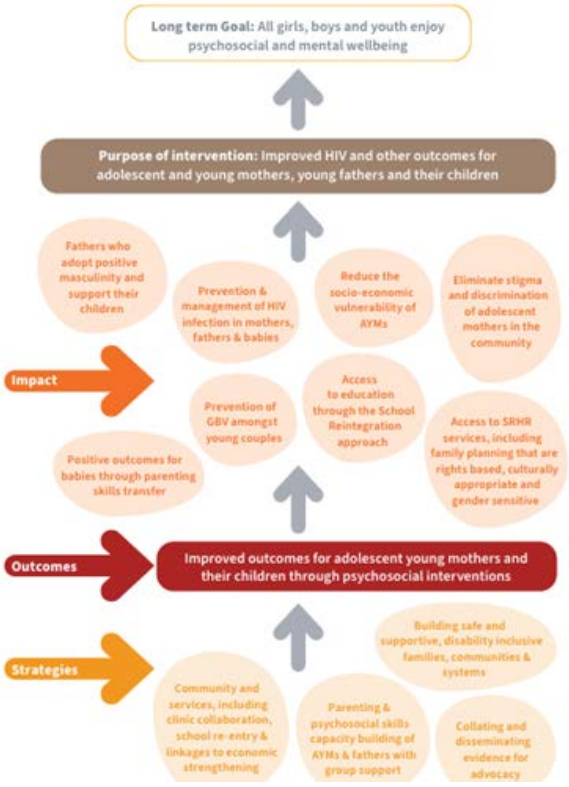

Figure. Theory of Change.

Conclusions/Next steps: By addressing the psychosocial and economic needs of young mothers, REPSSI's model enhances resilience, promotes SRHR access, and improves their mental wellbeing.

EP0768

Correlates of lifetime use of mental health and substance use services among youth with HIV in the United States

M. Stoner[1], T.B. Neilands[2], K. Ming[2], L. Smith[2], C. McCuistian[3], C. Balaban[2], H. Patani[4], K. Asman[1], V.A. Gruber[3], E. Moore[2], Y. Granados[4], M.O. Johnson[2], P. Saberi[2]
[1]RTI International, Oakland, United States, [2]Center for AIDS Prevention Studies, University of California San Francisco, San Francisco, United States, [3]University of California San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States, [4]AIDS Healthcare Foundation, Los Angeles, United States

Background: Youth and young adults with HIV (YWH) have higher rates of substance use (SU) and mental health (MH) challenges, including depression, anxiety, and post-traumatic stress disorder (PTSD). Despite the needed support for YWH in the US, many do not obtain MH or SU services due to barriers such as access, financial and housing instability, and stigma. We examined correlates of having ever used MH and SU services among YWH in the US.

Methods: We used baseline data from YWH (18–29 years old) enrolled from 2023-2024 in a randomized trial addressing HIV care barriers, MH, and SU. We examined relationships between self-reporting of having ever used MH or SU services with correlates including housing stability, economic stability, stigma, sleep quality, social support,

and HIV knowledge. We examined descriptive statistics and used log-Poisson models with robust standard errors to estimate risk ratios (RRs) adjusted for age, sex at birth, and race/ethnicity.

Results: Among 91 YWH enrolled at baseline, the median age was 27 years (interquartile range 24-28), 34.1% (n=31) had moderate to severe symptoms of depression, 35.2% (n=32) had moderate to severe symptoms of anxiety, 30.8% (n=28) had moderate to severe SU disorder, and 27.5% (n=25) had a likely diagnosis of PTSD. Roughly 65% (n=59) had ever received MH services and 19.8% (n=18) had ever received SU services.

Of those with moderate to severe symptoms of depression, anxiety, or PTSD (n=40), 72.5% (n=29) had ever received MH services. Of those who reported moderate to severe SU disorders (n=28), 39.3% (n=11) had ever received SU services.

Those who had received MH services had lower HIV stigma (RR 0.9, 95% CI 0.96-1.00, p=0.024), and higher MH (RR 1.02, 95% CI 1.01-1.04, p=0.008) and SU treatment stigma (RR 1.02 95% CI 1.01-1.04, p=0.003). We did not observe statistically significant associations between other factors and MH services, or with SU services.

Conclusions: YWH who accessed MH services had lower HIV stigma but also higher stigma around MH and SU treatment. Interventions are needed to address stigma in seeking MH and SU care and to ensure that those who do access services receive quality care.

EP0769

The incidence of intentional self-harm in insured people with and without HIV in South Africa

A.D. Haas[1], V.W. Skrivankova[1], M. Tlali[2], N. Folb[3], C. Chinogurei[2], S. Seedat[4], M.-A. Davies[2], M. Egger[1], G. Maartens[2], J.J. Joska[2], S. Rabie[2], IeDEA Southern Africa

[1]University of Bern, Bern, Switzerland, [2]University of Cape Town, Cape Town, South Africa, [3]Medscheme, Cape Town, South Africa, [4]Stellenbosch University, Cape Town, South Africa

Background: The dual burden of HIV and suicide is a major public health concern in South Africa. This study investigates the incidence of intentional self-harm by HIV status among members of South African medical insurance schemes.

Methods: We analyzed claims data (01/2011-10/2022) from people with and without HIV aged ≥10 years who enrolled with a private-sector HIV program or a medical insurance scheme. We estimated the incidence of a first healthcare encounter for intentional self-harm by sex and HIV status using flexible parametric survival models, and calculated sex- and age-adjusted hazard ratios (aHR) for HIV and mental disorders using Cox models.

Results: We included 1,356,119 individuals, including 177,193 people with HIV. The incidence of a first intentional self-harm encounter per 100,000 person-years was 139. The highest incidence occurred in females with HIV in their early 20s, followed by females without HIV in their late teens, males with HIV in their mid-20s, and males without HIV in their early 20s *(Figure 1)*.

People with HIV were at modestly increased risk of intentional self-harm (HR 1.23, 95% CI 1.16-1.30), whereas people with mental disorders were at strongly increased risk *(Figure 2)*.

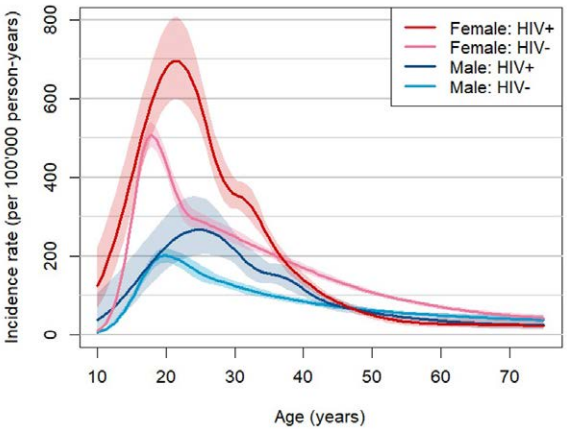

Figure 1. Incidence of a first intentional self-harm event by sex and HIV status as a continuous function of age.

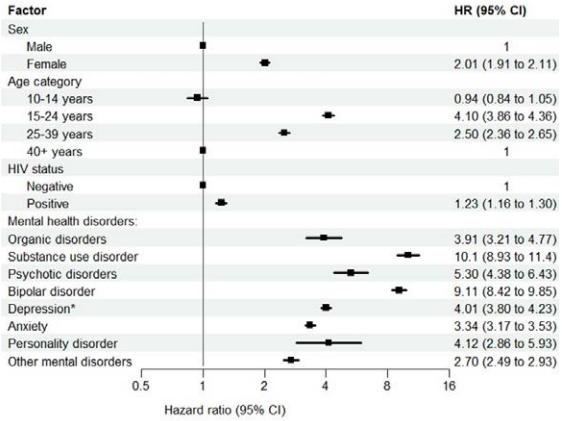

Figure 2. Risk factors for the first intentional self-harm encounter.

Conclusions: While 80% of the suicides in South Africa occur in males, we found a high incidence of intentional self-harm among young females. Importantly, our results suggest an increased risk for suicidal behavior among people with HIV, irrespective of sex.

Further research is needed to develop and evaluate models for integrating screening and management of suicidal behavior in South Africa's HIV treatment programs.

EP0770

Assessment of anxiety and depressive symptoms among gay, bisexual, and other men who have sex with men in Nepal: findings from a cross-sectional study

S.H. Sujan[1], K. Paudel[1], K. Gautam[1], A. Pandey[2], J.A. Wickersham[3], P.R. Chowdhury[4], M. Dhakal[4], S. Sharma[4], R. Shrestha[1]
[1]University of Connecticut, Storrs, United States, [2]Tribhuvan University, Kathmandu, Nepal, [3]Department of Medicine, Yale School of Medicine, New Haven, United States, [4]Blue Diamond Society, Kathmandu, Nepal

Background: Anxiety and depressive symptoms among gay, bisexual, and other men who have sex with men (GBMSM) are growing public health concerns. Despite extensive global research on these issues among GBMSM, they are understudied in low- and middle-income settings like Nepal.
Therefore, the present study focused on assessing the prevalence and associated factors of anxiety and depressive symptoms among GBMSM in Nepal.
Methods: A nationwide cross-sectional online survey was conducted among 842 GBMSM in Nepal between March and May 2024. The generalized anxiety disorder (GAD-7) and the patient's health questionnaire (PHQ-9) were employed to assess anxiety and depressive symptoms, respectively. Bivariate and multivariate logistic regression analyses examined the relationships between the outcome variables (i.e., anxiety, and depressive symptoms).
Results: The participant's mean age was 27.6 (SD=7.1) years. Overall, anxiety and depressive symptoms among GBMSM were 36.0% and 33.8%, respectively. Engagement in transactional sex and substance use were associated with increased anxiety ([aOR: 1.6, 95% CI: 1.1-2.3] and [aOR: 3.0, 95% CI: 2.0-4.6], respectively) and depressive symptoms ([aOR: 1.5, 95% CI: (1.1-2.2)] and [aOR: 1.9, 95% CI: 1.3-2.9], respectively).
Participants who had engaged in chemsex were also more likely to have depressive symptoms ([aOR: 1.6, 95% CI: 1.1-2.3]). Conversely, single participants were less likely to experience depressive symptoms ([aOR: 0.7, 95% CI: 0.5-0.9]).
Conclusions: Our study revealed a noteworthy prevalence of anxiety and depressive symptoms among GBMSM in Nepal. These findings underscore the critical need for targeted mental health interventions, specifically tailored to address the unique needs of GBMSM engaged in substance use and chemsex.

EP0771

Integrating mental health support for adolescent girls and young women aged 15-24 years in HIV prevention program in Kenya

A.N. Ikahu[1]
[1]LVCT Health, Programs, Nairobi, Kenya

Background: Adolescents and young adults attain optimal psychological, social functioning and well-being if they have adequate mental health. They possess a strong sense of self-worth and identity, healthy connections with their family and peers, ability to study and be productive, overcome developmental obstacles, and make the most of cultural resources to further their progress. Adolescents and young adults must maintain good mental health in order to engage in social and economic activities.
LVCT Health implements HIV prevention program offering life skills development, educational subsidies, and vocational training to females between the ages of 15 and 24. For this demographic, various stresses they encounter, including poverty, gender-based violence, and social stigma, worsen their mental health.
The abstract aims to describe how WHO-recommended interpersonal psychotherapy (IPT) was integrated to alleviate depression symptoms by enhancing interpersonal relationships and social functions among the girls.
Description: Mentors received training on IPT facilitation and used PHQ 2 and PHQ 9 tools to assess depression among the girls. Those with significant scores were grouped into 12-member cohorts for structured sessions facilitated by mentors, which included psychoeducation, skill-building exercises, and talk therapy. Assessments were done at midline and at termination of the sessions. Suicidal individuals were immediately referred to a psychologist.
Lessons learned: 8,787 Young women aged 15 to 24 years were sensitized on depression signs and symptoms. A total of 5,662 underwent PHQ-2 pre-assessment, and a further 3,302 were identified as depressed using PHQ-9. 3,275 participated in grouped IPT sessions. Average PHQ-9 scores stood at 13.6% at the start, decreasing to 4.4% at midline assessment and further dropping to 1.7% at termination.This confirmed decrease in depression symptoms at the end of the IPT sessions.
Conclusions/Next steps: Integrating interpersonal therapy within the HIV prevention program offers a promising avenue to address mental health concerns among Adolescents Girls and Young Women in Kenya. Scaling up the intervention and addressing attendance barriers could enhance mental health support for AGYW in a cost-effective and accessible manner.

EP0772

The impact of peer support on mental health outcome in HIV care at Baylor College of Medicine Children's Foundation Malawi in Lilongwe

V. Zulu[1,2]
[1]Lake Malawi Anglican University, Public Health, Lilongwe, Malawi, [2]Y+ Malawi, HIV, Lilongwe, Malawi

Background: Baylor College of Medicine Children's Foundation Malawi implements a peer support program aiming at improving mental health outcomes among young people living with HIV. The purpose of the program is to provide emotional support, counseling, and education to young people living with HIV. The objective of the program is to reduce symptoms of depression and anxiety, enhance quality of life, and promote adherence to antiretroviral therapy (ART).
Description: The peer support program is for a period of 24 months in Lilongwe. the program is structured into one-on-one mentoring and group sessions. Activities group discussions, counselling sessions and educational sessions through teen clubs. Interventions undertaken in support of the program includes training of peer supporters, supervision , social work and psychosocial referral-services.
Lessons learned: the program has so far reached 265 young people living with HIV, with 80% of participants experiencing positive outcomes, including reduced symptoms of depression and anxiety, and enhanced quality of life. the program has also increased social support, self-efficacy, and adherence to ART. Analysis of the programs\'s outcomes revealed that peer support is a critical component of comprehensive HIV care, addressing the complex mental health needs of young people living with HIV. Best practices includes the use of trained peer mentors, regular supervision, psychosocial referrals.
Conclusions/Next steps: Findings highlight the significance of peer support programs in improving mental health outcomes for young people living with HIV. It emphasizes the need to integrate peer support into existing HIV care services and calls for increased investment in these programs, particularly in resource-limited settings

EP0773

Psychometric properties of the IsiZulu version of the short HIV Stigma Scale (HSS) among adult people living with HIV in South Africa

M.Q. Luthuli[1,2], J. John-Langba[2]
[1]North-West University, Social Work, Potchefstroom, South Africa, [2]University of KwaZulu-Natal, Social Work, Durban, South Africa

Background: The psychosocial impact of HIV/AIDS is often unique and complex across various context, necessitating reliable tools for assessing the psychosocial factors such as HIV-related Stigma in diverse populations. This study aimed to validate the 12-item HIV Stigma Scale (HSS-12) in a sample of adult people living with HIV (PLHIV) using cross-cultural adaptation and psychometric evaluation.
Methods: A cross-sectional design was used with a sample of 141 adult PLHIV recruited from a tertiary hospital in South Africa. The HSS-12 was translated into IsiZulu version, and its measurement properties were assessed using exploratory and confirmatory factor analyses.
Results: The scale reliability was robust, with an overall Cronbach's alpha of 0.88 and for subscales ranging from 0.74 to 0.83. The exploratory factor analysis supported a three-factor structure consisting of Personalised Stigma, Disclosure Concerns, and Internalized Stigma.
Confirmatory factory analysis revealed better fit indices for the theoretical four-factor model (RMSEA = 0.055, CFI = 0.97, TLI = 0.96) compared to the empirical three-factor model (RMSEA = 0.083, CFI = 0.93, TLI = 0.91). Both models demonstrated acceptable but varying fit across indices, which highlighted areas for improvement in measuring HIV stigma constructs.
Conclusions: The HSS-12 is a reliable and valid tool for measuring HIV-related stigma among IsiZulu-speaking South African PLHIV, with strong internal consistency and factorial validity. Its use can help researchers better understand how stigma affects health and well-being of PLHIV in South Africa.
Further improvements are recommended to enhance the fit of the scale for different cultures and populations.

EP0774

Enhancing mental health and sexual health literacy through digital platforms: InspireIT's innovative approach to HIV prevention

O. Mlanzeli[1], A. Ononiwu[2], S. Ndimbira[1]
[1]Africa REACH, Cape Town, South Africa, [2]Technology for Inspiration Initiative-InspireIT, Abuja, Nigeria

Background: Adolescents in Nigeria face intersecting challenges of limited access to mental health support and comprehensive sexual health education. These gaps are exacerbated by stigma, cultural taboos, and a lack of inclusive platforms tailored to their needs.
InspireIT, supported by Africa REACH, developed a podcast that evolved into Red Ribbon, a digital health platform providing a safe space for adolescents to access reliable information on mental health, sexual health, and HIV prevention.
Description: The podcast initiative began with semi-structured interviews to identify knowledge gaps and psychosocial challenges faced by adolescent girls. Using this data, InspireIT produced engaging content that combined evidence-based SRH education with mental health topics such as managing stigma, building resilience, and fostering healthy relationships. Building on the podcast's success, the Red Ribbon platform integrates interactive tools, mental health resources, and digital literacy modules to address broader adolescent needs. Data collection includes podcast analytics, user feedback, and surveys of adolescents and stakeholders to refine the platform's design and impact.
Lessons learned: The podcast provided adolescents with a much-needed space to learn and discuss taboo topics, improving their mental health and confidence in

navigating SRH issues. Adolescents reported feeling more empowered and less stigmatised. The evolution into Red Ribbon reflects the importance of scaling innovative approaches to ensure sustainable, accessible support for adolescent mental health and HIV prevention. Preliminary insights indicate that interactive, adolescent-focused platforms can effectively combine SRH and mental health interventions.

Conclusions/Next steps: InspireIT's work illustrates the potential of digital health innovations to address the intersection of mental health and HIV prevention. Through integrating mental health support and sexual health education into a single, inclusive platform, Red Ribbon aims to build healthier, more resilient adolescents. This approach highlights the importance of holistic, community-centred strategies in advancing adolescent health and well-being.

EP0775

Dyadic internalized stigma, resilience, and psychiatric distress among people with HIV and their family members: An actor-partner interdependence mediation model analysis

F. Shi[1], X. Yang[1], S. Qiao[2], C.C. Tam[1], Y. Zhou[3], S. Liu[3], B. Olatosi[2], X. Li[1]

[1]University of South Carolina, Health Promotion, Education, and Behavior, Columbia, United States, [2]University of South Carolina, Columbia, United States, [3]Guangxi Center for Disease Control and Prevention, Nanning, China

Background: Despite the robust evidence regarding the association of internalized HIV stigma with psychological distress and the mediation role of resilience among people with HIV (PWH), less is known about the dyadic interdependence of this mechanism among PWH and their family members (FM) in a distinguishable dyadic relationship. The examination of the potential dyadic effect could contribute to a better understanding of the relationship between internalized stigma and psychological distress and shed light on potential effective interventions to mitigate the deleterious effect of internalized stigma.

This study aimed to explore the actor-partner effect and mediation role of resilience in the relationship between internalized stigma and psychological distress among PWH and their FM dyads.

Methods: Between October 2023 and December 2023, a total of 800 PWH-FM dyads were recruited from two urban cities and nine rural counties in Guangxi, China. All participants completed validated questionnaires capturing demographic characteristics, internalized stigma, resilience, and psychological distress.

This study employed the actor-partner interdependence mediation model (APIMeM) to examine both individual (actor) and dyadic (partner) pathways, along with resilience as a potential mediator.

Results: Analysis revealed that internalized stigma had significant actor effects on psychological distress for both PWH (b = 0.180, p<0.001) and their FM (b = 0.456, p<0.01). Resilience partially mediated the relationship between internalized stigma and psychological distress in PWH (b = 0.029, p<0.001) but not in their FM (b = -0.003, p=0.684). Additionally, significant indirect partner effects were observed in the association between family members' internalized stigma and PWH's psychological distress through PWH's resilience (b = 0.030, p<0.01).

Conclusions: This study underscores the complex interplay between internalized stigma, resilience, and psychological distress in PWH-FM dyads. The mediating role of resilience and the observed partner effects suggest that interventions targeting stigma reduction among FM could have far-reaching benefits for PWH.

Health professionals could adopt family-centered strategies that simultaneously focus on enhancing resilience and reducing stigma to effectively mitigate psychological distress and improve the overall well-being of both PWH and their FM.

EP0776

Enhancing ART re-engagement among clients late for pharmacy pickups through mental health interventions in four Zambian provinces from October 2023 to September 2024

C. Chambwe[1], J. Simpungwe[2], M. Chitala[3], V. Munthali[3], C. Mudenda[3], S. Kamono[3], T. Savory[3], M. Mwanza[3], F. Assefa[4], H.-Y. Kim[4], A. Bershteyn[4]

[1]Centre for Infectious Disease Research in Zambia, Clinical, Lusaka, Zambia, [2]Centers for Disease Control and Prevention, Clinical, Lusaka, Zambia, [3]Centre for Infectious Disease Research in Zambia, clinical, Lusaka, Zambia, [4]New York University, Population Health, New York, United States

Background: Engagement in HIV care and adhering to antiretroviral therapy (ART) is vital for effective HIV management, but treatment interruptions are common. These interruptions, especially among clients who have been late for pharmacy appointments for ≥ 28 days, are often driven by psychosocial challenges, stigma, transport barriers, and inadequate support. In the study period, the Centre for Infectious Disease Research in Zambia implemented the Common Elements Treatment Approach (CETA), which integrates mental health and ART adherence strategies to enhance client retention and health outcomes. CETA is a transdiagnostic cognitive behavioral therapy which manages depression, anxiety, alcohol/substance use and trauma.

Methods: This survey analyzed ART re-engagement outcomes from October 2023 to September 2024 in Lusaka, Southern, Eastern, and Western Provinces. Eligible clients were those who experienced a late pharmacy pick-up in the last 28 days and were screened for CETA using the client monitoring form (CMF), which includes validated tools to measure depression (PHQ-9), anxiety (GAD-7), and alcohol use disorder (AUDIT). Weekly CETA sessions were provided over 6–8 weeks, incorporating individual counseling and psychosocial support.

Data from the District Health Information Systems 2 (DHIS2) and SmartCare (SC) electronic health record systems were abstracted and analyzed to assess ART re-engagement, defined as active in care with consistent pharmacy visits 90 days post-intervention.

Results: The analysis revealed that 91% of clients classified as "late pharmacy pickups" successfully resumed ART after participating in CETA interventions.

Late pharmacy clients removed from Tx_Curr (Oct 2023 to Sep 2024)	Still active on ART 90 days post CETA	%active on ART after CETA	Not active	Lost to follow-up (LTFU)	Transferred out	Died	Not in Smart Care
830	758	91%	20	12	7	3	30

Table 1. Outcomes of the CETA Intervention on Late Pharmacy Pickups in Western, Eastern, Lusaka, and Southern Provinces, Zambia (October 2023–September 2024)

Abbreviations: CETA – Common Elements Treatment approach, ART – Antiretroviral therapy

Conclusions: Integration of mental health services with ART adherence strategies has the potential to improve client retention by addressing the psychosocial challenges associated with treatment.

While systemic barriers such as data inconsistencies and resource limitations may limit the impact of CETA, further exploration of these factors is warranted.

Strengthening human resources for mental health support could play a crucial role in providing comprehensive care for all recipients.

EP0777

Depression and anxiety; addressing mental health issues among individuals with HIV and HCV

O. Samwel[1], L. Lordlaro[2]

[1]Maseno University, Public Health, Kisumu, Kenya, [2]HOYMAS, Human Rights Defender, Nairobi, Kenya

Background: Health problems, especially depression and anxiety, are common in people living with HIV and HCV. Depression and anxiety can decrease treatment adherence, quality of life and ultimately health outcomes among HIV and HCV infected patients.

The aim of this study was to investigate the hybridity between mental health and viral infection, the effect of mental health on disease course and treatment compliance while suggesting applicable strategies for mental health care during these crises.

Methods: A facility-based cross-sectional survey was conducted in Kisumu, Nairobi, Kakamega and Nakuru Counties in Kenya from August to November 2023. Purposive sampling was employed to recruit 450 clients (150 each). 30 interviews and 25 FGDs were conducted to collect qualitative data which was analyzed thematically.

Structured surveys with mental assessment tools (PCL-5 for PTSD, PHQ-9 for depression and GAD-7 for anxiety were used to collect quantitative data which was analyzed using MS excel.

Results: Clients with major depression symptoms were 60%, while 45% dealt with medium to bad anxiety. Clients with mental health care inclusive of therapy, psychiatrists' help and social services stuck to their HIV/HCV treatments better and felt healthier overall and 32% without mental health help felt more stressed, judged and neglected. Talks with clients showed 84% had trouble getting mental health care while facing judgment from their culture.

Conclusions: It is key to treat mental health as part of full-body care. Care models that mix medical treatment with mental health help work well to make both mental health and virus levels suppressed. There is need for more awareness, learning and resource consolidation to deal with mental health in HIV and HCV care places with prospective Health policies and practices aiming to give these groups easy-to-access full mental health care and cut down on stigma Cultural integration is therefore critical to ensure which ways work best and ensure usability in different cultures and places with different resources.

EP0778

Higher prevalence of depression and anxiety among postpartum women with HIV than women without HIV during 3-year follow-up

W. Jiang[1], I. Njuguna[1,2], D. Wamalwa[3], M. King'e[3], A. Onyango[2], M. Kumar[3], M. Bulterys[1], J. Neary[1], H. Moraa[2], G. John-Stewart[1]

[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya, [3]University of Nairobi, Nairobi, Kenya

Background: There are few longitudinal studies examining socio-economic and demographic risk profiles of psychological disorders in postpartum mothers with HIV (MLHIV) and without HIV.

Methods: We enrolled Kenyan MLHIV or without HIV and their infants at 6-week postnatal visits. Depression (Patient Health Questionnaire-9 [PHQ-9] score ≥5) and anxiety (Kessler Psychological Distress Scale [K-10] score ≥16) were collected every 6 months for 3 years. Distress was defined as PHQ-9 score ≥5 or K-10 score ≥16. We used linear mixed effects models to identify predictors of psychological disorders, clustered by individual and site.

Results: Among 2,000 mothers (1000 MLHIV, 1000 without), median age was 29 years (IQR 25-33). Most MLHIV (98.7%) received ART during pregnancy; 77% with a DTG-regimen. MLHIV were older, less likely to be partnered, and experienced more food insecurity (p<0.001 for each).

At 6-weeks postpartum, psychological disorders were more prevalent among MLHIV (depression: 22.1% vs. 18.5%, p=0.046; anxiety: 24.6% vs. 15.8%, p<0.001; distress: 31.6% vs. 24.4%, p<0.001). Prevalence of depression and distress decreased during 3-year follow-up among all mothers (depression: 20.3% baseline vs. 10.9% at 3-years, distress: 28.0% vs. 22.8%, respectively, p<0.001); in both subgroups by HIV status for depression and among MLHIV for distress.

In longitudinal models, MLHIV had higher risks of all outcomes (depression: prevalence ratio [PR] 1.30 [95% confidence interval 1.17-1.45], p<0.001; anxiety: PR 1.15 [1.02-1.30], p=0.025; distress: PR 1.22 [1.11-1.33], p<0.001). Adjusted for maternal HIV, distress was lower among mothers who were younger (PR 0.87 [0.78-0.98], p=0.022), partnered (PR 0.72 [0.63-0.83], p<0.001) and with secondary education (PR 0.81 [0.73-0.89], p<0.001). Higher risk was associated with prenatal hospitalization (PR 1.27 [1.03-1.57], p=0.025) and food insecurity (PR 1.54 [1.37-1.72], p<0.001). Results were similar for depression and anxiety.

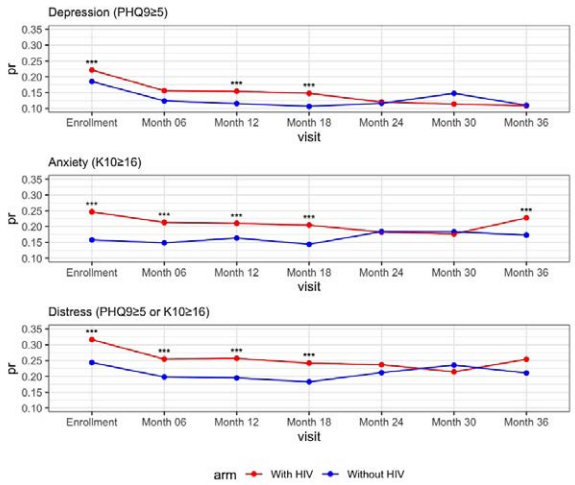

Figure 1. Proportions of psychosocial disorders over time by HIV status.

Conclusions: Our findings highlight needs for integrated mental health care in maternal-child healthcare, particularly among MLHIV and those at heightened risk for psychological disorders.

EP0779

Depressive disorder, HIV testing, and high-risk behaviors among transgender persons in a US national study

X. Li[1], V. Umutoni[2], Y. Xiang[3], J.Q. Freeman[2], Y.G. Lee[4]
[1]The Geroge Washington University, Milken Institute School of Public Health, Washington, United States, [2]University of Chicago, Department of Public Health Sciences, Chicago, United States, [3]University of Southern California, Department of Population and Public Health Sciences, Los Angeles, United States, [4]University of Hong Kong, Department of Social Work and Social Administration, Pokfulam, Hong Kong, SAR of China

Background: HIV disproportionally impacts the transgender population in the US. Depressive disorders are often associated with risk factors for HIV acquisition and health-seeking behaviors including HIV testing.
We investigated the associations between depressive disorders and HIV testing as well as high-risk behaviors among transgender adults in the US.
Methods: We analyzed data from the 2022 Behavioral Risk Factor Surveillance System. This study included respondents who self-identified as transgender male-to-female, female-to-male, or gender nonconforming.
We examined the association between ever having a depressive disorder and
1. High-risk behaviors including any drug injection other than those prescribed for you, STD treatment, or having given/received money or drugs in exchange for sex in the past year;
2. Ever tested for HIV, and;
3. Tested for HIV in the past year.
We compared weighted percentages using Rao-Scott Chi-Squared tests and conducted weighted logistic regression, adjusting for sociodemographic characteristics. All analyses accounted for complex survey design.
Results: Among 259,709 participants, 1603 (0.8%) self-reported as transgender; of them, 53.8% ever had a depressive disorder, 18.4% reported high-risk behaviors in the past year, and 41.9% ever tested for HIV. Of those who ever tested for HIV, 12.9% tested in the last year. Age, sex at birth, race/ethnicity, education, general health, and region significantly differed by depression status and were controlled in the models.
After covariate adjustment, transgender persons with a depressive disorder had higher odds of having high-risk behaviors (adjusted odds ratio [AOR]: 2.16, 95%CI: 1.23, 3.79) and ever having been tested for HIV (AOR: 1.69, 95%CI: 1.09, 2.63) than those without.
However, among transgender persons who had ever been tested for HIV, no difference was found in past-year HIV testing between those with and without a depressive disorder (AOR: 1.03, 95%CI: 0.45, 2.38).
Conclusions: In this US transgender population, depressive disorders are prevalent and lifetime HIV testing is low. We found a significant relationship between depressive disorders and high-risk behaviors, highlighting that mental health wellness should be incorporated into HIV prevention.
Our findings also suggest that improving timely HIV testing and tailored risk-reduction interventions are needed particularly for transgender persons with depression or having risky behaviors.

EP0780

The effects of nutrition and food accessibility on depression among adolescent and young people 10-24 years living with HIV in Rwanda 2024

P. Mutesi[1], J.B. Tugirimana[1], G. Mujawamariya[2], D. Mutambuka[1], G. N. Rwibasira[2]
[1]Rwanda Network of People Living with HIV/AIDS (RRP+), Kigali City, Rwanda, [2]Rwanda Biomedical Center (RBC), Kigali City, Rwanda

Background: Even with the existence of well-developed HIV care programs, there is still limited integration with nutritional and mental health support services. The study aimed to assess nutritional, food availability, accessibility and diversity factors associated with depression among Adolescent and Young People 10-24 years Living with HIV (AYPLHIV) in Rwanda.
Methods: In a cross-sectional study, 457 randomly chosen AYPLHIV who lived in Kigali and four secondary cities in Rwanda were assessed using the Patient Health Questionnaire-9 (PHQ-9) for depression. Data analysis and the scores used to classify people with depression were generated using STATA 16. The adjusted odds ratios (AOR) from bivariate and multivariable logistic regression analysis were used to measure the association, and a p-value<0.005 indicated statistical significance.
Results: The prevalence of depression was 26.5%. BMI as a proxy for nutrition status (underweight, p=0.603 and overweight/obese, p=0.636) was not associated with depression and there was no evidence that lack of food availability or diversity was associated with depression but if you often ate a smaller meal than you felt you

needed, you were 5.6 (95%CI:2.730-11.380) times as likely to be depressed than one who had access to enough food. Other factors significantly associated with depression were experience of being bullied for having HIV (OR=2.013, 95%CI:1.138-3.559), experiencing a family or household death(s) (OR=2.490, 95%CI:1.463-4.240), physical abuse, or witnessing physical violence in the home (OR=2.853, 95%CI:1.305-6.237), experience of forced sex (OR=2.072, 95%CI:1.053-4.075).

Depression was approximately 4-5 times higher among AYPLHIV where the mode of HIV transmission was sexual as compared to those where the mode of transmission was vertical. The odds of being depressed increased with the length as AYPLHIV stayed on ART treatment (p-value=0.007).

Depression was highest among AYPLHIVs who learnt about their HIV status when they heard others talking about it and lowest among AYPLHIV who were informed by their parents (OR=0.213, 95%CI:0.054-0.837).

Conclusions: The findings of this study highlighted the complex interplay of sociodemographic and psychosocial factors in influencing the mental health outcomes of AYPLHIV in Rwanda. The high prevalence of depression underscores the need for targeted interventions to address the mental health needs of this vulnerable population.

EP0781

Feasibility and preliminary impact of lay counselor delivered depression counseling for adolescents living with HIV in Malawi

N.L. Bhushan[1], T.R. Filipowicz[2], S. Mphonda[3], T. Dao[2], H. Mortensen[2], B.W. Pence[2], M.A. Stockton[4], B.N. Gaynes[2]
[1]RTI International, Research Triangle Park, United States, [2]University of North Carolina at Chapel Hill, Chapel Hill, United States, [3]UNC Project Malawi, Lilongwe, Malawi, [4]University of Pennsylvania, Philadelphia, United States

Background: Depression amongst the 1.4 million adolescents living with HIV (ALWH) in sub-Saharan Africa is prevalent and a significant barrier to HIV care engagement. In Malawi, where more than 75,000 ALWH live, estimates of depression among ALWH range from 18%–26%, and there are few resources for mental health care. Resource-appropriate interventions that improve depression and incorporate ALWH preferences for service delivery are urgently needed to improve both mental health and HIV care outcomes for this population.

Methods: Preliminary data are from a pilot 3-arm randomized controlled trial (HEADS-UP) evaluating the feasibility and impact of an evidence-based counseling intervention (Friendship Bench) on improving depression amongst ALWH (N=105) at four public health centers in Lilongwe, Malawi. Eligible ALWH (age 13-19, Beck Depression Inventory II ≥ 13) randomized to the intervention arms (n = 70) were offered six counseling sessions, where youth-friendly lay-counselors provided problem-solving therapy every 7-10 days. Depressive symptoms were monitored with the Patient Health Questionnaire-9 (PHQ-9) during counseling sessions.

Results: The median age of participants randomized to the intervention arms (N =70) was 16.3 (IQR 15.0-17.3) and more than half were female (60%). Most participants (n=67, 96%) completed all six counseling sessions with a mean duration of 6.4 weeks. Amongst participants completing all six sessions, the proportion screening positive for depressive symptoms (PHQ-9 ≥ 5) decreased from session 1 (79%, n = 53) to session 6 (25%, n = 17) by 68%. Similarly, mean PHQ-9 scores decreased from session 1 (mean: 9.1, standard deviation: 4.1) to session 6 (mean: 4.0, standard deviation: 4.1) by 63%.

The proportion of ALWH experiencing moderately severe and severe depressive symptoms (PHQ-9 > 14) also decreased from session 1 (15%, n = 10) to session 6 (1%, n=1) by 90%.

Conclusions: These preliminary results demonstrate the feasibility of engaging and retaining adolescents living with HIV and experiencing depression in a six-week counseling intervention in this setting.

The results also suggest that fewer ALWH experienced depressive symptoms, particularly moderately severe to severe symptoms, after completing all six counseling sessions, pointing to the potential of lay-counselor delivered interventions for improving mental health outcomes for this population.

EP0782

"It is the foundation for the child": caregiver perspectives on the Nurturing Care Framework in Kenya and Botswana

M. Bulterys[1], S. Garcia[2], I. Njuguna[3], K. Thankane[4], I. Kitsi[4], H. Okinyi[5], P. Mulupi[5], I. Maeri[5], S. Schenkel[6], S. Kgole[4], G. Masasa[4], A. Kellogg[2], D. Wamalwa[7], A. Cassidy[8], J. Makhema[4], G. John-Stewart[1], K. Powis[6]
[1]University of Washington, Global Health, Seattle, United States, [2]University of Washington, Epidemiology, Seattle, United States, [3]Kenyatta National Hospital, Nairobi, Kenya, [4]Botswana Harvard Health Partnership, Gaborone, Botswana, [5]University of Washington Kenya, Nairobi, Kenya, [6]Mass General Hospital, Boston, United States, [7]University of Nairobi, Nairobi, Kenya, [8]Mayo Clinic, Departments of Psychiatry & Psychology and Pediatric & Adolescent Medicine, Rochester, United States

Background: The WHO/UNICEF Nurturing Care Framework (NCF) features five domains necessary for healthy child development – physical and mental health, responsive caregiving, adequate nutrition, security and safety, and opportunities for early learning. We explored caregiver perspectives on the NCF and unique challenges faced by families affected by HIV.

Methods: Between Nov 2023 – Jul 2024, 14 FGDs were conducted with caregivers living with and without HIV; eight with mothers in Gaborone, Botswana, and six in Nairobi, Kenya (three with mothers and three with fathers). FGDs were stratified by country, sex, HIV status, and partnership status. Semi-structured interviews with interactive activities elicited perspectives on the NCF , including the "most important", "easiest", and "most challenging" domains to fulfill.

Results: Botswanan and Kenyan caregivers identified physical and mental health as the "most important" domain ("*If you have pain, that pain affects your child*").
The "most challenging" domains were adequate nutrition in Botswana, due to stigma around infant feeding choice (breast vs. formula) and widespread formula shortages. Ensuring security and safety was challenging in Kenya, because caregivers often left children in others' care during the workday.
The "easiest" domains were responsive caregiving in Botswana and opportunities for early learning in Kenya. Kenyan caregivers noted that *spiritual nourishment* was also critical for wellbeing but was missing from the NCF.
Caregivers living with HIV experienced isolation, stigma, and treatment disruption, impacting their ability to provide nurturing care; they highlighted the importance of self-acceptance, disclosure, mental health counseling, and treatment adherence.

Figure 1a. NCF activity for mothers only, by country

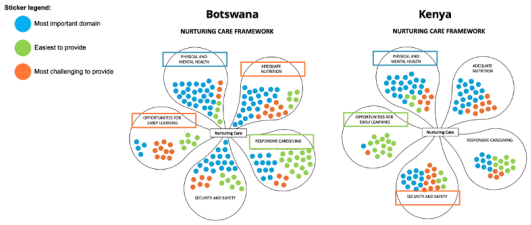

Figure 1b. NCF activity for Kenyan caregivers only, by caregiver sex

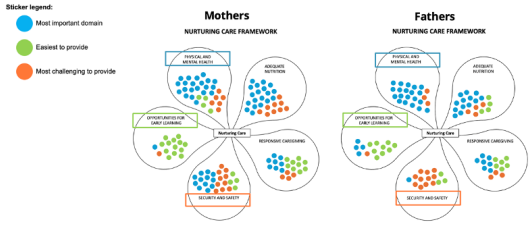

Note: Each participant was given 2 blue stickers, 1 green sticker, and 1 orange sticker to place on an individual card, to not be influenced by others' responses.

Conclusions: Caregivers faced uniqautoue challenges depending on their environments, cultural norms, and HIV status. HIV disrupts caregivers' physical and mental health, which has important implications for raising children within families affected by HIV.
Interventions that support caregivers' abilities to fulfill all NCF domains and address common challenges will be essential to ensure children reach their developmental potential.

EP0783

New awareness of a sexually transmitted infection and depressive symptom burden among women with HIV in the United States

T.R. Filipowicz[1], A. Edmonds[1], W.C. Miller[1], B. Turan[2], B.N. Gaynes[3,1], J.M. Turan[4], D.L. Jones[5], A.N. Sheth[6], M. Floris-Moore[7], G. D'Souza[8], E.M. Daubert[9], S.D. Weiser[10], D. Merenstein[11], T.N. Taylor[12], A. Adedimeji[13], B.W. Pence[1]
[1]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [2]College of Social Sciences and Humanities, Koç University, Department of Psychology, Istanbul, Türkiye, [3]University of North Carolina at Chapel Hill, Department of Psychiatry, Chapel Hill, United States, [4]University of Alabama at Birmingham, Department of Public Health, Birmingham, United States, [5]University of Miami Miller School of Medicine, Department of Psychiatry & Behavioral Sciences, Miami, United States, [6]Emory University, Division of Infectious Diseases, Department of Medicine, Atlanta, United States, [7]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States, [8]Johns Hopkins University, Department of Epidemiology, Baltimore, United States, [9]Hektoen Institute of Medicine, Chicago, United States, [10]University of California, San Francisco, Division of HIV, Infectious Disease and Global Medicine, Department of Medicine, San Francisco, United States, [11]Georgetown University, Department of Family Medicine, Washington DC, United States, [12]State University of New York Downstate Health Sciences University, College of Medicine, Division of Infectious Diseases, Brooklyn, United States, [13]Wake Forest University School of Medicine, Division of Public Health Sciences, Department of Social Sciences and Health Policy, Winston-Salem, United States

Background: Women with HIV (WWH) experience depressive symptoms at four times the rate of women without HIV. Co-infection with a sexually transmitted infection (STI) is common among WWH. For WWH, a new STI may worsen depressive symptoms via retraumatization (process that reshapes a reaction to trauma based on previous trauma).
We examined whether new awareness of an STI is associated with depressive symptoms among WWH in different racial/ethnic groups in the United States (US).
Methods: The Women's Interagency HIV Study (WIHS) is the longest standing cohort of WWH in the US. Participants attend semiannual visits for clinical examinations and health-related and psychosocial data collection. We used data from 2013-2019 on STIs (self-report or study clinicians' clinical impressions: chlamydia, gonorrhea, syphilis, herpes simplex 2, genital warts, or trichomoniasis) and depressive symptoms [CES-D 20 scores (range 0 – 60)].
We used a generalized linear model with generalized estimating equations to estimate the longitudinal association of new awareness of an STI (binary) with depressive symptoms (continuous) within five race/ethnicity strata. Inverse probability of treatment and censoring weights controlled confounding (by psychosocial and demographic factors) and loss to follow up. Standard errors for 95% confidence intervals were estimated from 200 bootstraps.

Results: Overall, 1,763 WWH contributed 14,368 visits to this analysis. Mean age was 47.1(std: 9.1) at first visit and 72.4% of participants were Black/Non-Hispanic. Across all visits, 8.5% person-visits experienced new awareness of an STI. Weighted results are below.

Stratum	Mean Difference	95% Confidence Interval
White, Non-Hispanic	-0.99	(-3.47, 1.49)
White, Hispanic	-2.80	(-5.02, -0.57)
Black, Non-Hispanic	1.56	(0.63, 2.49)
Black, Hispanic	-4.39	(-9.22, 0.43)
Other	-1.08	(-3.10, 0.95)

Table. Mean difference in CES-D Scores in WWH with new awareness of an STI vs WWH without.

Conclusions: At visits with new awareness of an STI, Black non-Hispanic WWH, but not other racial groups of WWH, had increased depressive symptoms compared to visits without. Interestingly, this relationship is reversed in all other race/ethnicity strata and warrants future investigation to understand this complex phenomenon among WWH with new awareness of an STI.

Our analyses suggest that providing increased mental health support at the time of a new STI may reduce depressive symptom burden in some populations, such as Black Non-Hispanic WWH.

EP0784

Empowering adolescents with perinatally acquired HIV: exploring Self-Efficacy for Exercise (SEE) and its impact on physical activity engagement

H. Sathyamoorthy[1], B. Seenappa[2], K. Filian[3], S. Sannigrahi[3], S. Reddy[2], M. Gowda[2], M. Babu Raj[2], S.K. Sk[4], L. Ganapathi[5], A. Shet[3]

[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]RISHI Foundation, Bengaluru, India, [3]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [4]YR Gaitonde Medical Educational and Research Foundation, Chennai, India, [5]Massachusetts General Hospital / Harvard Medical School, Division of Pediatric Global Health, Boston, United States

Background: Adolescents with perinatally acquired HIV (APHIV) face unique challenges in maintaining physical health, including barriers to regular exercise. Lifelong exposure to HIV and antiretroviral therapy (ART) contributes to metabolic disorders and chronic inflammation, potentially limiting physical capacity.

Furthermore, stigma-related psychosocial barriers can discourage participation in group exercise programs.

We aimed to assess exercise self-efficacy—the confidence in one's ability to sustain physical activity in various circumstances—to identify factors that influence the sustainability and effectiveness of exercise-based interventions.

Description: The Positive Running Program in southern India offers a structured physical activity regimen integrating running, strength training, health education, exercise physiology, and leadership development. Grounded in the Social Cognitive Theory, which emphasizes the role of self-efficacy in behavior change, we measured exercise self-efficacy in APHIV who received the intervention for at least one year. Following informed consent, participants completed the Self-Efficacy for Exercise (SEE) Scale, measuring confidence in scenarios such as exercising while fatigued, stressed, or unmotivated.

Participants also completed the Child and Youth Resilience Measurement (CYRM). Data were analyzed using descriptive statistics and logistic regression.

Lessons learned: Among 150 APHIV participants, mean age was 16.9 years (SD 3.9); 33.7% were females (n=50). Mean SEE score was 13.1 (SD 6.1; range 2-25); 27.5% had "low" overall confidence (SEE score 0-9) for physical activity under various circumstances.

Higher SEE scores were significantly associated with older age (p=0.03), greater engagement in physical activity (p=0.010), higher adherence to the intervention (p=0.003), and higher resilience scores (p=0.042). Internal factors such as emotional states (feeling stressed or sad) emerged as greater barriers to exercise than external environmental factors (weather or competing activities).

Conclusions/Next steps: This study underscores the critical role of self-efficacy in sustaining exercise adherence among APHIV, especially under challenging conditions. The Positive Running Program demonstrates the transformative impact of structured exercise to enhance self-efficacy through strategies like progressive mastery of physical activities, positive reinforcement, and targeted support to overcome emotional challenges and environmental stressors.

By integrating physical activity into a holistic health promotion framework, such interventions can improve resilience, well-being, and quality of life in APHIV, with potential to enhance long-term health outcomes.

EP0785

Symptoms of depression, anxiety, and post-traumatic stress among adolescents and young adults living with HIV at enrollment in the Sauti ya Vijana randomized clinical trial in Tanzania

G.J. Mollel[1], E. Ketang'enyi[2], L. Komba[3], B.T. Mmbaga[4,5], G. Sigalla[1], E. Senkoro[4], A. Shayo[6,7], J.A. Gallis[8,9], E.L. Turner[8,9], K. O'Donnell[10], D.E. Dow[8,4,11]

[1]Ifakara Health Institute, Biomedical Research and Clinical Trials, Morogoro, Tanzania, the United Republic of, [2]Baylor College of Medicine Children Foundation of Tanzania, Mwanza, Tanzania, the United Republic of, [3]Baylor College of Medicine Children Foundation of Tanzania, Mbeya, Tanzania, the United Republic of, [4]Kilimanjaro Christian Medical Center-Duke Collaboration, Moshi, Tanzania, the United Republic of, [5]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, the United Republic of, [6]Kilimanjaro Christian Medical Centre, Department of Pediatrics, Moshi, Tanzania, the United Republic of, [7]Kilimanjaro Christian Medical University College, Moshi, Tanzania, the United Republic of, [8]Duke Global Health Institute, Durham, NC, United States, [9]Duke University, Duke Department of Biostatistics & Bioinformatics, Durham, NC, United States, [10]Sandford School of Public Policy, Center for Child and Family Policy, Durham, NC, United States, [11]Duke University Medical Center, Durham, United States

Background: Adolescents and young adults (AYA) are facing a growing mental health (MH) crisis. This is particularly true for AYA with HIV (AYAWH) who in this critical period of self-realization and physical, social, and brain maturation, they also navigate HIV related stigma and disclosure. As a result, adherence to antiretroviral therapy may decrease resulting in unsuppressed HIV and risk of transmitting to others.

We describe symptoms of depression, anxiety, and post-traumatic stress among AYAWH enrolled in a mental health Sauti ya Vijana (SYV, The Voice of Youth) trial.

Methods: SYV is a randomized clinical trial conducted across four regions of Tanzania (Moshi, Ifakara, Mbeya and Mwanza), enrolling participants aged 10-24 years, on ART for at least six months, aware of their HIV diagnosis, and able to attend weekly intervention sessions if randomized to intervention arm.

Study enrolment period was from March 2023 to July 2024. Youth with active psychosis or cognitive disability precluding their ability to consent, or participate actively in group were excluded. Interviewer-led MH assessments included: PHQ-9 for depression (range 0-27, symptomatic ≥ 5); GAD-7 for anxiety (range 0-21, symptomatic ≥ 5); and UCLA-RI for post-traumatic stress (modified range 0-51, symptomatic ≥ 18). Data were collected using REDCap Mobile and analysed descriptively using R software.

Results: We enrolled 690 participants across sites. The mean age was 17.5 years (SD 2.5 years); 50% were females. At enrolment, 23% of participants reported symptoms of depression, 10% reported symptoms of anxiety, and 16% reported symptoms of post-traumatic stress (Table). Furthermore, 6% reported to have intentionally harmed themselves in the past, and 2% reported current intent to self-harm. Appropriate MH referral and care was provided.

Variable	Ifakara (N = 168)	Mbeya (N = 178)	Moshi (N = 168)	Mwanza (N = 176)	Total (N = 690)
Age, mean (SD) years	17.1 (3.4)	18.0 (2.1)	17.5 (2.0)	17.3 (2.2)	17.5 (2.5)
Gender (Female)	88 (52%)	89 (50%)	83 (49%)	87 (49%)	347 (50%)
PHQ 9 ≥10	5 (3%)	4 (2%)	4 (2%)	9 (5%)	22 (3%)
PHQ 9 ≥5	54 (32%)	20 (11%)	33 (20%)	54 (31%)	161 (23%)
GAD 7 ≥10	5 (3%)	0 (0%)	4 (2%)	2 (1%)	11 (2%)
GAD 7 ≥5	23 (14%)	6 (3%)	23 (14%)	19 (11%)	71 (10%)
UCLA trauma ≥18	6 (24%)	2 (4%)	11 (46%)	7 (11%)	26 (16%)

Conclusions: Symptoms of depression, anxiety, and post-traumatic stress were common at enrolment into SYV trial, suggesting the need for routine MH screening for AYAWH. The trial is ongoing, and will be unblinded to evaluate overtime changes by trial arm.

EP0786

A mixed methods evaluation of a stepped care model integrating HIV and mental health services for adolescents and young adults living with HIV (AYLHIV) in Western Kenya

S. Hicks[1], F.C. Mukumbang[2], J. Kibugi[3], J. Badia[3], W.A. Owade[3], N.A. Ounda[3], O.A. Okumu[3], L.A. Ouma[3], P.O. Odote[3], V.A. Songa[3], P. Kohler[4], G. John-Stewart[5], K.M. Beima-Sofie[2]

[1]University of Washington, Epidemiology, Seattle, United States, [2]University of Washington, Global Health, Seattle, United States, [3]IMPACT Research & Development Organization, Kisumu, Kenya, [4]University of Washington, Global Health; Child, Family, and Population Health Nursing, Seattle, United States, [5]University of Washington, Epidemiology; Global Health; Medicine - Allergy and Infectious Disease; Pediatrics, Seattle, United States

Background: Adolescents and young adults living with HIV (AYLHIV) are at increased risk of poor retention and adherence. Stepped care models tailor HIV services to AYLHIV needs, including use of differentiated service delivery for stable AYLHIV.

Methods: The *Data-Informed Stepped Care* (DiSC) study, a cluster randomized clinical trial conducted in 24 facilities across three counties in Western Kenya, tested implementation of a Stepped Care intervention that matched youth needs to service intensity. Using a convergent parallel mixed methods design, we conducted post-trial surveys and focus group discussions (FGDs) with AYLHIV from intervention sites. FGDs were conducted among participants from six intervention sites, and were recorded, transcribed, and analyzed using a thematic analysis approach. Satisfaction surveys were conducted among all participants at study exit (12 months) and analyzed using descriptive statistics.

Results: A total of 73 AYLHIV participated in 18 FGDs; 39 (53%) were aged 15-19; 66 AYLHIV completed the demographics survey, and 60.6% were female. Among 790 AYLHIV who completed the satisfaction survey, median

age was 18 (IQR: 15-20) and 59.6% were female. FGD participants reported positive experiences during DiSC, describing more comprehensive and supportive discussions with providers and faster appointments due to tailored services. Correspondingly, the majority of quantitative survey respondents reported short wait times (83%), trust in their providers (91%), and believed providers listened to their concerns (93%). FGD participants reported being more likely to attend clinic appointments and adhere to ART during DiSC.

Participants receiving higher intensity services reported benefits from mental health counseling and improved caregiver relationships. Some FGD participants felt depressive symptoms significantly decreased. Among 57 participants who reported receiving counseling services, 98% were satisfied with the counseling, 95% felt they could express themselves without restrictions, and 100% reported at least some benefits and that they would like to receive additional counseling.

Some FGD participants reported challenges during the study, including minor schedule disruptions, lack of transportation, and disclosure fears, although DiSC was not designed to primarily address these determinants.

Conclusions: This mixed methods evaluation demonstrated that the stepped care intervention effectively matched services to AYLHIV needs, and the majority found the intervention highly acceptable.

EP0787

Exploring pet ownership as a novel intervention for mental health in people living with HIV (PLHIV): a global review of prevalence and benefits

O. Ogunlana[1], M. Terra[2], A.E. Bassey[3], C.D. Nwosu[4], V. Nabisere[5], O. Noah[6], R. Abdullateef[7,1]

[1]University of Ibadan, College of Medicine, Ibadan, Nigeria, [2]Mansoura University, Faculty of Medicine, Mansoura, Egypt, [3]University of Warwick, Coventry, United Kingdom, [4]Coventry University, Faculty of Business and Law, Coventry, United Kingdom, [5]Makerere University, Kampala, Uganda, [6]University of Lagos, College of Medicine, Lagos, Nigeria, [7]College Research and Innovation Hub, Ibadan, Nigeria

Background: People living with HIV (PLHIV) frequently experience mental health challenges such as depression, anxiety, and social isolation. Pet ownership has been associated with psychological benefits in other populations, but its impact on PLHIV is understudied. Addressing these mental health challenges is crucial for enhancing their health outcomes and ensuring their retention in care.

This systematic review and meta-analysis evaluated the prevalence of pet ownership among PLHIV and explored its association with mental health outcomes, including depression, emotional well-being, and social interactions.

Methods: A comprehensive search of databases (MEDLINE/PubMed, Web of Science, Scopus) and grey literature identified studies on pet ownership and mental health outcomes in PLHIV. Inclusion criteria focused on observational or interventional studies measuring standardized mental health outcomes.

Three studies met the eligibility criteria, involving a total of 1,035 participants. The risk of bias was assessed using the Newcastle-Ottawa Scale and Cochrane Risk of Bias Tool 2.0. Data were synthesized narratively, and a random-effects meta-analysis was performed to estimate the pooled prevalence of pet ownership.

Results: The pooled prevalence of pet ownership among PLHIV was 61% (95% CI: 52–66%, I^2 = 85.4%). Individual studies reported high ownership rates: 68.3% in Muldoon et al. (2017), 60.2% in Hutton et al. (2014), and 54% in Siegel et al. (1999). Pet ownership, particularly dog ownership, was consistently associated with improved mental health outcomes. In Muldoon et al., dog owners had significantly lower odds of depression compared to non-owners (OR = 3.01, CI 1.54–6.21). Hutton et al. found greater emotional well-being and reduced unsupportive social interactions in companion animal owners. Siegel et al. reported that pet ownership reduced depression, especially among individuals with AIDS and limited social support.

Despite these benefits, the limited number of studies highlights a gap in understanding the long-term impacts of pet ownership on PLHIV.

Conclusions: Pet ownership is prevalent among PLHIV and appears to provide significant mental health benefits, including reduced depression and improved emotional well-being.

However, the limited evidence base underscores the need for longitudinal and interventional research. Promoting pet ownership or animal-assisted interventions may serve as a novel strategy to enhance the psychological well-being of PLHIV

EP0788

Integrating mental health and psychosocial support into community-based HIV and GBV programming: a holistic approach to adversities healing towards improved health outcomes

C. Shyaka[1], J.S. Ndikumana[1], P. Sebagenzi[1], J. Ntakirutimana[1]

[1]Caritas Rwanda, Kigali, Rwanda

Background: HIV and GBV amplify community mental health and psychosocial challenges, accelerating vulnerability for affected individuals, families, and communities as manifested through self/community stigma, and emotional distress. Fear of rejection and social isolation increases mental health issues, particularly among children and adolescents living with HIV (C/ALHIV) and those having experienced violence. Integrating mental health into HIV and GBV programming offers a holistic approach that enhances service delivery, fosters resilience, reduces stigma, and promotes self-esteem and psychosocial well-being.

Description: USAID Igire Gimbuka, a community-driven program that supports orphans and vulnerable children by addressing HIV prevention and GBV mitigation while focusing on mental, emotional, and social needs, implemented by Caritas Rwanda in four districts of Western Province. To enhance community-centered mental health efforts, RBC, in collaboration with various stakeholders,

developed and endorsed a community-based MHPSS toolkit, employing a multi-stakeholder approach that engages health professionals, local leaders, volunteers, and community members. Key strategies include, training of 78 mental health service providers, offering clinical supervision for 234 clinicians to prevent burnout, facilitating peer-to-peer support for 975 C/ALHIV, and providing psychosocial peer support to 493 GBV survivors.

Program promotes self-reliance through social and economic services and organizes community dialogues to reduce stigma and raise awareness around psychosocial challenges. Furthermore, the program strengthens referral networks to connect clients with specialized mental health professionals.

Lessons learned: Engaging and empowering community volunteers, coupled with fostering effective collaboration with health professionals, have proven essential to helping people regulating and recovering from HIV/GBV related adversities, significantly improved adherence to treatment and retention in care, resulting 99.2% of viral load suppression among participants living with HIV and reduced stigma.

Peer-to-peer mental health support has become a valuable intervention, where individuals who experienced mental health challenges or GBV share their feelings, empathy, and encouragements, thus breaking their loneliness and isolation.

Conclusions/Next steps: Strengthen peer-to-peer counseling for early mental health detection and referrals, foster resilience, and shared support; Foster community involvement through stigma-reducing awareness campaigns that inspire active participation in mental health initiatives; Implement multilevel interventions to address HIV prevention barriers, prioritizing at-risk individuals with mental health challenges, including those confined to households or frequently in public spaces.

Scaling success: peer support models achieve outstanding ART adherence and viral suppression for young people living with HIV

I. Jebet[1]

[1]Global Network of Young People living with HIV, Nairobi, Kenya

Background: Adherence to antiretroviral therapy (ART) is essential for viral suppression and positive health outcomes among young people living with HIV (YPLHIV). However, adherence is often hindered by stigma, lack of support, and mental health challenges.

The YouthWise (YW) project (2021-2024), funded by Aidsfonds and implemented in Kenya and Malawi, aimed to mitigate these barriers through a peer-led, youth-driven support model.

Description: The YW project used a combination of inputs and approaches to foster ART adherence:

- Youth-Driven Peer Support Groups: 5 support groups were established in Kenya and Malawi, these groups created safe spaces for YPLHIV to support one another's adherence journeys.
- Self-Care Toolkit: Adapted from WHO guidelines, this youth-friendly toolkit empowered peer mentors to educate group members on HIV self-care and adherence strategies.
- Local Partnerships: Leveraging existing networks, support groups in Malawi, and working with health providers and community leaders strengthened group outreach and acceptance.
- Capacity Building: Peer mentors were trained, enabling them to lead impactful sessions and effectively relay information.

Lessons learned: A mixed-methods approach was used, with quantitative data from surveys and qualitative insights from safe circles and focus groups conducted in Nairobi, Mombasa, Chikwawa, and Mangochi. Ninety-three participants (ages 19-34) provided data on ART adherence, self-care practices, and community support, with a focus on adherence rates, viral load suppression, and peer support's role in adherence.

The results were

- Adherence: 97% of participants had reliable ART access, 94% were on ART, and 82% reported consistent adherence.
- Viral Load Suppression: 89% reported an undetectable viral load.
- Well-Being and Support from peers: 75% felt "very happy" or "happy," and 88% felt "healthy" or "very healthy," with 95% rating peer support as "supportive" or "totally supportive."

Conclusions/Next steps: The YW project's peer-led model significantly enhanced ART adherence and well-being for YPLHIV, demonstrating the power of stigma-free, youth-centered approaches. By empowering peer mentors and fostering community partnerships, the intervention created a replicable framework for improving HIV care outcomes. This model has since been adopted by other initiatives, such as the You(th) Care project in Zambia, Kenya, and Tanzania, showcasing its potential for scalability and broader impact on YPLHIV communities globally.

Prevalence of suicidal ideation among newly diagnosed PLHIV in Nairobi County: insights from the HOYMAS Kenya Program

J. Kamau[1], J. Mathenge[2], A. Onyango[3], P. Macharia[4], J. Maina[5], K. Mwangi[6]

[1]HOYMAS KENYA, HIV Lead Clinician, Nairobi, Kenya, [2]HOYMAS KENYA, Executive Director, Nairobi, Kenya, [3]HOYMAS KENYA, Monitoring, Evaluation , Research & Learning, Nairobi, Kenya, [4]HOYMAS KENYA, Programs, Nairobi, Kenya, [5]HOYMAS KENYA, Grants, Nairobi, Kenya, [6]HOYMAS KENYA, Case Navigator, Nairobi, Kenya

Background: Despite advancements transforming HIV into a manageable condition, mental health comorbidities, particularly suicidal ideation, remain a critical concern among people living with HIV (PLHIV). The vulnerable period immediately following HIV diagnosis is marked by emotional and social challenges.

Suicidal ideation among newly diagnosed clients represents a significant individual burden, impacting daily activities and causing immense suffering, and has broader public health implications, negatively affecting treatment adherence and contributing to preventable mortality.

Pre-existing mental health conditions, lack of social support, discrimination, and socioeconomic disparities may exacerbate this risk. Understanding the prevalence and associated risk factors of suicidal ideation among newly diagnosed HIV client is crucial for developing effective prevention and intervention strategies.

Description: HOYMAS Kenya implements a HIV Care and treatment program for Men who have sex with Men and Male Sex Workers in Nairobi County executed a project to understand the prevalence and the risk factors for suicidal ideation among PLHIV post diagnosis.

Lessons learned: Programmatic data collected at HOYMAS between January 2024 and December 2024, indicates that a total of 70 clients tested positive for HIV and offered linkage onsite.

A total of 67 (95.7%) were linked to care on the same day and 3 were linked within 30 days of testing.

All of them were offered three sessions of enhanced adherence counselling and screened for depression and anxiety using the standard PHQ-9 and GAD-7 with 49 (70%) showing a degree of anxiety and 52 (74.2% having depression within the first three month of linkage

19 (27.1%) aged <29 years displayed and openly discussed their suicidal thoughts with no disclosure

4 clients out of 19 had interruption in treatment in navigated back to treatment.

Conclusions/Next steps:

- The diagnosis of HIV is a experience that implicates anxiety, depression and trauma
- Disclosure support
- Integration of a comprehensive mental health package for PLHIV and support services.
- Strengthening case navigators in post diagnosis care and community followup
- Advocate for full implementation of the kenya mental framework for the key and Vulnerable population.
- Capacity building for HCPs to understand and better handle clients experiencing depression, PTSD and suicidal thoughts.

Depression and HIV-related self-efficacy among people with TB/HIV initiating TB treatment who were recently diagnosed with HIV versus those who already knew their HIV status

B.P. Makhutha[1], E. Amesimeku[2], A. Medina-Marino[1], A. Sweetland[2]

[1]Desmond Tutu Health Foundation, Family Medicine, East London, South Africa, [2]Columbia University, Department of Psychiatry, New York, United States

Background: Depression is a common comorbidity in people with HIV/TB coinfection, influencing treatment adherence and outcomes. Knowing that many people in South Africa do not learn of their HIV diagnosis until they get sick with TB, we sought to explore whether being simultaneously diagnosed with TB and HIV was associated with a greater risk for depression and whether it impacted their HIV treatment adherence self-efficacy to initiate HIV treatment.

Understanding the role of depression and its relationship with HIV-related self-efficacy, particularly in those recently diagnosed with HIV and TB same day, is critical for improving HIV treatment engagement in resource-limited settings.

Methods: A cross-sectional study utilized data from 295 individuals within their first month of initiating TB treatment who were coinfected with HIV. Depression was assessed using the Patient Health Questionnaire (PHQ-9), and HIV-related self-efficacy was measured using the HIV Treatment Adherence Self-Efficacy Scale (HIV-ASES).

Using bivariate analyses and linear regression, we explored differences in depressive symptoms and HIV treatment-related self-efficacy among those recently co-diagnosed with TB and HIV compared to individuals who already knew their HIV status at the time of being diagnosed with TB. Statistical significance was set at $p<0.05$.

Results: Among the participants (mean age 39.1, 51.5% female), 36.9% had elevated depressive symptoms suggestive of a probable depression diagnosis. While there were no statistically significant differences in depressive symptoms based on demographic characteristics (age, gender, education) nor the timing of the HIV diagnosis, participants recently diagnosed with HIV exhibited significantly lower HIV-related self-efficacy compared to those previously aware of their diagnosis (estimate=-2.716, $p<0.001$). No significant associations were found between HIV-related self-efficacy and age, gender, or education level.

Conclusions: This study highlights the impact of recent HIV diagnosis on HIV-related self-efficacy, underscoring the need for targeted interventions to improve HIV treatment readiness among individuals who are simultaneously diagnosed with TB and HIV.

Addressing depressive symptoms and fostering positive treatment intentions may improve adherence and outcomes among TB/HIV coinfected populations.

EP0792

Development and piloting of a novel peer-led substance use intervention for young people living with HIV in Zimbabwe

C. Shava[1], C. Wogrin[1], E. Gwenzi[1], B. Tapesana[1], M. Mawodzeke[1], S. Bondayi[1], N. Willis[2]
[1]Zvandiri, Service Delivery, Harare, Zimbabwe, [2]Zvandiri, Executive, Harare, Zimbabwe

Background: Substance use presents significant risks for adolescents and young adults, particularly those living with HIV (AYALHIV). It exacerbates physical, psychological, and social challenges and negatively impacts treatment adherence. In low- and middle-income countries, systemic challenges and limited access to mental health services complicates these issues.
To address this, Zvandiri piloted a peer-led intervention aimed at helping AYALHIV reduce substance use while enhancing resilience and self-efficacy.
Description: Formative research conducted in June and November 2023 involved 12 participants which included trained and mentored peer counsellors, Community Adolescent Treatment Supporters (CATS) and recipients of care (RoCs), six of whom were former substance users and wanted to support their peers to stop.
Themes identified included stressors leading to substance use, the need for coping strategies, and the importance of peer support. This informed a 10-session group intervention based on cognitive behavioural therapy principles and the Transtheoretical Model.
The sessions were held from January to November 2024. The sessions covered substance use reasons, psychoeducation on common substances used, triggers, relational issues, and coping strategies. Participants included 21 CATS and RoCs aged 15–24 years, with 6 having ceased substance use and 15 desiring to stop.
The aim of the intervention was two-fold. The six trained individuals were provided support to maintain abstinence and develop the requisite counselling skills to support their peers.
